## Publisher's Note

This book is published by the Oncology Nursing Society (ONS). ONS neither represents nor guarantees that the practices described herein will, if followed, ensure safe and effective patient care. The recommendations contained in this book reflect ONS's judgment regarding the state of general knowledge and practice in the field as of the date of publication. The recommendations may not be appropriate for use in all circumstances. Those who use this book should make their own determinations regarding specific safe and appropriate patient care practices, taking into account the personnel, equipment, and practices available at the hospital or other facility at which they are located. The editors and publisher cannot be held responsible for any liability incurred as a consequence from the use or application of any of the contents of this book. Figures and tables are used as examples only. They are not meant to be all-inclusive, nor do they represent endorsement of any particular institution by ONS. Mention of specific products and opinions related to those products do not indicate or imply endorsement by ONS. Websites mentioned are provided for information only; the hosts are responsible for their own content and availability. Unless otherwise indicated, dollar amounts reflect U.S. dollars.

ONS publications are originally published in English. Publishers wishing to translate ONS publications must contact ONS about licensing arrangements. ONS publications cannot be translated without obtaining written permission from ONS. (Individual tables and figures that are reprinted or adapted require additional permission from the original source.) Because translations from English may not always be accurate or precise, ONS disclaims any responsibility for inaccuracies in words or meaning that may occur as a result of the translation. Readers relying on precise information should check the original English version.

## Editors

**MiKaela Olsen, DNP, APRN-CNS, AOCNS®, FAAN**

Clinical Program Director, Oncology  
Johns Hopkins Hospital and Johns Hopkins Health System  
Baltimore, Maryland  
*Chapter 6. Chemotherapy; Chapter 17. Pulmonary Toxicities*

**Kristine B. LeFebvre, DNP, RN, NPJ-BC, AOCN®**

Oncology Clinical Specialist  
Oncology Nursing Society  
Pittsburgh, Pennsylvania  
*Chapter 1. Professional Practice Considerations; Chapter 17. Pulmonary Toxicities*

**Suzanne L. Walker, PhD, CRNP, BC, AOCN®**

Senior Advanced Practice Provider  
Abramson Cancer Center at Penn Presbyterian Medical Center  
Advanced Senior Lecturer  
Adult Oncology Specialty Minor/Post-Master's Certificate  
University of Pennsylvania School of Nursing  
Philadelphia, Pennsylvania  
*Chapter 17. Pulmonary Toxicities*

**Elizabeth Prechtel Dunphy, DNP, CRNP, BC, AOCN®**

Nurse Practitioner, Senior Advanced Practice Provider  
Coordinator Gastrointestinal Malignancies  
Abramson Cancer Center at Penn Presbyterian Medical Center  
Advanced Senior Lecturer B, Biobehavioral and Health Sciences  
Division  
University of Pennsylvania School of Nursing  
Philadelphia, Pennsylvania  
*Chapter 17. Pulmonary Toxicities*

## Authors

**Kristine D. Abueg, RN, MSN, OCN®, CBCN®**

Clinical Research Nurse  
Kaiser Permanente  
Roseville, California  
*Chapter 9. Principles of the Immune System*

**Mary K. Anderson, BSN, RN, OCN®**

Oral Oncolytic Nurse Navigator  
Norton Cancer Institute  
Louisville, Kentucky  
*Chapter 4. Overview of Cancer and Cancer Treatment*

**Fedrick D. Barber, PhD, ANP-BC, AOCNP®, FAANP, FAAN**

Manager, Advanced Practice Providers, Investigational Cancer  
Therapeutics  
University of Texas MD Anderson Cancer Center  
Houston, Texas  
*Chapter 9. Principles of the Immune System*

**Tom K. Bauer, MBA, RT(R)**

Senior Director of Patient Education and Engagement  
Johns Hopkins Health System  
Baltimore, Maryland  
*Chapter 3. Patient Education*

**Veronica Joyce Brady, PhD, MSN, FNP-BC, BC-ADM, CDCES**

Assistant Professor  
University of Texas Houston Cizik School of Nursing  
Houston, Texas  
*Chapter 22. Endocrine Toxicities*

**Kelly G. Bugos, MSN, RN, ANP-BC, NPJ-BC, AOCNP®**

Director of Advanced Practice-APP Fellowship and  
Professional Development  
Center for Advanced Practice  
Stanford Health Care  
Stanford, California  
*Chapter 26. Post-Treatment and Survivorship Care*

**Bradley Burton, PharmD, BCOP**

Patient Safety Scientist, Oncology  
AstraZeneca  
Gaithersburg, Maryland  
*Chapter 7. Hormone Therapy*

**Donna Copeland, DNP, RN, NE-BC, CPN, CPON®, AE-C**

Assistant Professor  
University of South Alabama  
Mobile, Alabama  
*Chapter 15. Gastrointestinal and Mucosal Toxicities*

**Megan Corbett, MSN, RN, NPD-BC, OCN®**

Clinical Specialist  
Dana-Farber Cancer Institute  
Boston, Massachusetts  
*Chapter 13. Infusion-Related Complications*

**Kerri A. Dalton, DNP, RN, AOCNS®**

Oncology Clinical Nurse Specialist  
Duke University Health System  
Durham, North Carolina  
*Chapter 15. Gastrointestinal and Mucosal Toxicities*

**Erin Dickman, MS, RN, OCN®**

Oncology Clinical Specialist  
Oncology Nursing Society  
Pittsburgh, Pennsylvania  
*Chapter 4. Overview of Cancer and Cancer Treatment*

**Rebecca L. Duchman, MSN, MA, RN, NEA-BC**

Director, Infusion/Treatment Services  
Nebraska Medicine, Buffett Cancer Center  
Omaha, Nebraska  
*Chapter 24. Neurologic Toxicities*

**Anecita Fadol, PhD, FNP-BC, FAANP, FAAN**

Associate Professor, Departments of Nursing and Cardiology  
University of Texas MD Anderson Cancer Center  
Houston, Texas  
*Chapter 16. Cardiovascular Toxicities*

**Dane Fritzsche, PharmD, BCOP**

Oncology Clinical Pharmacist  
University of Washington Medicine Fred Hutchinson Cancer Center  
Clinical Instructor  
University of Washington School of Pharmacy  
Seattle, Washington  
*Chapter 6. Chemotherapy*

**RuthAnn Gordon, MSN, FNP-BC, OCN®**

Director, Clinical Trials Nursing  
Memorial Sloan Kettering Cancer Center  
New York, New York  
*Chapter 10. Immunotherapy*

**Theresa Gorman, MSN, RN, AOCNS®, BMTCN®**

Quality Assurance Coordinator  
Thomas Jefferson University Hospital  
Philadelphia, Pennsylvania  
*Chapter 19. Genitourinary Toxicities*

**Jennifer Hadjar, MSN, RN, OCN®**

Director of Nursing  
Ambulatory Pediatric Hematology & Oncology  
Ambulatory Adult Malignant Hematology  
Section of Transplant and Cell Therapy in the Division of Blood Disorders  
Rutgers Cancer Institute of New Jersey  
*Chapter 20. Altered Sexual and Reproductive Functioning*

**Natalie Jackson, APRN, FNP-C**

Advanced Practice Nurse  
University of Texas MD Anderson Cancer Center  
Houston, Texas  
*Chapter 10. Immunotherapy*

**Catherine Jansen, PhD, RN, AOCNS®**

Oncology Clinical Nurse Specialist  
The Permanente Medical Group  
San Francisco, California  
*Chapter 24. Neurologic Toxicities*

**Alice S. Kerber, MN, APRN, ACNS-BC, AOCN®, ACGN**

Oncology and Genetics Nurse Specialist  
Atlanta, Georgia  
*Chapter 2. Ethical and Legal Issues*

**Jerrica Knight-Donnelly, PS, PharmD**

Midland, Texas  
*Chapter 7. Hormone Therapy*

**Tracy Krause, BS, PharmD, BCOP**

Unit-Based Clinical Pharmacist/Oncology Clinical Pharmacy Specialist  
Hospital of the University of Pennsylvania  
Philadelphia, Pennsylvania  
*Chapter 10. Immunotherapy*

**Brendan Mangan, PharmD, BCOP**

Hematology/Oncology Clinical Pharmacy Specialist  
Hospital of the University of Pennsylvania  
Philadelphia, Pennsylvania  
*Chapter 10. Immunotherapy*

**Ashley L. Martinez, NPD-BC, DNP, APRN, FNP-BC, AOCNP®, CBCN®, CPHQ, NEA-BC**

Director, Advanced Practice  
University of Texas MD Anderson Cancer Center  
Houston, Texas  
*Chapter 10. Immunotherapy*

**Alice Maupin, MSN, RN, AGCNS-BC, OCN®**

Oncology Nurse Leader  
Duke University Health System  
Durham, North Carolina  
*Chapter 15. Gastrointestinal and Mucosal Toxicities*

**Sandra A. Mitchell, PhD, CRNP, AOCN®, FAAN**

Senior Scientist and Program Director  
Outcomes Research Branch, Healthcare Delivery Research Program  
Division of Cancer Control and Population Sciences  
National Cancer Institute  
Rockville, Maryland  
*Chapter 23. Fatigue*

**Kathy Mooney, MSN, RN, ACNS-BC, BMTCN®, OCN®**

Oncology Clinical Nurse Specialist  
 Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins  
 Hospital  
 Baltimore, Maryland  
*Chapter 21. Cutaneous Toxicities and Alopecia*

**Amy E. Moore, MSN, RN, AOCNS®, WTA-C**

Clinical Nurse Specialist, Oncology/Autologous Bone Marrow  
 Transplantation  
 Hospital of the University of Pennsylvania  
 Philadelphia, Pennsylvania  
*Chapter 19. Genitourinary Toxicities*

**Marylou Nesbitt, MS, RN, AOCN®**

Clinical Specialist  
 Dana-Farber Cancer Institute  
 Boston, Massachusetts  
*Chapter 13. Infusion-Related Complications*

**Elizabeth Ness, MS, BSN, RN, CRN-BC**

Director, Office of Education and Compliance  
 Center for Cancer Research  
 National Cancer Institute  
 National Institutes of Health  
 Bethesda, Maryland  
*Chapter 5. Clinical Trials and Drug Development*

**Shan Li O'Connor, PharmD, BCOP**

Hematology Medical Science Liaison WA/AK  
 AbbVie US Medical Affairs  
 Mettawa, Illinois  
*Chapter 6. Chemotherapy*

**Kim Peterson, MSN, APRN-CNS, ACCNS-AG, OCN®**

Ambulatory Oncology Nurse Manager  
 Marlene and Stewart Greenebaum Comprehensive Cancer  
 Center  
 University of Maryland Medical Center  
 Baltimore, Maryland  
*Chapter 15. Gastrointestinal and Mucosal Toxicities*

**Michelle Y. Ranaghan, MSN, RN, CRNI®, OCN®**

Clinical Specialist  
 Dana-Farber Cancer Institute  
 Boston, Massachusetts  
*Chapter 13. Infusion-Related Complications*

**Zandra R. Rivera, DNP, APRN, ANP-BC, BMTCN®**

Supervisor, Advanced Practice Provider, Stem Cell Transplan-  
 tation  
 University of Texas MD Anderson Cancer Center  
 Houston, Texas  
*Chapter 18. Hepatic Toxicities*

**Danielle Roman, PharmD, BCOP**

Manager, Clinical Pharmacy Services  
 PGY2 Oncology Pharmacy Residency Program Director  
 Allegheny Health Network Cancer Institute  
 Pittsburgh, Pennsylvania  
*Chapter 8. Targeted Therapy*

**Mary L. Schmitt, MS, APRN, FNP-BC, AOCNP®**

Oncology Nurse Practitioner  
 St. Joseph Hospital  
 Nashua, New Hampshire  
*Chapter 4. Overview of Cancer and Cancer Treatment*

**Gary E.B. Shelton, DNP, MSN, NP, ANP-BC, AOCNP®**

Adult Health Nurse Practitioner and Oncology Clinical Nurse Spe-  
 cialist  
 Mount Sinai Health System  
 New York, New York  
*Chapter 25. Ocular Toxicities*

**Lisa Hartkopf Smith, MS, RN, AOCN®, CHPN**

Oncology Clinical Nurse Specialist  
 Ohio Health Riverside Methodist Hospital  
 Columbus, Ohio  
*Chapter 1. Professional Practice Considerations; Chapter 11. Administration Considerations*

**Carol C. Tipian, MSN, RN, AGACNP-BC**

Adult Bone Marrow Transplant and Cellular Therapy Advanced  
 Practice Provider  
 Memorial Sloan Kettering Cancer Center  
 New York, New York  
*Chapter 10. Immunotherapy*

**AnnMarie L. Walton, PhD, MPH, RN, OCN®, CHES, FAAN**

Associate Professor  
 Duke University School of Nursing  
 Durham, North Carolina  
*Chapter 12. Safe Handling of Hazardous Drugs*

**Justine Wang, PharmD, BCPS**

Clinical Pharmacy Specialist  
 Pharmacy Clinical Programs  
 University of Texas MD Anderson Cancer Center  
 Houston, Texas  
*Chapter 16. Cardiovascular Toxicities*

**Jaime Weimer, MSN, RN, AGCNS-BC, AOCNS®**

Oncology Clinical Specialist  
 Oncology Nursing Society  
 Pittsburgh, Pennsylvania  
*Chapter 15. Gastrointestinal and Mucosal Toxicities*

**Barbara J. Wilson, MS, RN, AOCN®, ACNS-BC**

Director, Oncology Professional Practice  
 Wellstar Cancer Network  
 Marietta, Georgia  
*Chapter 14. Myelosuppression*

**Laurie Winkelbauer, BSN, RN, OCN®**

Manager, Infusion/Treatment Services  
 Nebraska Medicine, Buffett Cancer Center  
 Omaha, Nebraska  
*Chapter 24. Neurologic Toxicities*

## Disclosure

Editors and authors of books and guidelines provided by the Oncology Nursing Society are expected to disclose to the readers any significant financial interest or other relationships with the manufacturer(s) of any commercial products.

A vested interest may be considered to exist if a contributor is affiliated with or has a financial interest in commercial organizations that may have a direct or indirect interest in the subject matter. A "financial interest" may include, but is not limited to, being a shareholder in the organization; being an employee of the commercial organization; serving on an organization's speakers bureau; or receiving research funding from the organization. An "affiliation" may be holding a position on an advisory board or some other role of benefit to the commercial organization. Vested interest statements appear in the front matter for each publication.

Contributors are expected to disclose any unlabeled or investigational use of products discussed in their content. This information is acknowledged solely for the information of the readers.

The contributors provided the following disclosure and vested interest information:

MiKaela Olsen, DNP, APRN-CNS, AOCNS®, FAAN: Beckinsson, Dickinson and Company, honoraria

Kristine B. LeFebvre, DNP, RN, NPD-BC, AOCN®: American Nurses Credentialing Center, consultant or advisory role

Elizabeth Prechtel Dunphy, DNP, CRNP, BC, AOCN®: Incyte, honoraria

Bradley Burton, PharmD, BCOP: AstraZeneca, stock ownership

Alice S. Kerber, MN, APRN, ACNS-BC, AOCN®, ACGN: Myriad Genetics, Pfizer, honoraria

Ashley L. Martinez, DNP, APRN, FNP-BC, AOCNP®, CBCN®: American Nurses Credentialing Center, Curio, consultant or advisory role

## Licensing Opportunities

The Oncology Nursing Society (ONS) produces some of the most highly respected educational resources in the field of oncology nursing, including ONS's award-winning journals, books, online courses, evidence-based resources, core competencies, videos, and information available on the ONS website at [www.ons.org](http://www.ons.org). ONS welcomes opportunities to license reuse of these intellectual properties to other organizations.

Licensing opportunities include the following:

- **Reprints**—Purchase high-quality reprints of ONS journal articles, book chapters, and other content directly from ONS, or obtain permission to produce your own reprints.
- **Translations**—Translate and then resell or share ONS resources internationally.
- **Integration**—Purchase a license to incorporate ONS's oncology-specific telephone triage protocols or other resources into your institution's EMR or EHR system.
- **Cobranding**—Display your company's logo on ONS resources for distribution to your organization's employees or customers.
- **Educational reuse**—Supplement your staff or student educational programs using ONS resources.
- **Customization**—Customize ONS intellectual property for inclusion in your own products or services.
- **Bulk purchases**—Buy ONS books and online courses in high quantities to receive great savings compared to regular pricing.

As you read through the pages of this book, think about whether any of these opportunities are the right fit for you as you consider reusing ONS content—and the contents of this book—for your organization.

Contact [licensing@ons.org](mailto:licensing@ons.org) with your licensing questions or requests.

# Preface

Oncology nursing is a unique specialty that requires continuous learning to stay up to date on cancer pathophysiology, cutting-edge drugs, and the evidence-based management of cancer and cancer treatment–related toxicities. The Oncology Nursing Society’s (ONS’s) second edition of *Chemotherapy and Immunotherapy Guidelines and Recommendations for Practice* provides nurses with the tools to understand how medications are used in cancer treatment, the effect of medication-related toxicities, and evidence-based recommendations to manage and treat these toxicities. This edition features many new cancer therapies approved since the 2019 publication. Each drug is categorized as chemotherapy, hormone, targeted, or immunotherapy agents. Extensive drug tables in the book provide nurses with tips for managing patients receiving these drugs. The expansion of oral antineoplastic therapies, alone or in combination with infusion therapy, requires that nurses review a patient’s complete cancer treatment plan and consider the side effects, toxicities, and adherence to oral drugs to ensure patient tolerance and efficacy.

This second edition has seen content expanded on the topic of genomics as we move forward in the world of personalized oncology. Health equity is approached with information discussing financial distress, cultural disparities, and health literacy. The latest guidelines and recommendations for treatment, symptom management, and survivorship have been integrated into this new text.

This edition features a QR code, provided with the purchase of this book, to download periodic drug updates. You will see new evidence related to many aspects of cancer nursing care incorporated into this edition, such as hypersensitivity response, safe handling of hazardous drugs, and more.

The editors want to thank all of the contributors who worked tirelessly, despite a pandemic, to make this new edition a reality. This work builds on the knowledge of many generations of oncology nurses and has been used nationally and internationally to guide oncology nursing practice. We are proud to continue to serve oncology nurses worldwide with an essential resource to guide their practice.

MiKaela Olsen, DNP, APRN-CNS, AOCNS®, FAAN  
Kristine B. LeFebvre, DNP, RN, NPD-BC, AOCN®  
Suzanne L. Walker, PhD, CRNP, BC, AOCN®  
Elizabeth Prechtel Dunphy, DNP, CRNP, BC, AOCN®

Please scan the QR code to the right to receive periodic updates to select drug tables listed within this book. These updates will help oncology nurses stay up to date with current research and findings related to chemotherapy and immunotherapy guidelines.

## SECTION I

---

# Professional Practice Considerations

Chapter 1. Professional Practice Considerations

Chapter 2. Ethical and Legal Issues

Chapter 3. Patient Education

# CHAPTER 1

## Professional Practice Considerations

### A. Scope and standards

1. The safe administration of antineoplastic treatments in various settings is within the oncology nurse's scope of practice (Lubejko & Wilson, 2019).
2. Professional nursing practice is defined and overseen through regulatory influencers and five integral components (American Nurses Association, 2021).
  - a) *Evidence* incorporates scientific and research findings, the expertise of the nurse, and the preferences of the individual.
  - b) *Nursing practice* is the autonomous actions of the professional nurse in any role.
  - c) *Influencers* include state nurse practice acts, the scope and standards that guide practice and specialty practice, and institutional policies and procedures.
  - d) *Safety measures* protect the patient from harm or undesirable outcomes.
  - e) *Quality* strives to obtain desirable outcomes of nursing practice for patients, families, the organization, and the profession.
3. In 2008, the American Society of Clinical Oncology (ASCO) and the Oncology Nursing Society (ONS) began an ongoing collaboration to define and later revise safety standards for chemotherapy and other antineoplastic agents. The *ASCO/ONS Chemotherapy Administration Safety Standards* addressed staffing-related issues, antineoplastic therapy planning, documentation, orders, preparation, patient education, administration, and monitoring for all settings and patient populations (Neuss et al., 2016).

### B. Professional education

1. To promote a safe level of care for individuals receiving chemotherapy, targeted therapy, and immunotherapy, each institution or supporting agency should provide specialized education and preparation consisting of didactic learning followed by successful completion of a clinical practicum (ONS, 2020).
2. Didactic content is comprehensive, current, and evidence based. After the didactic course, a nurse

must demonstrate an understanding of the following (ONS, 2020):

- a) Types of antineoplastic medications, classifications, and routes of administration
  - b) Pharmacology of agents regardless of indications for use
  - c) Pertinent molecular biomarkers, including genomic assays
  - d) Chemotherapy and radiation therapy protectants
  - e) Principles of safe preparation, storage, labeling, transportation, and disposal of agents
  - f) Safe administration procedures
  - g) Procedures for safe handling of hazardous drugs, including spill management
  - h) Appropriate use and disposal of personal protective equipment
  - i) Use of engineering controls, if applicable to the practice setting, including the use of closed-system drug-transfer devices
  - j) Assessment, monitoring, and management of patients receiving therapy
  - k) Medication safety and system safeguards, such as infusion pump safety features
  - l) Appropriate procedures for emergency preparedness, including infusion reactions and extravasation
  - m) Appropriate documentation of treatment administration, patient education, and planned follow-up care and testing
  - n) Patient, family, and caregiver education for these agents, specific to side effects and related symptom management, and the process for urgent and ongoing follow-up
  - o) Education and coordination of post-treatment care and testing, adverse events, and long-term side effects; physical and psychosocial impacts of a cancer diagnosis and treatment; and follow-up care during survivorship
3. Clinical practicum
    - a) The clinical practicum allows the nurse to apply the knowledge gained in the didactic component to direct patient care situations.

- b) Emphasis is placed on the clinical skills that the nurse must demonstrate prior to being deemed competent to administer antineoplastic therapy (see Appendices A and B). The nurse must also display knowledge of organizational policies and procedures related to antineoplastic administration.
  - c) After the clinical practicum, the nurse will be able to perform the following:
    - (1) Demonstrate proficiency regarding safe preparation (when applicable), storage, transport, handling, spill management, administration, and disposal of antineoplastic drugs and equipment.
    - (2) Identify appropriate physical and laboratory assessments for specific agents.
    - (3) Demonstrate skill in venipuncture, including vein selection and maintenance of the site during and after drug administration.
    - (4) Demonstrate skill in the care and use of various vascular access devices.
    - (5) Identify patient and family educational needs related to agents.
    - (6) Identify acute local or systemic reactions, including extravasation and anaphylaxis, associated with antineoplastic drugs and identify appropriate interventions.
    - (7) Demonstrate proficiency in the safe administration of hazardous drugs and disposal of contaminated waste and equipment.
    - (8) Document pertinent information in the medical record.
4. Clinical activities
- a) Pair a nurse new to antineoplastic drug administration with an experienced nurse who can serve as a preceptor and provide clinical supervision and instruction (Lockhart, 2016).
  - b) The preceptor and the nurse establish specific objectives at the beginning of the clinical practicum. Ideally, the nurse and preceptor select a patient assignment. The nurse assumes the responsibility for planning and providing care for this patient under the guidance and supervision of the preceptor.
  - c) The time spent in the clinical practicum is dependent on the nurse's ability to meet specific objectives and institutional requirements.
  - d) The nurse should become proficient and independent in administering nonvesicants before progressing to vesicant administration.
  - e) Various clinical settings can be used for the nurse to demonstrate competency in antineoplastic drug administration. It may not be realistic for all settings or agencies to provide on-site education and training. Alternative methods can be used, including the following:
    - (1) Contracting with larger institutions for didactic education or clinical experience for specific learning needs (e.g., vesicant, nonvesicant, IV push, short infusion, continuous infusion)
    - (2) Creating or using a simulated laboratory to substitute for the clinical component
    - (3) Providing virtual simulation designed to meet specific learning objectives (Konrad et al., 2021)
5. Use an evaluation tool based on the desired outcomes to document the nurse's knowledge of and competency in the following:
- a) Agents and associated nursing implications
  - b) Technical skills required for the administration of agents (e.g., dose calculation, venipuncture, access device management)
  - c) Patient and family education about the treatment regimen
  - d) Steps to take in the event of an untoward response following drug administration (e.g., anaphylaxis, hypersensitivity reaction, extravasation)
6. Competency may be verified in a simulated setting (e.g., skills laboratory) or as a precepted experience in the clinical setting.
- a) The evaluation or documentation tool should meet the needs of the new nurse and the practice setting, including a minimum number of observed and documented antineoplastic drug administrations.
  - b) Observed administration of at least three different agents, types, and routes (i.e., nonvesicant and vesicant; IV push and short-term infusion) is recommended.
  - c) Competency for nontechnical skills, such as patient education, may be verified by role-playing, case scenarios, and observation (Wahl, 2017).
7. Annual continuing education and ongoing competency assessment are required for staff who order, prepare, and administer antineoplastic agents (Neuss et al., 2016).
- a) Educational content should be designed to meet the needs of staff in the healthcare setting (e.g., identified practice problems; high-risk, low volume procedures), and new information should be emphasized (Wahl, 2017).
    - (1) Methods that may be used to identify needs include but are not limited to staff or patient surveys, chart audits, quality improvement studies, clinical observation, and literature review.

- (2) Potential topics include new drugs or drug deliveries, reinforcement or training on policies and procedures, and prevention and management of treatment toxicities.
  - b) Competency assessment is ongoing, may be done by peers or supervisory staff, and is measured in several ways (Lockhart, 2016; Wahl, 2017).
    - (1) Testing
      - (a) Provide a packet of articles for the staff to read or a live educational program followed by an open-book test to measure knowledge.
      - (b) Consider a pretest and post-test to measure individual knowledge gains.
    - (2) Return demonstration
      - (a) Competency checklists can be used to document the performance of technical skills, such as the donning and doffing of personal protective equipment used during drug administration.
      - (b) Staff can also be observed and evaluated using a scoring rubric with a checklist of criteria detailing the steps to take in practice.
      - (c) Examples include monitoring a nurse administering a vesicant or completing dose verification.
      - (d) Actions can be observed in a practice or simulated environment and later debriefed.
    - (3) Simulation
      - (a) Simulation provides a safe environment for staff to practice clinical and critical-thinking skills.
      - (b) Staff can face a clinical challenge and problem-solve the steps to be followed, such as a patient experiencing an infusion reaction or extravasation.
      - (c) Asking nurses, “What would you do if . . .” challenges them to consider the implications of their actions.
      - (d) When a simulation lab is unavailable, it can be performed using role-play and mock scenarios in nearly any location.
  8. Antineoplastic medications administered outside designated oncology areas
    - a) The ONS (2020) position statement on the education of the nurse administering and providing care to patients receiving antineoplastic therapy applies to antineoplastic drugs regardless of indication, route, patient population, or setting.
    - b) All nurses should be knowledgeable about the drugs they administer, including mode of action, side effects, toxicity, dosage range, rate of administration, route of excretion, potential responses, and interactions with other medications and foods.
    - c) The format, length, and specific focus of educational initiatives, both didactic education and clinical experience, may vary according to the needs of the staff and setting. Select staff may require drug- or disease-specific education, whereas others require comprehensive education for all antineoplastic medications.
    - d) The educational plan should be addressed for all individuals working with antineoplastic therapy within institutional policy.
- C. Policies and procedures
1. Policies should be developed using a systematic, evidence-based approach to promote standardization of practice within an institution.
    - a) Policies identify and communicate practice expectations (Dols et al., 2017).
    - b) Procedures are a step-by-step guide to performing a specific task or operation (Esparza, 2019).
  2. Once a policy has been implemented, it must be enforced and followed by staff.
    - a) Individuals can be held liable if patient harm results from failure to follow a policy.
    - b) Institutions can have liability if a policy is unclear, contrasts with another policy, or could be interpreted incorrectly.
  3. Review policies and procedures at least every two years to ensure the practice is current with changing technology and evidence (Esparza, 2019).
  4. Collaboration between departments and professionals is recommended when creating antineoplastic policies and procedures. Input from the pharmacy, medicine, nursing, environmental services, occupational health, and other departments will result in a more comprehensive policy.
  5. Policies related to antineoplastic drug therapy address processes designed to promote the safe and efficient care of patients receiving these medications regardless of setting or department. Topics include the following (Institute for Safe Medication Practices [ISMP], 2022; Neuss et al., 2016):
    - a) Qualifications, including initial educational and ongoing competency requirements, credentialing process, and documentation of staff who order, prepare, and administer antineoplastic therapies
    - b) Hazardous drug management, including safe drug receipt, storage, compounding, transport, use of personal protective equipment, administration, post-treatment care, spill management, disposal, alternative duty, and medical surveil-

lance (Coyne et al., 2019; Polovich & Olsen, 2018; U.S. Pharmacopeial Convention, 2019)

- c) Order writing and dose verification, including process, standard regimens, rounding, cumulative dose, order format, and communication of modifications
- d) Informed consent process
- e) Standardized documentation tools for assessment and care
- f) Toxicity monitoring, including standardized documentation and communication of toxicities
- g) Procedures for care in medical emergencies
- h) Communication of status during transitions of care
- i) Reporting of adverse events and near misses

#### D. Antineoplastic medication safety

1. Published research has found that chemotherapy errors occur in at least 1%–3% of adult and pediatric patients (Reinhardt et al., 2019; Weingart et al., 2018).
  - a) Reinhardt et al. (2019) found a higher incidence of chemotherapy errors (3.6%) for modified or nonstandard orders.
  - b) Other situations identified as a higher risk for error include carboplatin, regimens with three or more agents, and oral chemotherapy (Reinhardt et al., 2019; Weingart et al., 2018).
2. Chemotherapy and other antineoplastic drugs are classified as high-alert medications, regardless of setting, by ISMP (2021). These medications have narrow therapeutic indices (i.e., benefit versus toxicity), multiple potential toxicities, and often are administered in complex regimens, protocols, and schedules (Griffin et al., 2016; Reinhardt et al., 2019; Weingart et al., 2018).
3. Errors may occur at any point during the drug delivery process (Ashokkumar et al., 2018; Reinhardt et al., 2019; Tariq et al., 2021; Weingart et al., 2018).
  - a) Ordering or prescribing errors, including unclear, incomplete, or erroneous orders; drug calculation; dose modification; omission of antineoplastic or supportive drugs or hydration; input and transcription; errors in cycle or day; and cumulative dose documentation or tracking
  - b) Drug preparation errors, including staging or loading a biosafety cabinet with incorrect equipment and supplies, rounding doses, reconstitution, compounding, label application, and dispensing (Gilbert et al., 2018)
  - c) Drug administration errors, including incorrect drug or dose, schedule or timing, patient identification, infusion rate, and route
  - d) Drug monitoring errors, including serum methotrexate level and failure to detect declining left

ventricular function in patients receiving trastuzumab

4. Medication errors can occur after patient discharge from hospital settings.
  - a) Nearly 50% of adult and older adult patients had medication errors or unintentional medication discrepancies after hospital discharge, and 20% reported adverse drug events (Alqenae et al., 2020).
  - b) Supportive medications for chemotherapy and immunotherapy (e.g., leucovorin rescue, anti-diarrheal agents, steroids, antiviral agents) taken incorrectly in the home setting can lead to serious consequences.
  - c) Patient education, clear instructions, and calendars can help prevent errors (Reinhardt et al., 2019).
5. Contributing factors to medication errors (Fyhr et al., 2015; ISMP, 2020; Prakash et al., 2014; Sessions et al., 2019; World Health Organization, 2016)
  - a) Poor communication among healthcare professionals or with patients
  - b) Look-alike, sound-alike medications
  - c) Batching or preparing more than one agent at a time
  - d) Distractions and interruptions
  - e) Heavy workload, fatigue, or stress
  - f) Lack of systematic processes or failure to follow safety processes
  - g) Medication supply and storage issues (e.g., drugs of similar names or dosage strengths stored in close proximity)
  - h) Equipment failure
  - i) Inadequate knowledge or experience of those ordering, preparing, or administering agents
  - j) Patient factors, including literacy, language barriers, and complexity of care
  - k) Ordering errors when using the computer order entry system (e.g., errors due to cut and paste)
6. The following strategies have been used to reduce the risk of medication errors in antineoplastic administration (Billstein-Leber et al., 2018; Coyne et al., 2019; Goldspiel et al., 2015; ISMP, 2022; Kuitunen et al., 2020; Neuss et al., 2016; ONS, 2020).
  - a) Develop policies and procedures using interprofessional collaboration. Include a risk assessment policy and strategies to promote adherence.
  - b) Establish a process of educational preparation and competency of those administering, preparing, or ordering antineoplastic medications. Nurses administering antineoplastic agents are qualified by education and training.
  - c) Ensure current drug information and resources for drug dosing, administration, and side effects are readily available.

- d) Measure and document weight in kilograms and height in centimeters.
- e) Use smart infusion pumps and barcode technology when available.
- f) Follow standards regarding antineoplastic medication orders.
  - (1) Orders are signed manually or by electronic approval by credentialed prescribers (ISMP, 2017a; Neuss et al., 2016).
  - (2) Advanced practice providers (e.g., clinical nurse specialists, nurse practitioners, physician assistants) identify prescribing as one of the most significant parts of their role (Bruinooge et al., 2018). The ability to prescribe antineoplastic medications is determined by the practice location (state and institution) and patient status.
  - (3) Verbal orders for chemotherapy, targeted therapy, and immunotherapy medications are not permitted, except to hold or stop drugs (ISMP, 2017a; Neuss et al., 2016).
  - (4) Text messaging of patient care orders is not permitted (ISMP, 2017b; Joint Commission, 2021).
  - (5) Standardized electronic or preprinted orders should be used for antineoplastic therapies (Neuss et al., 2016).
    - (a) Orders should be regimen based and include the elements outlined by current safety standards.  
Use of standardized, regimen-based preprinted or electronic orders has shown to increase evidence-based oncology care and decrease errors (Coyne et al., 2019; Srinivasamurthy et al., 2021). The National Comprehensive Cancer Network ([www.nccn.org](http://www.nccn.org)) provides disease-specific guidelines and chemotherapy order templates that include suggested patient monitoring for cancer type and stage (e.g., type and timing of imaging) and treatment regimen (e.g., toxicity monitoring). See Appendix C for an example of a chemotherapy order template.
    - (b) Abbreviations, acronyms, and other ambiguous methods of communicating drug information should be avoided.
  - (6) Safety advantages reported with the use of computerized prescriber order entry systems, along with clinical decision support systems, include the removal of interpretation or transcription errors, availability of information about drug doses and schedules, automatic calculation of medication doses, and alert and error-checking functions (Knols et al., 2020; Rahimi et al., 2018; Weingart et al., 2018).
    - (a) Errors in prescribing continue to occur with computerized prescriber order entry, including dose errors, medication choice, incomplete prescriptions, failure to acknowledge electronic alerts, and failure to validate orders.
    - (b) These errors are amplified with new or occasional prescribers and as the complexity of a treatment regimens increases (Weingart et al., 2018).
  - (7) A policy should be in place for prescribing antineoplastic regimens that vary from standard regimens. For example, the prescriber may be required to document supporting references for the variance.
- g) Use safety measures provided in electronic health record systems, such as drug interaction alerts, cumulative dose calculation (when applicable), and override restrictions (Rahimi et al., 2018; Reinhardt et al., 2019). In a study examining chemotherapy errors and electronic prescribing, Reinhardt et al. (2019) found that 61% could be avoided through further software development.
- h) Require at least two approved practitioners to perform dose and drug verification for all routes of delivery before preparation, upon preparation, and prior to administering antineoplastic medications (Neuss et al., 2016).
  - (1) Independent dual verification (i.e., independent double checks) is a process in which a second person verifies the accuracy of a prescribed therapy without revealing their findings to the other verifier until both have completed the process (ISMP, 2019).
  - (2) Numerous studies have demonstrated the ability of independent double checks to detect up to 95% of errors (Alsulami et al., 2012; ISMP, 2019).
  - (3) Identifying areas of vulnerability, training staff, and using checklists promotes an effective and consistent process (ISMP, 2019; Macias et al., 2018; Schwappach et al., 2018; see Appendix D).
  - (4) Prior to administering antineoplastic agents, the treatment plan should be reviewed. Orders, medication, patient identification, and pump programming must also be verified (Neuss et al., 2016).

See Chapter 11 for more information on dose verification.

- (5) Conducting a comprehensive review of the medication orders, including comparing the previous cycle rather than comparing the product to the order, is invaluable in catching prescribing errors (ISMP, 2019; Reinhardt et al., 2019).
- (6) Drug and dose verification must be performed in a distraction-free setting. Using timeout and speaking-out-loud checks at drug administration has increased safety (Coyne et al., 2019; Kalo et al., 2019; Prakash et al., 2014).
- (7) Creative staffing models can minimize interruptions with dose verification (Baldwin & Rodriguez, 2016).
- (8) Practitioner dose verification combined with automated double checks (e.g., barcode scanning) may improve safety (ISMP, 2019; Macias et al., 2018).
- i) Procedures for emergency preparedness should be established.
  - (1) 24–7 triage should be provided (e.g., on-call practitioners, emergency departments) (Neuss et al., 2016).
  - (2) At least one clinical staff member certified in basic life support must be present during chemotherapy administration. Staff certified in advanced cardiac life support or pediatric advanced life support may be indicated depending on the setting and treatment delivered (Neuss et al., 2016).
  - (3) When antineoplastics are administered in the healthcare setting, a licensed independent practitioner must be on site and immediately available to staff (Centers for Medicare and Medicaid Services, 2020; Neuss et al., 2016).
  - (4) Policies, procedures, and standardized orders should be in place to manage medical emergencies (ISMP, 2022; Neuss et al., 2016; Shaker et al., 2020). Procedures include the process for monitoring and tracking the availability and readiness of emergency equipment and the expiration date on medications, including antidotes and rescue agents.
  - (5) Staff should be educated regarding who to call and the process for contacting the provider or healthcare team (e.g., outpatient nurses need to be clear as to whether to contact 911 or the institution's code team).
  - (6) Orders for the treatment of infusion emergencies should be available to enable immediate intervention without waiting for the provider's order, with indications for each medication clearly defined (e.g., epinephrine, diphenhydramine, steroids) (Shaker et al., 2020).
- (7) All team members should understand their role and responsibilities in an emergency.
- (8) Verify that emergency equipment and supplies, including oxygen, are available and working and that staff are aware of their location. Infusion chairs functional to change position are recommended if needed.
- (9) Policies, procedures, and standardized orders should be established, with antidotes in place to manage vesicant extravasation (Neuss et al., 2016; see Chapter 13).
  - (a) Staff must be knowledgeable regarding the management of extravasation, the location of orders, and the process for obtaining antidotes.
  - (b) Coupled order sets, such as the inclusion of an order on the antineoplastic therapy order set (e.g., initiate extravasation orders for suspected extravasation), permit the prompt and evidence-based management of emergencies such as extravasation (ISMP, 2010).
- (10) Antidotes or rescue agents (where applicable) with directions for use should be readily available.
- (11) Process improvement projects and educational programs should be designed to provide patients with prompt, evidence-based interventions.
  - (a) Evaluate previous emergent situations to determine what worked and areas for improvement.
  - (b) Consider running mock codes and infusion reaction drills. Numerous studies have shown that these drills increase practitioner proficiency and confidence and decrease anxiety (Josey et al., 2018; LeBoeuf & Pritchett, 2020; Sharour, 2019).
- j) Standardized processes should be designed to promote effective communication and handoffs between care providers and care sites for patients receiving antineoplastic therapy (Coyne et al., 2019; Neuss et al., 2016).
  - (1) The highest safety risk times during drug administration should be identified to allow for clear communication.

- (2) Safety is improved with open interprofessional communication and a clear understanding of roles, responsibilities, accountability, and a process to de-escalate problems.
  - (3) Nursing bedside rounds and interprofessional rounds have been found to increase communication and decrease errors (Daniels, 2016).
  - (4) Any missed patient appointments or treatments should be documented, and follow-up should occur with the patient and other healthcare team members.
  - (5) An accurate treatment summary must be documented, including history, previous cancer treatments, and current treatment when a patient is transferred to a different healthcare setting. The ASCO Institute for Quality provides example templates on its website ([www.instituteforquality.org/cancer-treatment-plan-and-summary-templates](http://www.instituteforquality.org/cancer-treatment-plan-and-summary-templates)).
  - k) Ongoing patient education should be provided, including information, motivation, and encouragement to patients to become vigilant partners in safety measures (Coyne et al., 2019; Weingart et al., 2018).
7. Drug shortages in oncology care are multifactorial. Driving forces include low profitability for manufacturers of generic drugs, decreased drug quality in production, mergers of manufacturers, complex supply chains, natural disasters, and regulatory challenges (Jacob, 2020).
- a) Drug shortages can have significant clinical effects (Alpert & Jacobson, 2019; ISMP, 2018b; Unguru, 2020; U.S. Food and Drug Administration [FDA], n.d.).
    - (1) Treatment outcomes can be affected by omitted or reduced doses from delays or changes in treatment regimens.
    - (2) Medication errors
      - (a) Healthcare providers may not know about substitute medications when the preferred drug is unavailable, potentially resulting in errors in dosing, adverse effects, and drug interactions.
      - (b) A different concentration or brand is purchased, potentially affecting how the dose is prepared, dispensed, and administered.
      - (c) Look-alike or sound-alike medications are purchased from a different manufacturer.
    - (3) Increased costs
      - (a) Cost of replacement medications may be significant.
      - (b) Labor costs are associated with seeking replacement supplies, managing inventory, updating computer systems for replacement medications, and educating staff. These costs are estimated at \$359 million per year (Kacik, 2019).
      - (c) Financial and emotional burdens placed on patients can negatively affect patient satisfaction.
    - b) The Food and Drug Administration Safety and Innovation Act of 2012 requires pharmaceutical companies to notify FDA when a product may be affected by production changes or manufacturing interruptions (U.S. FDA, 2018).
    - c) FDA (n.d.) works with manufacturers to minimize the impact of drug shortages. A list of drugs in short supply is maintained on the FDA website ([www.accessdata.fda.gov/scripts/drugshortages/default.cfm](http://www.accessdata.fda.gov/scripts/drugshortages/default.cfm)).
- E. Quality and safety monitoring and improvement programs are encouraged in each practice setting (Neuss et al., 2016).
1. Third-party assessments in oncology related to the delivery of antineoplastic medications include the following organizations:
    - a) American College of Surgeons Commission on Cancer (ACoS CoC)
    - b) ASCO Quality Oncology Practice Initiative Certification Program (QOPI)
    - c) Foundation for the Accreditation of Cellular Therapy (FACT)
  2. Quality monitoring is encouraged in each setting, using internal and external data to establish benchmarks (ISMP, 2022). Topics for monitoring should meet the needs of the practice setting. Examples include the following:
    - a) Oral oncolytic management, including adherence, education, and prescribing processes
    - b) Care coordination, including communication at the transition of care
    - c) Access device management, including with infections and occlusions
    - d) Drug administration, including medication errors, safe handling of hazardous drugs, extravasation, and infusion reactions

## CHAPTER 2

# Ethical and Legal Issues

### A. Ethical issues

1. The ever-changing healthcare environment necessitates sensitivity to ethical and legal issues. Concerns arise in the care of all patients. However, they often have heightened intensity and complexity in the cancer population, as patients, families, and healthcare professionals face frequent and potentially difficult moral choices.
2. *Ethics* is a term that describes what is expected as correct and principled behavior. Issues may arise when conflicting values exist among individuals, groups, or organizations (Beauchamp & Childress, 2019).
3. Ethical issues related to cancer therapy
  - a) Healthcare realities that present potential ethical issues include the following:
    - (1) Major advances with increased availability and access to medical technology, heightened expectations, and changing moral attitudes combine to generate complex ethical and legal problems related to cancer and palliative care (Bressler et al., 2017; Butts & Rich, 2020). In particular, the use of life-sustaining measures may raise ethical questions when healthcare professionals perform the following errors (Kates, 2017; Marcelin et al., 2019; Sirilla et al., 2017; Sisk et al., 2016; Sullivan & Dickerson, 2016):
      - (a) Fail to discuss patient requests before a crisis develops
      - (b) Are reluctant or fail to communicate medical treatment options with a stressed and grief-stricken family
      - (c) Fail to consider supportive care measures
      - (d) Experience moral distress related to personal values or biases
    - (2) The changing healthcare environment (e.g., staffing shortages, reallocation of resources, consolidation, corporatization) has resulted in growing administrative dominance over clinical practice (Agency

for Healthcare Research and Quality, 2019; Figueroa et al., 2019).

- b) The large number of underinsured and undocumented individuals has led to ethical dilemmas in health care.
  - (1) Even for people with health insurance, co-payments or deductibles can lead to substantial debt (Yousuf Zafar, 2016).
  - (2) Financial toxicity is the unintended and unanticipated financial burden experienced by patients and is associated with negative consequences and increased risk of mortality (Witte et al., 2019). This definition includes a range of concerns from minimal financial vulnerability and worry to extreme financial toxicity.
    - (a) The adverse impact of a cancer diagnosis on financial well-being may result from direct or indirect costs and can be both objective and subjective (Arastu et al., 2020; Coumoundouros et al., 2019; Edward, 2020; Singleterry, 2017).
      - i. Material loss, including savings, home, loss of insurance, bankruptcy
      - ii. Balancing cancer care costs with family, food, housing, child care, and transportation
      - iii. Psychological distress related to uncertainty and resource insecurity
      - iv. Maladaptive coping strategies
      - v. Sense of loss of control
      - vi. Sense of vulnerability
    - (b) Consequences of financial toxicity may be immediate or long term.
      - i. Treatment nonadherence
      - ii. Decreased health-related quality of life
      - iii. Bankruptcy

- iv. Increased risk of mortality
- v. Changing family dynamics
- c) Informal caregivers are the primary source of support for patients with cancer, assisting with household tasks, medical care, and emotional support (Counmoundouros et al., 2019).
  - (1) Responsibilities often result in high levels of emotional, physical, social, and financial burden for the caregiver.
  - (2) The demand for informal cancer caregivers will increase as life expectancy rises and cancer incidence increases.
  - (3) Care time is the greatest source of caregiver cost and stress. Other sources include out-of-pocket and absenteeism costs.
- d) Some groups are at higher risk for perceived subjective financial distress resulting from objective financial burden.
  - (1) Individuals with lower socioeconomic status and multiple comorbidities may struggle to pay for daily living needs, such as food, housing, and monthly bills (Zheng et al., 2020).
  - (2) Children, younger cancer survivors, and low-income families are most affected by limited coverage and higher deductibles. Payment for care must be addressed for protected groups, such as incarcerated and homeless individuals (Lyckholm & Glancey, 2016; Yousuf Zafar, 2016).
  - (3) Some insurance plans do not cover select diagnostic testing or more expensive treatments, such as hematopoietic stem cell transplantation, proton beam therapy, clinical trials, or off-label use of medications (Brown et al., 2016; Centers for Medicare and Medicaid Services, 2022).
  - (4) Theoretical frameworks that incorporate medical and nonmedical aspects of financial hardship are limited, making it challenging to fully understand the interrelationship between cancer survivors and those with no personal history of cancer.
- e) Strategies to anticipate and reduce financial concerns along the cancer trajectory include the following:
  - (1) Increased transparency concerning costs of office visits, diagnostics, treatment, and palliative and other supportive care
  - (2) Early discussion of payment options and financial assistance
  - (3) Follow-up on financial discussions as circumstances change
  - (4) Practical suggestions for keeping track of precertifications, bills, and payments
  - (5) Clear discussion of goals, benefits, and costs of care
  - (6) Early referral to supportive services and navigation
  - (7) Access to a National Cancer Institute comprehensive cancer center
- f) Improvement requires multilevel, coordinated efforts among stakeholders, including patients, providers, health systems, payers, manufacturers, and policymakers (Edward, 2020; Lentz et al., 2019).
  - (1) Monitor the financial status of patient groups and their perceptions of subjective financial distress at different times (e.g., diagnosis, curative or palliative treatment, survivorship care).
  - (2) Evaluate the healthcare process by measuring changes in financial status in individual patients and groups.
  - (3) Assess the seriousness of the financial situation at different time frames.
  - (4) Individualize information and counseling needs.
- g) Expanding awareness and appreciation of cultural diversity is essential (Bressler et al., 2017).
  - (1) Cultural disparities in cancer care are unfavorable health outcomes related to inequities in health insurance coverage, access to and use of care, and quality of care (Pirschel, 2020; Underwood, 2019).
    - (a) Disparities adversely affect groups that have systematically experienced greater obstacles to health based on race or ethnicity; language and communication skills; religion; socioeconomic status; gender; age; mental health; cognitive, sensory, or physical disability; sexual orientation or gender identity; geographic location; or other characteristics historically linked to discrimination or exclusion (Office of Disease Prevention and Health Promotion, n.d.).
    - (b) A society is considered to have cultural diversity if it has many different cultural or ethnic groups. This includes social status, culture, language and communication skills, religion, personality, race and ethnicity, age, gender, sexual orientation, and decision-making ability (Betancur et al., 2020; Underwood, 2019).
    - (c) Social determinants of health are the conditions in an environment that impact an individual's health, func-

- tioning, and quality of life (Office of Disease Prevention and Health Promotion, n.d.). The five domains are economic stability, education, health care, neighborhood, and community context.
- (d) Cultural and communication differences and protections present challenges from discussion of surveillance, diagnosis, and prognosis to decisions about who will provide long-term care (Agency for Healthcare Research and Quality, 2019; Bressler et al., 2017; Butts & Rich, 2020).
  - (e) Implicit bias describes attitudes toward or associated stereotypes with individuals or groups of people without conscious knowledge.
  - (f) Designated priority populations are the focus of federal efforts to reduce disparities and include people of color, low-income populations, women, children or adolescents, older adults, individuals with special healthcare needs, and individuals living in rural and inner-city areas (Agrawal & Enekeuchi, 2020).
- (2) Actions to improve cultural awareness (Marcelin et al., 2019; Pirschel, 2020)
- (a) Begin the conversation during assessment and continue throughout the trajectory.
  - (b) Recognize personal biases.
  - (c) Identify individuals at risk for developing preventable cancer.
  - (d) Allow a safe space for a conversation about concerns.
  - (e) Provide education about cultures.
  - (f) Provide translation services.
  - (g) Personalize surveillance and management for cancer.
  - (h) Respect cultural differences.
  - (i) Display patient nondiscrimination policy and patient bill of rights.
  - (j) Encourage neutral language, asking for preferences.
  - (k) Be honest.
  - (l) Follow the tenets of the American Nurses Association (2015) code of ethics.
- (3) Advocacy for patients of diverse backgrounds
- (a) Coordinate community efforts to promote awareness of implicit and explicit bias, prejudice, and discrimination.
  - (b) Apply efforts to counteract implicit and explicit bias, prejudice, and discrimination.
  - (c) Address root causes of disparities in cancer care, including insurance issues and access to care.
  - (d) Use alternative therapies.
    - i. Evidence-based complementary and alternative medicine, in conjunction with or as a substitute for conventional treatment, is affected by variations in individual response to cancer and its treatment, the need for a sense of control, belief in individual rights and determination, and cultural and spiritual beliefs. Caregiver beliefs often limit the use of such therapies.
    - ii. In the search for cancer care with minimal side effects, survivors and families often embark on unproven therapies, which can cause adverse outcomes and insurmountable costs (Johnson et al., 2017).
    - iii. Oncology nurses must be educated about alternative methods to provide education about reliable options (American College of Surgeons Commission on Cancer, 2021; Butts & Rich, 2020; Cox et al., 2017).
  - (e) Precision oncology: As biomarker testing that leads to the use of targeted therapies becomes the standard of care, healthcare professionals are expected to apply this expanding science to practice and be aware of biomarker-directed targeted therapies and their mechanism of action, indications, and symptom management.
    - i. Understanding the technology and options for biomarker testing and its impact on care requires ongoing education.
    - ii. Reimbursement for testing and services, collection of an extensive family history, and costs of targeted and biologic therapies offer addi-

- tional challenges to patients, healthcare systems, and professionals (American Nurses Association & International Society of Nurses in Genetics, 2016; Mohammed et al., 2016; Roeland et al., 2017).
4. Ethical issues that oncology nurses face in daily practice (de Groot et al., 2017; Fiore & Goodman, 2016; Sisk et al., 2016; Sullivan & Dickerson, 2016)
    - a) Autonomy
      - (1) Patient autonomy and decision-making capacity
      - (2) Informed consent
      - (3) Cancer risk reduction (e.g., prophylactic surgeries)
      - (4) Treatment during pregnancy
      - (5) The right to refuse treatment
      - (6) Disparities in the wishes of a patient and their significant other
      - (7) Advocating for individuals who exhibit risky behaviors or make choices with which the caregiver disagrees
      - (8) Privacy in communications (e.g., medical records, messaging, telemedicine)
    - b) Healthcare environment and reform
      - (1) Undertreatment of pain, particularly in light of the opioid crisis
      - (2) Inequities in cancer care
      - (3) Access to care and clinical trials
      - (4) Access to high-cost cancer drugs and drug shortages
      - (5) Cultural diversity and potential bias
      - (6) Balance and justice in cancer care
      - (7) Expanding the use of telehealth
    - c) End-of-life and prolongation-of-life decisions
      - (1) Assisted dying (legal in several states)
      - (2) Treatment futility versus continuing experimental treatment
      - (3) Prognosis-related discussions
    - d) Confidentiality
      - (1) Biomarker testing and disclosure of results
      - (2) Scientific integrity
      - (3) Big data collection and warehousing
    - e) Conflict resolution and critical conversations
      - (1) Intrafamily conflicts
      - (2) Nurse–family conflicts
      - (3) Nurse–physician conflicts
      - (4) Physician–family conflicts
      - (5) Clarity in communications
    - f) Professional boundaries
      - (1) Giving or receiving gifts
      - (2) Social media (e.g., friend requests from patients)
      - (3) Electronic messaging
  5. The Joint Commission (2020) requires accredited institutions to provide access to an ethics consultation to assist in evaluating the decision-making capacity of an individual and assist with problem resolution.
  6. The ethical principles guiding decision-making are summarized in Table 2-1.
  7. The American Nurses Association (2015) code of ethics serves as an ethical framework for practice, providing direction regarding ethical relationships, nursing responsibilities, appropriate behaviors, and decision-making. Components of the framework include the following:
    - a) Respect for the inherent dignity, worth, and unique attributes of every person
    - b) Primary commitment to the patient
    - c) Protection of the rights, health, and safety of the patient
    - d) Authority, accountability, and responsibility for nursing practice
    - e) Same duties owed to self as to others
    - f) Establishment, maintenance, and improvement of the ethical environment of the work setting and conditions of employment
    - g) Advancement of the profession through research and scholarly inquiry
    - h) Protection of human rights, promotion of health diplomacy, and reduction of health disparities
    - i) Articulation of nursing values, maintenance of the integrity of the profession, and integration of the principle of social justice
- B. Legal issues related to cancer therapy
1. Adhering to national, state, and institutional standards is a fundamental responsibility of all nurses (American Nurses Association, 2015; Brown et al., 2016; Centers for Medicare and Medicaid Services, 2022).
  2. Acts and standards guiding oncology nursing practice are not all-inclusive, as the changing environment requires knowledge of specialty competencies depending on the practice setting.
    - a) Nurse practice acts are state laws that define nursing performance in fundamental terms for each state (American Nurses Association, 2021).
    - b) The Oncology Nursing Society's *Scope and Standards of Oncology Nursing Practice* explains the minimum standard of care by which an oncology nurse is expected to practice (Lubejko & Wilson, 2019).
    - c) The *American Society of Clinical Oncology/Oncology Nursing Society Chemotherapy Administration Safety Standards* detail the safety standards for chemotherapy prescription, preparation,

**TABLE 2-1.** Ethical Principles

| Principle      | Description                                                                    | Clinical Examples                                                                                                                                                                                 |
|----------------|--------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Autonomy       | Independent decision-making by an individual following their own best interest | Respecting an individual's choice, even when different from one's own<br>Providing supportive services                                                                                            |
| Beneficence    | The duty to act in the best interest of the involved person                    | Personalizing care based on individual desires, culture, disease, and other factors<br>Providing evidence-based care                                                                              |
| Fidelity       | Faithfulness to promises made                                                  | Providing follow-up as promised<br>Providing survivorship care planning<br>Fostering collegiality                                                                                                 |
| Justice        | Equitable distribution of available resources                                  | Offering or providing treatment regardless of ability to pay, culture, or socioeconomic status<br>Assisting with or referring for financial support                                               |
| Nonmaleficence | The duty to do no harm                                                         | Providing complete information<br>Providing survivorship services<br>Recognizing professional limitations and seeking consultation or collaboration<br>Adhering to professional standards of care |
| Veracity       | Truth telling                                                                  | Explaining treatment in understandable terms before it is initiated<br>Providing accurate information and educational materials                                                                   |

Note. Based on information from Beauchamp & Childress, 2019.

administration, and monitoring in all practice settings (Neuss et al., 2016).

- d) *Genetics/Genomics Nursing: Scope and Standards of Practice* describes standards and scope of practice for general and advanced practice nurses addressing genetic and genomic issues with examples from various practice settings (American Nurses Association & International Society of Nurses in Genetics, 2016).
- e) The Oncology Nursing Society's *Access Device Standards of Practice for Oncology Nursing* details the current standards for using access devices in cancer care (Camp-Sorrell & Matey, 2017).
- f) *Infusion Therapy Standards of Practice* explain the current standards of nursing practice for IV therapy (Infusion Nurses Society, 2021).
- g) American College of Surgeons Commission on Cancer's (2022) *Optimal Resources for Cancer Care* encompasses the requirements that cancer programs must meet to earn and maintain Commission on Cancer accreditation.
- h) Institution-specific standards may be outlined in the following:
  - (1) Standards of practice
  - (2) Nursing policy and procedure manuals
  - (3) Job descriptions
  - (4) Institutional review board decisions and guidance

### 3. Common legal issues

- a) Medication errors (see Chapter 1)
- b) Documentation issues: The duty to keep accurate records is a fundamental nursing responsibility. The medical record is scrutinized in the event of litigious action and is believed to reflect the care rendered (Naidu & Alicia, 2019; Neuss et al., 2016).
  - (1) Common documentation errors
    - (a) Omitting significant observations
    - (b) Failing to document response to an intervention
    - (c) Failing to document patient teaching and understanding
    - (d) Failing to document what was taught and to whom
  - (2) Nursing actions to include in the documentation
    - (a) Telephone, text, or other digital communications or conversations, particularly those in which nurses give patients instructions or advice
    - (b) Fax and email communications, particularly those in which the nurses give patients instructions or advice
    - (c) Virtual face-to-face communications, particularly those in which nurses give patients instructions or advice,

- including the type of communication, who was included, and the location (e.g., online meetings, forums, email distribution lists, telemedicine) (Knudsen et al., 2021)
  - (d) Pertinent conversations with patients, families, or other caregivers
  - (e) Interagency referrals, including telephone conversations with providers
  - (f) Antineoplastic drug administration (see Appendices A and B)
  - (g) Treatment-related documentation
    - i. Completion of independent verification of drug and dose
    - ii. Two unique patient identifiers (e.g., name, medical record number, date of birth)
    - iii. Patient-specific measurements used to calculate doses (e.g., body surface area)
    - iv. Pertinent laboratory and diagnostic test results
    - v. Date and time of therapy
    - vi. Drug name, dose, route, location of administration, and infusion duration
    - vii. Volume and type of IV fluids administered
    - viii. Assessment of the IV site before, during, and after infusion
    - ix. Information about the infusion device (e.g., vein selection, needle size, type of device, infusion pump)
    - x. Verification of venous access device patency, including the presence of a blood return before, during, and after IV therapy (also any issues with venous access)
  - (h) Patient assessment and evaluation of patient response to and tolerance of treatment
  - (i) Patient and family education related to the drugs received, toxicities, toxicity management, and follow-up care (especially when and who to call with specific resource numbers and times)
  - (j) Post-treatment or discharge instructions
- c) Informed consent
- (1) Process
    - (a) Patients must give informed consent for treatment, enrollment in a clinical trial, or participation in nursing research (Beauchamp & Childress, 2019; Butts & Rich, 2020; Klimaszewski, 2016).
    - (b) Except for research, each institution determines its practice related to how and if a patient must provide written informed consent before receiving cancer treatment, such as antineoplastic agents, targeted therapies, or immunotherapies (Neuss et al., 2016).
    - (c) It is essential to maintain consistency between policy and practice throughout the institution.
    - (d) Regardless of the method used to document informed consent, all needed elements of the informed decision-making process must be included. The following approaches have been used:
      - i. The patient signs a designated antineoplastic therapy consent form explicitly designed for administering chemotherapy, targeted therapy, or immunotherapy. This document reflects patient education, remains part of the medical record, and might be preferred by risk management. A sample template for chemotherapy consent is provided in Appendix E.
      - ii. The general hospital consent to treat serves as the signed permission to provide antineoplastic medications.
      - iii. Some centers use a general procedure consent form for cancer treatment.
      - iv. A specific form is not signed, but consent is documented within the medical record.
  - (2) Elements of consent (Elements of Informed Consent, 2022)
    - (a) Disclosure: The patient is informed of their cancer diagnosis, including the type, location, and stage.
    - (b) The patient is informed of the prognosis and goal of the proposed treatment (e.g., cure, control, palliation).
    - (c) Possible benefits of the treatment are discussed.
    - (d) Possible risks and adverse effects are discussed, including short- and long-term side effects.

- (e) Alternatives to treatment and associated risks are covered. Palliative care should be offered as an option when appropriate.
- (f) Patients younger than age 18 years may be legally able to give informed consent if they are emancipated minors. Assent is the willingness to participate in treatment by people who are, by definition, too young to give informed consent but are old enough to understand the diagnosis and proposed treatment (Neuss et al., 2016).
  - i. If assent is given, informed consent must still be obtained from the patient's parents or guardian.
  - ii. The main goal of child assent is to protect children involved in clinical trials (Tait & Geisser, 2017).
- (3) Requirements
  - (a) The informed consent document must state the right of the patient to refuse or discontinue treatment at any time.
  - (b) The informed consent document and, subsequently, healthcare providers assure patients that ongoing support and care will be provided if they decline or discontinue treatment connected with the trial or research.
  - (c) Nurses and physicians have different but complementary roles in the informed consent process.
  - (d) See Chapter 5 for additional information on the informed consent process related to clinical trials and the nurse's role.

## CHAPTER 3

# Patient Education

### A. Patient education overview

1. Patient education includes learning experiences that empower individuals or communities with health information. This is combined with instructions to help patients understand how to care for themselves throughout the treatment trajectory, when to obtain help in their care, and the risks of illness and how to prevent it.
2. Patient education is a continuous process throughout the cancer journey (Gidron, 2016; Vaartio-Rajalin et al., 2015).
  - a) Health education and promotion are key roles of the nursing profession, especially for oncology nurses. Education is essential for patients, their significant others, and the public.
    - (1) Using the models of patient engagement and shared decision-making, all practitioners must be involved in health education and promotion.
    - (2) This requires open collaboration and interprofessional communication across all healthcare settings (American Nurses Association, 2015; Blecher et al., 2016; Brant & Wickham, 2013; Tariman et al., 2016; Vaartio-Rajalin et al., 2015).
  - b) The Agency for Healthcare Research and Quality (AHRQ, 2020a) has identified universal precautions for health literacy; steps aimed at improving the communication of healthcare information, leading to improved comprehension and access; improving patients' ability to navigate the healthcare system; and supporting patients in their self-care.
  - c) Health literacy can be divided into personal or organizational health.
    - (1) *Personal health literacy* is defined by the Office of Disease Prevention and Health Promotion (2021) as “the degree to which individuals have the ability to find, understand, and use information and services to make informed health-related decisions and actions for themselves and others” (para. 3).

- (2) *Organizational health literacy* is defined by the Office of Disease Prevention and Health Promotion (2021) as “the degree to which organizations equitably enable individuals to find, understand, and use information and services to inform health-related decisions and actions for themselves and others” (para. 3).
- (3) According to the *National Action Plan to Improve Health Literacy*, “nearly 9 out of 10 adults have difficulty using the everyday health information that is routinely available in our health care facilities, retail outlets, media, and communities” (Office of Disease Prevention and Health Promotion, 2010, p. 6).
- (4) Given the high prevalence of low health literacy, the application of health literacy best practices should be universally applied to all patients. To support these efforts, AHRQ created the universal precautions approach to patient education (AHRQ, 2020).

### B. Short-term outcomes of patient education (Blecher et al., 2016; Neuss et al., 2016)

1. Empowerment of active participation in care
2. Autonomous decision-making regarding treatment options or the right to refuse treatment
3. An understanding of diagnosis and treatment options
4. Ability to communicate an understanding of the goals and duration of treatment
5. Identification of short- and long-term side effects, including those that need to be reported
6. Demonstration of the ability to perform self-care or adapt to potential limitations
7. Promotion of adaptive skills in a life-threatening situation
8. Identification and use of community resources

### C. Long-term outcomes of patient education (Joint Commission, 2021)

1. Improvement in self-care behaviors
2. Improvement in health-related quality of life
3. Decreased healthcare costs
4. Increased customer satisfaction
5. Improved ability to make informed healthcare decisions

#### D. Barriers to patient education

1. Barriers should be assessed on an individual basis. A learning needs assessment should be performed and documented to identify obstacles that prevent the effective delivery of healthcare information (Gumusay et al., 2016; Joint Commission, 2021; Neuss et al., 2016).
2. Barriers to learning
  - a) The individual's cognitive resources, including potential for problems with attention, working memory, or information processing related to the disease or treatment (Jewitt et al., 2016; Vaartio-Rajalin et al., 2015)
  - b) Lack of knowledge or understanding of the diagnosis and treatment plan and differences in professional and patient knowledge expectations (Jewitt et al., 2016; Vaartio-Rajalin et al., 2015)
  - c) Differing expectations of the purpose of treatment between the patient, caregiver, and healthcare team
  - d) Concerns or misconceptions regarding therapy due to prior experience or the experience of a friend or relative, which may deter the patient from undergoing treatment
  - e) Language barriers
    - (1) Access to effective interpreter translation services in real time can be a barrier.
    - (2) The 2020 U.S. Census concluded that 21.5% of residents speak a language other than English in the home (U.S. Census Bureau, n.d.).
    - (3) Language barriers keep patients from engaging in seamless conversations with their doctors and interacting with the healthcare industry.
  - f) Educational barriers
    - (1) The national adjusted cohort graduation rate for public high school students in 2018–2019 was 86%. This represents the highest rate since its first measurement in 2010–2011. Asian/Pacific Islander students had the highest rate (93%), followed by White (89%), Hispanic (82%), Black (80%), and American Indian/Alaska Native (74%) students (National Center for Education Statistics, 2021).
    - (2) High school graduation rates were historically low before 1950, putting older indi-

viduals at an increased risk for educational barriers (Swanson, 2010).

- g) Effects of low health literacy (AHRQ, 2020b; Centers for Disease Control and Prevention, 2015, 2021; Joint Commission, 2021; Katz, 2017; Nielsen-Bohlman et al., 2004)
  - (1) Poor patient outcomes
  - (2) Increased healthcare costs
  - (3) Increased risk for medication errors
  - (4) Inability to follow treatment instructions
  - (5) Less success navigating the healthcare system
  - (6) Increased risk for hospitalization
- h) Physical barriers, such as pain, visual disturbances, auditory or cognitive impairments, and the inability to speak, can interfere with comprehension (Joint Commission, 2021).
- i) Access is reduced because of geographic barriers, such as the availability of transportation and the distance from home to the treatment facility.
- j) Psychosocial or emotional issues may create barriers to learning and need to be addressed before learning occurs (Joint Commission, 2021).
- k) Interprofessional care coordination and communication barriers (Joint Commission, 2021; Tariman et al., 2016; Vaartio-Rajalin et al., 2015)
  - (1) Ineffective communication among healthcare team members
  - (2) Ineffective communication among healthcare facilities
  - (3) Differences among healthcare professionals in their perceptions of the patient education process
- l) Methods of overcoming barriers
  - (1) Facilitate time for patients to express concerns and attempt to manage their anxiety.
  - (2) Assess cognitive resources and knowledge expectations of the individuals being educated, keeping in mind that educational level alone does not always give the complete picture of an individual's abilities.
  - (3) Include the patient's support system (e.g., family, friends, significant others) in the patient education process, providing support to the patient and help with learning.
  - (4) Manage physical barriers, such as pain, and ensure that learners have all necessary assistive devices (e.g., glasses, hearing aids).
  - (5) Provide access to an interpreter, either in person or through telecommunication (Joint Commission, 2021).
    - (a) Hospitals are required to ensure the competency of interpreters and translators.

- (b) Use of significant others as translators or interpreters is not recommended because of role conflicts or inability to communicate complex medical terminology.
  - (c) Cancer-related Spanish-language literature is available through the National Cancer Institute ([www.cancer.gov](http://www.cancer.gov)) and the American Cancer Society ([www.cancer.org](http://www.cancer.org)). Language preference can be toggled for these resources.
- (6) Offer explanations for any misconceptions concerning diagnosis, treatment, and follow-up care using teach-back techniques (AHRQ, 2020b).
  - (7) Perform and document a learning needs assessment that addresses cultural and religious beliefs and preferences and the desire and motivation to learn. The assessment should also include emotional, physical, cognitive, and communication barriers and limitations (Joint Commission, 2021).
  - (8) Assess patients individually and tailor teaching to their level of understanding. Use short and simple words, chunking (short sections of information), active voice, and concrete examples (AHRQ, 2020a; Cancer Patient Education Network, 2013; Joint Commission, 2021; Office of Disease Prevention and Health Promotion, 2015). Cancer-related literature for low-literacy patients is available through the National Cancer Institute ([www.cancer.gov](http://www.cancer.gov)) and the American Cancer Society ([www.cancer.org](http://www.cancer.org)).
  - (9) Engage patients in the learning process with patient portals, interactive educational activities, shared decision-making, and patient-reported outcome measurement.
  - (10) Effective care coordination and transition may be facilitated through handoff tools to improve continuity of care and collaboration between professionals. Patient navigators can be an effective link for patient and healthcare provider communication and satisfaction.
  - (11) Cultural respect is a strategy that enables organizations to work effectively in cross-cultural situations.
    - (a) Developing and implementing a cultural competency framework in health systems is an extended process that ultimately reduces health disparities and improves access to high-quality health care.
    - (b) Cultural respect benefits consumers, stakeholders, and communities.
    - (c) Because several elements can influence health communication (e.g., behaviors, language, customs, beliefs, perspectives), cultural respect is also critical for achieving accuracy in medical research (National Institutes of Health, n.d.).
3. Barriers to educator effectiveness (AHRQ, 2020b; Blecher et al., 2016)
    - a) The educator's expertise regarding the information provided
    - b) The educator's understanding of teaching-learning principles
    - c) The educator's understanding of differences in learning styles
    - d) The methods available to the educator for patient education
    - e) The educator's ability to match the appropriate teaching methods and language to specific content and learning styles; the language must be adapted to individual learning abilities, healthcare-related literacy, and ability to speak, read, and understand English.
    - f) The educator's ability to involve individuals in the learning process
    - g) The educator's ability to communicate with other members of the healthcare team to provide continuity of care between the various points of care (e.g., hospital, physician practice, home, extended-care facilities)
    - h) The decreased length of hospital stay and the increased need to deliver complex information to patients
- E. Methods of patient education (Blecher et al., 2016; Hopmans et al., 2014; Laszewski et al., 2016; LeFebvre & Felice, 2016; Neuss et al., 2016; Şahin & Ergüney, 2016; Sullivan et al., 2016)
1. Educational methods should be selected based on preferences and abilities. They may include any combination of the following:
    - a) Auditory, such as audiotapes, podcasts, or face-to-face live presentations
    - b) Printed or visual materials, including animations, three-dimensional graphics, educational videos, booklets, chemotherapy cards, infographics, and printed instructions regarding procedures or self-care measures
    - c) Computer-based learning using three-dimensional interactive animations, compact

- discs, flash drives, preloaded devices, screen sharing, or e-gaming
  - d) Web-based learning, including patient portals, learning management systems, and reliable external websites
    - (1) National Cancer Institute ([www.cancer.gov](http://www.cancer.gov))
    - (2) American Cancer Society ([www.cancer.org](http://www.cancer.org))
    - (3) American Society of Clinical Oncology ([www.cancer.net](http://www.cancer.net))
  - e) Demonstration and tactile methods using models
2. Patient education in any format includes teach-back techniques to reinforce learning and document strategies.
    - a) If the patient cannot teach back the message, a different mode of education should be considered when reteaching.
    - b) For example, if the original message was conveyed orally, visualization or interactive modes of education should be considered in follow-up efforts.
  3. Patient education is the responsibility of all nurses and the entire healthcare team and continues as an ongoing process throughout the cancer care continuum (American Nurses Association, 2015).

#### F. Scope of information

1. Provide easily understandable verbal, video, audio, written, or web-based information (AHRQ, 2020b; Frentos, 2015; Iowa Health System et al., 2017; Narwani et al., 2016; Truccolo, 2016).
  - a) If printed material is used, ensure that the sentences and paragraphs are short.
  - b) Bullet points are helpful.
  - c) Always encourage patients and significant others to ask questions, provide feedback, and participate actively.
2. Use the chunk and check method (AHRQ, 2020a).
  - a) Do not wait until the end of the visit to initiate teach-back.
  - b) Chunk out information into small segments and have your patient teach it back.
  - c) Repeat several times during a visit.
  - d) This method minimizes the likelihood of overwhelming the learner.
3. Include patients and significant others, and provide education on the following topics (Gumusay et al., 2016; LeFebvre & Felice, 2016; Neuss et al., 2016; Şahin & Ergüney, 2016; Sullivan et al., 2016):
  - a) Disease and treatment plan
  - b) Goals of treatment
  - c) Duration and schedule of treatment
  - d) Cancer medication names, including generic and brand names; the dose and frequency of the

treatment and number of cycles (length of therapy); and the implications and plan for missed or delayed doses, especially with the use of oral anticancer medications

- e) Supportive care medications, including generic and brand names, and their dose and frequency
  - f) Drug–drug and drug–food interactions based on the most current medication list
  - g) Potential short- and long-term adverse effects and the subsequent management strategies
  - h) Contact information for and directions regarding communicating with healthcare team members
  - i) Symptoms that require immediate discontinuation of self-administered medications or treatments
  - j) Procedures for handling medications in the home, including safe storage, handling, and management of unused medication
  - k) Procedures for handling body secretions and waste in the home
  - l) Procedures for disposing of medical waste sharps per state or local guidelines
  - m) Follow-up schedules, including laboratory and healthcare provider visits
  - n) A list of credible resources where more information can be obtained if desired
4. Encourage patients to write down questions between visits and bring them to follow-up appointments. At each visit, healthcare providers should address patient and caregiver questions.
  5. Use tools such as the Patient Education Materials Assessment Tool (PEMAT) to evaluate patient education materials (AHRQ, 2020c)

#### G. Documentation

1. Nurses assess and document patient understanding of the education provided (Joint Commission, 2021).
2. Documentation of understanding includes the patient's ability to verbalize or demonstrate learning and the need for information reinforcement. If patients cannot comprehend the information or refuse education, this must be documented with alternative plans.
3. Methods of assessing patient (and significant other) understanding include the following (Iowa Health System et al., 2017; Joint Commission, 2021):
  - a) The patient or their significant other communicates an understanding of the information presented, including medication names and the purpose of the therapy.
  - b) The patient or their significant other identifies crucial instructions for self-care.
  - c) The patient or their significant other identifies symptoms and side effects to report and how to contact the providers if needed.

- d) The patient brings new prescriptions to a follow-up visit and correctly states the instructions for use.
- e) The patient performs a return demonstration of procedures, such as temperature monitoring and handwashing.
- f) The patient or their significant other accurately identifies the date and time of the next follow-up visit.
- g) For oral agents, the patient or their significant other verbalizes the name of the medication, the correct procedure for administration (e.g., with or without food), and safe handling and disposal procedures. See Chapter 4 for a discussion on adherence to oral antineoplastics.
- h) The patient or their significant other shares where or how to obtain additional information if desired.
- i) The patient or their significant other communicates the need for additional teaching sessions if issues are identified or if complex or multimodal treatments are planned.

# Cancer and Cancer Treatment

Chapter 4. Overview of Cancer and Cancer Treatment

Chapter 5. Clinical Trials and Drug Development

## CHAPTER 4

# Overview of Cancer and Cancer Treatment

### A. Definition of cancer

1. Cancer is fundamentally a disease of genomic alteration.

a) Hanahan and Weinberg proposed the hallmarks of cancer as a framework to describe eight functional characteristics acquired by cancer cells during tumorigenesis (Devita et al., 2020; Hanahan & Weinberg, 2011; see Table 4-1).

- (1) Sustained proliferative signaling
- (2) Evading growth suppressors
- (3) Resisting cell death
- (4) Enabling immortality
- (5) Inducing angiogenesis
- (6) Activating invasion and metastasis
- (7) Reprogramming energy metabolism
- (8) Evading immune response

b) The authors further described the developmental processes which foster the actuation of the original eight functional characteristics with enabling and emerging characteristics (Hanahan, 2022; Hanahan & Weinberg, 2011).

- (1) Genome instability
- (2) Tumor-promoting inflammation
- (3) Unlocking phenotypic plasticity
- (4) Nonmutational epigenetic reprogramming
- (5) Polymorphic microbiomes
- (6) Senescent cells

2. Theories of cancer origins (Eggert, 2018)

a) Clonal theory: Initial DNA changes result in benign growth, from which cloned cells accumulate multiple genomic alterations over time, resulting in malignancy.

b) Cancer stem cell theories

- (1) In the cancer stem cell model, cancer cells arise from cancer stem cells, which may have limited proliferative capability, and at least one cell line becomes tumorigenic.
- (2) The plasticity model builds on the cancer stem cell model, suggesting that noncancer stem cell versions of cells can change

throughout their life cycle and are converted to cancer stem cells.

c) Inflammation theory: Chronic inflammation is a prolonged immune response triggered by persistent infection, hypersensitivity disease, and long-term exposure to toxic agents, leading to tissue damage and ultimately cancer (e.g., hepatitis B infection leading to liver cancer).

3. Cancer genome

a) Cancer is a disease in which cells begin to divide and grow uncontrollably through genomic alterations in specific genes (Sanchez-Vega et al., 2018).

b) Abnormal behaviors demonstrated by cancer cells result from a cascade of pathogenic variations or alterations (formerly known as mutations) in the DNA of two types of key regulatory genes.

- (1) Proto-oncogenes encode for protein products that stimulate cell growth and division. In their natural state, or wild-type, these genes are known as proto-oncogenes; when DNA is altered, they become oncogenic and drive cancer growth.

- (2) Tumor suppressor genes encode for protein products that inhibit cellular division, repair damaged DNA, and promote apoptosis (programmed cell death) for damaged or aging cells. When altered, these genes become inactivated and allow uncontrolled cancer growth.

c) Oncogenic genes, known as driver variants, are activated during carcinogenesis. Many are genes that govern growth factors, growth factor receptors, and cell signaling and, when altered, continuously send signals to the nucleus of the cell to grow and divide (see Table 4-2).

d) Passenger variants, in contrast to driver variants, arise during carcinogenesis and do not contribute directly to disease.

e) Pathogenic variants inactivate tumor suppressor genes during carcinogenesis. Tumor sup-

**TABLE 4-1.** Hallmarks of Cancer

| Hallmark                           | Healthy Cells                                                                                                                                                                                                                     | Cancer Cells                                                                                                                                                                                                       | Example                                                                                                                                                                                                                                                                                                      |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Proliferative signaling            | Healthy cells rely on external growth factor signaling to grow and maintain homeostasis.                                                                                                                                          | Cancer cells have the ability to sustain continuous growth signaling and do not require external stimulation to proliferate.                                                                                       | BRAF is a protein involved in directing cellular growth. Pathogenic variants in BRAF are therapeutic targets in treating melanoma and colon cancer.                                                                                                                                                          |
| Evading growth suppression         | Cells react to signals from tumor suppressor genes and contact inhibition to govern growth and division; growth suppression is regulated by a group of enzymes known as cyclin-dependent kinases.                                 | Cancer cells evade anti-growth signals by suppressing the retinoblastoma protein and other proteins, which leads to the continuous activation of cyclin-dependent kinases.                                         | Cyclin-dependent kinase 4/6 inhibitors reduce the activity of cyclin-dependent kinases and restore the growth suppression properties of the retinoblastoma protein.                                                                                                                                          |
| Resisting cell death               | Apoptosis is preprogrammed cellular death for damaged or aging cells.                                                                                                                                                             | Cancer cells evade apoptosis pathways to divide and grow uncontrollably.                                                                                                                                           | The <i>TP53</i> gene is responsible for repairing DNA damage; if repair is not possible, apoptosis is induced. Clinical trials targeting <i>TP53</i> dysfunction in cancer are ongoing.                                                                                                                      |
| Enabling immortality               | Cells are programmed with a limited number of growth-and-division cycles; DNA sequences called telomeres, located at the ends of chromosomes, control the cell division limit through a shortening process leading to cell death. | Cancer cells become immortal, reversing the telomere shortening process with the enzyme telomerase.                                                                                                                | Telomerase reverse transcriptase (TERT), an enzyme that reactivates telomerase, is being pursued as a direct therapeutic target. Clinical trials are ongoing.                                                                                                                                                |
| Inducing angiogenesis              | Angiogenesis is how new blood vessels are formed, which occurs only when needed during fetal development, menstrual cycle, and wound healing.                                                                                     | The growth of a vascular network is necessary for metastasis, as cancer cells require a supply of nutrients and oxygen and a system for waste removal.                                                             | Vascular endothelial growth factor is a cytokine that stimulates vascular endothelial cells to form new blood vessels under normal conditions and in tumor angiogenesis. It is a crucial therapeutic target in the development of antiangiogenic therapies.                                                  |
| Activating invasion and metastasis | Unlike blood cells, other cells cannot travel throughout the body, are governed by contact inhibition, and do not invade other tissue.                                                                                            | Invasion is the direct extension and penetration by cancer cells into neighboring tissue. Metastasis is the ability of the cancer cells to penetrate lymph and blood vessels to migrate and invade distant tissue. | Alterations in the <i>MET</i> gene lead to tumor cell proliferation, migration, and survival and are therapeutic targets in the treatment of non-small cell lung cancer.                                                                                                                                     |
| Reprogramming energy metabolism    | Cells generate energy through the orderly process of glycolysis, the Krebs cycle, and electron transport.                                                                                                                         | Cancer cells rely on glycolysis alone for energy production; in the presence of oxygen, cancer cells reprogram glucose metabolism by aerobic glycolysis, known as the Warburg effect.                              | Mechanistic target of rapamycin is a protein kinase that balances nutrient and energy availability with cellular growth and is involved in the Warburg effect. These inhibitors are used to treat renal cell carcinoma and are being studied in other cancers.                                               |
| Evading immune destruction         | Healthy cells develop immune checkpoints to protect against autoimmunity.                                                                                                                                                         | Cancer cells exploit these immune checkpoints to evade immune detection and elimination                                                                                                                            | Monoclonal antibodies block immune checkpoint proteins, programmed cell death protein 1, programmed cell death-ligand 1, and cytotoxic T-lymphocyte antigen 4. The immune system overcomes cancer's ability to resist immune responses and stimulates the body's mechanisms to defend itself against cancer. |

Note. Based on information from Devita et al., 2020; Hanahan & Weinberg, 2011.

**TABLE 4-2.** Oncogenic Driver Variants

| Oncogene                                       | Function                                                                                                               | Tumor Types                                                                |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| <i>ABL</i>                                     | Increases cell proliferation                                                                                           | Chronic myeloid leukemia                                                   |
| <i>BCL2</i>                                    | Regulates apoptosis                                                                                                    | Lymphoma                                                                   |
| <i>BRAF</i>                                    | Controls growth signaling in MAPK pathway                                                                              | Colorectal and gastric cancer and melanoma                                 |
| Epidermal growth factor receptor (EGFR; ERBB1) | Cell surface receptor that activates signaling pathways within the cell, promoting cell growth, division, and survival | Amplified in colorectal, lung, breast, head and neck, and prostate cancers |
| HER2 (ERBB2)                                   | Cell surface receptor that activates signaling pathways within the cell, promoting cell growth, division, and survival | Amplified in breast, gastric, lung, and colorectal cancers                 |
| <i>MET</i>                                     | Regulates cell growth and motility                                                                                     | Papillary renal cell and lung cancer                                       |
| <i>MYC</i>                                     | Family of regulator and transcription genes that control cell division and malignant formation                         | Burkett lymphoma                                                           |
| <i>RAS</i>                                     | Family of genes that govern signaling pathways in cells                                                                | KRAS and NRAS: colorectal and lung cancer<br>NRAS: melanoma                |
| <i>RET</i>                                     | Cell signaling from outside and inside of the cell that promotes growth and maturation                                 | Thyroid and multiple endocrine neoplasias                                  |

Note. Based on information from Devita et al., 2020; Wilkes, 2018.

pressor genes are associated with DNA repair, limit cell division, and control apoptosis (see Table 4-3).

- f) Cancer cells are highly diverse or heterogeneous and contain many different types of DNA damage which constantly accumulate within the cancer genome.
- (1) Both large and small alterations can impact cellular behavior.
  - (2) Damage in the genes associated with DNA repair causes further genomic instability, leading to errors. These errors include

missense, nonsense, and frameshift variants; DNA deletions; translocations; amplifications; and mismatched nucleotide pairs, which accumulate and result in malignancy.

- g) Epigenetic changes (changes in genetic expression rather than DNA sequence) can affect the efficacy of DNA repair genes, altering specific gene expression and disrupting healthy expression of proto-oncogenes and tumor suppressor genes (e.g., DNA methylation).
  - h) Somatic cancer versus hereditary (germline) cancer
    - (1) Most pathogenic alterations accumulate throughout the lifetime of human somatic cells, leading to sporadic cancer.
    - (2) A small percentage of cancers, approximately 5%–10% depending on cancer type, are caused by germline pathogenic variants of tumor suppressor genes, which are inherited DNA changes passed between generations in the germ line (sperm and ova) (National Cancer Institute [NCI], 2017).
4. Multiple factors often interact, leading to the development of cancer. Healthy cells may change because of the following:
- a) Spontaneous transformation: No causative agent is identified, but cellular traits are characteristic of cancer cells.
  - b) Chronic or occupational exposure: Substances such as asbestos, benzene, radiation, tobacco, arsenic, nickel, and some chemotherapy agents are implicated in cancer development.
  - c) Changes in the microenvironment: Cancer cell plasticity, immune cell and signaling molecule involvement, and metabolic changes brought about by changes in oncogenes and tumor suppressor genes all contribute to the progression of cancer growth (Eggert, 2018).
  - d) Exposure to viruses: Genetic changes can occur to cells through viral infections (e.g., human papillomavirus [HPV] is the primary cause of cervical cancer) (Inan et al., 2017).

- B. The Cancer Care Continuum framework illustrates the various stages and pathways of patient care (Young et al., 2020).
1. Healthy lifestyles and the early detection of cancer can prevent up to 50% of cancers.
  2. Diagnosis and shared decision-making between the healthcare team, patient, and family help determine the treatment plan and goals of care.
  3. Goals of cancer therapy

**TABLE 4-3.** Tumor Suppressor Genes

| Tumor Suppressor Gene                | Function                                                                                              | Associated Hereditary Cancer Syndromes                       |
|--------------------------------------|-------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|
| <i>APC</i>                           | Controls cell division and contact inhibition                                                         | Familial adenomatous polyposis                               |
| <i>ATM</i>                           | Controls rate of cell growth and repairs damaged DNA                                                  | <i>ATM</i> -associated breast cancer                         |
| <i>BRCA1, BRCA2</i>                  | DNA repair genes                                                                                      | Hereditary breast, ovarian, prostate, and pancreatic cancers |
| <i>CDK4</i>                          | Controls progression through G <sub>1</sub> phase of cell cycle                                       | Melanoma                                                     |
| <i>MSH2, MSH6, MLH1, PMS2, EPCAM</i> | Mismatch repair genes                                                                                 | Hereditary nonpolyposis colon cancer (Lynch syndrome)        |
| <i>RB1</i>                           | Controls cell cycle                                                                                   | Retinoblastoma                                               |
| <i>TP53</i>                          | Most common altered gene in cancer; guardian of the genome; detects DNA damage and triggers apoptosis | Li-Fraumeni syndrome and many solid tumors                   |

Note. Based on information from Devita et al., 2020; Wilkes, 2018.

- a) Treatment planning includes shared decision-making that integrates the patient's personal goals, needs, and values as part of care planning (Cranley et al., 2017).

- b) Prevention (Mahon, 2018)

- (1) Primary cancer prevention includes measures taken to avoid carcinogen exposure and promote health or prevent disease development. Examples include avoidance of tobacco products and immunization against HPV.

- (a) Chemoprevention may include tamoxifen for women at risk for breast cancer or HPV vaccination to protect against HPV infection, which can cause cancers of the cervix, vagina, penis, anus, and oropharynx.

- (b) Lifestyle and behavioral modification of risk factors, including dietary choices, obesity, and smok-

ing, are associated with the development of some cancers (Smith et al., 2018).

- (2) Secondary cancer prevention includes early detection and treatment of cancer (e.g., mammogram, colonoscopy).

- (3) Tertiary cancer prevention includes monitoring for or preventing recurrence of the original cancer or second malignancies (e.g., rehabilitation and exercise programs, nutritional changes, psychosocial support) (Smith et al., 2018).

- c) Curative intent is a treatment that has the potential to eliminate disease (American Cancer Society [ACS], 2019a).

- d) Control is when a cure is not possible. The goal may be to administer treatment to slow the growth or spread of cancer and allow patients to live longer than if therapy had not been given (ACS, 2019a).

- e) Palliation is an interprofessional team-based approach that improves the quality of life for patients and families through expert assessment and treatment of physical, spiritual, psychological, and social problems associated with severe illness (World Health Organization [WHO], n.d.).

4. Cancer treatment and palliative care, which includes many cancer treatment modalities, uses as a monotherapy or combination therapy approach.

- a) Types of cancer treatment modalities include surgery, radiation therapy, chemotherapy, hormone therapy, immunotherapy, gene therapy, targeted therapy, and hematopoietic stem cell transplantation.

- b) Palliative care should be integrated early into treatment plans and is key to effective patient management. It can be provided in many care settings, including inpatient, outpatient, primary care, and community settings (WHO, n.d.).

5. Post-treatment care is referred to as *survivorship care* (NCI, n.d.-b).

- a) Practicing cancer prevention and making healthy lifestyle choices

- b) Providing follow-up cancer screenings

- c) Addressing physical and psychosocial late effects of treatment

- d) Rehabilitating with monitoring and management of long-term treatment effects

- e) Assessing for concerns such as financial toxicity and disability

- f) Transitioning to primary care management and referring to other specialists if indicated

6. End-of-life care encompasses symptom management and remembrance.

C. Cancer staging and grading (American College of Surgeons, n.d.; Amin et al., 2017; Vogel, 2018)

1. Staging

- a) Staging verifies the extent of the disease by assessing the location and size of the primary tumor and determining if it has spread to other tissues or organs.
- b) It informs prognosis, treatment planning, identification of suitable clinical trials, and treatment response.
- c) Staging conventions provide a common language that the healthcare team can use to communicate about a patient's case.
- d) Criteria are unique for many types of cancer (American College of Surgeons, n.d.; NCI, 2015).
- e) Four types of staging exist (American College of Surgeons, n.d.; Amin et al., 2017).
  - (1) Clinical: based on physical examination, imaging, and biopsy
  - (2) Pathologic: Based on tissue, fluids, or exploration during surgery; is combined with clinical staging
  - (3) Post-therapy/post-neoadjuvant therapy: used for confirming cancer remaining after systemic chemotherapy or hormone therapy, radiation therapy prior to surgery, or when no surgery is performed
  - (4) Restaging: used for determining the extent of recurrence; helpful for planning future treatment options
- f) The tumor, node, metastasis (TNM) staging system is maintained by the American Joint Committee on Cancer and the Union for International Cancer Control. It is the most commonly used anatomic staging system and is based on specific criteria. It is combined with a staging number (0–IV) and sometimes with substage classifications (e.g., IIa, IIb). In general, stage I confers a more favorable prognosis than stage IV (American College of Surgeons, n.d.; Amin et al., 2017; Vogel, 2018; see Figure 4-1).
- g) Hematologic malignancies, malignant melanoma, brain cancers, and other cancers are staged according to different systems (American Brain Tumor Association, n.d.; Leukemia and Lymphoma Society, n.d.-a, n.d.-b; Multiple Myeloma Research Foundation, 2021; Vogel, 2018).
  - (1) The Ann Arbor staging system is used to stage Hodgkin lymphoma.

- (2) The Rai staging system is used to stage chronic lymphocytic leukemia.
- (3) The International Staging System is used for multiple myeloma.

2. Grading

- a) Cellular differentiation is based on how closely tumor cells resemble healthy cells in structure and maturity.
- b) Differentiation is graded from GX (cannot be assessed) to G4 (undifferentiated, where the parent cell is impossible to distinguish).
  - (1) Grade 1 tumor cells appear very similar to healthy cells. They are referred to as low grade or well differentiated.
  - (2) Grade 2 tumor cells show more differences from healthy cells. They are referred to as intermediate grade or moderately differentiated.
  - (3) Grade 3–4 tumor cells have minimal similarities to healthy cells and are considered high grade or poorly differentiated.
- c) Cells are obtained by biopsy or surgical removal for microscopic examination by a pathologist. Cancer cell differentiation can vary over time, and cells with several differentiation grades can exist within a single tumor.
- d) Tumor grade is a prognostic indicator used in treatment planning. A higher grade indicates a more aggressive tumor (Vogel, 2018).

D. Cancer treatment modalities

1. Table 4-4 summarizes the history and evolution of antineoplastic therapy.
2. Surgery (Lester, 2018)
  - a) Surgery is a precise local treatment. It may be robotic assisted (Doyle-Lindrud, 2015).
  - b) Surgery may remove all or a portion of the primary tumor, lymph nodes, and adjacent tissues.
  - c) It can be used to obtain specimens for cytopathology.
  - d) Surgery may be the only treatment a patient requires.
  - e) It may be preceded by (neoadjuvant) or followed by (adjuvant) modalities, such as chemotherapy, immunotherapy, or radiation therapy.
  - f) Surgery may be used in the palliative setting to alleviate or lessen intolerable symptoms.
3. Radiation therapy (Behrend, 2018; Gosselin, 2018)
  - a) Radiation therapy is a local treatment in which energy is precisely aimed at a specific target.
  - b) It may be planned before surgery to decrease tumor burden (neoadjuvant) or after surgery (adjuvant) to prevent recurrence of the primary tumor.

**FIGURE 4-1.** Tumor, Node, Metastasis (TNM) Staging

| <b>T = tumor size</b>                                                                                                                                                                                 | <b>N = nodal involvement</b>                                                                                                                                                                                                                                                              | <b>M = metastasis</b>                                                                                                          |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>• TX = not assessed</li> <li>• Tis = in situ cancer</li> <li>• T0 = no primary tumor found</li> <li>• T1, T2, T3, T4 based on the tumor size/extent</li> </ul> | <ul style="list-style-type: none"> <li>• NX = not assessed</li> <li>• N0 = no lymph nodes involved</li> <li>• N1, N2, N3 based on the number/location of lymph nodes involved</li> <li>• Nmi = micrometastasis in the node</li> <li>• N(i-) = isolated tumor cells in the node</li> </ul> | <ul style="list-style-type: none"> <li>• MX = not assessed</li> <li>• M0 = no metastasis</li> <li>• M1 = metastasis</li> </ul> |

A patient's TNM stage may also have one or more letters at the beginning. These letters indicate when staging occurred.

- **cTNM** or **TNM**: No letter or a "c" indicates a clinical staging.
- **pTNM**: A "p" indicates a pathologic staging.
- **ycTNM**: A "yc" indicates a clinical staging following systemic or radiation therapy.
- **ypTNM**: A "yp" indicates a pathologic staging following systemic or radiation therapy.
- **rTNM**: An "r" indicates staging following a recurrence of cancer.
- **aTNM**: An "a" is used for staging cancer that was found during an autopsy.

Note. Based on information from American College of Surgeons, n.d.; Amin et al., 2017.

- c) This therapy is more effective for some diseases than others.
- d) Multiple treatment delivery methods exist, including various external beam treatments, stereotactic radiosurgery, image-guided CyberKnife® radiosurgery, brachytherapy, and sealed and unsealed radionuclide therapy.
- e) It is often given in combination with other antineoplastic therapies and termed chemoradiation or radioimmunotherapy, depending on the classification of the concurrent treatment.
4. Chemotherapy is the most traditional systemic cancer therapy (Dowling et al., 2017; see Chapter 6).
  - a) Chemotherapy is most commonly administered as a systemic treatment.
  - b) It may be used locally for instillations (e.g., bladder, peritoneum) or as a topical therapy.
  - c) Chemotherapy may be used as a single agent or, more commonly, in combination.
  - d) It may be dose limiting from cytotoxic effects on healthy tissues.
  - e) This therapy disrupts the cell cycle at different points, triggering cellular death.
  - f) It is used in high doses for hematopoietic stem cell transplantation.
  - g) Examples include alkylating agents, antimetabolites, antitumor antibiotics, nitrosoureas, and plant alkaloids (e.g., taxanes, vinca alkaloids, camptothecins).
5. Hormone therapy (Tortorice, 2018; see Chapter 7)
  - a) Hormone therapy is a systemic treatment, often combined with other antineoplastic agents. It can be oral or injectable.
  - b) It has various mechanisms of action and unique side effect profiles.
  - c) Examples include corticosteroids, androgens, antiandrogens, selective estrogen receptor modulators, estrogen receptor antagonists, aromatase inhibitors, and luteinizing hormone-releasing hormone antagonists and agonists.
6. Immunotherapies and gene therapies (Bayer et al., 2017; Lea, 2018; Martin, 2017; Muehlbauer et al., 2018; Vioral, 2018; see Chapter 10)
  - a) Immunotherapies and gene therapies are systemic treatments that use the patient's immune system through various pathophysiologic mechanisms.
  - b) They may be synthetic (e.g., chimeric antigen receptor T cells), biologically derived (e.g., monoclonal antibodies), or nonpathogenic or pathogenic virus (requiring modification for use).
  - c) Examples include chimeric antigen receptor T-cell therapies, checkpoint inhibitors, monoclonal antibodies, cancer vaccines, immunomodulators, cytokines, and oncolytic viruses.
  - d) These therapies cause significant cytokine release syndrome, hypersensitivity reactions, and other unique side effects because of the immune response to the drug.
  - e) This is a rapidly developing class of treatment options.
  - f) Gene therapies typically correct defective genes by inserting a healthy gene into the nuclei of abnormal cells to repair, replace, or alter its function through viral vectors.
  - g) Biosimilars are biologic products similar to, but not the same as, the reference drug they mimic.
    - (1) Biosimilar drugs have no clinically meaningful differences from the reference product.
    - (2) They are not generic forms of a reference drug (which are chemically identical to the reference drug) instead they are chemically similar, and structural and chemical changes should not affect efficacy (U.S. Food and Drug Administration [U.S. FDA], 2021b).

- (3) Biosimilars are produced through an abbreviated manufacturing process and are expected to be an affordable alternative to some therapy agents.
7. Targeted therapies (Devita et al., 2020; Wilkes, 2018; see Chapter 8)
- Targeted therapies are treatments that act on key altered oncogenes or tumor suppressor genes (see Table 4-5).
  - Key oncogenes encode for protein kinases, are involved in signaling pathways, are sensitive to pharmacologic inhibition, and are actionable therapy targets.
  - Genomic alterations have become highly sensitive, and specific biomarkers for disease detection, monitoring, and treatment selection have been identified to select appropriate targeted therapy.
- d) Targeted agents include tyrosine kinase inhibitors, anaplastic lymphoma kinase inhibitors, cyclin-dependent kinase inhibitors, and epidermal growth factor receptor inhibitors. Many other targets exist, and most of these agents are oral.
- e) Unlike traditional chemotherapy, which disrupts cellular division in healthy and cancer cells, targeted agents affect only altered cancer cells, minimizing toxicity in nonmalignant cells (Wilkes, 2018).
8. High-dose chemotherapy with hematopoietic stem cell transplantation
- High-dose chemotherapy, with or without radiation, is administered with the intention of bone

**TABLE 4-4.** History of Cancer Treatments

| Period           | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pre-20th century | <p>In the 1500s, heavy metals were used systemically to treat cancers; however, their effectiveness was limited, and their toxicity was significant (Burchenal, 1977).</p> <p>Prior to 1890, surgical treatment or cauterization of tumors was the most common therapeutic option (Falzone et al., 2018).</p> <p>In the 1890s, William Coley developed and explored Coley toxins, the first nonspecific immunostimulants used to treat cancer.</p> <p>In 1899, Marie and Pierre Curie proposed using radiation to treat cancer (Falzone et al., 2018).</p>                                                                                                                                                                                                                                                                                                                                                                                                              |
| 1930–1940        | <p>The use of nitrogen mustard gas as a chemical weapon in World War I and the accidental use of this banned weapon in World War II led to the discovery of the first DNA alkylating agent, as its toxic effect led to bone marrow and white blood cell suppression. This discovery led to the use of chemotherapy to treat hematologic and solid tumors (Falzone et al., 2018). Alkylating agents became recognized as a successful treatment for lymphoma (Gilman &amp; Philips, 1946). Folic acid antagonists, later called methotrexate, were found to be effective against pediatric acute lymphoblastic leukemia (Farber et al., 1948).</p> <p>Congress passed the National Cancer Act in 1937, establishing the National Cancer Institute.</p>                                                                                                                                                                                                                   |
| 1950s            | <p>Research dedicated to nonhematologic cancers began with actinomycin-D in pediatric solid tumors (Falzone et al., 2018). The Children's Cancer Group (now part of the merged Children's Oncology Group) was formed as the first cooperative group dedicated to finding effective treatments for pediatric cancer.</p> <p>Metastatic choriocarcinoma was the first metastatic disease cured by treatment with methotrexate in 1956.</p> <p>The first bone marrow transplant was performed in 1956.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 1960–1970        | <p>Combined therapeutic protocols using several chemotherapy drugs with different mechanisms of action became the standard in clinical practice (Falzone et al., 2018).</p> <p>The Philadelphia chromosome was discovered in the cells of chronic myeloid leukemia. This genetic abnormality is a fusion gene called <i>BCR-ABL 1</i>, which continuously promotes cancer growth. This marked the beginning of the search for targeted therapies against this abnormal cancer cell behavior.</p> <p>Mechlorethamine, vincristine, procarbazine, and prednisone (MOPP), the first combination chemotherapy, were used and found to be curative against Hodgkin lymphoma (Noonan, 2007).</p> <p>Chemotherapy was used with surgery and radiation, beginning combination treatment for cancer.</p> <p>The development of hybridoma technology began leading to the discovery of monoclonal antibodies.</p> <p>Tamoxifen is synthesized in 1962 and first used in 1969.</p> |
| 1970s            | <p>The National Cancer Act of 1971 provided funding for cancer research.</p> <p>Adjuvant chemotherapy became a standard cancer treatment (Bonadonna et al., 1995; Fisher et al., 1986).</p> <p>The discovery of the human leukocyte antigen histocompatibility system expanded the use of and survival from bone marrow transplantation (Perry &amp; Linch, 1996).</p> <p>The <i>TP53</i> gene, the most commonly altered gene in human cancer, was discovered in 1979, beginning the search for the genetic basis of cancer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**TABLE 4-4.** History of Cancer Treatments (*Continued*)

| Period       | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1980s        | <p>Community clinical oncology programs were developed in 1983 to contribute to National Cancer Institute chemotherapy clinical trials.</p> <p>Focus turned to symptom management to alleviate dose-limiting toxicities related to neutropenia, nausea and vomiting, and cardiotoxicity.</p> <p>Scientists investigated recombinant DNA technology, leading to treatments involving interferon alpha and erythropoietin. This marked the beginning of biotechnical advancements in cancer treatment (Devita et al., 2020).</p> <p>High-dose chemotherapy was used for myeloablation prior to bone marrow and stem cell transplantation (Perry &amp; Linch, 1996).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 1990s        | <p>New classifications of drugs (e.g., taxanes) were developed; paclitaxel was found to be effective against ovarian and breast cancers (Rowinsky et al., 1992).</p> <p>Biotechnical advancements continued with approvals of granulocyte-colony-stimulating factor and granulocyte macrophage-colony-stimulating factor, interleukin-2, interleukin-11, and the first cancer-directed monoclonal antibodies rituximab and trastuzumab.</p> <p>The approval and widespread use of ondansetron for the prevention of chemotherapy-induced nausea and vomiting had an enormous impact on symptom management, improved quality of life for chemotherapy patients, and allowed for the greater development of outpatient treatment protocols (Perez, 1995).</p> <p>Based on the studies by Mary-Claire King, the first tumor suppressor and breast cancer susceptibility gene, <i>BRCA1</i>, was sequenced in 1994. <i>BRCA2</i> was discovered the following year. These breakthroughs confirmed the genetic basis of some cancers (Gnarra et al., 1995; Hoskins et al., 1995; Miki et al., 1994).</p> <p>Aromatase inhibitors were approved for breast cancer treatment. This marked a step forward for hormone therapy.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 2000s        | <p>The U.S. Food and Drug Administration approved imatinib to treat chronic myeloid leukemia, the first targeted treatment that disrupts the action of the altered <i>BCR-ABL</i> gene (Falzone et al., 2018).</p> <p>The Human Genome Project was completed, meeting the goal of mapping and understanding of all the genes of human beings (Devita et al., 2020).</p> <p>Radioimmunotherapy was developed to deliver radioactivity directly to select tumor cells, avoiding damage to healthy tissue (e.g., ibritumomab tiuxetan, tositumomab, iodine-131).</p> <p>The U.S. Food and Drug Administration approved the following:</p> <ul style="list-style-type: none"> <li>• Bevacizumab is the first approved antiangiogenic agent for cancer (American Society of Clinical Oncology, n.d.-a).</li> <li>• Aprepitant, a neurokinin-1 antagonist, is used in combination with other antiemetic drugs to prevent chemotherapy-induced nausea and vomiting.</li> <li>• A prophylactic vaccine prevents human papillomavirus infections that cause cervical cancer (American Society of Clinical Oncology, n.d.-a).</li> <li>• Targeted therapies were developed to affect epidermal growth factor receptors in lung cancer (gefitinib and erlotinib) and colon cancer (cetuximab and panitumumab) (American Society of Clinical Oncology, n.d.-a).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 2010–present | <p>In 2010, the Patient Protection and Affordable Care Act was signed into law.</p> <p>American cancer survivors numbered 13.7 million, the highest total to date (American Society of Clinical Oncology, n.d.-a).</p> <p>The U.S. Food and Drug Administration approved the following:</p> <ul style="list-style-type: none"> <li>• Sipuleucel-T was the first cancer treatment vaccine to use the patient's dendritic cells in the immune system to attack cancer cells (Anassi &amp; Ndefo, 2011).</li> <li>• The immunotherapy drug ipilimumab for unresectable or metastatic melanoma stimulates the body's immune system to attack cancer cells (Bristol-Myers Squibb, 2011; National Cancer Institute, 2015).</li> <li>• The first antibody-drug conjugate, ado-trastuzumab emtansine (T-DM1), links trastuzumab (the monoclonal antibody) with a microtubular inhibitor.</li> <li>• The first programmed cell death-ligand 1 checkpoint inhibitor, atezolizumab, is used to treat advanced bladder cancer (American Society of Clinical Oncology, n.d.-b).</li> <li>• Chimeric antigen receptor T-cell therapy is used for select patients with B-cell acute lymphoblastic leukemia. It is the first gene therapy that uses technology to reprogram the patient's immune system to destroy cancer cells (Novartis Pharmaceuticals, 2017).</li> <li>• Bevacizumab-awwb is the first biosimilar approved in the United States to treat cancer (U.S. Food and Drug Administration, 2017b).</li> <li>• Larotretinib was the first agent approved to treat a genetic variant, rather than the tumor location, marking the beginning of tumor agnostic therapies (Raez &amp; Santos, 2018).</li> <li>• By May 2021, more than 70 U.S. Food and Drug Administration–approved targeted agents were available to treat solid and hematologic malignancies based on biomarkers detected in the tumor (National Cancer Institute, 2020a).</li> </ul> |

marrow ablation, with subsequent rescue using peripheral, bone marrow, or umbilical stem cells.

- b) Transplants can be autologous, allogeneic, syngeneic, or haploidentical. High-dose chemotherapy with hematopoietic stem cell transplantation is the standard of care for many hematologic malignancies (Tortorice, 2018).

#### E. Treatment approaches

1. Chemoprevention uses selected pharmacologic agents to prevent cancer in high-risk individuals (e.g., tamoxifen for women whose personal health history indicates a statistically increased risk for developing breast cancer) (Smith et al., 2018).
2. Neoadjuvant therapy uses one or more treatment modalities before the primary treatment (e.g., chemotherapy before surgery). The goal is to debulk the primary tumor before surgery or address micrometastases (Tajima et al., 2017; Tortorice, 2018).
3. Adjuvant therapy follows the primary treatment modality (e.g., chemotherapy or radiation after surgery). The goal is to target minimal disease or micrometastases for patients at high risk for recurrence (Tortorice, 2018).
4. Conditioning or preparative therapy is the administration of chemotherapy, sometimes with total body irradiation, to eliminate residual disease or ablate the marrow space before receiving a hematopoietic stem cell transplantation (also referred to as myeloablation).
  - a) Myeloablative therapy includes the obliteration of bone marrow with chemotherapy agents that are typically administered in high doses in preparation for hematopoietic stem cell transplantation. This therapy does not allow for spontaneous marrow recovery because of the lethal doses of agents used; therefore, it must be followed by transplantation to prevent death (Zack, 2018).
  - b) Nonmyeloablative therapy is reduced-intensity conditioning using doses that are not lethal to bone marrow (Epperla et al., 2017). This type of transplant is dependent on the graft-versus-tumor effect.
5. Immunosuppression is the administration of anti-neoplastic agents at doses sufficient to blunt a patient's immune response. Agents such as methotrexate are given post-transplantation to prevent graft-versus-host disease. Select agents are used to treat noncancerous conditions, such as autoimmune diseases.

#### F. Treatment strategies

1. Over the past two decades, unprecedented advancements in molecular biology, genomics, and gene sequencing technology have led to a shift from tra-

ditional cancer treatments toward genomically guided care known as precision oncology (Devita et al., 2020).

2. Traditional cancer treatments are designed to remove solid tumors surgically and halt tumor growth through systemic disruption of mitotic division in all cells (through radiation or chemotherapy). This is accomplished via single or combination therapies (Haque et al., 2017; Jin et al., 2017; Mokhtari et al., 2017; Tortorice, 2018; Zhang et al., 2017).
  - a) Drug combinations or drug–therapy combinations (e.g., drug plus radiation therapy) provide superior efficacy and survival advantage over monotherapy in many tumor types and combination regimens.
  - b) The mechanism by which this occurs is not fully understood in some cases.
  - c) Hypotheses include that one agent may potentiate the effect of another or that the combined agents or therapies create effects that together are unique.

**TABLE 4-5.** Genomic Alterations Used to Select Treatment

| Genomic Alteration              | Disease Type With Approved Treatment                      |
|---------------------------------|-----------------------------------------------------------|
| <b>Oncogene Driver Variants</b> |                                                           |
| <i>ABL1</i>                     | Chronic myeloid leukemia and acute lymphoblastic leukemia |
| <i>ALK</i>                      | Lung cancer and melanoma                                  |
| <i>BRAF</i>                     | Melanoma and colorectal and lung cancers                  |
| <i>EGFR</i>                     | Lung cancers                                              |
| <i>ERBB2</i> (HER2)             | Breast, colorectal, endometrial, and gastric cancers      |
| <i>ESR1</i>                     | Breast cancers                                            |
| <i>KRAS</i>                     | Lung and colorectal cancers                               |
| <i>MET</i>                      | Lung cancers                                              |
| <i>NRAS</i>                     | Lung and colorectal cancers                               |
| <i>NTRK</i> fusions             | All solid tumors                                          |
| <i>PIK3CA</i>                   | Breast cancers                                            |
| <i>ROS1</i>                     | Lung cancers                                              |
| <b>Tumor Suppressor Genes</b>   |                                                           |
| <i>ATM</i>                      | Prostate cancers                                          |
| <i>BRCA1</i> and <i>BRCA2</i>   | Breast, ovarian, pancreatic, and prostate cancers         |

Note. Based on information from Devita et al., 2020; Wilkes, 2018.

- (1) Tumor cell populations are heterogeneous; therefore, a combination of agents or therapies with different mechanisms of action can increase the number of cells killed at any one time.
  - (2) Combination agents or therapies with different mechanisms of action also reduce the possibility of drug resistance, as researcher consensus concludes that many mechanisms of resistance are likely to be occurring within a single tumor (Mokhtari et al., 2017; NCI, 2016).
  - (3) Combinations of drugs can be used synergistically to access sanctuary sites. One drug's solubility or affinity for specific tissues may be different from, but complementary to, another particular drug's characteristics (Mokhtari et al., 2017).
  - (4) Drugs with similar toxicities generally are avoided; however, this is not always possible. Therapy combinations may potentiate the toxic effects of either or both therapies or may be lessened because of different targeted mechanisms of action (Mokhtari et al., 2017).
3. Dosing of cytotoxic chemotherapy
- a) Treatment cycles are designed to permit recovery from damage to healthy tissues and organs and are based on the known pharmacokinetics of agents. Because the average white blood cell nadir is 10–14 days, many regimens are based on this time frame (Drooger et al., 2016; Tortorice, 2018).
  - b) Dose density refers to the drug dose per unit of time. Higher dose density is achieved by shortening the intervals between treatments (Lambertini et al., 2017). Reducing the time between chemotherapy cycles may diminish tumor regrowth.
  - c) Dose intensity is the amount of drug delivered over time.
    - (1) Dose reduction or delay resulting from chemotherapy side effects, scheduling conflicts, or any other reason reduces dose intensity and may negatively affect patient survival (Matikas et al., 2017).
    - (2) The prophylactic use of a myeloid growth factor has allowed for the administration of dose-dense and dose-intense chemotherapy regimens that would otherwise result in unacceptable neutropenia (Matikas et al., 2017).
  - d) Relative dose intensity is calculated by comparing the received dose to the referenced (standard) dose. Proactively managing symptoms and educating patients on maintaining the prescribed dosing schedule are paramount to optimal outcomes (Matikas et al., 2017).
  - e) Dose density and intensity and relative dose intensity concepts may not apply to targeted therapies, immunotherapies, and hormone therapies because of different toxicity profiles.
4. Genomically guided treatment with molecular or genomic biomarkers
- a) Detecting protein biomarkers for estrogen and progesterone receptors through the immunohistochemistry staining technique was one of the earliest applications in patient management (Dai et al., 2016).
    - (1) The overexpression of estrogen receptors and progesterone receptors in breast cancer predicts the potential for a clinical response to hormone therapy.
    - (2) Estrogen receptor status is also a prognostic indicator in that patients with hormone receptor positivity generally have a more favorable prognosis (Dai et al., 2016).
  - b) Tumor-specific genomic alterations in driver genes, which promote growth and tumor formation, and some tumor suppressor genes are predictive biomarkers for response to targeted agents in the treatment of malignancy (Malone et al., 2020).
    - (1) DNA sequencing is a laboratory process used to learn the exact order (or sequence) of the four building blocks that make up DNA and find alterations that may cause diseases such as cancer (NCI, n.d.-c).
    - (2) The Cancer Genome Atlas was a collaboration between NCI and the National Human Genome Research Institute that resulted in the development of comprehensive maps of the key genomic changes taking place in 33 different types of cancer (NCI, n.d.-a).
    - (3) Specific variants in the tyrosine kinase signaling pathway lead to uncontrolled cell proliferation and tumor formation.
      - (a) By stimulating the downstream intracellular signaling process, these variants cause accelerated cell proliferation, extended cell survival, and increased angiogenesis.
      - (b) Biomarker testing for these variants can guide the prioritization of therapies specific to these receptors for patients most likely to benefit from a targeted agent. It can also identify

those who will not benefit from a targeted agent.

- (c) Numerous small molecule tyrosine kinase inhibitors have been designed to block phosphorylation and suppress tumor growth (Malone et al., 2020; Wilkes, 2018).

As of May 2021, more than 70 FDA-approved targeted agents exist to treat solid and hematologic malignancies based on biomarkers detected in the tumor (NCI, 2020b; see Chapter 8).

- c) Programmed cell death-ligand 1 (PD-L1) protein is found on healthy and cancer cells.

- (1) Overexpression of PD-L1 by tumor cells inactivates the body's immune activity against the cancer cell by binding with the programmed cell death protein 1 (PD-1) antigen on the T cell. By suppressing the T cell, the cancer cell can evade attack by the body's immune system.

- (2) Immunotherapy treatments that target either PD-L1 or PD-1 block this binding, keeping PD-L1 from inactivating the T cell and boosting the immune system in its response against the cancer cell (Bayer et al., 2017).

- (a) PD-1 inhibitors help treat several types of cancer, including melanoma, non-small cell lung cancer, kidney cancer, bladder cancer, head and neck cancer, and Hodgkin lymphoma.

- (b) PD-L1 inhibitors have effectively treated bladder cancer, non-small cell lung cancer, and Merkel cell carcinoma (ACS, 2019b).

#### G. Measuring response

1. The earliest measures of determining response date back to 1976. Since then, many tools and factors have been considered when measuring response. A gold standard for all tumor types is not used.
2. Objective tumor response and quantitative measurement
  - a) Objective tumor response is assessed through quantitative measurements, such as surgical examinations, imaging studies, or serum biomarkers.
  - b) Baseline measurements recorded at the time of diagnosis are compared to those recorded after treatment completion.
  - c) The Response Evaluation Criteria in Solid Tumors (RECIST) guidelines were published in 2000 by members of the European Organisation

for Research and Treatment of Cancer, NCI, and NCI of Canada. These guidelines addressed most of the deficiencies in the WHO criteria.

- (1) RECIST guidelines recommended the use of one-dimensional tumor measurements (the longest diameter) rather than the cross product (Bates & Fojo, 2019).

- (a) Complete response is the complete disappearance of the disease.

- (b) Partial response is a 30% or more significant reduction in the sum of the longest diameter of the target lesion.

- (c) Stable disease is a change that does not meet the criteria for response or progression.

- (d) Progression includes a 20% or more significant increase in the sum of the longest diameter of target lesions.

- (2) RECIST 1.1 was developed in 2009 as technology and medicine advanced. Using the same criteria for response as RECIST 1.0, it also identified and addressed its predecessor's issues. For example, criteria were updated to include nodal disease (Bates & Fojo, 2019). RECIST 1.1 also has known limitations, including the following (Persigehl et al., 2020):

- (a) The criteria depend solely on anatomic measurements and do not consider tumor vascularity or functional imaging parameters.

- (b) In 2017, iRECIST was published to include a modified set of response criteria to address therapy response patterns seen with immunotherapy.

- (c) Traditional cytotoxic chemotherapy often results in the reduction of tumor size. However, newer targeted agents that interfere with or inhibit cell growth and division by inhibiting molecular pathways are considered cytostatic, meaning they block tumor cell proliferation. In contrast, standard chemotherapy agents are cytotoxic, meaning they kill tumor cells.

- (d) Studies of several cancer types, such as prostate cancer, mesothelioma, soft tissue sarcoma, and neuroendocrine tumors, have also shown that RECIST 1.1 criteria are inaccurate in reporting response to therapy (Sandra-segaran, 2015).

3. Clinical benefit response
  - a) The concept of clinical benefit response was developed when patients did not have measurable tumor shrinkage but experienced a reduction in symptoms (e.g., pancreatic cancer).
  - b) Clinical benefit is a combination of reduction or improvement in pain, performance status, and weight (Bates & Fojo, 2019; U.S. FDA, 2018).
4. Pathologic complete response in high-risk, early-stage breast cancer is the end point used to evaluate response after neoadjuvant treatment.
  - a) After a standard neoadjuvant chemotherapy regimen, the breast is resected and evaluated for remaining breast cancer cells.
  - b) The absence of cancer cells in the resected breast is referred to as a pathological complete response (Bates & Fojo, 2019; U.S. FDA, 2020).
5. Computed tomography–based tumor density is frequently used with diseases that respond to treatment but have minimal tumor shrinkage, such as gastrointestinal stromal tumor, renal cell cancer, or hepatocellular cancer (Bates & Fojo, 2019).
6. Glucose analog tracer, fluorine-18 fluorodeoxyglucose positron-emission tomography
  - a) In 2007, the International Working Group incorporated guidelines using positron-emission tomography (PET) assessments in metabolically active lymph nodes. Although widely used in clinical trials as part of the standardized response criteria for lymphoma, PET imaging in solid tumors is used to detect new or recurrent disease sites. It can also be an adjunct for evaluating disease progression when using RECIST criteria (Bates & Fojo, 2019).
  - b) The most recent effort to standardize PET criteria is Positron Emission Tomography Response Criteria in Solid Tumors (PERCIST 1.0) by the European Organisation for Research and Treatment of Cancer and NCI. PERCIST specifies that the percentage of change in metabolic activity from baseline to post-treatment scans be recorded to provide a continuous plot of tumor activity. However, because of variations in patient activity, carbohydrate intake, blood glucose, and timing of scans, the comparability of PET images remains a challenge (Bates & Fojo, 2019; O et al., 2016).
7. Monitoring biomarkers
  - a) Monitoring biomarkers are proteins that can be measured in the blood to indirectly evaluate cancer progression.
  - b) These biomarkers are most useful in monitoring response to a treatment or progression of disease.
  - c) The direction, whether future levels increase or decrease, and the rate of change allow the provider to determine treatment efficacy.
  - d) Therefore, it is helpful to obtain baseline biomarkers before the tumor is excised and before the initiation of treatment (U.S. FDA, 2021a).
8. Circulating tumor cells and circulating tumor DNA are indicated in some solid tumors (e.g., ovarian, non-small cell lung, breast, prostate) and under investigation in hematologic malignancies (NCI, 2020a).
  - a) The number of circulating tumor cells in the blood is prognostic, with higher levels conferring a poor prognosis.
  - b) The amount of circulating tumor DNA appears to correlate with tumor burden and increases with stage.
9. Immune-related response criteria
  - a) Several new therapy options are being studied and have been FDA approved to harness the immune system in controlling malignancy.
  - b) The patterns of response to treatment with immunotherapy agents differ from treatments with targeted therapies, hormone therapies, or cytotoxic agents in several important respects (Persigehl et al., 2020).
    - (1) Patients may have transient worsening of disease before it stabilizes or the tumor regresses; therefore, caution should be taken in discontinuing treatment early.
    - (2) Treatment response can take longer to become apparent than cytotoxic therapy.
    - (3) Some patients who do not meet the criteria for objective response can have prolonged periods of stable disease that are clinically significant.
  - c) The iRECIST criteria were developed to properly recognize these nontraditional patterns of response seen with checkpoint inhibitors and other immunotherapies. Without these criteria, the application of RECIST criteria in patients treated with checkpoint inhibitors may lead to premature discontinuation of treatment in those who will eventually respond to treatment or have prolonged disease (Persigehl et al., 2020).
    - (1) Immune-related complete response is the complete resolution of all lesions, with no new lesions. It must be confirmed by a consecutive assessment after at least four weeks.
    - (2) Immune-related partial response is a decrease in the total tumor burden of 50% or more compared to baseline, which

must be confirmed with a second assessment after at least four weeks. This allows for the inclusion of progression of some lesions or the appearance of new lesions as long as the total tumor burden meets the response criteria.

- (3) In immune-related stable disease, the tumor does not meet the criteria for a partial or complete response or progressive disease.
  - (4) Immune-related progressive disease is an increase in tumor burden by 25% or more relative to the minimum recorded tumor burden. It must be confirmed by a second assessment no less than four weeks after the initial documentation of an increase in the tumor.
10. Patient outcomes
- a) Direct evidence of treatment benefit is derived from clinical trial effectiveness end points that measure survival or meaningful aspects of how patients feel or function in daily life (U.S. FDA, 2017a).
    - (1) In the 1970s, FDA approved cancer drugs based on objective response rates determined by tumor assessments.
    - (2) However, in the 1980s, FDA determined that cancer drug approval should be based on more direct evidence of clinical benefits, such as improved survival, tumor-related symptoms, quality of life, or physical functioning (U.S. FDA, 2018).
  - b) Survival data are gathered to assess the efficacy of cancer treatment.
    - (1) The starting point for survival measurement may be the date of diagnosis, first visit to the physician or clinic, hospital admission, treatment initiation, or randomization to a clinical trial (Hess, 2017).
    - (2) The vital status of each patient is noted as alive, dead, or unknown. The status is recorded at the end point of participation in a study, including the completion of the study or when the individual is lost to follow-up or dies (Hess, 2017).
  - c) Tumor assessment (U.S. FDA, 2018)
    - (1) Time to progression and progression-free survival have also served as primary end points for drug approval. Time to progression is the time from randomization to progression, whereas progression-free survival is the time from randomization until disease progression or death.
    - (2) Disease-free survival is the time from randomization until tumor recurrence or death from any cause. This end point is most frequently used in the adjuvant setting after definitive surgery or radiation therapy.
    - (3) Objective response rate refers to the proportion of patients in a study with a reduction in tumor burden of a predetermined amount and for a minimum period. Response duration is measured from the initial response until documented tumor progression. Per FDA, if available, standardization criteria should be used to ascertain response (e.g., RECIST criteria has been considered appropriate).
    - (4) Time to treatment failure is the end point measuring time from randomization to discontinuation of treatment for any reason, including progression, treatment toxicity, or death.
  - d) Symptom assessment on quality of life
    - (1) The American Society of Clinical Oncology Cancer Research Committee stated, "In arriving at goals for clinical trials, both survival and quality of life were considered as important to outcomes that are clinically meaningful for patients" (Stenger, 2014, "Primary Goal," para. 1).
    - (2) The committee also stated that cancer progression symptoms and treatment tolerability are essential factors when considering whether a new treatment is associated with a clinically meaningful outcome (Stenger, 2014).
  - e) Performance status
    - (1) Performance status is the level of normal daily activity that patients can sustain to care for themselves. This includes their physical ability, such as walking and working. Performance status is affected by cancer, complications of cancer, and comorbid conditions (Scott et al., 2020).
    - (2) Assessing performance status is a way for physicians to track changes in a level of functioning due to cancer treatment. Documenting performance status using a standardized index allows clinicians to consistently report patient response to clinical trials (ECOG-ACRIN Cancer Research Group, n.d.).
    - (3) Commonly used measurements of performance status

- (a) Eastern Cooperative Oncology Group (ECOG) Performance Status Scale
  - i. First published in 1982, it is also called the WHO or Zubrod score. Key elements of the ECOG scale first appeared in medical literature in 1960 by C. Gordon Zubrod (Zubrod, 1984).
  - ii. This rating scale uses scores from 0 to 5, indicating poorer performance status as the score increases (ECOG-ACRIN Cancer Research Group, n.d.).
- (b) The Karnofsky Performance Status Scale was first introduced in 1949 with an index rating between 100 and 0, with a higher score indicating better performance (ECOG-ACRIN Cancer Research Group, n.d.).
- (c) The Lansky Play-Performance Scale for Pediatric Patients classifies patients younger than age 16 years. The form is completed by parents based on the child's activity over the past week and is repeated over time to assess for changes in performance status (Lansky et al., 1987).
- (d) Table 4-6 compares the three performance rating scales.

#### H. Factors affecting treatment response

1. *Comorbidity* refers to the coexistence of disorders in addition to a primary disease of interest (Fowler et al., 2020).
  - a) In one large-scale population-based study, up to two-thirds of patients had at least one chronic condition at the time of cancer diagnosis, and half of these patients had multiple comorbidities (Fowler et al., 2020).
  - b) Comorbidity has consistently been found to negatively impact cancer detection, treatment, treatment adherence, and overall survival (Fowler et al., 2020).
  - c) Patients with comorbidities are less likely to receive adjuvant therapy, more likely to receive a reduced dose, and less likely to complete a course of treatment (Fowler et al., 2020).
  - d) Cancer or its treatment may affect comorbidity outcomes. Antineoplastic therapies can increase the risk of cardiovascular, metabolic, musculoskeletal, and other conditions and can worsen preexisting comorbidities (Fowler et al., 2020).
2. According to NCI (n.d.-d), tumor burden is the number of cancer cells, the size of the tumor, or the

amount of cancer in the body. The larger the tumor (sometimes referred to as the bulkiness of the disease), the greater the chance of spreading and developing metastatic disease.

3. The genomic instability of the tumor cell and the emergence of drug resistance are currently considered the most significant determination of response (Tortorice, 2018).

a) Temporary or relative resistance is usually a function of the drug's inability to reach the target cell. Causes of temporary resistance include the following (Tortorice, 2018):

- (1) Poor blood supply
- (2) Anatomic sanctuary sites (e.g., testes, central nervous system)
- (3) Altered pharmacokinetic parameters

(a) Pharmacokinetics is defined as the action of the body in response to a drug (Grogan & Preuss, 2021).

(b) Pharmacokinetic resistance is a concept that describes the body-related factors that alter a drug's effectiveness so that it does not reach its target or accomplish its intended goal. Pharmacokinetic resistance is universal to all drug therapy. The following factors can affect pharmacokinetic resistance (Grogan & Preuss, 2021):

- i. Absorption: Orally ingested agents for cancer can be affected by the presence or absence of food in the patient's stomach and permeability glycoprotein, or P-glycoprotein, which is found along the gastrointestinal tract. P-glycoprotein has been shown to reduce the oral bioavailability of some anticancer drugs.
- ii. Distribution: A higher volume of distribution means more drug penetrates into a tissue while it is more diluted in the plasma. The volume of distribution can be affected by gender, weight, plasma proteins, and circadian rhythm.
- iii. Metabolism: Cytochrome P450 enzymes are responsible for drug metabolism. Overexpression might lead to resistance due to the rapid inactivation of the drug.
- iv. Excretion of drugs: The kidney is the primary organ where

drugs are excreted. Changes in the glomerular filtration rate based on gender and ethnic differences can directly affect drug availability.

- (c) Coadministration of drugs might result in antagonism such that one drug may counteract or neutralize another. A common example is

tamoxifen, which needs to be converted to its active form by the metabolizing enzyme CYP2D6. This same enzyme is inhibited by specific selective serotonin reuptake inhibitors, thus reducing the efficacy of tamoxifen (Wang et al., 2019).

- (d) In some conditions, temporary resistance may be reversed by altering

**TABLE 4-6.** Performance Status Scales

| Scale                                                                                                                  | Grade/Score | Description                                                                                                  |
|------------------------------------------------------------------------------------------------------------------------|-------------|--------------------------------------------------------------------------------------------------------------|
| Eastern Cooperative Oncology Group (also known as ECOG, Zubrod, or World Health Organization) Performance Status Scale | 0           | Fully active; no performance restrictions                                                                    |
|                                                                                                                        | 1           | Strenuous physical activity restricted; fully ambulatory and able to carry out light work                    |
|                                                                                                                        | 2           | Capable of all self-care but unable to carry out any work activities; up and about > 50% of waking hours     |
|                                                                                                                        | 3           | Capable of only limited self-care; confined to bed or chair > 50% of waking hours                            |
|                                                                                                                        | 4           | Completely disabled; cannot carry out any self-care; totally confined to bed or chair                        |
|                                                                                                                        | 5           | Dead                                                                                                         |
| Karnofsky Performance Status Scale                                                                                     | 100         | Normal; no complaints; no evidence of disease                                                                |
|                                                                                                                        | 90          | Able to carry on normal activity; minor signs or symptoms of disease                                         |
|                                                                                                                        | 80          | Normal activity with effort; some signs or symptoms of disease                                               |
|                                                                                                                        | 70          | Cares for self; unable to carry on normal activity or do active work                                         |
|                                                                                                                        | 60          | Requires occasional assistance but able to care for most needs                                               |
|                                                                                                                        | 50          | Requires considerable assistance and frequent medical care                                                   |
|                                                                                                                        | 40          | Disabled; requires special care and assistance                                                               |
|                                                                                                                        | 30          | Severely disabled; hospitalization indicated although death not imminent                                     |
|                                                                                                                        | 20          | Hospitalization necessary; very sick; active supportive treatment necessary                                  |
|                                                                                                                        | 10          | Moribund; fatal processes progressing rapidly                                                                |
|                                                                                                                        | 0           | Dead                                                                                                         |
| Lansky Play-Performance Scale for Pediatric Patients                                                                   | 100         | Fully active; normal                                                                                         |
|                                                                                                                        | 90          | Minor restrictions with strenuous physical activity                                                          |
|                                                                                                                        | 80          | Active, but gets tired more quickly                                                                          |
|                                                                                                                        | 70          | Both greater restriction of and less time spent in active play                                               |
|                                                                                                                        | 60          | Up and around but minimal active play; keeps busy with quieter activities                                    |
|                                                                                                                        | 50          | Lying around much of the day but gets dressed; no active play; participates in all quiet play and activities |
|                                                                                                                        | 40          | Mostly stays in bed; participates in quiet activities                                                        |
|                                                                                                                        | 30          | Stuck in bed; needs help even for quiet play                                                                 |
|                                                                                                                        | 20          | Often sleeping; play is entirely limited to very passive activities                                          |
|                                                                                                                        | 10          | Does not play or get out of bed                                                                              |
|                                                                                                                        | 0           | Unresponsive                                                                                                 |

Note. Based on information from ECOG-ACRIN Cancer Research Group, n.d.; Lansky et al., 1987.

- drug delivery, dose, or scheduling of drug administration (Tortorice, 2018).
- b) Cancer cells develop resistance to antineoplastic agents via several mechanisms and pathways (Pan et al., 2016).
- (1) Primary or intrinsic resistance exists before patients receive treatment (Wang et al., 2019).
    - (a) Preexisting genomic alterations in some tumors may result in decreased responsiveness of cancer cells, such as triple-negative breast cancer, to chemotherapy and targeted agents (Wang et al., 2019).
    - (b) Tumor heterogeneity refers to the differences between tumors of the same type in different patients and the diverse genomic variation of the cancer cells within a tumor. Heterogeneity increases the risk for primary or secondary resistance. As cells divide, new variants emerge. With successive alterations, new driver variants continue to evolve, causing cancer cells to become resistant (Pan et al., 2016; Wang et al., 2019).
  - (2) Secondary or acquired resistance develops after exposure to the cytotoxic drug. Tumors initially respond to treatment, but genomic alterations and adaptive responses allow cancer cells to evade drug therapy (Pan et al., 2016; Vasan et al., 2019).
- c) Multidrug resistance is observed when tumor cells develop mechanisms to protect themselves against cytotoxic drugs (Tortorice, 2018).
- (1) Drug inactivation: Many cancer drugs must undergo metabolic activation to acquire clinical efficacy. However, cancer cells can develop resistance through decreased drug activation (Mansoori et al., 2017).
  - (2) Drug target alteration: A drug's efficacy is influenced by its molecular target and alterations of this target. In cancers, a second alteration in the target protein or changes in expression level due to epigenetic forces can ultimately lead to drug resistance (Wang et al., 2019).
  - (3) Drug efflux: This process involves reducing drug accumulation by removing the drug inside the cancer cell. Members of the adenosine triphosphate-binding cassette (ABC) transporter family include proteins that can stop drugs from entering a cell or remove them once they have entered (Vasan et al., 2019).
- (4) DNA reparability: Following chemotherapy-induced DNA damage, DNA repair pathways are activated in response to restoring the damage, leading to decreased efficacy (Vasan et al., 2019).
- (5) Inhibition of apoptosis
- (a) Tumor suppressor protein p53 (TP53) is a regulator protein that allows cells with undamaged DNA to proceed into the cell cycle. Following exposure to the DNA-damaging agents of cytotoxic therapy, an intact *TP53* gene prevents the tumor cell from entering the cell cycle, leading to apoptosis and decreased efficacy (Tortorice, 2018).
  - (b) Variants in the *TP53* gene are among the most common genetic changes observed in tumor cells and may occur in at least 50% of all tumors. When *TP53* function is lost, damaged cells can proliferate and transfer altered DNA to the next generations (Hientz et al., 2017). This leads to unregulated cellular proliferation; thus, the *TP53* variant usually indicates a poorer prognosis (Tortorice, 2018).
- (6) Changes to the tumor microenvironment: Tumors are composed of cells (e.g., immune and inflammatory cells), blood vessels, and an extracellular matrix, which respond uniquely to DNA-damaging treatment. The diversity of these responses adds to the cancer cell's ability to adapt to chemotherapy or targeted therapy (Wang et al., 2019).
- d) Poor adherence to cancer treatment, especially oral agents, includes misuse, overuse, and underuse. Lack of adherence negatively affects a provider's ability to determine treatment efficacy and effectiveness, contributes to increased healthcare costs, and can worsen disease and decrease overall patient survival (Atkinson et al., 2016).

## I. Adherence

1. Biomarker testing has revolutionized cancer treatment. As small molecule treatments are developed to target identified alterations, more patients are taking cancer treatment by mouth, either as a single agent or in combination with an immunotherapy or chemotherapy regimen.

2. Administration of oral anticancer medications (OAMs) in the home setting can provide convenience and enhanced quality of life (Huff, 2020; Murphy et al., 2019).
  - a) Fewer office visits
  - b) Less disruption of work and family life
  - c) Decreased patient travel
  - d) Ease of administration, including potentially less need for IV access
3. Challenges with the increased use of OAMs
  - a) Access concerns
    - (1) Financial burden
    - (2) Treatment delays due to prior authorization of financial coverage
    - (3) Drug procurement, including coordination with mail order or specialty pharmacies
  - b) Patient and caregiver safety due to exposure to hazardous medication or body fluids
  - c) Adherence concerns (Muluneh et al., 2018)
    - (1) Difficulty understanding label directions
    - (2) Misunderstanding the timing of the drug with food
    - (3) Discontinuing medication without informing the provider
  - d) Patient and caregiver knowledge of how to manage side effects
  - e) Lack of direct monitoring for adherence and toxicities (Murphy et al., 2019)
  - f) Patient population: Minority and uninsured patients may be negatively affected by oral oncolytic regimens because of a lack of access and adherence to medication regimens. Complex dosing, inability to identify and report toxicities, and insufficient funds to pay for treatment may affect adherence (Murphy et al., 2019).
4. Adherence is defined as the extent a patient's behavior conforms with the provider's recommendations about day-to-day treatment concerning timing, dosing, and frequency (Neuss et al., 2016).
  - a) Adherence to therapy is correlated with treatment success.
  - b) Nonadherence to the prescribed therapy can significantly affect outcomes (Krikorian et al., 2019; Morgan et al., 2017).
    - (1) Treatment failure and disease progression
    - (2) Increased toxicities and adverse drug events
    - (3) Increased healthcare costs
      - (a) Increased emergency department visits
      - (b) Unnecessary hospitalizations
      - (c) Additional diagnostic tests
      - (d) Additional prescriptions

5. Factors affecting the patient's ability to adhere to the prescribed medication regimen are multilayered, complex, and often occur simultaneously. These factors can generally be categorized into the following dimensions (Bryant et al., 2020; Dillmon et al., 2020; Goulart et al., 2021; Krikorian et al., 2019; Muluneh et al., 2018; Rosenberg et al., 2020; Washburn & Thompson, 2020; see Table 4-7):
  - a) Personal and patient
  - b) Medication and treatment
  - c) Healthcare system

**TABLE 4-7. Factors Influencing Adherence**

| Dimension                | Influencing Factors                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

*Note.* Based on information from Bryant et al., 2020; Dillmon et al., 2020; Goulart et al., 2021; Krikorian et al., 2019; Muluneh et al., 2018; Rosenberg et al., 2020; Washburn & Thompson, 2020.

## 6. Strategies to promote adherence to OAM

## a) Factors that correlate with improved adherence include the following (Morgan et al., 2017; Muluneh et al., 2018; Rosenberg et al., 2020):

- (1) Favorable perception by the patient about the advantages of adhering to the medication
- (2) Higher levels of patient self-advocacy
- (3) Access to the drug
- (4) Comprehensive drug education
- (5) Patient and caregiver knowledge about diagnosis and treatment
- (6) Timely management of adverse effects
- (7) Frequency of follow-up

## b) Pretreatment assessment

- (1) Early identification of warning signs of barriers to adherence may help improve outcomes, reduce healthcare costs, and meet regulatory value-based expectations (Washburn & Thompson, 2020).
- (2) American Society of Clinical Oncology and Oncology Nursing Society standards state that prior to patients beginning a new chemotherapy regimen, a comprehensive assessment is completed, including medical history, physical examination, psychosocial assessment, and patient and caregiver comprehension of the disease and treatment plan (Neuss et al., 2016).

## c) Education

- (1) Initial and ongoing education is essential to assisting patients in safely managing OAM in the home setting.
- (2) Education-focused interventions for chronic disease management have demonstrated improvements in adherence, disease-specific knowledge, and symptom burden (Murphy et al., 2019).
- (3) Prior to beginning therapy with an OAM, patients and their families or caregivers should receive comprehensive education about the medications to be prescribed, including the following (Neuss et al., 2016):
  - (a) Drugs to be administered, as well as the schedule and duration of treatment
  - (b) Short- and long-term side effects of treatment, including instructions on when to discontinue the drug or contact healthcare providers
  - (c) Possible drug–drug and drug–food interactions
  - (d) The plan for missed doses

(e) Safe storage and handling of the OAM in the home, including how to manage unused medication

(f) Safe handling of body secretions and waste in the home

(g) Plans for follow-up, including laboratory tests and provider visits

- (4) Oral Chemotherapy Education sheets ([www.oralchemoedsheets.com](http://www.oralchemoedsheets.com)) were developed by the National Community Oncology Dispensing Association, Hematology/Oncology Pharmacy Association, Association of Community Cancer Centers, and Oncology Nursing Society. They include education about the drug, administration, side effects, and safety. These patient education sheets can be individualized with clinic or pharmacy phone numbers and information on when to return to the clinic for laboratory or other monitoring.

d) Nurses are in an ideal position to provide resources and recommendations to meet the learning needs of each individual and provide suggestions to promote adherence. Interventions should be tailored to the needs of the patient by addressing identified barriers (Rosenberg et al., 2020; Washburn & Thompson, 2020).

- (1) Multi-intervention strategies promote patient adherence by helping the patient overcome the numerous challenges associated with medication access, understanding how to take medications, and managing side effects. Providing ongoing education and support can improve quality care and safe administration of OAMs in the outpatient setting (Dillmon et al., 2020).
- (2) Suggestions and tools to promote adherence (Bryant et al., 2020; Krikorian et al., 2019; Rosenberg et al., 2020)
  - (a) Educate patients on the importance of self-advocacy and adhering to therapy.
  - (b) Encourage a daily routine for OAM dosing.
  - (c) Involve the assistance of other family members and friends.
  - (d) Provide calendars and recommend diaries with daily medication checklists.
  - (e) Recommend pillboxes as permitted by each OAM storage recommendation.

- (f) Use electronic reminders.
      - i. Smartphone applications
      - ii. Electronic alarms
      - iii. Pill bottles with built-in timers on the cap
      - iv. Text messaging
      - v. Electronic patient portal
    - (g) Follow up with phone calls. Evidence suggests that oncology nurses can help minimize the severity of symptoms with timely intervention, thus preventing nonurgent or preventable use of health services (Davis et al., 2020).
- 7. Adherence assessment and monitoring
  - a) Criteria for assessing adherence to an oral chemotherapy treatment plan (Neuss et al., 2016)
    - (1) Confirmation that the patient filled the prescription as written
    - (2) Inquiry regarding concerns about treatment costs
    - (3) Verification that the patient understands how to take the OAM as prescribed
    - (4) Verification that the patient understands what to do in case of missed doses
    - (5) Assessment for potential toxicity during each clinical encounter and in phone encounters: Adverse effects remain one of the leading causes of nonadherence to oral oncolytics (Salgado et al., 2017).
  - b) Methods of adherence monitoring
    - (1) There are several ways to assess medication adherence, but no current standard exists. Patient-reported adherence is considered one of the most accurate measures of adherence, and consistent use of a patient-reported outcome tool may be beneficial in oral oncolytic therapy (Morgan et al., 2017; Nachar et al., 2019).
    - (2) Adherence assessment (Michigan Oncology Quality Consortium, n.d.)
      - (a) Ask open-ended questions.
      - (b) Inquire regarding the patient's ability to take the medication and their ability to swallow and open the bottle, container, or package.
        - i. Do you have difficulty swallowing any of your medication?
        - ii. Do you have any difficulty opening pill bottles or packaging?
- iii. How are you taking your medication?
    - iv. What causes you to miss your doses?
    - v. How comfortable are you in managing the side effects of your medication?
  - (c) Assess symptom burden and patient and caregiver confidence in managing symptoms.
- 8. Interprofessional approach to patient support
  - a) Studies have shown that an interprofessional approach is needed to ensure adherence to OAMs to optimize outcomes (Morgan et al., 2017).
  - b) A comprehensive oral chemotherapy program includes support from the entire interprofessional healthcare team.
    - (1) Physician or prescriber
    - (2) Advanced practice provider
    - (3) Oncology registered nurse, including a clinical nurse or phone triage nurse
    - (4) Financial advocate
    - (5) Clinical pharmacist
    - (6) Specialty pharmacist
    - (7) Oral oncology nurse navigator or patient navigator
    - (8) Social worker
    - (9) Patient and caregiver
  - c) Practice considerations
    - (1) Address clinical gaps and identify the role of each stakeholder.
    - (2) Define the communication strategy, preferably within a secure electronic health record.
    - (3) Enter medication and patient care orders into an electronic health record.
    - (4) Build treatment plans individualized to each medication. For example, the National Community Oncology Dispensing Association (n.d.) Positive Quality Interventions are peer-reviewed clinical guidance documents for healthcare providers and may serve as a drug therapy management resource.
    - (5) Provide a communication plan to staff.
    - (6) Develop a robust education program.
    - (7) Obtain patient informed consent.
    - (8) Designate a navigator to facilitate care coordination within the interprofessional team.
    - (9) All stakeholders document all interventions and clinical encounters.
    - (10) Collaborate with the specialty pharmacy through proactive communication.

- (11) Collaborate with the financial advocate.
  - (a) Screen patients at high risk for financial toxicity.
  - (b) Obtain preauthorization for insurance reimbursement.
  - (c) Communicate denials to the health-care provider and coordinate the appeal process.
  - (d) Enroll patients in assistance programs.
    - i. A manufacturer co-pay card may be available for brand-name medications with commercial insurance.
    - ii. Medicare Part D
      - Foundation co-pay assistance grants
      - Manufacturer patient assistance programs
      - Low-Income Subsidy (Extra Help) (Centers for Medicare and Medicaid Services, 2021) to help patients with Medicare pay for prescription drugs; strict income limits to qualify
- d) Patient monitoring and follow-up
  - (1) Schedule laboratory, other monitoring (e.g., electrocardiogram), and provider follow-up visits that coordinate with the date the patient started taking the OAM.
  - (2) Conduct follow-up telephone calls to promote adherence, assess toxicity concerns, and provide reeducation and support.
  - (3) Consider other electronic means of communication through patient portals.
  - (4) Perform medication reconciliation, adherence, and toxicity assessments at each office visit (Neuss et al., 2016).
  - (5) Document oral chemotherapy follow-up using standardized forms or flow sheets (Anderson & Bettencourt, 2020).
- e) Tracking tools developed in spreadsheet format effectively track touchpoints and facilitate interprofessional coordination of care (Anderson et al., 2019; Ferguson et al., 2019). Common components to include in a tracking tool are included in Figure 4-2.
- f) Staff development
  - (1) Develop policies and procedures.
  - (2) Designate an educator for staff.
  - (3) Create checklists for staff to remind them of key elements required for education.
  - (4) Ensure education materials are current and comprehensive.

**FIGURE 4-2.** Elements of Oral Anticancer Medication Tracking

- 
- Patient name or identifier
  - Provider
  - Medication name
  - Date of prescription or order
  - Education date
  - Informed consent completed
  - Results of pharmacy benefit investigation, including prior authorization dates and patient co-pay or out-of-pocket expenses
  - Financial or co-pay assistance obtained
  - Dispensing pharmacy
  - Medication start date
  - Monitoring and provider follow-up visits scheduled
  - Dates for planned outreach calls
  - Refill due date
- 

Note. Based on information from Anderson et al., 2019; Ferguson et al., 2019.

- g) Develop quality outcomes for measuring performance and evaluate the use, adherence, and effectiveness of the policies, procedures, and checklists.

#### J. Toxicity grading and documentation

1. *Common Terminology Criteria for Adverse Events* (CTCAE) is used for adverse event reporting and has become widely accepted throughout the oncology community as the standard classification and severity grading scale for adverse events caused by antineoplastic therapy (NCI Cancer Therapy Evaluation Program, 2017). It is commonly used in clinical trials and daily nursing practice, as drug package inserts frequently recommend dose reductions based on CTCAE toxicity grading.
  - a) NCI Cancer Therapy Evaluation Program released version 5.0 in November 2017. Version 6.0 is still under development at the time of this writing. To access the document, visit [https://ctep.cancer.gov/protocoldevelopment/electronic\\_applications/docs/ctcae\\_v5\\_quick\\_reference\\_5x7.pdf](https://ctep.cancer.gov/protocoldevelopment/electronic_applications/docs/ctcae_v5_quick_reference_5x7.pdf).
  - b) An adverse event is defined as “any unfavorable and unintended sign (including an abnormal laboratory finding), symptom, or disease temporally associated with the use of a medical treatment or procedure that may or may not be considered related to the medical treatment or procedure” (NCI Cancer Therapy Evaluation Program, 2017, p. 2).
  - c) The criteria incorporated into this toxicity grading scale are used to manage antineoplastic administration and dosing and in clinical trials to provide standardization and consistency in the definition of treatment-related toxicity (NCI Cancer Therapy Evaluation Program, 2017).

- d) In clinical trials, the grading system is designed to integrate into information networks for safety data exchange and influence data management for adverse event data collection, analysis, and patient outcomes associated with cancer research and care.
  - e) Grade refers to the severity of the adverse event. CTCAE displays grades 1–5 with unique clinical descriptions of severity for each adverse event based on the general guidelines listed in Table 4-8.
2. A patient-reported outcomes measurement system has been created as a companion to the CTCAE grading system. It considers the patient's perspective on adverse events that may be underdetected using the existing CTCAE system (NCI, 2022).
- a) Patient-reported outcomes are any report of the status of a patient's health condition that comes directly from the patient without interpretation by the clinician (Pirschel, 2017).
  - b) The MD Anderson Symptom Inventory is one patient-reported outcomes assessment tool and is

used to assess the severity and effect on daily living of 13 high-frequency or severity symptoms: pain, fatigue, nausea, disturbed sleep, distress, shortness of breath, difficulty remembering, lack of appetite, drowsiness, dry mouth, sadness, vomiting, and numbness and tingling (Cleeland, 2016).

- c) Any agent-specific symptoms (e.g., vincristine and peripheral neuropathy, methotrexate and stomatitis) should be assessed.

**TABLE 4-8.** Common Terminology Criteria for Adverse Events Grading System

| Grade | Severity         | Definition                                                                                                                                                                                                                                                                |
|-------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1     | Mild             | Asymptomatic or mild symptoms; clinical or diagnostic observations only; intervention not indicated.                                                                                                                                                                      |
| 2     | Moderate         | Minimal, local, or noninvasive intervention indicated; limiting age-appropriate instrumental activities of daily living (ADL) (e.g., preparing meals, shopping for groceries or clothes, using the telephone, managing money).                                            |
| 3     | Severe           | Medically significant but not immediately life threatening; hospitalization or prolongation of hospitalization indicated; disabling; limiting self-care ADL (e.g., bathing, dressing, undressing, feeding self, using the toilet, taking medications, and not bedridden). |
| 4     | Life threatening | Life-threatening consequences; urgent intervention indicated.                                                                                                                                                                                                             |
| 5     | Death            | Fatality occurs related to the adverse event.                                                                                                                                                                                                                             |

# CHAPTER 5

## Clinical Trials and Drug Development

### A. Clinical research

1. Clinical research involves studies conducted on human beings to develop knowledge about human health and illness. These studies may include individuals or groups or use data or materials from humans (i.e., biospecimens).
2. Types of clinical research (U.S. Food and Drug Administration [FDA], 2018e)
  - a) Patient-oriented research includes individuals, data, or biospecimens to study.
    - (1) Mechanisms of human disease
    - (2) Treatments or interventions for disease
    - (3) Development of technology related to disease
  - b) Epidemiologic and behavioral research studies the distribution of disease, the factors that affect health, and how people make health-related decisions.
  - c) Health services research identifies the most effective ways to organize, finance, manage, and deliver high-quality care, reduce medical errors, and improve patient safety.
  - d) Outcomes research identifies healthcare practices and interventions to support more informed patient care decisions.
3. Clinical trials
  - a) A clinical trial is a type of patient-oriented research in which the patient (i.e., research participant) is prospectively assigned to an intervention to evaluate the effects of the intervention on health-related biomedical or behavioral outcomes (National Institutes of Health, 2017). Table 5-1 summarizes five types of clinical trials (Lin, 2020; National Cancer Institute, 2020; Ness & Royce, 2017; Stoney & Johnson, 2018; U.S. FDA, 2018e).
  - b) Cancer clinical trials are essential for identifying new, more effective therapies to improve disease prevention, detection, treatment, and rehabilitation.
    - (1) Clinical trials have had a significant role in improving outcomes for people with cancer.

**TABLE 5-1.** Types of Clinical Trials

| Type of Trial   | Description                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Prevention      | Evaluate the effectiveness of ways to reduce the risk of developing a disease or preventing a disease from returning by one of the following: <ul style="list-style-type: none"> <li>• "Doing" something (e.g., lifestyle changes, including diet, exercise, or smoking cessation)</li> <li>• "Taking" something (e.g., medications, vitamins, vaccines)</li> </ul>                                |
| Diagnostic      | Develop better tests or procedures to more accurately identify and diagnose a disease or condition (e.g., imaging tests, laboratory tests, biomarkers).                                                                                                                                                                                                                                            |
| Screening       | Assess new or better ways of detecting disease or health conditions earlier in healthy people. Examples include obtaining the following: <ul style="list-style-type: none"> <li>• Tissue samples</li> <li>• Laboratory tests, including genetic testing</li> <li>• Imaging tests</li> <li>• Physical examinations</li> <li>• Health histories, including family histories and pedigrees</li> </ul> |
| Quality of life | Evaluate measures to improve comfort and quality of life for people with chronic illnesses through better therapies or psychosocial interventions. <ul style="list-style-type: none"> <li>• Focus can be on the patient, families, or other caregivers.</li> <li>• These are also known as supportive care trials.</li> </ul>                                                                      |
| Treatment       | Test new treatments or devices, new combinations of drugs, or new approaches to surgery or radiation therapy. Treatment trials, especially trials for drugs that are not yet approved for general use (i.e., investigational drugs), are categorized by phases.                                                                                                                                    |

*Note.* Based on information from National Cancer Institute, 2020; Ness & Royce, 2017.

- (2) For example, results from breast cancer clinical trials have led to lengthened survival and improvements in screening, surgery, chemotherapy, radiation therapy, and hormone therapy.
  - c) Ideas for clinical trials are generated from clinical and basic sciences.
    - (1) Many ideas come from basic science research, which increases understanding of cancer biology. These ideas are first investigated in the laboratory. Treatments with the most promising results are studied in clinical trials.
    - (2) Some ideas come from the results of previous clinical research because new questions are often raised as previous ones are answered.
    - (3) Ideas for clinical trials also may come from patients and healthcare providers as they try to determine how to manage a disease and its side effects.
  - d) Patients choose to participate in clinical trials for different reasons. These reasons will depend on their beliefs, culture, disease status, treatment options, and knowledge and perception about clinical trials.
    - (1) Understanding an individual's reasons for participating in a clinical trial will help oncology nurses know how to best support them.
    - (2) Common reasons for patient participation in clinical trials (Anderson et al., 2018)
      - (a) Access to treatments that may not otherwise be affordable
      - (b) Hope that they will be given better treatment in the trial than the current standard
      - (c) Desire to contribute to research and advance science so that others may benefit in the future
      - (d) A lack of available treatment options
4. Clinical trial enrollment
- a) Validity
    - (1) The validity of clinic trial results partially depends on recruiting and enrolling adequate numbers of the required participant population.
    - (2) Approximately 20% of adult patients with cancer are eligible for a clinical trial, but only 2%–8% participate in a cancer clinical trial (Unger et al., 2021).
    - (3) Table 5-2 provides a snapshot of patient-specific barriers and the strategies that can be used to overcome them.
  - b) Barriers
    - (1) Restrictive eligibility criteria are barriers to enrolling patients in clinical trials.
      - (a) The American Society of Clinical Oncology and Friends of Cancer Research collaborated on a joint project to evaluate current eligibility criteria and determine how to broaden the criteria (Kim et al., 2017).
      - (b) The initial recommendations from the collaboration were to ease eligibility criteria without compromising safety. This resulted in FDA adopting the recommendations into guidance documents for patients with brain metastases, HIV/AIDS, organ dysfunction, prior and concurrent malignancies, and minimum age considerations for inclusion of pediatric patients.
      - (c) A second set of recommendations address broadening criteria related to washout periods and concomitant medications, performance status, laboratory test intervals and reference ranges, and prior therapies (Kim et al., 2021).
    - (2) Another barrier to enrollment includes provider lack of knowledge about clinical trials.
      - (a) Oncology nurses need to learn about clinical trials to help answer patient questions and dispel myths.
      - (b) Resources to help nurses and patients learn more about clinical trials include the following:
        - i. American Cancer Society Treatment and Support ([www.cancer.org/treatment.html](http://www.cancer.org/treatment.html))
        - ii. Cancer.Net ([www.cancer.net](http://www.cancer.net))
        - iii. Center for Information and Study on Clinical Research Participation Education Center ([www.cisrpf.org/education-center](http://www.cisrpf.org/education-center))
        - iv. National Cancer Institute Cancer Information Service ([www.cancer.gov/contact](http://www.cancer.gov/contact))
        - v. National Cancer Institute Clinical Trials Information for Patients and Caregivers ([www.cancer.gov/about-cancer/treatment/clinical-trials](http://www.cancer.gov/about-cancer/treatment/clinical-trials))
5. The protocol
- a) The written protocol is the heart of any research project; it serves as a recipe to ensure that the

**TABLE 5-2.** Patient Barriers to Recruitment in Clinical Trials

| Barrier Category                                                                                                                                                                     | Examples of Barriers                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Examples of Strategies                                                                                                                                                                                                                                                                                                                                                                                                   |

Note. Based on information from Anderson et al., 2018; Nipp et al., 2019; Niranjana et al., 2021; Vuong et al., 2020.

activities outlined in the study to answer scientific questions are performed in a consistent and repeatable manner.

- b) The protocol is written by a team that includes physicians, scientists, statisticians, nurses, and others (e.g., pharmacists).
- c) Every protocol should include the same parts, but the order may differ.
- d) The basic elements of a protocol are listed in Figure 5-1 (Bartrum & Karp, 2018; International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use, 2016; Ness & Royce, 2017).

- (1) The information included in a clinical trial protocol is used to write study-related orders, such as tests, procedures, and medications to be administered.
- (2) It also should include instructions on when to contact a research team member.
- (3) The protocol can also provide helpful information about the following:
  - (a) Potential or anticipated side effects or adverse events of the intervention and how to treat them
  - (b) Administration instructions
    - i. Rate of infusion for study medication
    - ii. Pre- and postmedication or hydration needs

- iii. How to treat side effects, including when to hold or reduce dosage of study medication

- (c) Safety assessments, including blood work and physical examinations
- (d) When biospecimens are to be collected
- (e) Randomization procedures

#### 6. Protecting research participants

- a) Good clinical practice in conducting research refers to a standard that ensures ethical and scientific quality in research with human participants (i.e., living individuals who volunteer to participate in clinical research).
- b) Adherence to the principles of good clinical practice, including adequate participant protection, is universally recognized as a critical requirement for research involving human participants (International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use, 2016).
- c) Human participants comprise living individuals, their data, and biospecimens.
- d) Although several historical events highlight unethical conduct in clinical research, the Nuremberg trials and the National Research Act of 1974 have significantly impacted how clinical research is conducted and how participants are protected.

**FIGURE 5-1.** Basic Sections of a Protocol

- Title page—title of study, version date, local protocol number, name of investigator(s)
- Table of contents
- Abstract—summary of the study background, objectives, eligibility, and design
- Introduction—outlines the objectives and scientific support for the study
- Eligibility assessment and enrollment—describes the patients who can participate in the study
  - Inclusion criteria—criteria that a patient must meet to be eligible for the clinical trial
  - Exclusion criteria—reasons that a patient may not be eligible for the clinical trial
- Study implementation—provides information about the study treatment and plan
  - Study design or structure
  - Information about how the intervention will be given
  - Other information or specimens that will be collected
  - What other treatments a patient can or cannot receive while on the study
  - Reason the patient might be taken off the study
  - What needs to be done after the patient goes off the study
- Supportive care—how a patient's symptoms can be managed while the patient is on the study
- Data collection, evaluation, and reporting
  - What types of information about a patient need to be collected
  - How this information needs to be documented and evaluated
- Human subjects protection procedures, including consent and assent
- Drug information, including known or suspected side effects

*Note.* Based on information from Bartrum & Karp, 2018; International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use, 2016; Ness & Royce, 2017.

- (1) Nuremberg trials
  - (a) The Nuremberg trials revealed horrific experimentation by Nazi doctors conducted on prisoners of German concentration camps during World War II.
  - (b) The knowledge of these atrocities led to the creation of 10 ethical principles for conducting clinical research outlined in the Nuremberg Code (<https://research.wayne.edu/irb/pdf/2-2-the-nuremberg-code.pdf>).
  - (c) These principles include voluntary consent of the individual to participate in research and their ability to withdraw that consent at any time; the need for animal experimentation before human experimentation; and the determination that the benefits outweigh the risks of participation to protect the individual from harm.
- (2) National Research Act of 1974 (National Commission for the Protection of Human

Subjects of Biomedical and Behavioral Research, 1979)

- (a) In 1974, U.S. Congress created the National Research Act, which codified human participant protection regulations.
  - (b) The act established the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research.
  - (c) This commission was charged with identifying basic ethical principles in conducting biomedical and behavioral research on human participants.
  - (d) This culminated in the Belmont Report, which delineated the difference between medical practice and research and outlined three ethical principles guiding human research—respect for persons, beneficence, and distributive justice.
  - (e) Table 5-3 summarizes these principles and how they are applied in clinical research.
- e) Regulations and guidance documents that affect the conduct of clinical trials are designed to protect patients participating in clinical research and ensure the accuracy of the data being collected. Several groups with regulatory authority are involved in clinical trials in the United States.
- (1) The Office for Human Research Protections maintains regulatory oversight and provides advice on ethical and regulatory issues in biomedical and behavioral research funded or supported by the U.S. Department of Health and Human Services.
  - (2) FDA has oversight for product development (e.g., drugs, biologics, devices) regardless of the funding source.
- f) Ethical review of the protocol
- (1) All clinical trials must have an ethical review and be approved by an institutional review board (IRB) prior to implementation (Institutional Review Boards, 2020; Protection of Human Subjects, 2018). If any changes happen in the protocol (i.e., protocol amendment), the IRB will also review the changes before implementation.
  - (2) The primary responsibility of the IRB is to protect the rights and safety of patients.
  - (3) The IRB must decide whether the anticipated benefit of new knowledge or

**TABLE 5-3.** Application of the Three Principles of the Belmont Report

| Principle                                                                                                                                                                                                 | Application                                                                                                                                                                                                                                                                          |

| <b>Respect for Persons</b> <ul style="list-style-type: none"> <li>• Individuals should be treated as autonomous agents.</li> <li>• People with diminished autonomy are entitled to protection.</li> </ul> | Participants must be given the opportunity to choose what shall or shall not happen to them.<br>The consent process must include three elements: <ul style="list-style-type: none"> <li>• Information sharing</li> <li>• Comprehension</li> <li>• Voluntary participation</li> </ul> |
| <b>Beneficence</b> <ul style="list-style-type: none"> <li>• Human participants should not be harmed.</li> <li>• Research should maximize possible benefits and minimize possible risks.</li> </ul>        | Assessment of risks and benefits should be performed by an investigator and an institutional review board.                                                                                                                                                                           |
| <b>Justice</b> <ul style="list-style-type: none"> <li>• The benefits and risks of research must be distributed fairly</li> </ul>                                                                          | Fair procedures and outcomes should be performed during selection of research participants.<br>Eligibility criteria should include those who may benefit and exclude those who may be harmed.                                                                                        |

Note. Based on information from National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research, 1979.

improved health in a clinical trial justifies the risks patients may experience.

- (4) The IRB cannot approve research where the risks are too high compared to the anticipated benefits.

g) Informed consent

- (1) Informed consent is an ongoing process of communication and understanding between a patient and investigator.
- (2) As a part of this process, the patient decides whether to agree to enter a clinical trial voluntarily.
- (3) The informed consent process includes sharing information about the nature of the research and evaluating the patient's comprehension of that information and their voluntary decision to participate (National Commission, 1979; Protection of Human Subjects, 2018, 2020).

(a) One tool used in this process is the informed consent document. Common information in this document is based on the federal regulations found in Figure 5-2 (Elements of Informed Consent, 2020; General Requirements for Informed Consent, 2018).

(b) The patient indicates initial agreement by signing an informed consent document. However, this does not mean that the patient must continue in the clinical trial if they decide to withdraw for any reason.

7. Roles and responsibilities: The clinical research enterprise is vast and involves many individuals and groups (Ness & Royce, 2017).

**FIGURE 5-2.** Common Elements of the Informed Consent Document

- Statement that the clinical trial involves research, including the following:
  - Explanation of the purpose of the research
  - Expected length of participation
  - Description of procedures to be followed
  - Identification of any procedures that are experimental
- Any predictable risks to patients, as well as a statement that the intervention or procedure may cause unforeseeable risks
- Any benefits to patients or others
- Any alternatives to study participation
- How patients' confidentiality will be maintained
- Contact people for questions related to research and the research participants' rights
- Statement that participation is voluntary and that there will be no penalty if patients do not want to participate
- Reason why investigators may stop treating patients on the clinical trial
- Costs for which patients may be responsible
- Whether patients will receive any compensation for participation in the clinical trial
- Statement that patients will be notified of new findings that may affect their decision to continue participation
- Statement about the use of or removal of personally identifiable information or identifiable biospecimens and use for future research or not
- For U.S. Food and Drug Administration–regulated applicable clinical trials: statement indicating that clinical trial information will be submitted for inclusion into a registry databank; specifically, the consent must read: "A description of this clinical trial will be available on <http://www.ClinicalTrials.gov>, as required by U.S. Law. This Web site will not include information that can identify you. At most, the Web site will include a summary of the results. You can search this Web site at any time" (General Requirements for Informed Consent, 2018, item c).

Note. Based on information from Elements of Informed Consent, 2020; General Requirements for Informed Consent, 2018.

a) Every clinical trial team will have a principal investigator responsible for the overall conduct of the clinical trial and the research participants. The team may also include the following:

- (1) Subinvestigators are selected by the principal investigator to provide support for the conduct of a clinical trial.
- (2) Study coordinators are responsible for organizing the day-to-day activities of a clinical trial at a specific site (e.g., gathering data).
- (3) Clinical data managers are responsible for organizing and collecting the data required by the protocol.

b) Nurses at all levels of education and practice play key roles in clinical research.

- (1) Nurse researchers provide leadership in clinical research development, performance, and analysis.
- (2) Clinical trial nurse
  - (a) Clinical trials nursing is a specialty nursing role that coordinates clinical trials and manages patients during those trials.
  - (b) Other titles for this role include clinical research nurse, clinical trials coordinator, and clinical research associate.
  - (c) Specific responsibilities and competencies for oncology clinical trial nurses have been developed by the Oncology Nursing Society (2016).
- (3) Direct care nurses are primarily responsible for the clinical care of patients. Their clinical trials responsibilities may include providing patient and caregiver education, finding information about clinical trials for patients, advocating for ethical care, administering treatments, collecting biospecimens, and monitoring for side effects (Parreco et al., 2012; see Table 5-4).

#### B. Drug and biologic development process

1. The development process is highly regulated and involves many steps to prove that a drug or biologic is safe and effective before being marketed. These steps can be divided into three main stages—discovery and preclinical testing, clinical testing, and FDA review (Buckley et al., 2020; U.S. FDA, 2018b; see Table 5-5).
2. The two essential roles for drug development in the United States are the sponsor and the FDA (Buckley et al., 2020).
  - a) Sponsor

- (1) The sponsor is responsible for developing the product (i.e., drug or biologic) and producing the evidence (i.e., safety and efficacy) to the FDA.

- (2) Most sponsors are pharmaceutical or biotechnology companies.

- (3) Other sponsors may include academic medical centers or the National Cancer Institute Cancer Therapy Evaluation Program.

b) FDA reviews the evidence against the standards of excellence (i.e., good clinical, manufacturing, and laboratory practice) to ensure that the product is safe and effective.

#### 3. Investigational New Drug (IND) application

a) Before beginning a clinical trial using a newly developed drug or biologic, the sponsor must submit an IND application to FDA (Investigational New Drug Application, 2020). This process protects clinical trial participants from unreasonable and significant risk.

b) Information included in the IND application

- (1) Animal study and toxicity data
- (2) Manufacturing information
- (3) Protocols for the clinical trials to be conducted
- (4) Information about the investigator

c) FDA review

- (1) The FDA has 30 days to review the initial IND application before clinical trials may begin.
- (2) If it finds any potential safety concerns (e.g., patients are exposed to unreasonable or significant risk; not enough information is provided about risk; the principal investigator is not qualified), the sponsor will need to resolve these concerns to FDA satisfaction.

d) The sponsor is responsible for informing the FDA about new protocols, amendments to existing protocols, and any serious side effects noted during the trials. This information continues until the sponsor files a marketing application or withdraws the IND.

e) The FDA assigns an IND number or a BB-IND number for biologic agents, often noted in the protocol (e.g., title page, pharmaceutical section).

#### 4. Conducting clinical trials

a) The FDA will notify the sponsor that the IND is safe to proceed, which means clinical trials may begin.

b) Clinical trials have three main phases, plus a fourth phase after a drug enters the market (Buckley et al., 2020; Investigational New Drug Application, 2020; see Table 5-6).

**TABLE 5-4.** Direct Care Nurse Responsibilities When Caring for a Clinical Trial Patient

| Research Activity                                  | Responsibilities                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Identifying which patients are on a clinical trial | Know how the organization identifies a patient on a clinical trial.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Maintaining the informed consent (IC) process      | <p>Locate the signed IC document. Ideally it should be in the patient's medical record, but the location depends on the organization's policy.</p> <p>Read the IC document to learn more about the clinical trial.</p> <p>Support the patient's decision to participate in the clinical trial. Encourage the patient to have others (e.g., family, referring physician) included in discussions about participation in a clinical trial. Encourage patient to read the IC document and other materials about the clinical trial and to ask questions.</p> <p>Assess the patient's comprehension of the study and his or her responsibilities by using open-ended questions.</p> <p>If asked to serve as a witness, know the organization's definition of witness (e.g., witness to the patient's signature or to the actual IC discussion).</p> <p>If unable to answer the patient's questions, contact the principal investigator or other designated member of the research team.</p> |
| Administering the study drug or intervention       | <p>Obtain a copy of the study protocol. Information about the study intervention is in either the study design or pharmaceutical section of the protocol. The medical orders should be consistent with the protocol.</p> <p>Determine if other medications or interventions are needed (e.g., specific hydration before or after chemotherapy administration).</p> <p>Understand the appropriate handling of the drug, including how soon an IV drug needs to be infused after it is mixed.</p> <p>For study medications that the patient will self-administer, reinforce the proper usage, storage, and disposal of the drug and what to do for a missed dose.</p>                                                                                                                                                                                                                                                                                                                     |
| Monitoring safety and response to intervention     | <p>The types of laboratory and/or imaging studies that will be used to monitor response to the study intervention should be listed in the protocol's study calendar.</p> <p>Assist in the identification of adverse events (AEs). An AE is similar to a side effect or toxicity except with these terms, a relationship to the intervention is implied. In research, the cause of the AE will be determined by the principal investigator and may or may not be related to the study intervention. Avoid asking questions about specific AEs that may be anticipated; these are found in the protocol and the IC document. Instead, ask the patient open-ended questions to help in the identification of AEs.</p> <p>Know when an AE should be reported to the research team and how to contact them.</p>                                                                                                                                                                              |
| Performing documentation and data collection       | <p>Document all prescription and over-the-counter medications, including complementary and alternative medications. Document the dose, how long the patient has been taking the medication, and the indication for its use.</p> <p>Document study-specific interventions. For IV study drugs, include the start and stop time.</p> <p>Document the AE details:</p> <ul style="list-style-type: none"> <li>• When the AE started</li> <li>• Description of the AE, which will be used by the research team to indicate its severity</li> <li>• Treatment for the AE</li> <li>• When the AE ended, if known</li> </ul> <p>For studies that require biospecimen collection, document the type of sample collected (e.g., blood, saliva), the time the sample was collected, how the sample is to be stored (e.g., room temperature, on ice), and whom to contact to pick up the specimen (e.g., research nurse, research assistant).</p>                                                   |

Note. Based on information from Parreco et al., 2012.

- c) The sponsor is responsible for ensuring that the clinical trials are monitored for patient safety and quality data.
5. The FDA review process starts with the sponsor applying to market a product. For drugs, this is called a new drug application (NDA), and for biologics, it is called a biologics license application (BLA) (Buckley et al., 2020; U.S. FDA, 2018b).

- a) The NDA or BLA should provide evidence of the product's safety and effectiveness, the appropriateness of the proposed labeling, and the consistent manufacturing of the drug.
- b) Clinical trial end points used by the FDA to assess effectiveness are based on tumor or symptom assessments (U.S. FDA, 2018a; see Table 5-7).

**TABLE 5-5.** Drug Development Process

| Drug Development Stage                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Discovery and preclinical testing                           | <p>Discovery includes finding a lead compound or a promising molecule that could become a drug by acting on a target to alter a disease. Sources of drugs include plants, animals, minerals, microbiology, semisynthetic or synthetic compounds, and recombinant DNA.</p> <p>Biologic products (e.g., monoclonal antibodies, vaccines, gene therapy) are made from living organisms and are larger molecules or a mixture of molecules.</p> <p>Completion of laboratory and animal testing to answer essential questions</p> <ul style="list-style-type: none"> <li>• Drug absorption, distribution, metabolism, and excretion</li> <li>• Potential benefits and mechanisms of action</li> <li>• Determination of the best dosage for a clinical trial</li> <li>• Side effects or adverse events (i.e., toxicity)</li> </ul> <p>Manufacturing of the drug</p> <ul style="list-style-type: none"> <li>• Preliminary stability of the drug</li> <li>• Finding the optimal drug formulation (e.g., oral or IV, additive needed)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Clinical testing                                            | <p>Begins with the submission of the investigational new drug (IND) application</p> <p>Designing and conducting clinical trials to answer specific research questions</p> <p>Selecting investigators and research sites</p> <p>Monitoring the clinical trials for patient protection and quality data</p> <p>Sharing safety information with investigators</p> <p>Ensuring accountability for all investigational drug supplies</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| U.S. Food and Drug Administration (FDA) review for approval | <p>Begins with sponsor submission of the new drug application (NDA) or biologics license application (BLA) to FDA</p> <p>Full review by each NDA reviewer of their section of the application (e.g., medical officer and statistician review the clinical data)</p> <ul style="list-style-type: none"> <li>• Routine inspections of clinical study sites to verify accuracy of the clinical data submitted by the sponsor in the NDA and that no data have been withheld</li> <li>• Facilities where the drug will be manufactured</li> </ul> <p>Review of the drug's labeling (also known as the package insert) to ensure appropriate information is communicated to healthcare professionals and patients and assist sponsor in refining the prescribing information</p> <p>Granting of FDA approval</p> <p>Regulatory mechanisms to speed up the review and approval process for drugs that treat serious diseases</p> <ul style="list-style-type: none"> <li>• Priority review: FDA's goal is to act on the NDA within 6 months.</li> <li>• Breakthrough therapy: This process is designed to expedite the development and review of drugs that may demonstrate substantial improvement over available therapy.</li> <li>• Accelerated approval: This allows surrogate end points (e.g., a laboratory measurement, radiographic image, physical sign) to be used for drug approval to fill an unmet need.</li> <li>• Fast track: This method facilitates the development and expedited review of drugs.</li> </ul> |

Note. Based on information from Lin, 2020; National Cancer Institute, 2020; Ness & Royce, 2017; Stoney & Johnson, 2018; U.S. Food and Drug Administration, 2018b, 2018d.

c) FDA's Center for Drug Evaluation and Research or Center for Biologics Evaluation and Research will then review the application against its standards of excellence.

d) An FDA approval grants a license for interstate commerce.

- (1) A drug or biologic is not licensed without a use.
- (2) Each drug or biologic is approved for a specific use, also referred to as an indication.
- (3) A drug or biologic may have more than one indication.

e) The license and description of the safe and effective use of the product are stated in the approved package insert (product label).

f) When a drug or biologic is not used per the prescribing information or indication, this is considered an off-label use.

6. Postapproval: Information about a drug's safety continues to evolve even after FDA approval. Sponsors also may continue the development of the drug for other indications (U.S. FDA, 2018b).

a) FDA reviews reports of problems with all drugs and can decide if cautions need to be added to prescribing information.

- b) After the initial approval to market a drug, a sponsor may want to add other indications, change the formulation (e.g., IV to oral) or dosage strengths, or perform other labeling changes. This requires the submission of a supplement application to FDA for approval.
7. Drug names
- a) The naming of drugs is complex.
- (1) All pharmaceutical substances have three main names—the chemical name, the approved official or generic name, and the proprietary or brand name.
  - (2) Generic names will start with a lower-case letter, whereas the proprietary name begins with a capital letter.
  - (3) For patient safety, it is important to avoid naming a drug too similar to an existing drug name (Karet, 2019).
- b) The chemical name is issued by the International Union of Pure and Applied Chemistry.
- (1) The scientific name is based on the compound's chemical structure.
  - (2) This name is not used to identify the drug in clinical practice.
- c) A generic or nonpropriety name is given to the active drug ingredient.
- (1) The United States Adopted Name (USAN) program assigns the generic name.
  - (2) The assigning of the generic name is part of the drug development process because a drug cannot be marketed without it.
  - (3) This is the name used in clinical practice.
- d) Proprietary names are created by the company that patents the drug.
- (1) The name identifies the drug during the years that the company has exclusive rights to make, sell, and use the drug.
  - (2) Initially, an alphanumeric name may be used until a propriety or generic name is available.

**TABLE 5-6.** Phases of Clinical Trials

| Phase | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1     | <p>Goal: Determine a dose or dosing schedule that is safe in humans—the maximum tolerated dose (MTD). Studies are small, usually 15–60 patients. Eligible patients may have a variety of cancers but have no available standard therapy options. All patients receive the study drug. Drug doses are increased slowly, and patients are monitored for side effects until the MTD is found. Phase 1 clinical trials help to determine the drug's pharmacokinetics, measuring how the drug is absorbed, distributed, metabolized, and excreted, revealing the following:</p> <ul style="list-style-type: none"> <li>• Drug dose</li> <li>• Administration schedule</li> <li>• Dose adjustments for certain medical conditions</li> <li>• Possible drug interactions</li> </ul>                                                                                                                                                                                                                                                                                             |
| 2     | <p>Goal: Evaluate the activity or effectiveness of the drug or regimen and determine if there should be further development of an intervention. Studies are larger in size (e.g., 100–300) and include patients for whom the current standard of care is not effective. In most phase 2 clinical trials, all patients receive the same intervention, including the same dose of the drug being studied (if it is a drug clinical trial). However, different trial designs exist (e.g., adaptive, Bayesian), in which patients may be randomized to one of several treatment groups.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 3     | <p>Goal: Compare a new drug or treatment to a current standard treatment. Studies include large numbers of patients (e.g., hundreds to thousands) and are conducted at many locations. The standard design for a phase 3 clinical trial is a randomized controlled trial, allowing comparison of a new intervention to the current standard of care. Patients on the clinical trial will be assigned to one of two or more groups:</p> <ul style="list-style-type: none"> <li>• The treatment group, receiving the new intervention</li> <li>• A control group, receiving either the standard of care or a placebo, if there is no treatment option</li> </ul> <p>To ensure study results are due to the intervention, researchers may use the following:</p> <ul style="list-style-type: none"> <li>• Randomization: Patients are assigned to the study groups with an equal chance of receiving each of the treatment options.</li> <li>• Masking or blinding: Patients and research team members do not know which intervention each patient is receiving.</li> </ul> |
| 4     | <p>Goal: Further evaluate risks, benefits, and uses in real-life scenarios. Phase 4 trials are follow-up investigations for a drug recently marketed to and available for use by the general public. Studies include very large numbers of patients (e.g., thousands).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

Note. Based on information from Investigational New Drug Application, 2020; Stoney & Johnson, 2018; U.S. Food and Drug Administration, 2018b, 2018e.

**TABLE 5-7. End Points for Drug and Biologic Approval**

| End Point                              | Definition                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Based on Tumor Assessments</b>      |                                                                                                                                                                                                                                                                                                                               |
| Disease-free survival                  | Time from randomization until disease recurrence or death from any cause                                                                                                                                                                                                                                                      |
| Objective response rate                | Proportion of patients with reduction of tumor size of a predefined amount and for a minimum time period<br>Sum of partial responses plus complete responses<br>Measure from time of initial response until progression<br>Standardized criteria (e.g., Response Evaluation Criteria in Solid Tumors [RECIST]) when available |
| Progression-free survival              | Time from randomization until objective tumor progression or death                                                                                                                                                                                                                                                            |
| Time to progression                    | Time from randomization until objective tumor progression, excluding death                                                                                                                                                                                                                                                    |
| Time to treatment failure              | Composite end point from time of randomization to discontinuation of treatment for any reason (e.g., progressive disease, toxicity, death)                                                                                                                                                                                    |
| <b>Based on Symptom Assessments</b>    |                                                                                                                                                                                                                                                                                                                               |
| Symptom improvement or palliation      | Direct measure of clinical benefit rather than a surrogate end point                                                                                                                                                                                                                                                          |
| Time to progression of cancer symptoms | Direct measure of clinical benefit rather than a potential surrogate end point                                                                                                                                                                                                                                                |

Note. Based on information from U.S. Food and Drug Administration, 2018a.

- (3) The FDA reviews the proprietary name as part of the product labeling review for an NDA.

#### 8. Generic drugs

- Once a new drug is approved, the sponsor (i.e., the company manufacturing the drug) has exclusive rights to market the drug for a period. Other drug manufacturers may develop the drug once the patent and exclusive marketing rights have expired (U.S. FDA, 2018b).
- Generic drugs must have the same dosage, safety, strength, quality, mechanism of action, and prescribing information as the brand-name drug.
- Generic drug manufacturers conduct bioequivalence studies and file an abbreviated NDA. Bioequivalence studies include pharmacokinetic, pharmacodynamic, clinical, and in vitro studies.

#### 9. Biosimilars

- The FDA approves the originator biological product (reference product) through the traditional drug approval process, known as a stand-alone BLA.
  - An abbreviated biological licensure pathway can be used when a biological product is demonstrated to be highly similar to an existing FDA-licensed biological product.
  - These similar products are referred to as biosimilars. They have “no clinically meaningful differences between the biological product and the reference product in terms of the safety, purity, and potency” (U.S. FDA, 2015, p. 3).
  - Biosimilars undergo a rigorous evaluation by the FDA (Declerck et al., 2017; Harvey, 2017; U.S. FDA, 2017).
- When naming a biologic product, the nonproprietary or proper name reflects scientific characteristics, such as chemical structure and pharmacologic properties.
  - The FDA designates the proper name in the license for the use of each product.
  - This name helps healthcare providers identify products and distinguish biological products from one another.
  - The proprietary name is the trademarked name (U.S. FDA, 2017).
- FDA’s naming convention for biologics consists of a core name (e.g., filgrastim, epoetin alfa) and an FDA-designated suffix.
  - The core name is designated by the USAN program.
  - This name will be the same for biosimilars.
  - The suffix is composed of four lower-case letters and signifies the originator of the product (e.g., replicamab-cznm, replicamab-hjxf).
  - The FDA may attach a prefix to distinguish a product under a different BLA prior to 2017 (e.g., ado-trastuzumab emtansine, trastuzumab).
  - These are important differences to understand to ensure patient safety (U.S. FDA, 2017).
- Biosimilars can be approved for fewer indications and conditions than the approved biologic reference product.
  - The labeling information for a biosimilar has more details comparing the biosimilar to the reference products.
  - Nurses and other healthcare providers should read the product labeling for uses,

routes of administration, and therapeutic profiles for each biosimilar agent (Buske et al., 2017; Harvey, 2017; U.S. FDA, 2017).

### C. Expanded access

1. Expanded access (compassionate use) is a pathway to allow patients access to a drug, biologic, or device that has not yet been approved or cleared by the FDA for use outside of a clinical trial.
2. Expanded access may be used when a patient has an immediately life-threatening or severe disease or condition, a patient has exhausted all approved treatment options and is not eligible for a clinical trial, the drug or biologic has demonstrated benefit that outweighs the risk, and there is no compromise to the sponsor's development of the product (Fountzilas et al., 2018; U.S. FDA, 2018c, 2021).
3. Expanded access is not the same as off-label use when an FDA-approved drug or biologic is used for a condition other than what was approved (Fountzilas et al., 2018).
  - a) The most common type of expanded access use is for an individual patient.
    - (1) In this situation, the patient's physician is responsible for submitting paperwork to the FDA, seeking the drug or biologic from the manufacturer, and obtaining IRB approval.
    - (2) This is also referred to as an individual patient expanded access IND or single-patient IND (Fountzilas et al., 2018; U.S. FDA, 2018c, 2021).
  - b) Other expanded access INDs exist based on the size of the planned treatment population. These include intermediate size (i.e., less than 1,000 individuals) and widespread use. Typically, the sponsor undertakes these INDs (Fountzilas et al., 2018; U.S. FDA, 2018c, 2021).
  - c) All of these expanded access IND mechanisms have paperwork requirements from the FDA and require IRB approval. The FDA will assign an IND number, review the application, and notify the physician or sponsor of its decision typically within 30 days (Fountzilas et al., 2018; U.S. FDA, 2018c, 2021).
  - d) Emergency use INDs are an exception in that they can be initiated by phone and reported to the IRB within five working days.
    - (1) The expanded access pathway is often used in oncology (Fountzilas et al., 2018; U.S. FDA, 2018c, 2021).
    - (2) Between 2005 and 2014, more than 10,700 single-patient INDs were submitted to the FDA, with approximately 25% being cancer diagnoses (Fountzilas et al., 2018).

# CHAPTER 6

## Chemotherapy

### A. Chemotherapy in the treatment of cancer

1. Chemotherapy drugs are chemical agents used to treat cancer. This practice dates back to the 1940s when nitrogen mustard, an alkylating agent, was first noted to have activity against lymphoma, a cancer of the lymph nodes. It is essential to review the principles of chemotherapy to understand how chemotherapy works, including the kinetics of cellular growth. For a general overview of cancer treatment strategies, tumor response definitions, drug resistance, and dosing strategies, see Chapter 4.
2. Cellular kinetics: Three types of cells exist simultaneously.
  - a) Nondividing and terminally differentiated
  - b) Continually proliferating
  - c) Resting cells that can be recruited into the cell cycle at any time (e.g., stem cells)
3. Tumor kinetics (Vlcek, 2022)
  - a) The rate of growth of a tumor is dependent on the following:
    - (1) Growth fraction—the proportion of actively dividing cells
    - (2) Cell cycle time—the average time for a cell in the tumor to go through the entire cell cycle
    - (3) Doubling time—the time it takes for the tumor to double in size. This time is correlated with the length of the cell cycle.
    - (4) Rate of cell loss or death
  - b) Tumor doubling time varies with tumor size.
    - (1) Larger tumors tend to grow slower because of limited blood and oxygen supply.
    - (2) Smaller tumors tend to be more responsive to cytotoxic therapy.
  - c) The cell life cycle is a five-stage reproductive process occurring in healthy and malignant cells (see Figure 6-1).
    - (1) The most important regulatory components of the cell cycle are cyclins and cyclin-dependent kinase (CDK) enzymes.

Cyclins, a family of proteins, activate CDK enzymes and form a complex that promotes cell cycle progression. CDK inhibitors prevent cells from progressing through the cell cycle (Hydbring et al., 2016; Vlcek, 2022).

- (2) Chemotherapy agents target different cell cycle phases and halt cell growth and division, leading to cell death. Chemotherapy is administered using various schedules and doses designed to achieve therapeutic goals and based on the principles of cellular kinetics.

### 4. Phases of the cell cycle

#### a) Gap 0 ( $G_0$ )

- (1)  $G_0$  is the resting or dormant phase of the cycle.
- (2) Cells are temporarily out of the cycle and not actively proliferating; however, all other cellular activities occur.

**FIGURE 6-1.** The Cell Cycle

Note. Image courtesy of University of Texas MD Anderson Cancer Center. Used with permission.

- (3) Cells continue in  $G_0$  until a stimulus causes them to reenter the cell cycle.
    - (4) Because they are not actively proliferating, cells in this phase have some protection from exposure to cell cycle-specific chemotherapy agents.
  - b) Gap 1 ( $G_1$ )
    - (1) This is known as the postmitotic phase of the cell cycle.
    - (2) Cells begin the first phase of reproduction and growth by synthesizing the proteins and RNA necessary for cell division.
  - c) Synthesis (S): DNA is replicated.
  - d) Gap 2 ( $G_2$ )
    - (1) The  $G_2$  phase is also known as the premittotic (or postsynthetic) phase.
    - (2) The second phase of protein and RNA synthesis occurs.
    - (3) Preparation for mitotic spindle formation occurs.
    - (4) The cell is now prepared for division.
  - e) Mitosis (M)
    - (1) Cell division occurs.
    - (2) This is the shortest phase of the cell life cycle.
    - (3) Mitosis results in the formation of two daughter cells with exact copies of the parent cell's DNA. Cells either reenter the cell cycle to reproduce or perform the specific functions of the tissue for which they are programmed.
5. Cyclin-CDK complexes (Hydbring et al., 2016; Murphy & Dickler, 2015)
- a) Cyclins are cell cycle kinase regulators (e.g., cyclin D).
  - b) CDKs are cell cycle kinase inhibitors (e.g., CDK4).
  - c) Cyclins and CDKs unite and create complexes that propel the cell through each phase of the cell cycle (e.g., cyclin D-CDK4, cyclin D-CDK6, cyclin E-CDK2 drive  $G_1$ ).
  - d) CDK variations have been linked to tumor formation. For example, CDK6 is overexpressed in many hematologic malignancies, glioblastoma, and lung cancer.
  - e) Anti-CDK/cyclin inhibitors are currently being used to treat patients with metastatic breast cancer. Additional agents are being developed and tested in clinical trials in various cancer types.
- B. Classification of chemotherapy agents
1. Drugs are classified according to their pharmacologic action or effect on cell reproduction (see Table 6-1).
  2. Cell cycle-specific drugs exert effect within a specific phase of the cell cycle (Tortorice, 2018).
    - a) These drugs are most effective when given in divided but frequent doses or continuous infusions. This allows the maximum number of cells to be exposed to the drug at the specific time in their life cycle when they are vulnerable to the drug.
    - b) Classifications include antimetabolites, plant alkaloids (e.g., camptothecins, epipodophyllotoxins, taxanes, vinca alkaloids), and other miscellaneous agents.
  3. Cell cycle-nonspecific drugs exert effect in all phases of the cell cycle, including the  $G_0$  (resting) phase (Tortorice, 2018).
    - a) Cell cycle-nonspecific drugs may effectively treat tumors with more slowly dividing cells.
    - b) If the cancer is sensitive to the agent used, the drug is incorporated into the cell. The cell kill may not be instantaneous but may occur when the cell attempts to divide but encounters irreparable damage.
      - (1) Destruction of tumor cells is directly proportional to the amount of drug administered.
      - (2) These drugs are given intermittently, allowing the individual to recover from dose-limiting toxicities before the drug is repeated at the next interval.
      - (3) The most frequent dose-limiting toxicity is bone marrow suppression.
      - (4) In general, the greater the dose of the drug, the greater the cell kill.
    - c) Classifications include alkylating agents, antitumor antibiotics, hormone therapies, and nitrosoureas.
- C. Chemotherapy classifications (Sparreboom & Baker, 2015)
1. Alkylating agents
    - a) Alkylating agents were the first anticancer agents developed.
    - b) They are cell cycle nonspecific.
    - c) Alkylating agents cause breakage in the DNA helix strand, interfering with DNA replication and ultimately resulting in cell death.
    - d) Dose-limiting toxicities include bone marrow suppression, gastrointestinal toxicities, and organ-specific toxicities (e.g., renal and hepatic, dependent on drug and dose; see Figure 6-2).
    - e) Other effects include carcinogenic and mutagenic effects and impaired fertility.
    - f) Examples include bendamustine, busulfan, cyclophosphamide, cisplatin, and carboplatin.

**TABLE 6-1.** Chemotherapy Agents

| Classification    | Mechanism of Action                                               | Drug                                                             | Route  | Indications                                                                                      | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                 | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**TABLE 6-1.** Chemotherapy Agents (*Continued*)

| Classification                     | Mechanism of Action | Drug                         | Route | Indications                                                                                                                  | Side Effects                                                                                                                                                                                                                                                                                 | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------|---------------------|------------------------------|-------|------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Alkylating agents ( <i>Cont.</i> ) |                     | Carboplatin ( <i>Cont.</i> ) |       |                                                                                                                              |                                                                                                                                                                                                                                                                                              | The emetic potential is based on AUC. High emetic potential is AUC $\geq 4$ ; moderate emetic potential is AUC $< 4$ .<br>Emergency medications should be made available for hypersensitivity reaction, which may occur during any therapy dose or be delayed (around dose 6–8). Most patients can be successfully desensitized via a multistep titration.<br>(National Comprehensive Cancer Network, 2022; Teva Parenteral Medicines, 2016)                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                                    |                     | Chlorambucil (Leukeran®)     | PO    | Chronic lymphocytic leukemia<br>HL<br>NHL                                                                                    | Dose-limiting toxicities: myelosuppression, skin reactions<br>Ovarian or sperm suppression, second malignancy                                                                                                                                                                                | Drugs should be taken on an empty stomach.<br>Chlorambucil should be used with caution in patients with a seizure history and within 1 month of radiation or cytotoxic therapy.<br>(Aspen Global, 2016)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                                    |                     | Cisplatin                    | IV    | Ovarian cancer<br>Testicular cancer<br>Bladder cancer<br>Off-label uses in various solid tumors and hematologic malignancies | Dose-limiting toxicities: severe nephrotoxicity, myelosuppression<br>Severe acute and delayed nausea, vomiting, ototoxicity (tinnitus and high-frequency hearing loss are most common), hypersensitivity reaction, hypomagnesemia and other electrolyte abnormalities, peripheral neuropathy | Cisplatin is a vesicant at high concentration and an irritant at low concentration. The IV infusion concentration should be $< 0.5$ mg/ml.<br>Adequate hydration should be ensured before, during, and following cisplatin administration. Cisplatin can result in potassium and magnesium depletion and should be monitored and repleted as needed. SCr must be monitored prior to each dose. Renal function must return to normal before subsequent doses are administered; renal toxicity becomes more prolonged and severe with repeated courses.<br>Cisplatin can cause severe nausea and vomiting, necessitating highly effective antiemetics. Nausea and vomiting are dose related and can last up to 5 days. A baseline audiogram should be considered. Ototoxicity is related to the cumulative dose received.<br>(Teva Parenteral Medicines, 2015) |

| Classification                     | Mechanism of Action                                                                                                                                                                                      | Drug                           | Route      | Indications                     | Side Effects                                                                                                                                                                                                                                           | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|------------|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Alkylating agents ( <i>Cont.</i> ) |                                                                                                                                                                                                          | Trabectedin (Yondelis®)        | IV         | Leiomyosarcoma<br>Liposarcoma   | Dose-limiting toxicities: myelosuppression (neutropenic sepsis), hepatotoxicity, cardiomyopathy<br>Rhabdomyolysis, capillary leak syndrome, nausea, fatigue, vomiting, constipation, decreased appetite, diarrhea, peripheral edema, dyspnea, headache | Primary prophylaxis with granulocyte-colony-stimulating factor is required. Moderate to high emetic potential exists. Patients must have appropriate antiemetics prior to each dose.<br>Trabectedin is administered as a 24-hour continuous infusion and must be given through a central line. A 0.2-micron filter must be used.<br>Trabectedin is a vesicant; extravasation can result in severe tissue injury.<br>Premedicate with 20 mg IV dexamethasone 30 minutes prior to infusion.<br>Dose reduce in patients with hepatic impairment.<br>Monitor creatine phosphokinase prior to each dose due to the risk of rhabdomyolysis. (Janssen Biotech, 2020)                                                                                                                                                                                                                                                                                       |
| Antimetabolites                    | Pyrimidine nucleoside analog of cytidine that inhibits DNA/RNA methyltransferases; reduces DNA and RNA methylation, alters DNA gene expression, decreases RNA stability, and decreases protein synthesis | Azacitidine (Onureg®, Vidaza®) | IV, SC, PO | AML<br>Myelodysplastic syndrome | Dose-limiting toxicities: myelosuppression, elevated SCr, nausea, vomiting, diarrhea, fatigue, fever, erythema at the injection site, constipation                                                                                                     | IV: Mix in 50–100 ml NS or lactated Ringer's solution only. Infuse over 10–40 minutes. The administration should be completed within 1 hour of reconstitution.<br>Ensure patients take a prophylactic antiemetic prior to each dose for the first 2 cycles of PO azacitidine.<br>SC: Resuspend suspension immediately before administration by rolling syringe between palms; the solution should be uniformly cloudy. It is stable at room temperature for 1 hour and under refrigeration for 8 hours (when reconstituted using room-temperature water).<br>Divide doses > 3 ml into multiple syringes and inject into separate sites. Administer new injections at least 1 inch from the old site.<br>To minimize skin irritation, ensure that the needle is empty of the drug and do not expel air into the needle before giving the injection. Do not use ice on the injection site, as it may decrease drug absorption. (Celgene, 2016, 2020b) |

**TABLE 6-1.** Chemotherapy Agents (*Continued*)

| Classification                      | Mechanism of Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Drug                      | Route | Indications                                                                                                                                                       | Side Effects                                                                                                                                                                                                | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Antimetabolites<br>( <i>Cont.</i> ) | <p>Prodrug of 5-FU; after ingestion, undergoes hydrolysis in the liver to form 5-FU; is a nucleoside metabolic inhibitor that interferes with the synthesis of DNA and, to a lesser extent, inhibits the formation of RNA</p> <p>Most other anti-metabolites interfere with one or more enzymes or their reactions that are necessary for DNA synthesis. They affect DNA synthesis by acting as a substitute to the metabolites that would be used in the normal metabolism (e.g., antifolates interfere with the use of folic acid).</p> | Capecitabine<br>(Xeloda®) | PO    | <p>Colon cancer</p> <p>Metastatic breast cancer</p> <p>Metastatic colorectal cancer</p> <p>Off-label use in pancreatic cancers and hepatobiliary tract cancer</p> | <p>Dose-limiting toxicities:</p> <p>Diarrhea, palmar-plantar erythrodysesthesia (hand-foot syndrome)</p> <p>Mucositis, nausea, vomiting, myelosuppression, increased bilirubin, fatigue, cardiotoxicity</p> | <p>Capecitabine can significantly affect prothrombin time/international normalized ratio and increase bleeding risk. Recommend switching patients to alternative anticoagulants such as direct-acting oral anticoagulants or enoxaparin. Monitor prothrombin time/international normalized ratio closely for those on concomitant warfarin and capecitabine.</p> <p>Administer with food and water. Taking the drug on an empty stomach will increase absorption, increasing toxicities.</p> <p>Dose reduction is necessary for older adult patients and those with CrCl &lt; 50 ml/min.</p> <p>Ensure patients have antidiarrheal medication when starting capecitabine.</p> <p>Concomitant use of capecitabine and proton pump inhibitor (e.g., pantoprazole, omeprazole) may reduce efficacy and survival and should be avoided if necessary.</p> <p>Uridine triacetate (Vistogard®) is U.S. Food and Drug Administration approved for the emergency treatment of 5-FU or capecitabine overdose regardless of the presence of symptoms or in patients who exhibit early-onset (within 96 hours of administration) severe or life-threatening cardiac or CNS toxicity and/or early-onset (within 96 hours of administration) unusually severe adverse reactions (GI toxicities and/or neutropenia). Uridine triacetate is a prodrug of uridine, which competes with 5-fluorouridine triphosphate, a toxic metabolite of 5-FU, for incorporation into RNA during RNA sequencing. (Genentech, 2021; Wellstat Therapeutics, 2017)</p> |

| Antimetabolites<br>( <i>Cont.</i> ) |                     | 5-FU<br>(Adrucil®)<br>( <i>Cont.</i> ) |                    |                                                                                                                                                                                                                          |                                                                                                                                                                                                                                                                       | cardiac or CNS toxicity and/or early-onset (within 96 hours of administration) unusually severe adverse reactions (GI toxicities and/or neutropenia). Uridine triacetate is a prodrug of uridine, which competes with 5-fluorouridine triphosphate, a toxic metabolite of 5-FU, for incorporation into RNA during RNA sequencing.<br>(Teva Parenteral Medicines, 2017a; Wellstat Therapeutics, 2017)                                                                                                    |
|                                     |                     | Gemcitabine<br>(Gemzar®)               | IV, intra-vesical  | Breast cancer<br>Pancreatic cancer<br>NSCLC<br>Ovarian cancer<br>Off-label indications for various solid tumor and hematologic malignancies, including soft tissue sarcoma and relapsed/refractory lymphomas             | Dose-limiting toxicity: myelosuppression (especially thrombocytopenia)<br>Nausea; vomiting; flu-like symptoms, including fever, headache, arthralgias, and myalgias; rash; peripheral edema; dyspnea; pulmonary toxicity with increased infusion time; hepatotoxicity | Gemcitabine is an irritant. Infuse over 30 minutes for the majority of indications. When used in soft tissue sarcoma, it is often given at a fixed rate of 10 mg/m <sup>2</sup> /min; more prolonged infusion will result in more hematologic toxicity. Increased (severe and life-threatening) toxicity may occur when gemcitabine is administered within 7 days of radiation therapy.<br>(Eli Lilly and Company, 2019b)                                                                               |
|                                     |                     | 6-Mercaptopurine (6-MP; Purinethol®)   | PO                 | ALL                                                                                                                                                                                                                      | Myelosuppression, hepatotoxicity, mucositis, nausea, vomiting, anorexia, hyperuricemia, hyperuricosuria, alopecia, rash, hyperpigmentation                                                                                                                            | Reduce oral dose by 75% when used concurrently with allopurinol. Instruct patients to take on an empty stomach.<br>(Kantarjian et al., 2000; Mylan Pharmaceuticals, 2013)                                                                                                                                                                                                                                                                                                                               |
|                                     |                     | Methotrexate                           | IM, IT, IV, PO, SC | Breast cancer<br>Choriadenoma destruens<br>CNS metastasis<br>Gestational choriocarcinoma<br>Gestational trophoblastic tumor<br>Hydatidiform mole<br>Leukemia<br>NHL<br>Osteosarcoma<br>Psoriasis<br>Rheumatoid arthritis | Dose-limiting toxicities: hepatotoxicity, renal toxicity<br>Mucositis, nausea, vomiting, myelosuppression, oral or GI ulceration, pneumonitis, photosensitivity, neurotoxicity associated with high-dose therapy                                                      | High-dose methotrexate doses are adjusted for patients with renal dysfunction. High doses must be followed by timely administration of leucovorin and alkaline hydration. Follow the dosing schedule carefully. Monitor serum methotrexate levels until ≤ 0.05–0.1 mcmol/L. Monitor urine pH and maintain ≥ 7 before and until serum methotrexate levels ≤ 0.05 mcmol/L. Depending on methotrexate clearance, some patients may require additional leucovorin rescue and serum methotrexate monitoring. |

**TABLE 6-1.** Chemotherapy Agents (*Continued*)

| Classification                      | Mechanism of Action | Drug                                        | Route | Indications                | Side Effects                                                                                                                                                                                                          | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------|---------------------|---------------------------------------------|-------|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Antimetabolites<br>( <i>Cont.</i> ) |                     | Pemetrexed<br>(Alimta®)<br>( <i>Cont.</i> ) |       |                            |                                                                                                                                                                                                                       | Hold treatment if ANC < 1,500/mm <sup>3</sup> , platelets < 100,000/mm <sup>3</sup> , or CrCl < 45 ml/min. Monitor renal and liver function. Patients should avoid using nonsteroidal anti-inflammatory drugs while on pemetrexed, as concurrent use may increase the risk of renal damage. (Eli Lilly and Company, 2019a)                                                                                                                                                                                                                                                                                                                                                                    |
|                                     |                     | Pentostatin<br>(Nipent™)                    | IV    | Hairy cell leukemia        | Dose-limiting toxicity: myelosuppression<br>Acute pulmonary edema, hypotension, fever, chills, nausea, vomiting, rash, renal toxicity, confusion, hepatic enzyme elevation, heightened infection risk, cough, cardiac | Administer with 500–1,000 ml D <sub>5</sub> W in 0.5 NS prior to infusion and an additional 500 ml after infusion. Do not administer with fludarabine, carmustine, etoposide, or high-dose cyclophosphamide. (Hospira, 2019)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                                     |                     | Pralatrexate<br>(Foloty®)                   | IV    | Peripheral T-cell lymphoma | Dose-limiting toxicity: myelosuppression<br>Mucositis, dermatologic reactions, hepatotoxicity, edema, fatigue                                                                                                         | Pralatrexate is administered as an IV push over 3–5 minutes. Consider dose reduction in patients with impaired renal function (estimated glomerular filtration rate < 30 ml/min/1.73 m <sup>2</sup> ). Prophylactic folic acid and vitamin B <sub>12</sub> supplements must be given. Supplement patients with vitamin B <sub>12</sub> 1,000 mcg IM every 8–10 weeks and folic acid 1–1.25 mg PO daily. Monitor liver and renal function.<br><br>Consider adding oral leucovorin 25 mg 3 times daily for 6 doses to help reduce oral mucositis. Leucovorin should be initiated 24 hours after each pralatrexate dose. (Acrotech Biopharma, 2020; National Comprehensive Cancer Network, 2022) |
|                                     |                     | Thioguanine<br>(6-TG; Tabloid®)             | PO    | ALL                        | Dose-limiting toxicity: myelosuppression<br>Hyperuricemia, nausea, hepatotoxicity, diarrhea                                                                                                                           | Monitor liver function. Patients should take the drug on an empty stomach to reduce the risk of nausea and vomiting. (Aspen Global, 2012b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Classification        | Mechanism of Action                                      | Drug                                    | Route                     | Indications                                                                                                                          | Side Effects                                                                                                                                                                                                                                                    | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|----------------------------------------------------------|-----------------------------------------|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Antitumor antibiotics | Binds with DNA, thereby inhibiting DNA and RNA synthesis | Bleomycin                               | IM, intra-pleural, IV, SC | HL<br>Malignant pleural effusion<br>NHL<br>Testicular cancer<br>Squamous cell cancers of the head and neck, cervix, vulva, and penis | Dose-limiting toxicities: hypersensitivity or anaphylactic reaction (rare), pulmonary toxicity<br>Hyperpigmentation, alopecia, photosensitivity, renal toxicity, hepatotoxicity, fever, chills, erythema, rash, mucositis                                       | Bleomycin is ordered in units. Bleomycin is not compatible with D <sub>5</sub> W. Patients who have received prior bleomycin are at risk for pulmonary toxicity when exposed to oxygen during surgery. Ensure that patients and family members understand the lifelong necessity of disclosing previous use of bleomycin when future needs for anesthesia occur to prevent a fatal episode of pulmonary failure. Because of the dose-related incidence of pulmonary fibrosis, the cumulative lifetime dose should not exceed 400 units. Pulmonary function tests are recommended at initiation of bleomycin and every 1–2 months thereafter. Consider stopping the drug if a 30%–35% decrease from pretreatment values occurs. Acetaminophen and an antihistamine may decrease fever and chills in the first 24 hours after administration. Consider dose reductions in patients with CrCl < 50 ml/min. (Fresenius Kabi USA, 2016a) |
|                       |                                                          | Dactinomycin (Actinomycin-D; Cosmegen®) | IV                        | Pediatric rhabdomyosarcoma<br>Gestational trophoblastic disease<br>Ewing sarcoma<br>Testicular cancer<br>Wilms tumor                 | Dose-limiting toxicity: myelosuppression<br>Nausea, vomiting, alopecia, mucositis, diarrhea, ovarian or sperm suppression, radiation recall (hyperpigmentation of previously irradiated areas), sinusoidal obstruction syndrome, renal toxicity, hepatotoxicity | Dactinomycin is a vesicant; extravasation can result in severe tissue injury. Administer through the side port of a free-flowing IV. Dactinomycin is highly toxic and corrosive to soft tissues; inhalation and contact with the eyes must be avoided. This drug may be ordered in micrograms; check the dose carefully. Dactinomycin is contraindicated in patients with concurrent or recent chicken pox or herpes zoster. Avoid within 2 months of radiation therapy for right-sided Wilms tumor. (Recordati Rare Diseases, 2018)                                                                                                                                                                                                                                                                                                                                                                                                |

| Classification                        | Mechanism of Action                                      | Drug                                           | Route            | Indications                                           | Side Effects                                                                                                                                 | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------|----------------------------------------------------------|------------------------------------------------|------------------|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Antitumor antibiotics<br>(Cont.)      |                                                          | Mitomycin C (Mutamycin®)                       | Intravesical, IV | Bladder cancer<br>Pancreatic cancer<br>Gastric cancer | Dose-limiting toxicity: myelosuppression<br>Nausea, vomiting, anorexia, fever, renal toxicity, pulmonary toxicity, fatigue                   | The drug is purple-blue in color. Mitomycin is a vesicant; extravasation can result in severe tissue injury. Administer through the side port of a free-flowing IV. Nadir occurs within 8 weeks after treatment begins (average of 4 weeks). Acute shortness of breath and bronchospasm can occur very suddenly when this drug is given with a vinca alkaloid. Withhold doses for platelets < 100,000/mm <sup>3</sup> or white blood cells < 4,000/mm <sup>3</sup> . Do not use in patients with SCr > 1.7 mg/dl. Hemolytic uremic syndrome has been seen with a single dose ≥ 60 mg. Mitomycin is contraindicated in patients with coagulation disorders. The prepared solution needs to be protected from light. (Accord BioPharma, 2016) |
| Antitumor antibiotics: anthracyclines | Binds with DNA, thereby inhibiting DNA and RNA synthesis | Daunorubicin (Cerubidine®)                     | IV               | ALL in children<br>AML                                | Dose-limiting toxicities: myelosuppression, cardiotoxicity<br>Nausea, vomiting, alopecia, hyperuricemia, radiation recall, red-colored urine | The drug is red in color. Daunorubicin is a vesicant; extravasation can result in severe tissue injury. Administer through the side arm of a free-flowing IV. Dose reduce in patients with hepatic or renal impairment. Test cardiac ejection fraction before starting therapy. The maximum lifetime dose is 550 mg/m <sup>2</sup> in adults without cardiovascular risk factors and 400 mg/m <sup>2</sup> in adults receiving chest irradiation. (Teva Parenteral Medicines, 2014)                                                                                                                                                                                                                                                         |
|                                       |                                                          | Daunorubicin and cytarabine liposome (Vyxeos™) | IV               | AML                                                   | Dose-limiting toxicities: myelosuppression, cardiotoxicity, hypersensitivity reaction<br>Hemorrhage events, copper overload                  | Administer over 90 minutes through a central line. Maximum lifetime daunorubicin dose is 550 mg/m <sup>2</sup> in adults without cardiovascular risk factors and 400 mg/m <sup>2</sup> in adults receiving chest irradiation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**TABLE 6-1.** Chemotherapy Agents (*Continued*)

| Classification                    | Mechanism of Action                                                                                                                                            | Drug                                 | Route | Indications                                                                                                    | Side Effects                                                                                                                                                                                    | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|-------|----------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Miscellaneous<br>( <i>Cont.</i> ) | Semisynthetic analog of epothilone B; binds to beta-tubulin on microtubules, leading to cell death by blocking cells in the M phase of the cell division cycle | Ixabepilone (Ixempra®)               | IV    | Metastatic or locally advanced breast cancer                                                                   | Dose-limiting toxicities: peripheral sensory neuropathy, myelosuppression, hypersensitivity reaction<br>Fatigue, myalgia, alopecia, nausea, vomiting, mucositis, diarrhea, musculoskeletal pain | Administer IV over 3 hours. Use non-PVC, non-DEHP bags and tubing; the solution is only stable for 6 hours.<br>Administer through a 0.2- to 1.2-micron in-line filter.<br>The drug is contraindicated in combination with capecitabine if bilirubin > 1 × ULN or aspartate aminotransferase or alanine aminotransferase > 2.5 × ULN. Patients may still receive monotherapy ixabepilone.<br>CYP3A4 inhibitors may increase ixabepilone concentration, and CYP3A4 inducers may decrease ixabepilone concentration. Avoid St. John's wort.<br>Premedicate with diphenhydramine (50 mg PO) and ranitidine (150–300 mg PO) 1 hour prior to dose to decrease the risk of hypersensitivity reaction.<br>(R-Pharm US, 2016) |
|                                   | Inhibits adrenal steroid production                                                                                                                            | Mitotane (Lysodren®)                 | PO    | Adrenocortical cancer                                                                                          | CNS toxicity, adrenal insufficiency/crisis, ovarian macrocysts in premenopausal women, anorexia, nausea, vomiting, mucositis, lethargy, dizziness or vertigo, rash                              | Monitor prothrombin time/international normalized ratio closely in patients on warfarin therapy.<br>Adrenal steroid replacement is indicated. Consider dose reduction in patients with renal or hepatic impairment.<br>(Bristol-Myers Squibb, 2017d)                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                                   | Inhibits protein synthesis and is independent of direct BCR-ABL1 binding                                                                                       | Omacetaxine mepesuccinate (Synribo®) | SC    | CML in chronic or accelerated phase with resistance and/or intolerance to 2 or more tyrosine kinase inhibitors | Dose-limiting toxicity: myelosuppression<br>Thrombocytopenia with bleeding risk, hyperglycemia, nausea, vomiting, diarrhea, alopecia, fatigue                                                   | Monitor patients for bleeding. Rotate injection sites.<br>(Teva Pharmaceuticals, 2021)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**TABLE 6-1.** Chemotherapy Agents (*Continued*)

| Classification                    | Mechanism of Action                                                                 | Drug                     | Route                             | Indications                         | Side Effects                                                                                                                                                                                                             | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------|-------------------------------------------------------------------------------------|--------------------------|-----------------------------------|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Miscellaneous<br>( <i>Cont.</i> ) | Depletes plasma asparagine, leading to leukemic cell death                          | Pegaspargase (Oncaspar®) | IM, IV                            | ALL                                 | Pancreatitis, thrombosis, glucose intolerance, coagulopathy, hepatotoxicity, allergic reactions (including anaphylaxis)                                                                                                  | Sometimes patients can be premedicated with acetaminophen, antihistamine, diphenhydramine, and corticosteroid (hydrocortisone). Refer to specific protocol.<br>Dosing is different based on the patient's age. For patients younger than 21 years: 2,500 unit/m <sup>2</sup> ; for patients older than 21 years: 2,000 units/m <sup>2</sup><br>When given IM, the maximum volume per injection site is 2 ml.<br>When given via IV, administer over 1–2 hours.<br>(Servier Pharmaceuticals, 2020)                                                                                                                                                  |
|                                   | May inhibit protein, RNA, and DNA synthesis                                         | Procarbazine (Matulane®) | PO                                | HL                                  | Dose-limiting toxicity: myelosuppression<br>Nausea, vomiting, hepatic dysfunction                                                                                                                                        | Patients should avoid foods high in tyramine, such as aged cheeses, air-dried or cured meats, fava or broad bean pods, tap/draft beer, wine (> 120 ml), vermouth, marmite concentrate, sauerkraut, and soy sauce and other soybean condiments because procarbazine inhibits monoamine oxidase.<br>Patients should avoid alcohol for the possibility of a disulfiram-like reaction.<br>(Sigma-Tau Pharmaceuticals, 2016)                                                                                                                                                                                                                           |
| Nitrosoureas                      | Breaks DNA helix, interfering with DNA replication; crosses the blood–brain barrier | Carmustine (BiCNU®)      | Implantation (Gliadel® wafer), IV | CNS tumors<br>Off-label use in HSCT | Dose-limiting toxicities: myelosuppression, pulmonary toxicity<br>Nausea, vomiting, renal toxicity<br>Gliadel-specific toxicities: seizures, intracranial hypertension, meningitis, impaired neurosurgical wound healing | Nadir occurs 4–6 weeks after start of therapy. Because of delayed toxicity, successive treatments usually are given no more frequently than once every 6–8 weeks.<br>Rapid infusion may cause burning along the vein and flushing of the skin (infuse over at least 2 hours).<br>Long-term therapy can result in irreversible pulmonary fibrosis, which may present as an insidious cough and dyspnea or sudden respiratory failure.<br>Use non-PVC, non-DEHP bags and tubing. The cumulative dose of 1,400 mg/m <sup>2</sup> should not be exceeded because of pulmonary toxicity.<br>(Arbor Pharmaceuticals, 2018; Bristol-Myers Squibb, 2017a) |

| Plant alkaloids: camptothecins ( <i>Cont.</i> ) | Inhibits topoisomerase I                                                                                                                                       | Irinotecan liposomal (Onivyde®)                                          | IV     | Relapsed/refractory metastatic adenocarcinoma of the pancreas                       | Interstitial lung disease, diarrhea, fatigue, nausea, vomiting, stomatitis, pyrexia                                      | Administer 70 mg/m <sup>2</sup> IV over 90 minutes every 2 weeks in combination with 5-FU and leucovorin. The recommended dose for patients homozygous for UGT1A1*28 is 50 mg/m <sup>2</sup> every 2 weeks. Premedicate with a corticosteroid and an antiemetic 30 minutes prior to administration. Ensure patients have anti-diarrheal medication to use if diarrhea occurs. (Ipsen Biopharmaceuticals, 2020)                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                                                 |                                                                                                                                                                | Topotecan (Hycamtin®)                                                    | IV, PO | Cervical cancer<br>Metastatic ovarian cancer<br>Small cell lung cancer              | Dose-limiting toxicity: myelosuppression<br>Diarrhea, alopecia, nausea, vomiting, fatigue, interstitial lung disease     | Do not administer to patients with baseline ANC < 1,500/mm <sup>3</sup> or platelets <100,000/mm <sup>3</sup> . Consider dose reduction in patients with renal impairment. (Novartis Pharmaceuticals, 2018)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Plant alkaloids: epipodophylotoxins             | Induces irreversible blockade of cells in premitotic phases of cell cycle (late G <sub>2</sub> and S phases); interferes with topoisomerase II enzyme reaction | Etoposide (VP-16, Toposar®, VePesid®); etoposide phosphate (Etoposphos®) | IV, PO | Testicular cancer<br>Small cell lung cancer<br>Off-label uses in lymphomas and HSCT | Dose-limiting toxicity: myelosuppression<br>Hypersensitivity reaction, nausea, vomiting, alopecia, anorexia, hypotension | Do not administer via rapid IV infusion or IV push. Infuse over at least 30 minutes to avoid hypotension. Infusion time will be determined on final volume (30 minutes to 4 hours). Stability varies based on concentration. Drug may crystallize if concentration > 1 mg/ml. If patients have an allergic reaction to etoposide, premedicate with diphenhydramine. Consider dose reduction in patients with renal impairment. When used for HSCT, doses are very high. The undiluted drug will be used. The risk of hypotension increases due to the amount of alcohol in liquid etoposide. PO etoposide causes more nausea; ensure patients have scheduled antiemetics prior to each dose. Daily doses > 200 mg should be given in divided doses (twice daily) for tolerability. **TABLE 6-1.** Chemotherapy Agents (*Continued*)

| Classification                                       | Mechanism of Action                                                                         | Drug                   | Route | Indications                                                                                                                            | Side Effects                                                                                                                                        | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------------|---------------------------------------------------------------------------------------------|------------------------|-------|----------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Plant alkaloids: epipodophylotoxins ( <i>Cont.</i> ) |                                                                                             | Teniposide             | IV    | Induction therapy in pediatric ALL                                                                                                     | Dose-limiting toxicity: myelosuppression<br>Hypersensitivity reaction, anaphylaxis, nausea, vomiting, mucositis, diarrhea, alopecia                 | The drug may cause an allergic reaction. Do not administer via rapid infusion. Infuse over 30–60 minutes to avoid hypotension. Use non-PVC, non-DEHP bags and tubing. The drug is contraindicated in patients with a history of reactions to teniposide or other drugs formulated in polyoxyl 35 castor oil (a solvent). Consider dose reduction in patients with renal or hepatic impairment. (WG Critical Care, 2015)                                                                                                                                                                                                                                                                       |
| Plant alkaloids: taxanes                             | Stabilizes microtubules, inhibiting cell division; effective in G <sub>2</sub> and M phases | Cabazitaxel (Jevtana®) | IV    | Hormone-refractory metastatic prostate cancer                                                                                          | Hypersensitivity reaction, myelosuppression, fatigue, diarrhea, nausea, vomiting, peripheral neuropathy                                             | Withhold dose for ANC < 1,500/mm <sup>3</sup> . Severe myelosuppression can occur; consider primary prophylaxis with granulocyte-colony-stimulating factor. Premedicate with the following to prevent hypersensitivity reaction, including anaphylaxis, at least 30 minutes before treatment: IV diphenhydramine 25 mg, dexamethasone 8 mg, and ranitidine 50 mg. Infuse over 1 hour, through a 0.2-micron in-line filter. Use non-PVC bags and tubing. Do not use in patients with severe hepatic impairment (total bilirubin > 3 × ULN). Dose adjustment is needed for mildly elevated total bilirubin or aspartate aminotransferase/alanine aminotransferase. (Sanofi-Aventis U.S., 2021a) |
|                                                      |                                                                                             | Docetaxel (Taxotere®)  | IV    | Breast cancer<br>Gastric adenocarcinoma<br>Hormone-refractory prostate cancer<br>NSCLC<br>Squamous cell carcinoma of the head and neck | Myelosuppression, febrile neutropenia, hypersensitivity reaction, fluid retention, alopecia, skin and nail changes, nausea, vomiting, neurotoxicity | Premedicate with the following to reduce the severity of hypersensitivity reaction and fluid retention: dexamethasone 8 mg PO twice daily for 3 days, beginning 1 day prior to docetaxel treatment. Docetaxel extravasation may cause local pain, edema, erythema, and hyperpigmentation at the infusion site. Do not administer if bilirubin > ULN or aspartate aminotransferase and/or alanine aminotransferase > 1.5 × ULN with alkaline phosphatase > 2.5 × ULN.                                                                                                                                                                                                                          |

*Note.* For drugs listed as vesicants or irritants, refer to Chapter 13. Review package inserts for dosing and prescribing information.

ALL—acute lymphoblastic leukemia; AML—acute myeloid leukemia; ANC—absolute neutrophil count; AUC—area under the plasma concentration versus-time curve; CBC—complete blood count; CLL—chronic lymphocyte leukemia; CML—chronic myeloid leukemia; CNS—central nervous system; CrCl—creatinine clearance; CYP—cytochrome P450; DEHP—di(2-ethylhexyl) phthalate; D<sub>5</sub>W—5% dextrose in water; 5-FU—5-fluorouracil; FDA—U.S. Food and Drug Administration; GI—gastrointestinal; G<sub>2</sub>—gap 2; HL—Hodgkin lymphoma; HSCT—hematopoietic stem cell transplantation; IM—intramuscular; IT—intrathecal; IV—intravenous; M—mitosis; ms—millisecond; NHL—non-Hodgkin lymphoma; NS—normal saline; NSCLC—non-small cell lung cancer; PO—by mouth; PVC—polyvinyl chloride; QTc—QT interval corrected; S—synthesis; SC—subcutaneous; Scr—serum creatinine; TLS—tumor lysis syndrome; UGT—uridine diphosphate-glucuronosyltransferase; ULN—upper limit of normal

## 2. Antimetabolites

- Antimetabolites block DNA and RNA growth by interfering with enzymes. For example, antifolates interfere with folate, which is necessary for healthy cellular metabolism.
- Antimetabolites are often divided into folate analogs, purine analogs, adenosine analogs, pyrimidine analogs, and substituted ureas.
- Tumors with a high growth rate or a high percentage of cells in the S phase are the most susceptible to antimetabolites (Vlcek, 2022). Healthy cells with high division rates, such as gastrointestinal mucosal and bone marrow cells, are sensitive to antimetabolites, resulting in mucositis, diarrhea, and myelosuppression.
- Examples include capecitabine, cytarabine, 5-fluorouracil, gemcitabine, and methotrexate.

## 3. Antitumor antibiotics (Vlcek, 2022)

- Antitumor antibiotics interfere with the synthesis of DNA and RNA through various mechanisms.
- Myelosuppression, gastrointestinal toxicities, and alopecia are common.
- A number of these agents are cardiotoxic or pulmonary toxic.
- Examples include doxorubicin, bleomycin, epirubicin, mitoxantrone, and dactinomycin.

## 4. Miscellaneous agents

- The drugs in this category have a unique mechanism of action and side effect profile. They cannot be grouped with other chemotherapy agents.
- Examples include asparaginase, arsenic, and vorinostat.
  - Asparaginase is an enzyme derived from bacteria (*Escherichia coli* or *Erwinia chrysanthemi*) that depletes circulating levels of asparagine, resulting in cell death.
  - Arsenic is a differentiating agent that causes fragmented changes in DNA, leading to apoptosis. It inhibits the self-renewal of leukemia cells due to free radical formation (Vlcek, 2022).

## 5. Nitrosoureas

- Nitrosoureas are a distinct group of drugs that can cross the blood–brain barrier (high lipid solubility). They are sometimes categorized with alkylating agents.
- Nitrosoureas cause breakage in the DNA helix strand, interfering with DNA replication and ultimately resulting in cell death.
- Dose-limiting toxicities include bone marrow suppression, gastrointestinal toxicities, and organ-specific toxicities (e.g., renal and hepatic, dependent on drug and dose).

d) Other effects include carcinogenic and mutagenic effects and impaired fertility.

e) Examples include carmustine, lomustine, and streptozocin.

## 6. Plant alkaloids

## a) Camptothecins

- Camptothecins are semisynthetic analogs of the alkaloid camptothecin obtained from the Chinese ornamental tree *Camptotheca acuminata*.
- They target topoisomerase I, an enzyme necessary for DNA synthesis, causing DNA damage and cell death.
- Diarrhea and myelosuppression are the most common dose-limiting toxicities.

**FIGURE 6-2.** Potential Side Effects and Toxicities of Chemotherapy by System

GI—gastrointestinal; LFTs—liver function tests; SIADH—syndrome of inappropriate antidiuretic hormone secretion

Note. Image courtesy of University of Texas MD Anderson Cancer Center. Used with permission.

- (4) Examples include irinotecan and topotecan.

b) Epipodophyllotoxins

- (1) Epipodophyllotoxins are an antimicrotubule agent derived from the plant *Podophyllum peltatum*, or mandrake.
- (2) They induce irreversible blockage of cells in the premitotic cell cycle phases (late G<sub>2</sub> and S) and interfere with topoisomerase II enzyme reaction.
- (3) Myelosuppression with a nadir of 10–14 days is a dose-limiting toxicity. Mild to moderate nausea, vomiting, mucositis, and alopecia also can occur with this class and are dose dependent.
- (4) These agents may also have carcinogenic and mutagenic effects.

c) Taxanes

- (1) Taxanes are semisynthetic derivatives of precursors from yew plants.
- (2) They stabilize microtubules, inhibiting cell division, and are effective in the G<sub>2</sub> and M phases.
- (3) Common side effects include infusion reactions, peripheral neuropathy, myelosuppression, arthralgias, and myalgias. Docetaxel is associated with edema and nail changes.

d) Vinca alkaloids

- (1) Vinca alkaloids are derived from the plant *Vinca rosea*, or periwinkle.
- (2) They depolymerize microtubules and destroy mitotic spindles.
- (3) Myelosuppression (except with vincristine) and neurologic and hepatic toxicities are common.
- (4) The drugs in this category are vesicants.
- (5) The drugs in this category are fatal if given into the central nervous system.

## D. Combination chemotherapy principles

### 1. Benefits

- a) Maximum cell kill within dose limits
- b) Broader coverage to overcome resistant cell lines

### 2. Drug selection for combination chemotherapy

- a) Are active as single agents
- b) Have differing mechanisms of action, making them synergistic
- c) Have differing dose-limiting toxicities to allow therapy doses to be tolerated
- d) Have differing patterns of resistance
- e) Should be used at the optimal schedule and dose
- f) Should be given at consistent intervals

## CHAPTER 7

# Hormone Therapy

### A. Hormone therapy in the treatment of cancer

1. Hormone manipulation is used to treat many hormonally sensitive cancers. Although prostate and breast cancers are prime examples, endocrine treatment is also used for adrenal, thyroid, and androgen-sensitive salivary gland cancers.
2. Current endocrine treatments involve decreasing the levels of a specific hormone in the body by interfering with its release, blocking other hormones that trigger its production and release, blocking hormone receptors, or destroying the hormone entirely.
3. Although effective in prolonging survival, hormone treatments have side effects that may affect an individual's quality of life or be associated with physiologic changes that increase the risk for other health conditions.
4. This chapter will provide a brief overview of cancers treated with endocrine therapy, describe categories of hormones used in cancer treatment, identify associated side effects and health risks (see Figure 7-1), and discuss implications for nursing care. See Table 7-1 for additional drug-specific information.

### B. Cancers treated with hormone therapy

1. Prostate and breast cancer are the most commonly diagnosed cancers among men and women, respectively, and are the most common malignancies treated with hormone therapy. Although both cancers exist in a hormone milieu, differences exist in mechanisms and response to hormone therapy (National Comprehensive Cancer Network [NCCN], 2021a, 2022; Siegel et al., 2021).
2. Hormone therapy for specific cancers
  - a) Prostate cancer
    - (1) Androgens (e.g., testosterone, dihydrotestosterone) are hormones essential for reproductive function, secondary sexual characteristics, and muscle and bone growth in men (Zhou et al., 2018).
    - (2) Testosterone is synthesized in the testes and adrenal glands before being released into the circulation.

**TABLE 7-1.** Hormone Therapy Agents

| Classification                                 | Drug                   | Route and Dosing                                                                         | Indications                                                                                                                | Side Effects                                                                                                                                                                                                                                                                                                           | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------------|------------------------|------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Adrenolytics                                   | Mitotane (Lysodren®)   | 0.5–2 g PO daily, titrated up every 1–2 weeks to serum concentrations between 14–20 mg/L | Adrenal cancer                                                                                                             | Anorexia, nausea, diarrhea, transaminitis, hypercholesterolemia, hypothyroidism, glucocorticoid excess                                                                                                                                                                                                                 | Administer in 3–4 divided daily doses. Cerebellar ataxia and other neurologic symptoms may develop with concentrations > 20 mg/L. (Corden Pharma Latina, 2021)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Androgen receptor inhibitors and antiandrogens | Darolutamide (Nubeqa™) | 300 mg PO twice daily                                                                    | Nonmetastatic, castration-resistant prostate cancer                                                                        | Pain in extremities, rash, fatigue, renal toxicity and hepatotoxicity, neutropenia                                                                                                                                                                                                                                     | Tablets should be swallowed whole and taken with food. If patients miss a dose, it should be taken as soon as remembered and should not be doubled. Patients should concomitantly receive a gonadotropin-releasing hormone analog or should have had a bilateral orchiectomy. Advise male patients with female partners of reproductive potential to use effective contraception during treatment and for 1 week after the final dose of darolutamide. Darolutamide may impair fertility in males of reproductive potential. The safety of darolutamide for female partners who are breastfeeding has not been established. Concomitant use with combined P-gp and strong or moderate CYP3A inducers or inhibitors should be avoided. Monitor patients more frequently for adverse reactions. Concomitant use with drugs that are BCRP substrates should be avoided when possible. Monitor patients more frequently for adverse reactions and consider a dose reduction of the BCRP substrate drug if use cannot be avoided. (Bayer HealthCare Pharmaceuticals, 2021) |
|                                                | Apalutamide (Erleada™) | 240 mg PO daily                                                                          | Prostate cancer<br>Nonmetastatic, castration-resistant prostate cancer<br>Metastatic, castration-sensitive prostate cancer | GI effects (nausea, diarrhea), fatigue, decreased appetite, seizures, falls or fracture, hypertension, rash, weight loss, arthralgia, peripheral edema<br>Adverse events, such as the potential for ischemic cardiovascular events, fractures, increased risk for falls in older adult patients, embryo-fetal toxicity | Patients should receive apalutamide with a gonadotropin-releasing hormone analog concurrently or should have a bilateral orchiectomy. Men should be counseled not to donate sperm during treatment and for at least 3 months following the final dose of apalutamide. CYP–drug interactions are possible. Drug should be swallowed whole and may be taken with or without food. Monitor for signs and symptoms of ischemic heart disease. In the presence of ≥ grade 3 toxicity or intolerable side effects, withhold dose until symptoms improve to ≤ grade 1; once symptoms are controlled, resume drug at the same or a reduced dose.                                                                                                                                                                                                                                                                                                                                                                                                                              |

**TABLE 7-1.** Hormone Therapy Agents (*Continued*)

| Classification                         | Drug                               | Route and Dosing                                                                   | Indications                         | Side Effects                                                                                                                                                                                               | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------|------------------------------------|------------------------------------------------------------------------------------|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Selective estrogen receptor modulators | Tamoxifen (Nolvadex <sup>®</sup> ) | Breast: 20 mg PO daily<br>Endometrial: 40 mg PO daily (one 20 mg dose twice daily) | Breast cancer<br>Endometrial cancer | Black box warnings: stroke, pulmonary embolism, uterine malignancies<br>Hyperlipidemia, BMD changes (increased in postmenopausal patients, decreased in premenopausal patients), hot flashes, mood changes | Certain selective serotonin reuptake inhibitors may reduce tamoxifen efficacy. Citalopram, escitalopram, and venlafaxine are preferred in place of other selective serotonin reuptake inhibitors. Another selective estrogen receptor modulator may be given if adverse effects are intolerable. Drug can be used in pre- or postmenopausal patients. (AstraZeneca Pharmaceuticals, 2021) |
|                                        | Raloxifene (Evista <sup>®</sup> )  | 60 mg PO daily                                                                     | Breast cancer risk reduction        | Black box warnings: stroke, deep vein thrombosis, pulmonary embolism<br>Hypertriglyceridemia, hot flashes, leg cramps                                                                                      | Use is not recommended in the following populations due to limited clinical efficacy and safety data: <ul style="list-style-type: none"> <li>• Premenopausal women</li> <li>• Men</li> <li>• Concomitant estrogen therapy</li> <li>• Renal and hepatic impairment</li> <li>• Prior history of breast cancer</li> </ul> (Eli Lilly and Company, 2022)                                      |

*Note.* Review package inserts for dosing and prescribing information.

BCRP—breast cancer resistance protein; BMD—bone mineral density; CVD—cardiovascular disease; CYP—cytochrome P450; GI—gastrointestinal; HR—hormone receptor; IM—intramuscular; LHRH—luteinizing hormone-releasing hormone; P-gp—P-glycoprotein; PO—by mouth; QTc—QT interval corrected; SC—subcutaneous; UGT—uridine diphosphate-glucuronosyltransferase

- (a) Upon reaching prostate tissue, testosterone and its precursors are transformed into the more potent androgen dihydrotestosterone.
    - (b) Androgens bind with and activate the androgen receptor, which results in physiologic effects.
    - (c) Androgens also serve as primary drivers in promoting prostate cancer growth and proliferation (NCCN, 2022; Zhou et al., 2018)
  - (3) Androgen deprivation therapy effectively slows the growth of prostate cancer cells.
    - (a) This can be accomplished by decreasing serum testosterone levels to castrate concentrations ( $< 50$  ng/dl) through orchiectomy or medication therapy (i.e., chemical castration).
    - (b) The expansion of oral and injectable pharmacologic agents in recent decades has led to a significant decline in the use of orchiectomy to treat prostate cancer (Crawford et al., 2019; NCCN, 2022).
  - (4) Over time, prostate cancers can become resistant to hormone therapy and lose androgen sensitivity, resulting in a resurgence in the growth and proliferation of prostate cancer cells and what is referred to as castration-resistant or hormone-refractory prostate cancer (Crawford et al., 2019).
- b) Breast cancer
- (1) Hormone receptor–positive breast cancer grows in response to action by estrogen or progesterone.
  - (2) Hormone receptor–positive breast cancer is the most common type and accounts for approximately 70% of all breast cancers (American Cancer Society, 2021).
  - (3) The ultimate goal of hormone therapy is to decrease concentrations of estrogens and progestins or prevent interaction with their receptors; however, treatment is highly dependent on whether a woman is premenopausal or postmenopausal and hormone receptor status (Burstein et al., 2018).
- c) Ovarian, endometrial, and uterine cancers
- (1) Endometrial carcinoma is the most common uterine cancer, followed by uterine sarcoma.
  - (2) First-line therapy consists of treatment with progestins. Second-line strategies include tamoxifen or tamoxifen in combination with progestins.
- (3) Of note, optimal responses are found most frequently in estrogen receptor (ER)–positive disease and endometrioid tumors (van Weelden et al., 2019).
- d) Adrenal cancer
- (1) Adrenocortical carcinomas are rare and occur mainly in adults.
  - (2) Although primary treatment is resection of the adrenal gland, adrenolytic antihormone therapy, with or without cytotoxic chemotherapy, is used for unresectable or widely metastatic tumors (National Cancer Institute, 2019).
- e) Thyroid cancers
- (1) Thyroidectomy followed by ablation with radioactive iodine is the usual treatment for most early-stage thyroid cancers.
    - (a) Radioactive iodine may be followed by the replacement of thyroid hormones (e.g., levothyroxine) in several clinical scenarios.
    - (b) Thyroglobulin and thyroid-stimulating hormone levels help evaluate response to therapy (Filetti et al., 2019).
  - (2) Hormone therapy is rarely used to treat metastatic or refractory disease (Filetti et al., 2019).
- f) Pituitary adenomas
- (1) Pituitary adenomas are classified as non-functioning, prolactin secreting (e.g., prolactinoma), growth hormone secreting (e.g., acromegaly), adrenocorticotrophic hormone secreting (e.g., Cushing disease), or thyrotropin secreting. Transsphenoidal surgical adenoma resection is the initial treatment chosen for all tumors except prolactinomas (Molitch, 2017).
  - (2) Dopamine agonists (e.g., bromocriptine, cabergoline) are used to achieve hormone control in patients with prolactinomas. Somatostatin analogs (e.g., octreotide, lanreotide) are used to manage acromegaly, Cushing disease, and thyrotropin-secreting tumors (Molitch, 2017).
- C. Hormone treatment categories
1. Luteinizing hormone–releasing hormone (LHRH) antagonists and agonists
    - a) LHRH antagonists and agonists are primarily used to treat breast and prostate cancer. Current literature demonstrates that concurrent radiation

therapy with LHRH antagonists and agonists in patients with prostate cancer improves overall survival in select nonmetastatic stages compared with standalone therapy (Crawford et al., 2019; Juloori et al., 2016).

- b) LHRH antagonists immediately block LHRH release from the hypothalamus, preventing the release of luteinizing hormone and follicle-stimulating hormone from the anterior pituitary gland (Crawford et al., 2019).
- c) LHRH agonists produce an initial increase in luteinizing hormone and follicle-stimulating hormone, which translates to increased testosterone concentrations (flare). Concentrations gradually reach castrate levels within two to four weeks, as LHRH release slows significantly in response to the downregulation of LHRH receptors in the anterior pituitary (Crawford et al., 2019).
- d) Although LHRH agonists and antagonists share similar side effect profiles, individuals receiving LHRH agonists may initially suffer from worsening symptoms at active cancer sites (e.g., urinary retention, bone pain) secondary to a phenomenon known as tumor flare.
  - (1) Symptoms of tumor flare will resolve as androgen levels decrease and can be prevented by adding a nonsteroidal antiandrogen during the first two weeks after LHRH agonist initiation.
  - (2) Other side effects of LHRH agonists include decreased bone mineral density, increased insulin resistance, dyslipidemia, increased visceral fat deposition, erectile dysfunction, decreased libido, neurocognitive changes, and depression (Crawford et al., 2019).
- e) LHRH agonists work similarly when used to treat breast cancer. These agents also downregulate the ovarian production of estrogen by preventing the release of luteinizing hormone. LHRH agonists are used in the adjuvant setting for women with ER-positive or progesterone receptor-positive premenopausal breast cancer with or without tamoxifen to reduce recurrence and preserve ovarian function (NCCN, 2021a).
- f) NCCN (2021a, 2022) guidelines for breast cancer recommend select LHRH agonists (e.g., leuprolide, goserelin) to treat breast cancer. The guidelines for prostate cancer state that LHRH antagonists (e.g., degarelix, relugolix) and agonists (e.g., leuprolide, goserelin, triptorelin) may be used interchangeably when androgen deprivation therapy is indicated.
- g) Nursing implications
  - (1) Recent literature has shown that men are particularly susceptible to specific car-

diovascular and metabolic adverse effects from LHRH agonist and antagonist therapy (Levine et al., 2010).

- (a) Nurses should educate men and their families on the increased risk for diabetes, heart attack, hypertension, weight gain, visceral fat deposition, loss of lean muscle mass, and bone fracture.
  - (b) Additionally, men can suffer from declines in psychosocial health, namely neurocognitive dysfunction and depression, which can sometimes be exacerbated by erectile dysfunction, hot flashes, and gynecomastia.
- (2) Counseling and social work services should be available to evaluate psychosocial health.
    - (a) Referral for medical services should be made for dyslipidemia or other cardiac issues, impaired glucose (e.g., abnormal blood glucose, increased hemoglobin A1c), and evaluation of bone mineral density, pain management, and nutrition as necessary.
    - (b) It is essential to include the patient's family and caregivers in the overall management plan.
  - (3) Women should be monitored for menopausal symptoms that may develop with endocrine therapy. Although estrogen supplementation is not recommended, nurses can assist women with other interventions to relieve symptoms. Metabolic syndrome and bone mineral density should also be regularly monitored.

## 2. Antiandrogens

- a) Antiandrogens block the effects of testosterone and dihydrotestosterone at their target receptors in tissues. As a result, they do not reduce the serum concentration of androgens and are not often used as single agents to treat prostate cancer (AA Pharma., 2019; ANI Pharmaceuticals, 2015; Astra-Zeneca Pharmaceuticals, 2017; NCCN, 2022).
- b) First-generation antiandrogens (e.g., bicalutamide, flutamide, nilutamide) are used in prostate cancer to mitigate tumor flare with LHRH agonists.
  - (1) They can also be adjunctive agents to LHRH agonist or antagonist therapy after disease progression in a treatment strategy known as combined androgen blockade.
  - (2) Although combined androgen blockade has been shown to achieve greater sup-

- pression of circulating testosterone and improve survival, it is associated with additional adverse events and poorer quality of life (Crawford et al., 2019).
- (3) Transaminitis and diarrhea are associated with the administration of first-generation agents. Nilutamide is also associated with visual field changes and disulfiram-like reactions.
  - (4) Because of disulfiram-like reactions, patients should be educated to avoid alcohol use while on therapy (AA Pharma., 2019; ANI Pharmaceuticals, 2015; AstraZeneca Pharmaceuticals, 2017).
  - c) Second-generation antiandrogens (e.g., enzalutamide, apalutamide, darolutamide) can be used as single agents or in combination with LHRH agonist or antagonist therapy (enzalutamide and apalutamide only) based on clinical features. These antiandrogens are primarily used in the castration-resistant prostate cancer setting (NCCN, 2022).
3. CYP17 inhibitors
    - a) Ketoconazole and abiraterone are indicated for prostate cancer treatment after progression on LHRH agonist or antagonist therapy (Janssen Pharmaceutical Companies, 2014, 2020b). Abiraterone is more widely used for castration-refractory prostate cancer (NCCN, 2022).
    - b) These agents decrease extragonadal production of androgens by inhibiting the CYP17 enzyme.
      - (1) This action blocks the formation of dehydroepiandrosterone from pregnenolone, thereby inhibiting the synthesis of androgens.
      - (2) Most extragonadal testosterone production occurs in the adrenal glands through steroid hormone biosynthesis pathways for which cholesterol is the precursor molecule (Janssen Pharmaceutical Companies, 2014, 2020b; Sewer & Li, 2008).
    - c) Ketoconazole and abiraterone are associated with transaminitis and mineralocorticoid excess.
      - (1) Symptoms of mineralocorticoid excess include hyperkalemia and fluid retention.
      - (2) These agents should not be used in patients with New York Heart Association class III or IV heart failure.
      - (3) To mitigate symptoms of mineralocorticoid excess and hypothalamus–pituitary–adrenal axis suppression, these agents should be given with low-dose oral corticosteroids (Janssen Pharmaceutical Companies, 2013, 2020b; NCCN, 2022).
  4. ER antagonists and selective ER downregulators
    - a) Fulvestrant is indicated for the treatment of metastatic ER-positive breast cancer alone or in combination with various agents (e.g., trastuzumab, CDK4/6 inhibitors, alpelisib) (AstraZeneca Pharmaceuticals, 2020; NCCN, 2021a).
    - b) Fulvestrant binds to an ER and degrades it. Both actions render circulating estrogen unable to exert its effects on breast cancer cells (AstraZeneca Pharmaceuticals, 2020).
    - c) Fulvestrant is relatively well tolerated and is occasionally associated with injection site pain and hot flashes (AstraZeneca Pharmaceuticals, 2020).
  5. Aromatase inhibitors (AIs)
    - a) These agents are also used to treat ER-positive breast cancer in premenopausal and postmenopausal women (NCCN, 2021a).
    - b) In premenopausal women, concomitant ovarian ablation with LHRH agonist therapy is recommended in the adjuvant, recurrent, or metastatic setting (NCCN, 2021a).
    - c) AIs are also used to treat ER-positive breast cancer in men. Therapy in men should be guided by treatment recommendations for AIs in postmenopausal women (NCCN, 2021a).
    - d) AIs are classified as steroidal (type 1) or nonsteroidal (type 2) and inhibit the conversion of aromatase, which converts androgens to estrogen.
      - (1) Steroidal AIs bind aromatase irreversibly.
      - (2) They inhibit aromatase by binding covalently to its receptor site. Nonsteroidal AIs (e.g., anastrozole, letrozole) bind reversibly.
      - (3) The blockade of aromatase is dependent on the continuous presence of the inhibitor, and aromatase will begin to release in its absence (Mantas et al., 2016).
    - e) Adverse effects of these agents include menopausal symptoms, decreased bone mineral density, and musculoskeletal disorders (Mantas et al., 2016).
  6. Selective estrogen receptor modulators (SERMs)
    - a) Raloxifene and tamoxifen are SERMs indicated for use in various breast cancer settings (AstraZeneca Pharmaceuticals, 2021; Eli Lilly and Company, 2022).
    - b) Although both can be used as preventive therapy for patients with high-risk invasive breast cancer, tamoxifen can also be used for patients with ductal carcinoma in situ, as adjuvant endocrine therapy, and for patients with hormone receptor-positive metastatic cancer (AstraZeneca Pharmaceuticals, 2021; Eli Lilly and Company, 2022; NCCN, 2021a).
    - c) Tamoxifen can also be used alone or in conjunction with progestins in certain populations

affected by endometrial cancer (NCCN, 2021b). SERMs are characterized by estrogenic and antiestrogen properties and can downregulate and block ERs in different tissues (Komm & Mirkin, 2014).

d) SERMs have been associated with an increased risk of deep vein thrombosis and pulmonary embolism (AstraZeneca Pharmaceuticals, 2021; Eli Lilly and Company, 2022). They have also been associated with the development of uterine malignancies, hyperlipidemia, and menopausal symptoms (AstraZeneca Pharmaceuticals, 2021; Komm & Mirkin, 2014).

e) The duration of therapy with SERMs in the adjuvant setting is highly dependent on menopausal status and whether a patient has been treated with an AI.

- (1) Generally, treatment lasts 5–10 years.
- (2) Patients can be transitioned to or from AI therapy within that time frame based on menopausal status and tolerance (Early Breast Cancer Trialists' Collaborative Group, 2015; Komm & Mirkin, 2014; Mirkin & Pickar, 2015; NCCN, 2021a).

f) Nursing implications

- (1) Blocking or eliminating estrogen will cause premature menopause in premenopausal women and heightened or renewed symptoms in perimenopausal and postmenopausal women.
- (2) SERMs may put women at higher risk for endometrial cancer and deep vein thrombosis. Adherence is challenging for patients on AIs and SERMs because of the discomfort of side effects, such as hot flashes, cognitive changes, fatigue, myalgias and arthralgias, and physical changes (Huober et al., 2014; Lombard et al., 2016).
- (3) Nurses can provide education and support to women undergoing this treatment. Additionally, some women benefit from participation in support groups with other women.

## 7. Adrenolytics

- a) Drug therapy with mitotane is indicated in unresectable or metastatic adrenocortical cancer or as adjuvant treatment following complete resection.
- b) Although its mechanism has not entirely been elucidated, mitotane acts within the adrenal cortex as a cytotoxic agent. As a result, it affects malignant and nonmalignant adrenocortical tissues.
- c) Mitotane is associated with nausea, vomiting, diarrhea, ataxia, amnesia, confusion, and suppression of hormones synthesized and released from the adrenal cortex (i.e., corticosteroids) (Corden Pharma Latina, 2021).

d) Nursing implications

- (1) Therapeutic and toxic effects are correlated with plasma concentration, requiring close monitoring and supportive management of adverse effects using hydrocortisone, antiemetics, and antidiarrheals.
- (2) Thyroid and androgen supplementation may also be necessary. Serum hormone concentrations should be assessed at least every three months in patients receiving mitotane.
- (3) Patients should be educated about adherence to mitotane therapy drug monitoring and other follow-up recommendations to limit the risk of drug discontinuation due to toxicity (Kerkhofs et al., 2015).

## CHAPTER 8

# Targeted Therapy

### A. Targeted therapies in the treatment of cancer

1. Biomarker-directed antineoplastic agents selectively target molecular pathways that block the growth and spread of cancer, as opposed to traditional cytotoxic chemotherapy agents that target DNA, tubulin, or cell division machinery and are often less specific (National Cancer Institute, 2022).

- a) A growing number of unique molecular targets have been identified within cancer cells, resulting in the discovery of novel agents, many of which are administered via the oral route as tablets or capsules.
- b) The oral route allows for continuous administration of lower doses of agents, which may be primarily cytostatic, versus traditional infusional cytotoxic agents for which episodic delivery is necessary for adequate bone marrow recovery (National Cancer Institute, 2022).
- c) See Table 8-1 for a list of targeted therapies. Agents that target immune pathways and extracellular biomarkers are discussed in Chapter 10.
- d) Select targeted agents are designed to have activity against cancers with specific alterations or variants and may not have activity in cancers without the alteration. It is prudent to be aware of these specific indications when selecting therapy options for patients.

### 2. Tyrosine kinase inhibitors (TKIs)

- a) Tyrosine kinases direct many cellular functions, including cell signaling, growth, and division.
- b) These enzymes may be overly active in some cancer cells, and inhibition of them may stop cancer cell growth (National Cancer Institute, n.d.).
- c) See Figure 8-1 for a diagram of the basic principles of tyrosine kinases and Figure 8-2 for a depiction of epidermal growth factor receptor (EGFR) and vascular endothelial growth factor (VEGF) receptor pathways.
- d) When a TKI is introduced within these pathways, the enhanced activity is inhibited, leading

to decreased cell growth, proliferation, and differentiation (Zhong et al., 2021).

### 3. Agents by biomarker

#### a) Anaplastic lymphoma kinase (ALK) inhibitors

- (1) The fusion between echinoderm microtubule-associated protein-like 4 (EML4) and ALK is an oncogene present in 3%–5% of patients with non-small cell lung cancer, most commonly younger patients, never- or light-smokers with adenocarcinoma, and those without *EGFR* and *KRAS* driver variants (Khan et al., 2019).
- (2) The *ALK* gene rearrangement produces an abnormal ALK protein that leads to proliferation and survival of cancer cells through constitutive activation of RAS/RAF/MEK, PI3K/mTOR, and JAK/STAT pathways. (American Cancer Society, 2021).
- (3) Examples include alectinib (oral), brigatinib (oral), ceritinib (oral), crizotinib (oral), and lorlatinib (oral).

#### b) Breakpoint cluster region protein–Abelson tyrosine-protein kinase 1 (BCR-ABL1) TKIs

- (1) The BCR-ABL1 protein can become a driver variant resistant to some formulations of BCR-ABL1 TKIs.
- (2) Patients taking these medications for chronic myeloid leukemia require long-term therapy.
- (3) Data demonstrate the need for adherence monitoring, as adherent patients have a better early response and long-term outcomes (Cuellar et al., 2018).
- (4) Examples include imatinib (oral), bosutinib (oral), dasatinib (oral), nilotinib (oral), ponatinib (oral), and asciminib (oral).

#### c) *BRAF* V600E inhibitors and mitogen-activated extracellular signal regulated kinase (MEK) inhibitors

**TABLE 8-1.** Targeted Therapies

| Drug                       | Mechanism of Action                                                                                                                                    | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Side Effects                                                                                                                                                                                                                                                                  | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Alectinib (Alecensa®) | TKI that targets ALK and RET to decrease tumor cell viability in cell lines harboring ALK fusions, amplifications, or activating variants     | PO    | ALK-positive metastatic NSCLC                                                                                                                                                                                    | Common: fatigue, constipation, edema, myalgia, anemia<br>Severe: hepatotoxicity, ILD, bradycardia, CPK elevation, renal impairment, hemolytic anemia                                                                                                                                                                                                                                                                            | <p>Patients should take every 12 hours with food. Do not open or dissolve the contents of the capsule.</p> <p>If patients miss or vomit a dose, they should take the next dose at the scheduled time. Dose modifications are recommended for severe hepatic impairment (Child-Pugh C). Monitor heart rate and BP regularly. Monitor LFTs every 2 weeks for 3 months, then once monthly and as clinically indicated. Monitor CPK levels every 2 weeks for 1 month and as clinically indicated. Advise patients to report any unexplained muscle pain, tenderness, or weakness. The median time to grade 3 CPK elevation is 14 days.</p> <p>Advise patients to minimize sun exposure and use broad-spectrum sunscreen during treatment and for at least 7 days after discontinuation.</p> <p>Women of reproductive potential should use contraception during treatment and for 1 week following completion of therapy. Males with female partners of reproductive potential should use contraception during treatment and for 3 months following completion of therapy. (Genentech, 2021)</p> |
| Apelisib (Piqray®)    | Inhibits PI3K, with inhibitory activity predominantly against PI3K- $\alpha$ ; inhibits the PI3K/AKT signaling pathway to reduce tumor growth | PO    | HR-positive, HER2-negative, PI3KCA-variated, advanced or metastatic breast cancer in men and postmenopausal women, in combination with fulvestrant, following progression on or after an endocrine-based regimen | Common: increased glucose, increased creatinine, diarrhea, rash, decreased lymphocyte count, increased gamma glutamyl transferase, nausea, increased ALT, increased lipase, fatigue, decreased hemoglobin, decreased appetite, stomatitis, vomiting, weight loss, decreased calcium, decreased glucose, prolonged activated partial thromboplastin time, alopecia<br>Severe: hypersensitivity, cutaneous reactions, pneumonitis | <p>Patients should take once daily with food. Tablets should not be crushed, chewed, or split prior to swallowing.</p> <p>If patients miss a dose, it can be taken within 9 hours after the time it is usually taken. After more than 9 hours, patients should skip the dose for that day.</p> <p>If patients vomit a dose, they should skip that dose and take the usual dose the following day.</p> <p>Before initiating treatment, test fasting plasma glucose and hemoglobin A1c; optimize blood glucose. After initiating treatment, monitor blood glucose once weekly for 2 weeks, then at least once every 4 weeks and</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**TABLE 8-1.** Targeted Therapies (*Continued*)

| Drug                               | Mechanism of Action                                                                                                                               | Route | Indications                                                                                                                                                                                                                 | Side Effects                                                                                                                                                                                                                                                                                                                                   | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Axitinib<br>(Inlyta <sup>®</sup> ) | Inhibits tyrosine kinases, including VEGFR1, VEGFR2, and VEGFR3, leading to interferences with tumor angiogenesis, growth, and cancer progression | PO    | Advanced RCC, in combination with avelumab as first-line treatment<br>Advanced RCC, in combination with pembrolizumab as first-line treatment<br>Advanced RCC, as a single agent, after failure of 1 prior systemic therapy | Common: hypertension, diarrhea, fatigue/asthenia, palmar-plantar erythrodysesthesia (hand-foot syndrome), nausea, decreased appetite, musculoskeletal pain, mucositis, hypothyroidism, hepatotoxicity, rash, abdominal pain, headache, dysphonia, cough, decreased weight, vomiting, constipation<br>Severe: hypertension, hypertensive crisis | <p>Patients should take every 12 hours, swallowing whole with a glass of water, with or without food.</p> <p>If patients vomit or miss a dose, they should not take an additional dose. Advise patients to take the next prescribed dose at the regularly scheduled time.</p> <p>Dose modifications are recommended for moderate hepatic impairment (Child-Pugh B). No data are available for severe hepatic impairment (Child-Pugh C).</p> <p>Drug interactions exist with CYP3A4/5 inhibitors, (including grapefruit) and inducers.</p> <p>Dosing should be held beginning at least 48 hours before elective surgery because of the risk of impaired wound healing. Do not administer for at least 2 weeks following major surgery and until adequate wound healing. Time to restart therapy is based on clinical judgment.</p> <p>Do not use in patients with untreated brain metastasis or recent active GI bleeding because of risk of hemorrhage.</p> <p>BP should be well-controlled prior to initiating the drug. Monitor for hypertension and treat as needed.</p> <p>Monitor thyroid function, urine for proteinuria, ALT, AST, and bilirubin before initiation and periodically throughout treatment.</p> <p>Monitor for arterial and venous thromboembolic events.</p> <p>Consider more frequent monitoring of ALT, AST, and bilirubin for patients receiving the drug in combination with avelumab or pembrolizumab.</p> <p>Women of reproductive potential and males with female partners of reproductive potential should use effective contraception during treatment and for 1 week following completion of therapy.</p> <p>(Pfizer, 2020b)</p> |

**TABLE 8-1.** Targeted Therapies (Continued)

| Drug                                | Mechanism of Action                                                                                                                                                                                                   | Route | Indications                                       | Side Effects                                                                                                                                                                                                                                                                 | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Belinostat (Beleodaq <sup>®</sup> ) | Inhibits HDAC, causing accumulation of acetylated histones and other proteins, leading to cell cycle arrest or apoptosis of transformed cells; preferential cytotoxicity toward tumor cells compared to healthy cells | IV    | Relapsed or refractory peripheral T-cell lymphoma | <p>Common: anemia, hepatotoxicity, nausea, fatigue, fever, vomiting, diarrhea, constipation, dyspnea, rash, peripheral edema</p> <p>Severe: hematologic toxicity (e.g., thrombocytopenia, leukopenia, anemia), infections (e.g., pneumonia, sepsis), hepatotoxicity, TLS</p> | <p>Infuse IV on days 1–5 of a 21-day cycle. Administer over 30 minutes with a 0.22-micron in-line filter. If infusion pain or other symptoms potentially attributable to the infusion occur, infusion time may be extended to 45 minutes.</p> <p>The infusion bag with drug solution may be stored at room temperature for up to 36 hours, including infusion time.</p> <p>Drug interactions exist with strong inhibitors of UGT1A1.</p> <p>Avoid use in patients with moderate or severe hepatic dysfunction and severe renal dysfunction.</p> <p>ANC should be <math>\geq 1,000/\text{mm}^3</math> and platelet count should be <math>\geq 50,000/\text{mm}^3</math> prior to the start of each cycle.</p> <p>Monitor CBC with differential at baseline and weekly.</p> <p>Monitor serum chemistry tests (including renal and liver function) prior to the start of each cycle.</p> <p>Monitor patients with advanced stage disease and high tumor burden for TLS.</p> <p>Women of reproductive potential should use effective contraception during treatment and for 6 months following completion of therapy. Males with female partners of reproductive potential should use effective contraception during treatment and for 3 months following completion of therapy.</p> <p>Drug is cytotoxic. Follow hazardous drug handling and disposal procedures. (Acrotech Biopharma, 2020)</p> |

| Drug                                | Mechanism of Action                                                                                                                                                                                                                                     | Route | Indications                                                                                                    | Side Effects                                                                                                                                                                                                                                                                                                               | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Binimetinib (Mektovi <sup>®</sup> ) | Inhibits MEK1 and MEK2 activity, which inhibits ERK phosphorylation; in combination with encorafenib, targets two different kinases in the RAS/RAF/MEK/ERK pathway, resulting in greater antiproliferative activity in BRAF variant-positive cell lines | PO    | Unresectable or metastatic melanoma with a <i>BRAF</i> V600E or V600K variant, in combination with encorafenib | Common: fatigue, nausea and vomiting, diarrhea, abdominal pain, visual disturbances, increased creatinine, increased CPK, increased LFTs<br>Severe: cardiomyopathy; venous thromboembolism; ocular toxicities, including retinopathy, retinal vein occlusion, and uveitis; ILD; hepatotoxicity; rhabdomyolysis; hemorrhage | <p>Patients should take twice daily (every 12 hours), with or without food.</p> <p>If patients miss a dose, they should skip the missed dose if within 6 hours of the next scheduled dose.</p> <p>If patients vomit a dose, an additional dose should not be taken. Advise patients to take the next prescribed dose at the usual time.</p> <p>Dose modification is recommended for patients with moderate or severe hepatic impairment.</p> <p>Assess LVEF before initiating treatment, after one month of treatment, then every 2–3 months thereafter.</p> <p>Perform an ophthalmologic evaluation at regular intervals and for any visual disturbances.</p> <p>Monitor LFTs before and monthly during treatment and as clinically indicated.</p> <p>Monitor CPK and creatinine periodically and as clinically indicated.</p> <p>If encorafenib is permanently discontinued, then discontinue binimetinib.</p> <p>The drug may interact with radiation and lead to increased CNS, pulmonary, dermatologic, and visceral toxicity. Consider holding <math>\geq 3</math> days before and after fractionated radiation and <math>\geq 1</math> day before and after stereotactic radiosurgery.</p> <p>Women of reproductive potential should use effective contraception during treatment and for 30 days after completion of therapy. (Array BioPharma, 2020b; National Comprehensive Cancer Network, 2022)</p> |

**TABLE 8-1.** Targeted Therapies (Continued)

| Drug                  | Mechanism of Action                                                                                                                                                       | Route  | Indications                              | Side Effects                                                                                                                                                                                                                                                                                                                                                                        | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bortezomib (Velcade®) | Inhibits chymotrypsin-like activity of 26S proteasome, resulting in disruption of proteolysis, which is needed for cellular homeostasis, ultimately leading to cell death | IV, SC | Multiple myeloma<br>Mantle cell lymphoma | <p>Common: peripheral neuropathy, neuralgia, nausea, vomiting, diarrhea, constipation, fatigue, thrombocytopenia, neutropenia, anemia, leukopenia, lymphopenia, rash, fever, anorexia</p> <p>Severe: peripheral neuropathy, hypotension, cardiac failure, pulmonary toxicity, RPLS, GI toxicity, thrombocytopenia, neutropenia, TLS, hepatotoxicity, thrombotic microangiopathy</p> | <p>Inject SC or IV once or twice weekly, depending on the specific regimen.</p> <p>For SC injection, the administration site should be rotated in the thigh or abdomen. Select new site at least 1 inch from previous site and avoid tender or bruised areas. Consider use of a less concentrated SC injection (1 mg/ml) for patients that experience local injection site reactions.</p> <p>For IV administration, administer as a 3- to 5-second bolus.</p> <p>The drug is given via routes other than SC or IV.</p> <p>Reconstitute only with NS. Use reconstituted solution within 8 hours. Concentrations of SC (2.5 mg/ml) and IV (1 mg/ml) doses are different, and final volume depends on calculated dose.</p> <p>Dose modification is recommended for patients with moderate or severe hepatic impairment.</p> <p>Drug interactions exist with strong CYP3A4 inhibitors (including grapefruit) and strong inducers. Patients on an oral antidiabetic agent require close monitoring of their blood glucose and may need adjustment of their antidiabetic medication.</p> <p>Monitor CBC frequently during treatment. Platelet count is recommended prior to each dose.</p> <p>There is less peripheral neuropathy with the SC route compared to the IV route.</p> <p>Women of reproductive potential should use effective contraception during treatment and for 7 months after completion of therapy. Males with female partners of reproductive potential should use effective contraception during treatment and for 4 months after completion of therapy.</p> <p>Follow hazardous drug handling and disposal procedures.</p> <p>(Millennium Pharmaceuticals, 2019)</p> |

**TABLE 8-1.** Targeted Therapies (*Continued*)

| Drug                      | Mechanism of Action                                                                                                                                                                                                                          | Route | Indications                                                                                                                                      | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bosutinib<br>(Bosulif®)   | Inhibits BCR-ABL1 tyrosine kinase created by the Ph-positive genetic abnormality, inhibiting proliferation, and induces apoptosis in BCR-ABL1-positive cell lines; also inhibits Src family kinases (Src, Lyn, Hck)                          | PO    | Newly diagnosed chronic phase Ph-positive CML<br>Chronic, accelerated, or blast phase Ph-positive CML resistant or intolerant to other therapies | Common: diarrhea, rash, nausea, vomiting, abdominal pain, fatigue, hepatic dysfunction, respiratory tract infection, fever, headache, thrombocytopenia, anemia, neutropenia, increased creatinine, decreased calcium, increased CPK, increased amylase, increased lipase<br>Severe: fluid retention presenting as pericardial effusion, pulmonary edema, peripheral edema, GI toxicity, myelosuppression, hepatic toxicity, cardiovascular toxicity, renal toxicity | Patients should take daily with food. Dose varies based on indication. Tablets should not be crushed or cut. If patients miss a dose beyond 12 hours, they should skip the dose and take the usual dose on the following day. Concomitant use with CYP3A4 inhibitors (including grapefruit) or inducers may alter exposure to the drug. Use of PPIs may reduce drug concentration and is not recommended. Use of antacids or H <sub>2</sub> antagonists should be separated from bosutinib administration by more than 2 hours. Monitor renal function at baseline and during therapy. Monitor liver enzymes at least monthly for the first 3 months and as needed. Hold dosing and adjust dose if severe or persistent thrombocytopenia or neutropenia occurs. Hold dosing if other clinically significant moderate or severe nonhematologic toxicities occur, then restart once symptoms abate. (Pfizer, 2021a) |
| Brigatinib<br>(Alunbrig®) | Multikinase inhibitor that targets ALK, insulin-like growth factor 1 receptor, FLT3, ROS1, and EGFR, which inhibits subsequent downstream signaling proteins signal transducer and activator of transcription 3 (STAT3), Akt, ERK1/2, and S6 | PO    | ALK-positive metastatic NSCLC                                                                                                                    | Common: diarrhea, fatigue, nausea, rash, cough, myalgia, headache, hypertension, vomiting, dyspnea<br>Severe: ILD/pneumonitis, hypertension, bradycardia, visual disturbance, CPK elevation, pancreatic enzyme elevation, hyperglycemia                                                                                                                                                                                                                             | Patients should take once daily with or without food. Tablets should be taken whole and not crushed or chewed. Dose should be increased on day 7 if tolerated. If drug therapy is interrupted for 14 days or longer, resume treatment at lower starting dose. If patients miss or vomit a dose, they should skip the dose and take the usual dose the following day. Dose modification is recommended for severe hepatic impairment (Child-Pugh C) and severe renal impairment (CrCl 15–29 ml/min). Drug interactions exist with moderate and strong CYP3A inhibitors (including grapefruit) and moderate and strong CYP3A inducers.                                                                                                                                                                                                                                                                              |

| Brigatinib<br>(Alunbrig®)<br>(Cont.)                         |                                                                                                                                                                                                                                                    |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Optimize BP prior to initiation. Monitor BP after 2 weeks and at least monthly during treatment. Monitor heart rate regularly. Monitor CPK, amylase, and lipase levels regularly during treatment. Monitor serum glucose at baseline and regularly during treatment. Women of reproductive potential should use contraception during treatment and for 4 months following completion of therapy. Males with female partners of reproductive potential should use contraception during treatment and for 3 months following completion of therapy. Hormonal contraceptives may be ineffective because of decreased exposure when used concurrently with brigatinib. (Takeda Pharmaceuticals, 2020)                                                                                                                                                        |
| Cabozantinib<br>(Cometriq® [capsules]; Cabometyx® [tablets]) | Inhibits tyrosine kinase activity of multiple receptor kinases (including RET, MET, VEGFR, KIT, TRKB, FLT3, ROS1, AXL, TYRO3, MER, TIE-2) involved with oncogenesis, metastasis, tumor angiogenesis, and maintenance of the tumor microenvironment | PO    | Cometriq capsules: progressive, metastatic, medullary thyroid cancer<br>Cabometyx tablets <ul style="list-style-type: none"> <li>• Advanced RCC</li> <li>• Advanced RCC, in combination with nivolumab as first-line treatment</li> <li>• HCC previously treated with sorafenib</li> <li>• Locally advanced or metastatic differentiated thyroid cancer that has progressed following prior VEGFR-targeted therapy in adult and pediatric patients ≥ 12 years of age who are refractory to or ineligible for radioactive iodine</li> </ul> | Common: diarrhea, stomatitis, palmar-plantar erythrodysesthesia, decreased weight, decreased appetite, nausea, fatigue, oral pain, hair color changes, dysgeusia, hypertension, abdominal pain, constipation, increased AST/ALT, lymphopenia, increased ALP, hypocalcemia, neutropenia, thrombocytopenia, hypophosphatemia, hyperbilirubinemia<br>Severe: perforations and fistulas, hemorrhage, thrombotic events (e.g., myocardial infarction, cerebral infarction), impaired wound healing, hypertension, osteonecrosis of the jaw, diarrhea, palmar-plantar erythrodysesthesia, proteinuria, RPLS | Do not substitute Cometriq capsules for Cabometyx tablets or vice versa. Patients should take once daily without food. Patients should not eat at least 2 hours before and 1 hour after taking cabozantinib. Capsules should be swallowed whole and not opened. Missed doses should not be taken within 12 hours of the next dose. Dose adjustments are required in patients with mild to moderate hepatic impairment (Child-Pugh A and B). Drug interactions exist with strong CYP3A4 inhibitors (including grapefruit) and strong CYP3A4 inducers. Hold drug for at least 3 weeks prior to elective surgery. Do not administer for at least 2 weeks following major surgery and until adequate wound healing. Hold for at least 3 weeks prior to invasive dental procedure and for development of osteonecrosis of the jaw. Monitor urine for protein. |

| Drug                    | Mechanism of Action                                                                                  | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                            | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|------------------------------------------------------------------------------------------------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Carfilzomib (Kyprolis®) | Binds to and inhibits the 20S proteasome, resulting in antiproliferative and proapoptotic activities | IV    | <p>Relapsed or refractory multiple myeloma in patients who have received 1–3 lines of therapy in combination with the following:</p> <ul style="list-style-type: none"> <li>• Lenalidomide and dexamethasone</li> <li>• Dexamethasone</li> <li>• Daratumumab (IV or SC) and dexamethasone</li> </ul> <p>Relapsed or refractory multiple myeloma, as a single agent, in patients who have received at least 1 prior line of therapy</p> | <p>Common: anemia, fatigue, thrombocytopenia, nausea, fever, dyspnea, diarrhea, headache, cough, peripheral edema, hypertension</p> <p>Severe: cardiac failure or ischemia, acute renal failure, TLS, pulmonary toxicity (acute respiratory distress syndrome, acute respiratory failure, acute diffuse infiltrative pulmonary disease), pulmonary hypertension, dyspnea, hypertension including hypertensive crisis, venous thromboembolism, infusion reactions, hemorrhage, thrombocytopenia, anemia, hepatotoxicity and hepatic failure, thrombotic microangiopathy, posterior reversible encephalopathy, progressive multifocal leukoencephalopathy</p> | <p>Administer IV over 10 or 30 minutes depending on the regimen. If patient's BSA exceeds 2.2 m<sup>2</sup>, calculate the dose based on a BSA of 2.2 m<sup>2</sup>.</p> <p>Adequate hydration is recommended prior to cycle 1, especially in patients at high-risk for TLS or renal toxicity. Recommended hydration includes oral fluids (30 ml/kg at least 48 hours before cycle 1, day 1) and IV fluids (250–500 ml of appropriate fluid). Consider posthydration with IV fluids.</p> <p>Premedicate with dexamethasone PO/IV prior to each dose during the first cycle and in subsequent cycles if infusion reactions occur. Premedication should be given at least 30 minutes, but no more than 4 hours, prior to all doses.</p> <p>Dose modification is recommended for mild or moderate hepatic impairment.</p> <p>For patients on hemodialysis, administer after dialysis procedure.</p> <p>Monitor serum potassium, renal function, LFTs, and CBC regularly during treatment. Optimize BP prior to treatment. Monitor BP regularly while on treatment.</p> <p>Antiviral prophylaxis should be considered to decrease risk of herpes zoster reactivation. Thromboprophylaxis should be administered in patients receiving concurrent therapy with dexamethasone or lenalidomide.</p> <p>Women of reproductive potential should use contraception during treatment and for 6 months following the completion of therapy. Males with female partners of reproductive potential should use contraception during treatment and for 3 months following final dose.</p> <p>Drug is cytotoxic. Follow hazardous drug handling and disposal procedures. (Onyx Pharmaceuticals, 2021)</p> |

**TABLE 8-1.** Targeted Therapies (*Continued*)

| Drug                              | Mechanism of Action                                                                                                                                              | Route | Indications                    | Side Effects                                                                                                                                                                                                                                 | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ceritinib (Zykadia <sup>®</sup> ) | Kinase inhibitor that targets ALK, insulin-like growth factor 1 receptor, insulin receptor, and ROS1, which inhibits proliferation of ALK-dependent cancer cells | PO    | ALK-positive, metastatic NSCLC | <p>Common: diarrhea, nausea, vomiting, abdominal pain, fatigue, decreased appetite, weight loss</p> <p>Severe: GI adverse reactions, hepatotoxicity, ILD/pneumonitis, QT interval prolongation, hyperglycemia, bradycardia, pancreatitis</p> | <p>Patients should take once daily with food. The drug is available as a tablet or capsule. If patients miss a dose, they should take that dose unless the next dose is due within 12 hours. If vomiting occurs, patients should not take an additional dose and continue with the next scheduled dose.</p> <p>Dose modifications are recommended for severe hepatic impairment (Child-Pugh C). Drug interactions exist with CYP3A4 inhibitors (including grapefruit), CYP3A inducers, CYP3A4 substrates, CYP2C9 substrates (e.g., fentanyl, warfarin), other drugs that prolong QTc interval, and drugs that cause bradycardia.</p> <p>Monitor heart rate and BP regularly. Advise patients to report any changes in heart or BP medication.</p> <p>Monitor LFTs at least monthly</p> <p>Monitor lipase, amylase, and fasting glucose prior to treatment and periodically during treatment.</p> <p>Monitor ECG and electrolytes for patients with CHF, bradyarrhythmias, electrolyte abnormalities, or those taking other medications that prolong QTc interval.</p> <p>Women of reproductive potential should use contraception during treatment and for 6 months following completion of therapy. Males with female partners of reproductive potential should use contraception during treatment and for 3 months following completion of therapy.</p> <p>(Novartis Pharmaceuticals, 2021g)</p> |

| Cobimetinib (Cotellic <sup>®</sup> ) | Reversible inhibitor of MAPK/MEK1 and MEK2, leading to inhibition of tumor cell growth                                                                                                                                                          | PO    | Unresectable or metastatic melanoma with <i>BRAF</i> V600E or V600K alteration, in combination with vemurafenib | <p>Common: diarrhea, photosensitivity, nausea, vomiting, fever, increased gamma glutamyl transferase, increased CPK, hypophosphatemia, increased LFTs, lymphopenia, hyponatremia</p> <p>Severe: second primary malignancies (cutaneous and non-cutaneous), hemorrhage, cardiomyopathy, severe skin rash, retinopathy/retinal vein occlusion, hepatotoxicity, rhabdomyolysis</p> | <p>Patients should take once daily, with or without food, for the first 21 days of a 28-day cycle.</p> <p>If patients miss or vomit a dose, they should skip the dose and take the usual dose on the following day.</p> <p>Drug interactions exist with moderate and strong CYP3A4 inhibitors (including grapefruit) and CYP3A4 inducers.</p> <p>Evaluate LVEF before treatment, after 1 month of treatment, then every 3 months during treatment.</p> <p>Monitor patients for second malignancies prior to initiation of therapy, while on therapy, and for up to 6 months following the completion of therapy.</p> <p>Perform an ophthalmologic evaluation at regular intervals and for any visual disturbances.</p> <p>Monitor LFTs prior to initiation, monthly during treatment, and as clinically indicated.</p> <p>Monitor CPK prior to initiation and periodically during treatment.</p> <p>Advise patients to minimize sun exposure and use broad-spectrum sunscreen and lip balm (SPF <math>\geq</math> 30).</p> <p>Women of reproductive potential should use contraception during treatment and for 2 weeks following completion of therapy. (Genentech, 2018)</p> |
| Copanlisib (Aliqopa <sup>®</sup> )   | Inhibits PI3K with inhibitory activity predominantly against PI3K-alpha and PI3K-delta isoforms expressed in malignant B cells, leading to induction of tumor cell death by apoptosis and inhibition of proliferation of malignant B-cell lines | IV    | Relapsed follicular lymphoma in patients who have received at least 2 prior systemic therapies                  | <p>Common: hyperglycemia, hypertension, diarrhea, decreased general strength and energy, leukopenia, neutropenia, thrombocytopenia, nausea, lower respiratory tract infections</p> <p>Severe: infections, noninfectious pneumonitis, hyperglycemia, hypertension, neutropenia, severe cutaneous reactions</p>                                                                   | <p>Administer IV over 60 minutes on days 1, 8, and 15 of a 28-day treatment cycle.</p> <p>Dilute reconstituted solution in 100 ml NS.</p> <p>Dose modifications are recommended for patients with moderate hepatic impairment (Child-Pugh B).</p> <p>Concomitant use with CYP3A4 inhibitors (including grapefruit) or CYP3A4 inducers may alter exposure to copanlisib.</p> <p>Consider PJP prophylaxis for populations at risk.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Copanlisib<br>(Aliqopa®)<br>( <i>Cont.</i> ) |                                                                                                                                                          |       |                                                                                                                                                         |                                                                                                                                                                                                                                                                                           | <p>Blood glucose levels typically peak 5–8 hours following infusion and subsequently decline to baseline in most patients. Optimize blood glucose control before starting each infusion.</p> <p>Monitor BP preinfusion and postinfusion. BP typically remains elevated for 6–8 hours following infusion. Withhold treatment until both systolic BP is &lt; 150 mm Hg and diastolic BP is &lt; 90 mm Hg.</p> <p>Monitor CBC at least weekly during treatment. Women of reproductive potential and males with female partners of reproductive potential should use contraception during treatment and for 1 month after completion of therapy.</p> <p>(Bayer HealthCare Pharmaceuticals, 2021a)</p>                                                                                                                                                                                                                     |
| Crizotinib<br>(Xalkori®)                     | Inhibits multiple tyrosine kinases, including ALK, hepatocyte growth factor receptor, ROS1, and RON, which reduces tumor cell proliferation and survival | PO    | Metastatic ALK-positive or ROS1-positive NSCLC<br>Relapsed or refractory, ALK-positive ALCL in pediatric patients aged 1 year or older and young adults | <p>Common: vision disorders, nausea, vomiting, diarrhea, edema, constipation, elevated transaminases, fatigue, decreased appetite, upper respiratory tract infection, dizziness, neuropathy</p> <p>Severe: hepatotoxicity, ILD/pneumonitis, QT prolongation, bradycardia, vision loss</p> | <p>Patients should take twice daily with or without food.</p> <p>Dosing is BSA based for lymphoma indication. Capsules should not be crushed, chewed, or opened.</p> <p>If patients miss a dose, they should take that dose unless the next dose is within 6 hours. If vomiting occurs after taking a dose, patients should take the next dose at the regularly scheduled time.</p> <p>Antiemetics are recommended prior to and during treatment if used to treat ALCL.</p> <p>Dose modifications are recommended for patients with moderate and severe hepatic impairment and severe renal impairment (CrCl &lt; 30 ml/min).</p> <p>Drug interactions exist with CYP3A inhibitors (including grapefruit), CYP3A inducers, and CYP3A4 substrates (e.g., fentanyl, midazolam).</p> <p>Monitor CBC with differential monthly and as clinically indicated; monitor weekly for the first month if used to treat ALCL.</p> |

| Crizotinib<br>(Xalkori®)<br>(Cont.) |                                                                                                                                                                                                                 |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                               | <p>Monitor LFTs every 2 weeks for the first 2 months of treatment, then monthly and as clinically indicated.</p> <p>Monitor ECG and electrolytes in patients with CHF bradyarrhythmias, electrolyte abnormalities (e.g., hypomagnesemia, hypokalemia), and those taking medications that prolong QT interval.</p> <p>Monitor heart rate and BP regularly. Advise patients to report any changes in heart or BP medications.</p> <p>If treating ALCL, obtain baseline ophthalmologic examination prior to starting treatment, within 1 month of starting therapy, every 3 months thereafter, and upon any new visual symptoms. If treating NSCLC, obtain ophthalmologic examination for any new onset visual symptoms.</p> <p>Women of reproductive potential should use contraception during treatment and for 45 days following completion of therapy. Males with female partners of reproductive potential should use condoms during treatment and for 90 days following completion of therapy.<br/>(Pfizer, 2021c)</p> |
| Dabrafenib<br>(Tafinlar®)           | Inhibits some altered forms of BRAF kinases to inhibit tumor cell growth. Dabrafenib and trametinib target two different kinases in the RAS/RAF/MEK/ERK pathway, leading to greater inhibition of tumor growth. | PO    | <p>Unresectable or metastatic melanoma with <i>BRAF</i> V600E alteration, as a single agent</p> <p>In combination with trametinib for the following:</p> <ul style="list-style-type: none"> <li>• Unresectable or metastatic melanoma with <i>BRAF</i> V600E or V600K alteration</li> <li>• Adjuvant treatment of melanoma with <i>BRAF</i> V600E or V600K alterations and involvement of lymph node(s) following complete resection</li> <li>• NSCLC with <i>BRAF</i> V600E variation</li> </ul> | <p>Common: hyperkeratosis, headache, fever, arthralgia, papuloma, alopecia, palmar-plantar erythrodysesthesia, rash (in combination with trametinib), diarrhea (in combination with trametinib)</p> <p>Severe: second primary malignancies (cutaneous and non-cutaneous), tumor promotion in BRAF wild-type melanoma, hemorrhage, cardiomyopathy, uveitis, febrile reactions, serious to mild skin rash, hyperglycemia, hemolytic anemia, hyperkeratosis,</p> | <p>Patients should take twice daily approximately 12 hours apart and at least 1 hour before or 2 hours after a meal.</p> <p>Capsules should not be opened, crushed, or broken.</p> <p>Patients should not take a missed dose within 6 hours of the next dose.</p> <p>Drug interactions exist with CYP3A4 or CYP2C8 inhibitors (including grapefruit) and substrates of CYP3A4 (i.e., midazolam), CYP2C8, CYP2C9, (i.e., warfarin), CYP2C19, and CYP2B6. Hormone contraceptives may be ineffective because of decreased exposure when used concurrently with dabrafenib. Monitor INR levels more frequently in patients receiving warfarin.</p>                                                                                                                                                                                                                                                                                                                                                                            |

| Drug                                      | Mechanism of Action | Route | Indications                                                                                                                                                                                         | Side Effects                                                                                                                                             | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Dabrafenib<br>(Tafinlar®)<br>(Cont.)      |                     |       | <ul style="list-style-type: none"><li>Locally advanced or meta-static anaplastic thyroid cancer with <i>BRAF</i> V600E alteration and with no satisfactory locoregional treatment options</li></ul> | headache, arthralgia, papil-loma, alopecia, hand-foot syn-drome, cough, fatigue, nausea, vomiting, diarrhea, dry skin, anorexia, edema, chills, dys-pnea | <p>Assess LVEF before initiation, 1 month after initiation, and then at intervals of 2–3 months while on treatment.</p> <p>Withhold for fever of <math>\geq 101.3^{\circ}\text{F}</math> or fever complicated by hypotension, rigors/chills, dehydration, or renal failure. For patients who develop a severe febrile reaction or fever associated with complications, administer antipyretics as secondary prophylaxis when resuming dabrafenib. Administer corticoste-roids (prednisone 10 mg daily) for at least 5 days for second or subsequent develop-ment of fever if temperature does not return to baseline within 3 days of onset.</p> <p>Perform dermatologic evaluations prior to ini-tiation, every 2 months while on therapy, and up to 6 months after discontinuation.</p> <p>Monitor for signs or symptoms of noncutane-ous malignancies.</p> <p>Monitor serum glucose levels in patients with preexisting diabetes or hyperglycemia.</p> <p>Women of reproductive potential should use nonhormonal contraception during treat-ment and for at least 2 weeks following com-pletion of therapy. Men with female partners of reproductive potential should use effec-tive contraception during treatment and for at least 2 weeks after completion of therapy.</p> <p>The drug may interact with radiation and lead to increased CNS, pulmonary, dermatologic, and visceral toxicity. Consider holding <math>\geq 3</math> days before and after fractionated radia-tion and <math>\geq 1</math> day before and after stereotac-tic radiosurgery.</p> <p>(National Comprehensive Cancer Network, 2022; Novartis Pharmaceuticals, 2021f)</p> |

**TABLE 8-1.** Targeted Therapies (Continued)

| Drug                    | Mechanism of Action                                                                                                                                                                                    | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                       | Side Effects                                                                                                                                                                                                                                                                                                                                               | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dacomitinib (Vizimpro®) | Irreversible inhibitor of the kinase activity of the human EGFR family (EGFR/HER1, HER2, HER4) and certain EGFR-activating alterations (exon 19 deletion or the exon 21 L858R substitution alteration) | PO    | Metastatic NSCLC with EGFR exon 19 deletion or exon 21 L858R substitution alteration, as first-line treatment                                                                                                                                                                                                                                                                                                                     | Common: diarrhea, rash, paronychia, stomatitis, decreased appetite, dry skin, decreased weight, alopecia, cough, pruritus<br>Severe: ILD, diarrhea, dermatologic adverse reactions                                                                                                                                                                         | Patients should take once daily at the same time each day, with or without food.<br>If patients vomit or miss a dose, they should skip the dose and take the usual dose the following day.<br>Drug interactions exist with CYP2D6 substrates and PPIs. Avoid the use of PPIs with dacomitinib. Administer dacomitinib at least 6 hours before or 10 hours after an H <sub>2</sub> antagonist.<br>Promptly initiate antidiarrheal treatment (loperamide or diphenoxylate hydrochloride with atropine sulfate) for diarrhea.<br>Most patients develop a rash. Incidence and severity of rash may increase with sun exposure. Advise patients to use moisturizers and to minimize sun exposure with protective clothing and sunscreen at the time of initiation.<br>Women of reproductive potential should use effective contraception during treatment and for 17 days following completion of therapy. (Pfizer, 2020e) |
| Dasatinib (Sprycel®)    | Inhibits multiple tyrosine kinases, including BCR-ABL, Src family, KIT, ephrin type-A receptor 2, and PDGFR-beta                                                                                       | PO    | Ph-positive CML in chronic phase, as first-line treatment<br>Chronic, accelerated, or myeloid or lymphoid blast phase<br>Ph-positive CML with resistance or intolerance to prior therapy, including imatinib<br>Ph-positive ALL with resistance or intolerance to prior therapy<br>Ph-positive CML in chronic phase or newly diagnosed<br>Ph-positive ALL in pediatric patients ≥ 1 year of age, in combination with chemotherapy | Common: myelosuppression, fluid retention (e.g., pleural effusions), diarrhea, headache, rash, hemorrhage, dyspnea, fatigue, nausea, musculoskeletal pain<br>Severe: myelosuppression, bleeding events, fluid retention (including pleural effusions), cardiac dysfunction, pulmonary arterial hypertension, QT prolongation, dermatologic toxicities, TLS | Patients should take once daily, with or without food, either in the morning or in the evening.<br>Tablets should not be crushed, cut, or chewed.<br>Drug interactions exist with CYP3A4 inhibitors (including grapefruit) and CYP3A4 inducers. Use of PPIs or H <sub>2</sub> antagonists may reduce drug concentration and is not recommended. Use of antacids should be separated from administration of dasatinib by ≥ 2 hours.<br>Monitor CBC every 2 weeks for 3 months, then every 3 months or as clinically indicated for patients with chronic phase CML and weekly for 2 months and monthly thereafter for patients with advanced phase CML or ALL.<br>Correct hypokalemia and hypomagnesemia prior to and during treatment to minimize risk of QTc prolongation.                                                                                                                                            |

**TABLE 8-1.** Targeted Therapies (*Continued*)

| Drug                                        | Mechanism of Action                                                                                                                                    | Route | Indications                                                                                                                                                | Side Effects                                                                                                                                                                                                                                                                                       | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dasatinib<br>(Sprycel®)<br>( <i>Cont.</i> ) |                                                                                                                                                        |       |                                                                                                                                                            |                                                                                                                                                                                                                                                                                                    | Fluid retention is typically managed by diuretics or short courses of steroids. Severe pleural effusion may require thoracentesis and oxygen therapy.<br>Women of reproductive potential and males with female partners of reproductive potential should use effective contraception during treatment and for 30 days following completion of therapy.<br>(Bristol-Myers Squibb, 2021)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Duvelisib<br>(Copiktra®)                    | Kinase inhibitor of PI3K, with inhibitory activity predominantly against PI3K-delta and PI3K-gamma isoforms expressed in healthy and malignant B cells | PO    | Relapsed or refractory CLL or SLL after at least 2 prior therapies<br>Relapsed or refractory follicular lymphoma after at least 2 prior systemic therapies | Common: neutropenia, diarrhea/colitis, rash, fatigue, fever, cough, nausea, upper respiratory infection, pneumonia, musculoskeletal pain, anemia<br>Black box warnings: infections, diarrhea/colitis, cutaneous reactions, pneumonitis<br>Other severe adverse events: hepatotoxicity, neutropenia | Patients should take twice daily, 12 hours apart, at the same time each day, with or without food.<br>Capsules should be swallowed whole. They should not be opened, broken, or chewed.<br>If patients miss a dose, it can be taken within 6 hours of the missed time. If a dose is missed by > 6 hours, patients should skip the dose and take the usual dose the following day.<br>Drug interactions exist with CYP3A inducers, CYP3A inhibitors (including grapefruit), and CYP3A substrates.<br>Monitor ANC at least every 2 weeks for the first 2 months of therapy.<br>Monitor liver function during treatment.<br>Provide prophylaxis for PJP during treatment. Following completion of treatment, continue prophylaxis until absolute CD4-positive T-cell count > 200/mm <sup>3</sup> .<br>Monitor for signs and symptoms of infection. The most common serious infections were pneumonia, sepsis, and lower respiratory infections.<br>The median time to onset of any grade diarrhea or colitis was 4 months.<br>Women of reproductive potential and males with female partners of reproductive potential should use effective contraception for 1 month following the completion of therapy.<br>(Verastem, 2019) |

**TABLE 8-1.** Targeted Therapies (Continued)

| Drug                    | Mechanism of Action                                                                                                                                                                                          | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Side Effects                                                                                                                                                                                                                                                                                                                                                                                             | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Eltrombopag (Promacta®) | TPO receptor agonist that interacts with the transmembrane domain of the human TPO receptor and initiates signaling cascades that induce proliferation and differentiation from bone marrow progenitor cells | PO    | Thrombocytopenia in adult and pediatric patients (≥ 1 year old) with chronic immune thrombocytopenia who have had an insufficient response to corticosteroids, immunoglobulins, or splenectomy<br>Thrombocytopenia with chronic hepatitis C to allow initiation and maintenance of interferon-based therapy<br>Severe aplastic anemia in adult and pediatric patients ≥ 2 years of age, in combination with standard immunosuppressive therapy as first-line treatment<br>Severe aplastic anemia with an insufficient response to immunosuppressive therapy | Common: anemia, nausea, pyrexia, increased ALT, cough, fatigue, headache, diarrhea<br>Black box warnings: In patients with chronic hepatitis C, eltrombopag in combination with interferon and ribavirin may increase the risk of hepatic decompensation.<br>Other severe adverse events: hepatotoxicity, increased risk of death and progression of MDS to AML, thrombotic/thromboembolic complications | The drug is available as tablets and an oral suspension.<br>Patients should take once daily without a meal or with a meal low in calcium (≤ 50 mg). Patients should take at least 2 hours before or 4 hours after other medications (e.g., antacids), calcium-rich foods, or supplements containing polyvalent cations (e.g., iron, calcium aluminum, magnesium, selenium, zinc). Patients should not split, chew, or crush tablets and mix with food or liquids.<br>Prior to using the oral suspension, patients or caregivers must receive proper education on dosing, preparation, and administration. Administer the oral suspension immediately after preparation. Discard any suspension not administered within 30 minutes of preparation. Prepare with water only. Do not use hot water.<br>Dose modifications are recommended for patients with mild, moderate, or severe hepatic impairment and some patients of East Asian ancestry.<br>Adjust dose to maintain a platelet count ≥ 50,000/mm <sup>3</sup> . Do not exceed 75 mg daily.<br>Monitor CBC with differential weekly until a stable platelet count has been achieved, then monitor monthly thereafter.<br>Monitor LFTs prior to initiation, every 2 weeks during dose adjustment phase, and monthly with stable dose.<br>Perform a baseline ocular examination prior to initiation and during therapy. Monitor for signs and symptoms of cataracts.<br>If no hematologic response has occurred after 16 weeks of therapy, discontinue the drug.<br>(Novartis Pharmaceuticals, 2021c) |

| Drug                    | Mechanism of Action                                                                                               | Route | Indications                                        | Side Effects                                                                                                                                                                                                                                                                                                                                                            | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------------------------|-------|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enasidenib<br>(Idhifa®) | Inhibits the IDH2 enzyme, leading to decreased 2-hydroxyglutarate levels and induction of myeloid differentiation | PO    | Relapsed or refractory AML with an IDH2 alteration | <p>Common: nausea, vomiting, diarrhea, elevated bilirubin, decreased appetite</p> <p>Black box warning: differentiation syndrome (symptoms: fever, dyspnea, acute respiratory distress, pulmonary infiltrates, pleural or pericardial effusions, rapid weight gain or peripheral edema, lymphadenopathy, bone pain, and hepatic, renal, and multiorgan dysfunction)</p> | <p>Patients should take once daily, at approximately the same time each day with or without food.</p> <p>For patients without disease progression or unacceptable toxicity, treat for a minimum of 6 months to allow time for response.</p> <p>Patients should not split or crush tablets; instruct patients to swallow whole with a cup of water.</p> <p>If a dose is vomited, missed, or not taken at the usual time, administer the dose as soon as possible on the same day, and return to the normal schedule the following day.</p> <p>Patients should not take 2 doses to make up for the missed dose.</p> <p>If differentiation syndrome is suspected, initiate PO or IV corticosteroids (e.g., dexamethasone 10 mg every 12 hours). Taper only after resolution of symptoms.</p> <p>Drug interactions exist with OATP1B1, OATP1B3, BCRP, and P-gp substrates.</p> <p>Monitor CBC and blood chemistries prior to initiation and at least every 2 weeks for the first 3 months of treatment.</p> <p>Hormonal contraceptives may be ineffective because of decreased exposure when used concurrently with enasidenib. Women of reproductive potential and men with female partners of reproductive potential should use contraception during treatment and for 2 months following completion of therapy.</p> <p>(Celgene, 2021a)</p> |

**TABLE 8-1.** Targeted Therapies (Continued)

| Drug                                 | Mechanism of Action                                    | Route | Indications                                                                                                                                                                                                                                                                    | Side Effects                                                                                                                                                                             | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------|--------------------------------------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Encorafenib (Braftovi <sup>®</sup> ) | Targets <i>BRAF</i> V600E to inhibit tumor cell growth | PO    | Unresectable or metastatic melanoma with a <i>BRAF</i> V600E or V600K alteration, in combination with binimetinib<br>Metastatic colorectal cancer with a <i>BRAF</i> V600E alteration, as detected by an FDA-approved test, in combination with cetuximab, after prior therapy | Common: fatigue, nausea, vomiting, abdominal pain, arthralgia<br>Severe: hemorrhage, uveitis, QT prolongation, new primary malignancies, tumor promotion in <i>BRAF</i> wild-type tumors | <p>Patients should take once daily with or without food.</p> <p>Patients should not take a missed dose if within 12 hours of the next scheduled dose. Patients should not take an additional dose if vomiting occurs but continue with the next scheduled dose.</p> <p>Drug interactions exist with CYP3A4 inhibitors (including grapefruit), CYP3A4 inducers, and CYP3A4 substrates. Avoid coadministration with hormonal contraceptives.</p> <p>Perform dermatologic evaluations prior to therapy, every 2 months while on therapy, and for up to 6 months following discontinuation.</p> <p>Monitor patients for signs and symptoms of noncutaneous malignancies.</p> <p>Perform ophthalmologic evaluation at regular intervals and for any visual disturbances.</p> <p>Monitor electrolytes before and during treatment. Monitor ECG for patients who already have or who are at significant risk for developing QTc prolongation (e.g., known long QT syndromes, clinically significant bradyarrhythmias).</p> <p>Women of reproductive potential and men with female partners of reproductive potential should use contraception during treatment and for 2 weeks following completion of therapy. Advise females to use an effective nonhormonal contraception because encorafenib can decrease effectiveness.</p> <p>The drug may interact with radiation and lead to increased CNS, pulmonary, dermatologic, and visceral toxicity. Consider holding <math>\geq 3</math> days before and after fractionated radiation and <math>\geq 1</math> day before and after stereotactic radiosurgery.</p> <p>(Array BioPharma, 2020a; National Comprehensive Cancer Network, 2022)</p> |

**TABLE 8-1.** Targeted Therapies (Continued)

| Drug                              | Mechanism of Action                                                                                                                                                                                                                              | Route     | Indications                                                                                                                                                                                                                                                                                                                   | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Erdaftinib<br/>(Balversa™)</p> | <p>Kinase inhibitor that binds to and inhibits enzymatic activity of FGFR1, FGFR2, FGFR3, and FGFR4; also binds to RET, CSF1R, PDGFR-alpha, PDGFR-beta, FLT4, KIT, and VEGFR2; demonstrates antitumor activity in FGFR-expressing cell lines</p> | <p>PO</p> | <p>Locally advanced or metastatic urothelial carcinoma with susceptible <i>FGFR3</i> or <i>FGFR2</i> genetic alterations that has progressed during or following at least a single line of prior platinum-containing chemotherapy, including within 12 months of neoadjuvant or adjuvant platinum-containing chemotherapy</p> | <p>Common: hyperphosphatemia, stomatitis, fatigue, anemia, increased SCr, diarrhea, dry mouth, onycholysis, elevated LFTs, hyponatremia, decreased appetite, hypoalbuminemia, dysgeusia, decreased hemoglobin, dry skin, dry eyes, alopecia, hypomagnesemia, constipation, palmar-plantar erythrodysesthesia, hypercalcemia, abdominal pain, nausea, musculoskeletal pain<br/>Severe: retinopathy/retinal pigment epithelial detachment, hyperphosphatemia</p> | <p>Patients should take once daily, with or without food, at approximately the same time each day.<br/>Dose may be increased 2–3 weeks after initiation based on serum phosphate levels and tolerability.<br/>Tablets should not be crushed, chewed, or split. If patients miss a dose, they should take it as soon as possible on the same day. Resume the regular daily dose schedule the next day. If patients vomit a dose, they should take the next dose on the next day.<br/>Drug interactions exist with moderate and strong CYP2C9 and CYP3A4 inhibitors (including grapefruit), moderate and strong CYP2C9 and CYP3A4 inducers, serum phosphate level-altering agents, CYP3A4 substrates, OCT2 substrates, and P-gp substrates.<br/>Monitor for CNS effects, including seizures, hallucinations, changes in cognitive function, mood (including suicidal ideation), speech, mental status, and sleep.<br/>Perform monthly ophthalmologic examinations during the first 4 months of treatment, every 3 months thereafter, and for any visual symptoms.<br/>All patients should receive dry eye prophylaxis with ocular demulcents as needed. Assess serum phosphate levels 14–21 days after initiation, then monthly during treatment.<br/>Women of reproductive potential and males with female partners of reproductive potential should use effective nonhormonal birth control during treatment and for 1 month following completion of therapy.<br/>(Janssen Biotech, 2020)</p> |

| Drug                                                                     | Mechanism of Action                                                                                                                                             | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Erlotinib<br>(Tarceva®)                                                  | Inhibits the kinase activity of EGFR, preventing autophosphorylation of tyrosine residues associated with EGFR, inhibiting further downstream signaling         | PO    | Metastatic NSCLC that has EGFR exon 19 deletions or exon 21 (L858R) substitution alterations, for first-line, maintenance, or second or subsequent treatment following at least 1 prior chemotherapy regimen<br>Locally advanced, unresectable, or metastatic pancreatic cancer, as first-line treatment in combination with gemcitabine                                                                                                                                                                                                                                          | Common: rash, diarrhea, anorexia, fatigue, dyspnea, cough, nausea, vomiting<br>Severe: ILD (e.g., dyspnea, cough, fever), renal failure, hepatotoxicity, GI perforations, bullous and exfoliative skin disorders, cerebrovascular accident (with pancreatic cancer), microangiopathic hemolytic anemia (with pancreatic cancer), ocular disorders, hemorrhage in combination with warfarin                                                                              | Patients should take once daily on an empty stomach at least 1 hour before or 2 hours after food.<br>Drug interactions exist with CYP3A4 and CYP1A2 inhibitors (including grapefruit). Cigarette smoking may decrease erlotinib concentrations; avoid concomitant use.<br>Drugs that increase gastric pH decrease erlotinib concentrations. Avoid concomitant use of PPIs. For H <sub>2</sub> antagonists, take erlotinib 10 hours after H <sub>2</sub> antagonist. For antacids, separate dosing by several hours.<br>Monitor renal function, electrolytes, and LFTs periodically during treatment.<br>Regularly monitor INR in patients receiving warfarin. Monitor for GI bleeding and elevated INR.<br>Diarrhea can be managed using loperamide.<br>Women of reproductive potential should use contraception during treatment and for at least 1 month following completion of therapy. (Genentech, 2016) |
| Everolimus<br>(Afinitor®, Afinitor Disperz® tablets for oral suspension) | Inhibits mTOR, which is a serine-threonine kinase downstream of the PI3K/Akt pathway, resulting in reduced cell proliferation, angiogenesis, and glucose uptake | PO    | Advanced HR-positive, HER2-negative breast cancer in postmenopausal women, in combination with exemestane after failed treatment with letrozole or anastrozole<br>Postmenopausal women with advanced HR-positive, HER2-negative breast cancer in combination with exemestane after failed treatment with letrozole or anastrozole<br>Progressive NET of pancreatic origin and progressive, well-differentiated, nonfunctional NETs of lung or GI origin that are unresectable, locally advanced, or metastatic<br>Advanced RCC after failed treatment with sunitinib or sorafenib | Common: stomatitis, infections, rash, fatigue, diarrhea, edema, abdominal pain, nausea, fever, asthenia, cough, headache, decreased appetite<br>Severe: noninfectious pneumonitis, infections, angioedema, hypersensitivity reactions, stomatitis, renal failure, impaired wound healing, myelosuppression, metabolic disorders (e.g., hyperglycemia, hyperlipidemia), risk of infection or reduced immune response with vaccination, radiation sensitization or recall | Patients should take once daily, with or without food, at the same time each day.<br>Tablets should not be broken or crushed.<br>If patients miss a dose, they can take it up to 6 hours after the time it is normally taken.<br>Double doses should not be taken to make up a missed dose.<br>Pediatric dose is based on BSA.<br>Disperz tablets can be used to prepare an oral suspension in an oral syringe or small drinking glass. See prescribing information for detailed preparation instructions.<br>Dose modification may be recommended for patients with hepatic impairment (Child-Pugh A, B, and C).<br>Drug interactions exist with CYP3A4 and P-gp inhibitors (including grapefruit) or CYP3A4 and P-gp inducers.<br>Patients should avoid live vaccines and close contact with those who have received live vaccines.                                                                         |

**TABLE 8-1.** Targeted Therapies (Continued)

| Drug                                                                                | Mechanism of Action | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Side Effects | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------------------------------------------------|---------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Everolimus<br>(Afinitor®, Afinitor Disperz® tablets for oral suspension)<br>(Cont.) |                     |       | <p>Renal angiomyolipoma and tuberous sclerosis complex not requiring immediate surgery</p> <p>Tuberous sclerosis complex in patients who have subependymal giant cell astrocytoma that requires therapeutic intervention but cannot be resected</p> <p><i>Note.</i> Afinitor is not indicated for the treatment of patients with functional carcinoid tumors.</p> <p>Afinitor and Afinitor Disperz are indicated for the treatment of adult and pediatric patients aged ≥ 1 year with tuberous sclerosis complex who have subependymal giant cell astrocytoma that requires therapeutic intervention but cannot be curatively resected.</p> <p>Afinitor Disperz is indicated for the adjunctive treatment of adult patients and pediatric patients aged ≥ 2 years with partial-onset seizures associated with tuberous sclerosis complex.</p> |              | <p>Stomatitis most often occurs within the first 8 weeks of treatment. Initiating dexamethasone alcohol-free mouthwash as a swish and spit reduces the incidence and severity of stomatitis. Patients should avoid alcohol-, hydrogen peroxide-, iodine-, or thyme-containing products, as they may exacerbate the condition.</p> <p>Monitor renal function, lipid panel, and fasting serum glucose prior to initiation of therapy and at least annually thereafter. Monitor fasting serum glucose more frequently in patients with diabetes.</p> <p>Monitor CBC prior to initiation, every 6 months for the first year, and annually thereafter.</p> <p>Hold drug for at least 1 week prior to elective surgery. Do not administer for at least 2 weeks following major surgery and until adequate wound healing.</p> <p>Patients taking concomitant angiotensin-converting enzyme inhibitors may be at increased risk for angioedema.</p> <p>Older adult patients should be closely monitored, and doses should be adjusted for adverse reactions.</p> <p>The drug is available in blister packs.</p> <p>Women of reproductive potential should use contraception during treatment and for at least 8 weeks following completion of therapy. Males with female partners of reproductive potential should use effective contraception during treatment and for 4 weeks after completion of therapy.</p> <p>(Novartis Pharmaceuticals, 2021a)</p> |

**TABLE 8-1.** Targeted Therapies (*Continued*)

| Drug                                  | Mechanism of Action                                                                                                                                                                                                                                                                                                                                           | Route | Indications                                                                                                             | Side Effects                                                                                                                                                                                                                                          | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fedratinib<br>(Inrebic <sup>®</sup> ) | Kinase inhibitor with activity against wild-type and variant activated JAK2 and FLT3; JAK2-selective inhibitor with higher inhibitory activity for JAK2 over other family members JAK1, JAK3, and tyrosine kinase inhibitor 2 (TYK2); abnormal activation of JAK2 associated with myeloproliferative neoplasms, including myelofibrosis and polycythemia vera | PO    | Intermediate-2 or high-risk primary or secondary (postpolycythemia vera or postessential thrombocythemia) myelofibrosis | Common: diarrhea, nausea, anemia, vomiting<br>Black box warning: serious and fatal encephalopathy (e.g., Wernicke encephalopathy)<br>Other severe adverse events: hepatotoxicity, anemia, thrombocytopenia, amylase and lipase elevation, GI toxicity | <p>Patients take once daily, with or without food, if baseline platelet count <math>\geq 50,000/\text{mm}^3</math>.</p> <p>Administration with a high-fat meal may reduce the incidence of nausea and vomiting.</p> <p>If patients miss a dose, they should skip the missed dose and take the usual dose the following day.</p> <p>Dose modifications exist for severe renal impairment (CrCl 15–29 ml/min). Avoid use in severe hepatic impairment.</p> <p>Drug interactions exist with strong CYP3A4 inhibitors, strong and moderate CYP3A4 inducers, and dual CYP3A4 and CYP2C19 inhibitors.</p> <p>Consider providing prophylactic antiemetic therapy (e.g., 5-HT<sub>3</sub> receptor antagonist) during treatment. Treat diarrhea with antidiarrheal promptly at the first onset of symptoms.</p> <p>Monitor thiamine levels prior to initiation, periodically during treatment, and as clinically indicated. Do not start in patients with thiamine deficiency. Replete thiamine prior to treatment initiation. If encephalopathy is suspected, immediately discontinue, and initiate parenteral thiamine.</p> <p>Monitor CBC, SCr, blood urea nitrogen, hepatic panel, amylase, and lipase prior to initiation, periodically during treatment, and as clinically indicated.</p> <p>No data exist for drug-associated risk of major birth defects, miscarriage, or adverse maternal or fetal outcomes.</p> <p>(Celgene, 2019)</p> |

**TABLE 8-1.** Targeted Therapies (Continued)

| Drug                             | Mechanism of Action                                                                                                                                                                                                           | Route | Indications                                                                                                       | Side Effects                                                                                                                                                          | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Gefitinib (Iressa <sup>®</sup> ) | Inhibits EGFR (exon 19 deletion and exon 21-point variant L858R) by inhibiting autophosphorylation of tyrosine kinase associated with EGFR, inhibiting further downstream signaling and blocking EGFR-dependent proliferation | PO    | Metastatic NSCLC with EGFR exon 19 deletions or exon 21 (L858R) substitution alterations, as first-line treatment | Common: skin reactions, diarrhea<br>Severe: ILD, hepatotoxicity, GI perforation, diarrhea, ocular disorders (e.g., keratitis), bullous and exfoliative skin disorders | <p>Patients should take once daily with or without food.</p> <p>If patients miss a dose, they should not take the missed dose within 12 hours of the next dose.</p> <p>For patients who have difficulty swallowing solids, immerse gefitinib in 4–8 oz of water and stir for approximately 15 minutes. Have patients drink immediately or administer through nasogastric tube. Rinse the container with 4–8 oz of water, and have patients drink immediately or administer through the nasogastric tube.</p> <p>Drug interactions exist with CYP3A4 inhibitors (including grapefruit) or CYP3A4 inducers. Regularly monitor INR in patients receiving warfarin. Monitor for GI bleeding and elevated INR.</p> <p>Drugs that increase gastric pH decrease gefitinib concentrations. Avoid concomitant use if possible. For PPIs, take gefitinib 12 hours after the last dose or 12 hours before the next dose of the PPI. For H<sub>2</sub> antagonists, take gefitinib 6 hours after or 6 hours before H<sub>2</sub> antagonist or an antacid.</p> <p>Monitor LFTs periodically during treatment. Women of reproductive potential should use contraception during treatment and for at least 2 weeks following completion of therapy.</p> <p>(AstraZeneca Pharmaceuticals, 2021a)</p> |

**TABLE 8-1.** Targeted Therapies (*Continued*)

| Drug                    | Mechanism of Action                                                                                                                                                                                                                                                                                     | Route | Indications                                                         | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|---------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Gilteritinib (Xospata®) | TKI of multiple receptor tyrosine kinases, including FLT3; inhibits FLT3 receptor signaling and proliferation in cells exogenously expressing FLT3, including FLT3-ITD, tyrosine kinase domain alterations, FLT3-D835Y, and FLT3-ITD-D835Y, and induces apoptosis in leukemic cells expressing FLT3-ITD | PO    | Relapsed or refractory AML in adult patients with a FLT3 alteration | <p>Common: increased transaminase, myalgia/arthralgia, fatigue/malaise, fever, mucositis, edema, rash, noninfectious diarrhea, dyspnea, nausea, cough, constipation, eye disorders, headache, dizziness, hypotension, vomiting, renal impairment</p> <p>Black box warning: differentiation syndrome (e.g., fever, dyspnea, hypoxia, pulmonary infiltrates, pleural or pericardial effusions, rapid weight gain, peripheral edema, hypotension, renal dysfunction)</p> <p>Other severe adverse events: posterior reversible encephalopathy, prolonged QT interval, pancreatitis</p> | <p>Patients should take once daily, with or without food, at the same time each day. Tablets should be taken whole with a glass of water. Tablets should not be opened, crushed, cut, or dissolved.</p> <p>If patients miss a dose, they should take it as soon as possible on the same day and at least 12 hours prior to the next scheduled dose. Patients should return to the normal schedule the following day. Patients should not take 2 doses within 12 hours.</p> <p>Treatment for a minimum of 6 months is recommended to allow time for a clinical response.</p> <p>Drug interactions exist with combined P-gp and strong CYP3A inducers and strong CYP3A inhibitors.</p> <p>Assess CBCs and blood chemistries, including CPK, prior to the initiation, at least once weekly for the first month, once every other week for the second month, and once monthly for the duration of therapy.</p> <p>Perform an ECG prior to initiation of treatment, on days 8 and 15 of cycle 1, and prior to the start of the 2 subsequent cycles. Correct hypokalemia or hypomagnesemia prior to and during treatment.</p> <p>Monitor for differentiation syndrome (2 days after the start and during the first 3 months on treatment). If differentiation is suspected, initiate corticosteroid therapy (dexamethasone 10 mg IV every 12 hours) and hemodynamic monitoring. Administer steroid for a minimum of 3 days.</p> <p>Women of reproductive potential should use effective contraception during treatment and for 6 months following completion of therapy. Men with female partners of reproductive potential should use effective contraception during treatment and for at least 4 months following completion of therapy. (Astellas Pharma, 2019)</p> |

**TABLE 8-1.** Targeted Therapies (Continued)

| Drug                               | Mechanism of Action                                                                                                                                                                                                                               | Route | Indications                                                                                                                                                                   | Side Effects                                                                                                                                                                                                                                                                                                                                                             | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Glasdegib (Daurismo <sup>®</sup> ) | Inhibits the Hedgehog pathway by binding to and inhibiting Smoothed, a transmembrane protein involved in Hedgehog signal transduction, leading to reduced tumor growth and reduced percentage of CD45-positive/CD33-positive blasts in the marrow | PO    | Newly diagnosed AML, in combination with low-dose cytarabine, in adult patients aged $\geq 75$ years with comorbidities that preclude use of intensive induction chemotherapy | Common: anemia, fatigue, hemorrhage, febrile neutropenia, musculoskeletal pain, nausea, edema, thrombocytopenia, dyspnea, decreased appetite, dysgeusia, mucositis, constipation, rash<br>Black box warning: embryo-fetal toxicity<br>Other severe adverse events: QTc interval prolongation<br>Less common: loose teeth, toothaches, alopecia, QT interval prolongation | <p>Patients should take once daily, with or without food, at the same time each day for 28 days in combination with cytarabine SC on days 1–10 of each 28-day cycle.</p> <p>Administer over a minimum of 6 cycles to allow time for clinical response.</p> <p>Tablets should not be crushed or split.</p> <p>If patients miss a dose, they should take it as soon as possible if <math>&gt; 12</math> hours prior to the next scheduled dose.</p> <p>If patients vomit a dose, they should not take another dose and should wait until the next scheduled dose.</p> <p>Drug interactions exist with strong CYP3A4 inhibitors (including grapefruit), strong and moderate CYP3A4 inducers, and QTc-prolonging drugs.</p> <p>Assess CBC, electrolytes, and renal and liver function prior to treatment initiation and at least once weekly for the first month.</p> <p>Monitor electrolytes and renal function once monthly for the duration of therapy.</p> <p>Obtain CPK levels prior to initiating therapy and as indicated clinically thereafter (e.g., if muscle symptoms are reported).</p> <p>Monitor ECG prior to therapy, approximately 1 week after initiation, and then once monthly for the next 2 months to assess for QTc prolongation. Repeat ECG if abnormal.</p> <p>Advise patients to not donate blood or platelets during treatment and for at least 30 days after the final dose because blood or blood products might be given to women of reproductive potential.</p> <p>Conduct pregnancy testing in women of reproductive potential within 7 days prior to initiation. They should use effective contraception for 30 days following the final dose. Men should use condoms, even after prior vasectomy, with a pregnant partner or a female partner of reproductive potential</p> |

**TABLE 8-1.** Targeted Therapies (Continued)

| Drug                  | Mechanism of Action                                                                                                                                                                                | Route | Indications                                                                                                                                                                                                                                                                                                                                                                    | Side Effects                                                                                                                                                                                                                                                                                                                            | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Idelalisib (Zydelig®) | Inhibits PI3K-delta, which is expressed in healthy and malignant B cells, leading to apoptosis and inhibited cell proliferation via inhibition of chemotaxis, adhesion, and reduced cell viability | PO    | <p>Relapsed CLL, in combination with rituximab, in patients for whom rituximab alone would be considered appropriate therapy because of other comorbidities</p> <p>Relapsed follicular B-cell non-Hodgkin lymphoma in patients who have received at least 2 prior systemic therapies</p> <p>Relapsed SLL in patients who have received at least 2 prior systemic therapies</p> | <p>Common: diarrhea, fatigue, nausea, cough, pyrexia, abdominal pain, pneumonia, rash, neutropenia, increased ALT/AST</p> <p>Black box warnings: hepatotoxicity, diarrhea, colitis, pneumonitis, infections, intestinal perforation</p> <p>Other severe adverse events: cutaneous reactions, hypersensitivity reaction, neutropenia</p> | <p>Patients should take twice daily with or without food.</p> <p>Tablets should be swallowed whole.</p> <p>If patients miss a dose by &lt; 6 hours, they should take the missed dose as soon as possible. If a dose is missed by &gt; 6 hours, they should skip the missed dose and take the next dose at the usual time.</p> <p>Drug interactions exist with CYP3A4 inhibitors (including grapefruit), CYP3A4 inducers, and CYP3A4 substrates.</p> <p>Patients should receive PJP prophylaxis.</p> <p>Clinical and laboratory monitoring for CMV infection is recommended in patients with a history of CMV infection or positive CMV serology at the start of treatment.</p> <p>Diarrhea caused by idelalisib responds poorly to antimotility agents. Drug interruption or corticosteroids may be needed to resolve diarrhea.</p> <p>Monitor LFTs prior to initiation, every 2 weeks for the first 3 months, every 4 weeks for the next 3 months, then every 1–3 months thereafter.</p> <p>Monitor CBC at least every 2 weeks for the first 6 months of therapy.</p> <p>Lymphocytosis has been observed in some patients taking idelalisib. It should not be considered progressive disease in the absence of other clinical findings.</p> <p>Women of reproductive potential should use contraception during treatment and for at least 1 month after completion of therapy.</p> <p>Males with female partners of reproductive potential should use contraception during treatment and for at least 3 months after completion of therapy.</p> <p>(Gilead Sciences, 2020)</p> |

| Drug                         | Mechanism of Action                                                                                                                                                                                                      | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Imatinib mesylate (Gleevec®) | Inhibits BCR-ABL1 tyrosine kinase created by the Ph-positive genetic abnormality, inhibiting proliferation and inducing apoptosis in BCR-ABL1–positive cell lines; also inhibits PDGF, stem cell factor, and KIT (c-KIT) | PO    | <p>Newly diagnosed Ph-positive CML in chronic phase, in adult and pediatric patients</p> <p>Ph-positive CML in blast crisis, accelerated phase, or chronic phase after failure of interferon-alfa therapy</p> <p>Relapsed or refractory Ph-positive ALL</p> <p>Newly diagnosed Ph-positive ALL in pediatric patients, in combination with chemotherapy</p> <p>MDS/myeloproliferative diseases associated with PDGFR gene rearrangements</p> <p>Aggressive systemic mastocytosis without KIT D816V alteration or unknown KIT alteration status</p> <p>Hypereosinophilic syndrome and/or chronic eosinophilic leukemia in patients who have the FIP1L1-PDGFR-alpha fusion kinase or unknown fusion kinase status</p> <p>Unresectable, recurrent, or metastatic dermatofibrosarcoma protuberans</p> <p>KIT-positive unresectable or metastatic malignant GIST</p> <p>Adjuvant treatment of resected KIT–positive GIST</p> | <p>Common: edema, nausea, vomiting, muscle cramps, musculoskeletal pain, diarrhea, rash, fatigue, abdominal pain</p> <p>Severe: edema and fluid retention, neutropenia, thrombocytopenia, anemia, CHF, left ventricular dysfunction, hepatotoxicity, hemorrhage, GI perforations, cardiogenic shock in patients with high eosinophil levels, bullous dermatologic reactions, hypothyroidism, growth retardation (children and preadolescents), TLS, reports of motor vehicle accidents in patients receiving imatinib, renal toxicity</p> | <p>Patients should take with a meal and a full glass of water to minimize GI irritation. Doses of 400 mg or 600 mg should be administered once daily. Doses of 800 mg should be administered as 400 mg twice daily.</p> <p>For patients unable to swallow tablets, tablets may be dissolved in a glass of water or apple juice immediately before administration. Use 50 ml for a 100 mg tablet and 200 ml for a 400 mg tablet.</p> <p>Drug interactions exist with CYP3A4 inhibitors (including grapefruit), CYP3A4 inducers, CYP3A4 and CYP2D6 substrates, and warfarin.</p> <p>Patients requiring anticoagulation should receive low-molecular-weight or standard heparin and not warfarin.</p> <p>Dose modifications are recommended in patients with severe hepatic impairment and moderate (CrCl 20–39 ml/min) or severe renal impairment.</p> <p>Weigh patients frequently and monitor for signs and symptoms of fluid retention.</p> <p>Monitor CBC weekly for the first month, biweekly for the second month, and periodically thereafter. Cytopenias generally occur within the first several months of therapy.</p> <p>Monitor LFTs prior to initiation and monthly thereafter or as clinically indicated.</p> <p>Monitor renal function prior to initiation and during therapy.</p> <p>In patients with high eosinophil levels, consider prophylactic use of systemic steroid for 1–2 weeks concurrently with initiation of imatinib.</p> <p>Women of reproductive potential should use contraception during treatment and for at least 14 days after completion of therapy. Males with female partners of reproductive potential should use contraception during treatment and for at least 3 months after completion of therapy.</p> <p>(Novartis Pharmaceuticals, 2020a)</p> |

| Drug                      | Mechanism of Action                                                                                                                        | Route | Indications                                                                                                                     | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Infigratinib (Truseltiq®) | Inhibits FGFR signaling and decreases cell proliferation in cancer cell lines with activating FGFR amplifications, variations, or fusions. | PO    | Previously treated, unresectable, locally advanced or metastatic cholangiocarcinoma with an FGFR2 fusion or other rearrangement | <p>Common: nail toxicity, stomatitis, dry eyes, fatigue, alopecia, palmar-plantar erythrodysesthesia, arthralgia, dysgeusia, constipation, abdominal pain, dry mouth, eyelash changes, diarrhea, dry skin, decreased appetite, blurred vision, vomiting, increased creatinine, increased and decreased phosphate, increased LFTs, decreased hemoglobin, increased lipase, increased calcium, decreased lymphocytes, decreased sodium, increased triglycerides, increased urate, decreased platelets, decreased leukocytes, decreased albumin, decreased potassium</p> <p>Severe: ocular toxicity (retinal pigment epithelial detachment), hyperphosphatemia, soft tissue mineralization</p> | <p>Patients should take once daily for 21 consecutive days, followed by 7 days off until disease progression or unacceptable toxicity.</p> <p>Patients should take on an empty stomach at least 1 hour before or 2 hours after food at approximately the same time each day.</p> <p>Capsules should be swallowed whole. They should not be crushed, chewed, or dissolved.</p> <p>If patients miss a dose by <math>\geq 4</math> hours or if vomiting occurs, they should skip the dose and resume the regular daily dose the next day.</p> <p>Dose modifications are recommended for mild to moderate renal or hepatic impairment.</p> <p>Drug interactions exist with strong and moderate CYP3A inhibitors (including grapefruit), strong and moderate CYP3A inducers, and gastric acid-reducing agents. Avoid coadministration if possible. Administer an <math>H_2</math> antagonist 2 hours before or 10 hours after infigratinib and locally acting antacid 2 hours before or after infigratinib.</p> <p>Perform a comprehensive ophthalmologic examination, including optical coherence tomography, prior to initiation and at 1 month, 3 months, and then every 3 months thereafter during treatment.</p> <p>Monitor for hyperphosphatemia throughout treatment. Initiate phosphate lowering therapy when serum phosphate is <math>&gt; 5.5</math> mg/dl.</p> <p>Advise patients to use artificial tear substitutes or hydrating or lubricating eye gels to prevent or treat dry eyes.</p> <p>Women of reproductive potential and males with female partners of reproductive potential should use contraception during treatment and for 1 month after completion of therapy.</p> <p>The drug is available in 21-day blister packs. | Drug                   | Mechanism of Action                                                   | Route | Indications                                                                                                                  | Side Effects                                                                                                                                                                                                                                                                | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------|-----------------------------------------------------------------------|-------|------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ixazomib<br>(Ninlaro®) | Reversible proteasome inhibitor leading to apoptosis of myeloma cells | PO    | Multiple myeloma, in combination with lenalidomide and dexamethasone, in patients who have received at least 1 prior therapy | Common: thrombocytopenia, diarrhea, constipation, nausea, vomiting, peripheral neuropathy, peripheral edema, back pain<br>Severe: thrombocytopenia, GI toxicities, peripheral neuropathy, peripheral edema, cutaneous reactions, thrombotic microangiopathy, hepatotoxicity | <p>Patients should take once weekly on days 1, 8, and 15 of a 28-day cycle at approximately the same time and with water. Patients should take on an empty stomach at least 1 hour before or 2 hours after food.</p> <p>Capsules should not be crushed, chewed, or opened. Drug should be stored in the original packaging and not removed until just prior to taking.</p> <p>If patients delay or miss a dose, they should take it if the next scheduled dose is <math>\geq 72</math> hours away. If patients vomit, they should not repeat the dose.</p> <p>Drug interactions exist with CYP3A4 inducers. Dose modifications are recommended in patients with moderate or severe hepatic impairment and severe renal impairment (<math>\text{CrCl} &lt; 30 \text{ ml/min}</math> or dialysis).</p> <p>Assess hematologic parameters prior to initiating a new cycle (<math>\text{ANC} \geq 1,000/\text{mm}^3</math> and platelets <math>\geq 75,000/\text{mm}^3</math>).</p> <p>Monitor CBC at least monthly prior to each cycle. Consider more frequent monitoring during the first 3 cycles.</p> <p>Monitor LFTs periodically.</p> <p>Consider antiviral prophylaxis to decrease risk of herpes zoster reactivation.</p> <p>Hormonal contraceptives may be ineffective when used concurrently (with dexamethasone). Women of reproductive potential should use nonhormonal contraception during treatment and for at least 90 days after completion of therapy. Males with female partners of reproductive potential should use effective contraception during treatment and for at least 90 days after the completion of therapy.</p> <p>(Millennium Pharmaceuticals, 2021)</p> |

| Drug                  | Mechanism of Action                                                                                                                                                     | Route | Indications                                                                                                                                                                                                                                                                                        | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ivosidenib (Tibsovo®) | Small molecule inhibitor that targets the altered IDH1 enzyme, inducing myeloid differentiation; reduces blast counts and increases percentages of mature myeloid cells | PO    | Newly diagnosed AML with a susceptible IDH1 alteration in patients aged ≥ 75 years or who have comorbidities that preclude use of intensive induction chemotherapy<br>Relapsed or refractory AML<br>Locally advanced or metastatic cholangiocarcinoma in patients who have been previously treated | Common: fatigue, leukocytosis, arthralgia, diarrhea, dyspnea, edema, nausea, mucositis, QT interval prolongation, rash, fever, cough, constipation, decreased appetite, myalgia, decreased hemoglobin, decreased calcium, decreased sodium, decreased magnesium, increased uric acid, decreased potassium, increased LFTs, decreased phosphate, increased creatinine, increased bilirubin, abdominal pain<br>Black box warning: differentiation syndrome in AML (e.g., fever; dyspnea; hypoxia; pulmonary infiltrates; pleural or pericardial effusions; rapid weight gain; peripheral edema; hypotension; hepatic, renal, or multiorgan dysfunction)<br>Other severe adverse events: QTc prolongation, Guillain-Barré syndrome | Patients should take once daily with or without food.<br>Tablets should not be taken with a high-fat meal because of increased ivosidenib concentration.<br>Tablets should not be split or crushed.<br>If treating AML, treat for a minimum of 6 months to allow time for clinical response.<br>If patients miss a dose, it should be taken as soon as possible if > 12 hours before the next scheduled dose. Patients should not take 2 doses within 12 hours.<br>If patients vomit a dose, they should not take a replacement dose; they should take the next dose at the regular time.<br>Drug interactions exist with strong CYP3A4 inhibitors, strong CYP3A4 inducers, sensitive CYP3A4 substrates, or QTc-prolonging drugs.<br>Assess CBC and blood chemistries prior to initiation, at least once weekly for the first month, once every two weeks for the second month, and once monthly for the duration of therapy.<br>Monitor CPK weekly for the first month.<br>Monitor ECG at least once weekly for the first 3 weeks of therapy then at least once monthly for duration of therapy.<br>Monitor for hypokalemia and hypomagnesemia.<br>If treating AML, monitor for differentiation syndrome 2 days after the start and during the first 3 months of treatment. If differentiation is suspected, initiate corticosteroid therapy (dexamethasone 10 mg IV every 12 hours) and hemodynamic monitoring. (Servier Pharmaceuticals, 2021) |

| Lapatinib (Tykerb®) | Inhibitor of the intracellular tyrosine kinase domains of EGFR and HER2 | PO    | Advanced or metastatic breast cancer that overexpresses HER2, in combination with capecitabine, in patients who have received prior therapy, including an anthracycline, a taxane, and trastuzumab<br>HR-positive metastatic breast cancer that overexpresses HER2, in combination with letrozole, in postmenopausal women for whom hormone therapy is indicated | Common: diarrhea, rash, nausea, fatigue<br>Black box: hepatotoxicity<br>Other severe adverse events: decreased LVEF, diarrhea, ILD/pneumonitis, QT prolongation, cutaneous reactions | <p>Patients should take once daily on an empty stomach at least 1 hour before or after a meal. Do not divide the daily dose. However, capecitabine should be taken with a meal or within 30 minutes after a meal.</p> <p>If patients miss a dose, they should not double the dose the following day.</p> <p>Drug interactions exist with strong CYP3A4 inhibitors (including grapefruit), strong CYP3A4 inducers, and substrates of CYP3A4, CYP2C8, and P-gp.</p> <p>Dose modifications are recommended for patients with severe hepatic impairment (Child-Pugh C).</p> <p>Confirm normal LVEF before initiation and throughout treatment. Lapatinib should be discontinued in patients if LVEF drops below lower limits of normal.</p> <p>Diarrhea may be managed with antidiarrheal agents (e.g., loperamide); replace fluids and electrolytes if severe.</p> <p>Monitor and correct for hypomagnesemia and hypokalemia to reduce risk of QT prolongation.</p> <p>Monitor LFTs prior to initiation, every 4–6 weeks during treatment, and as clinically indicated.</p> <p>Women of reproductive potential and males with female partners of reproductive potential should use effective contraception during treatment and for at least 1 week after completion of therapy.</p> <p>(Novartis Pharmaceuticals, 2020e)</p> |

| Drug                      | Mechanism of Action                                                                                                                                                                                                    | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                         | Side Effects                                                                                                                                                                                                                                                                                                                                                                  | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Larotrectinib (Vitrakvi®) | Inhibits TRKs (TRKA, TRKB, and TRKC), which are encoded by the genes <i>NTRK1</i> , <i>NTRK2</i> , and <i>NTRK3</i> , and can act as oncogenic drivers and promote cellular proliferation and tumor cell line survival | PO    | <p>Adult and pediatric patients with solid tumors with the following characteristics:</p> <ul style="list-style-type: none"> <li>• <i>NTRK</i> gene fusion without a known acquired resistance alteration</li> <li>• Metastatic disease or if surgical resection would likely result in severe morbidity</li> <li>• No satisfactory alternative treatment options or have progressed following treatment</li> </ul> | <p>Common: fatigue, nausea, dizziness, vomiting, increased LFTs, cough, anemia, musculoskeletal pain, hypoalbuminemia, neutropenia, leukopenia, constipation, diarrhea, hypocalcemia, pyrexia, lymphopenia, abdominal pain</p> <p>Severe: CNS effects (including dizziness, cognitive impairment, mood disorders, sleep disturbances), skeletal fractures, hepatotoxicity</p> | <p>Patients should take twice daily with or without food</p> <p>For pediatric patients with a BSA &lt; 1 m<sup>2</sup>, dose is BSA-based.</p> <p>The drug is available as a capsule or an oral solution.</p> <p>Capsules should be swallowed whole with water. They should not be crushed or chewed.</p> <p>If patients miss a dose, they should not make up the missed dose if within 6 hours of the next scheduled dose.</p> <p>If patients vomit a dose, they should skip that dose and take the usual dose the following day.</p> <p>If using oral solution, it can be stored in the refrigerator for up to 90 days after opening. Gloves should be worn by the caregiver during preparation and administration.</p> <p>Dose modification is recommended in patients with moderate (Child-Pugh B) to severe (Child-Pugh C) hepatic impairment.</p> <p>Drug interactions exist with strong CYP3A4 inhibitors, strong CYP3A4 inducers, and sensitive CYP3A4 substrates.</p> <p>Monitor for signs of neurotoxicity and advise patients not to drive or operate hazardous machinery if experiencing neurotoxicity.</p> <p>Monitor LFTs every 2 weeks during the first month of treatment, monthly thereafter, and as clinically indicated.</p> <p>Women of reproductive potential and males with female partners of reproductive potential should use effective contraception during treatment and for 1 week following completion of therapy.</p> <p>(Bayer HealthCare, 2021b)</p> |

| Drug                  | Mechanism of Action                                                                                                                                                              | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Lenvatinib (Lenvima®) | TKI of primarily VEGF receptors, which inhibits angiogenesis, tumor growth, and cancer progression; also inhibits FGFR1, FGFR2, FGFR3, and FGFR4; PDGFR- $\alpha$ , KIT; and RET | PO    | <p>Locally recurrent or metastatic, progressive, radioactive iodine–refractory differentiated thyroid cancer, as a single agent</p> <p>Advanced RCC, in combination with everolimus, following 1 prior antiangiogenic therapy</p> <p>Unresectable HCC, as first-line treatment</p> <p>Advanced endometrial carcinoma that is not microsatellite instability high or mismatch repair deficient, in combination with pembrolizumab, in patients who have disease progression following prior systemic therapy and are not candidates for curative surgery or radiation</p> | <p>Common: hypertension, fatigue, diarrhea, arthralgia/myalgia, decreased appetite, decreased weight, nausea, stomatitis, headache, vomiting, proteinuria, palmar-plantar erythrodysesthesia, abdominal pain, dysphonia</p> <p>Severe: hypertension, cardiac dysfunction, arterial thromboembolic events, hepatotoxicity, proteinuria, diarrhea, renal failure and impairment, GI perforation and fistula formation, QT interval prolongation, hypocalcemia, RPLS, hemorrhagic events, thyroid dysfunction, impaired wound healing, osteonecrosis of the jaw</p> | <p>Patients should take once daily at the same time with or without food. Capsule should be swallowed whole or dissolved in a small glass of water or apple juice.</p> <p>Dose modification is recommended for severe renal impairment (<math>\text{CrCl} &lt; 30 \text{ ml/min}</math>) and severe hepatic impairment (Child-Pugh C).</p> <p>Patient instructions for dissolving the drug: Measure 1 tablespoon of water or apple juice and put the capsules into the liquid without breaking or crushing them. Leave the capsules in the liquid for at least 10 minutes. Stir for at least 3 minutes. Drink the mixture. After drinking, add a new tablespoon of liquid to the glass, swirl a few times, and drink the contents.</p> <p>If patients miss a dose and it cannot be taken within 12 hours, they should skip that dose.</p> <p>Drug interactions exist with other drugs that prolong QT interval.</p> <p>Optimize BP prior to treatment and monitor during treatment after 1 week, then every 2 weeks for the first 2 months, then monthly during treatment.</p> <p>Monitor LFTs prior to treatment, every 2 weeks for the first 2 months, then once monthly during treatment.</p> <p>Monitor for proteinuria prior to initiation and periodically during treatment.</p> <p>Monitor blood calcium levels at least monthly and replace calcium as necessary.</p> <p>Monitor thyroid function prior to treatment and monthly during treatment.</p> <p>Hold for at least 1 week before elective surgery and do not administer for at least 2 weeks following major surgery and until adequate wound healing.</p> <p>Consider preventive dentistry prior to treatment. Diarrhea may be managed with antidiarrheal agents (e.g., loperamide) and hydration as needed.</p> <p>Women of reproductive potential should use contraception during treatment and for at least 30 days following completion of therapy. The drug is available as 5-day blister cards. (Eisai, 2021)</p> |

| Drug                   | Mechanism of Action                                                                                                                       | Route | Indications                                       | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|-------|---------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Lorlatinib (Lorbrena®) | TKI targeting ALK and RET to decrease tumor cell viability in cell lines harboring ALK fusions, amplifications, or activating alterations | PO    | Metastatic, ALK-positive NSCLC, as a single agent | <p>Common: edema, peripheral neuropathy, weight gain, cognitive effects, fatigue, dyspnea, arthralgia, diarrhea, mood effects</p> <p>Severe: risk of serious hepatotoxicity with concomitant use of strong CYP3A inducers, CNS effects (e.g., seizures, psychotic effects, changes in cognitive function), mood (e.g., suicidal ideation, mental status), speech, sleep disturbances, hypercholesterolemia, hypertriglyceridemia, cough, ILD/pneumonitis, hypertension, hyperglycemia, atrioventricular block</p> | <p>Patients should take once daily with or without food.</p> <p>Tablets should be swallowed whole and not chewed, crushed, or split.</p> <p>If patients miss a dose, they should take the missed dose unless the next dose is due within 4 hours.</p> <p>If patients vomit a dose, they should not take an additional dose but continue with the next scheduled dose.</p> <p>Dose modifications are recommended for severe renal impairment (CrCl 15 to &lt; 30 mL/min).</p> <p>Drug interactions exist for moderate to strong CYP3A inducers, strong CYP3A inhibitors, CYP3A substrates, P-gp substrates, and fluconazole.</p> <p>Monitor BP after 2 weeks and then at least monthly during treatment. Withhold for severe hypertension.</p> <p>Monitor fasting serum glucose prior to starting and regularly during treatment.</p> <p>Monitor serum cholesterol and triglycerides before initiating treatment, 1 and 2 months after initiation, and periodically thereafter.</p> <p>Monitor ECG at baseline and periodically.</p> <p>CNS effects occurred in more than 50% of patients in clinical trials. Median time to onset of any CNS effect was 1.4 months.</p> <p>Hormonal contraceptives may be ineffective when used concurrently with lorlatinib.</p> <p>Women of reproductive potential should be advised to use nonhormone contraception during treatment and for at least 6 months after the final dose. Males with female partners of reproductive potential should use effective contraception during treatment and for at least 3 months after completing therapy.</p> <p>(Pfizer, 2021b)</p> |

**TABLE 8-1.** Targeted Therapies (*Continued*)

| Drug                                     | Mechanism of Action                                                                                                                              | Route | Indications                                                                                                                                                                                                                                                                  | Side Effects                                                                                                                                                                                                                                                                                                                                          | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Midostaurin<br>(Rydapt <sup>®</sup> )    | Inhibits multiple receptor tyrosine kinases, primarily FLT3 receptor signaling, inducing apoptosis in FLT3-expressing cells                      | PO    | Newly diagnosed AML that is FLT3 alteration–positive in combination with standard cytarabine and daunorubicin induction and cytarabine consolidation<br>Aggressive systemic mastocytosis<br>Systemic mastocytosis with associated hematologic neoplasm<br>Mast cell leukemia | Common: febrile neutropenia, nausea, mucositis, vomiting, headache, petechiae, musculoskeletal pain, epistaxis, device-related infection, hyperglycemia, QT prolongation, upper respiratory tract infection, edema, abdominal pain, constipation, fever, dyspnea<br>Severe: pulmonary toxicity (ILD/pneumonitis)                                      | Patients should take twice daily, approximately every 12 hours with food. Capsules should not be opened or crushed. For AML, patients should take on days 8–21 of each cycle of induction or consolidation. If patients miss or vomit a dose, they should not make up the dose. They should take the next dose at the usual scheduled time. Drug interactions exist with strong CYP3A4 inhibitors (including grapefruit) and strong CYP3A4 inducers that may alter exposure to midostaurin. Administer a prophylactic antiemetic prior to each dose to reduce risk of nausea and vomiting. Women of reproductive potential and males with female partners of reproductive potential should use contraception during treatment and for at least 4 months following completion of therapy. (Novartis Pharmaceuticals, 2021d) |
| Mobocertinib<br>(Exkivity <sup>™</sup> ) | Kinase inhibitor of EGFR that irreversibly binds to and inhibits EGFR exon 20 insertion alterations at a lower concentration than wild-type EGFR | PO    | Locally advanced or metastatic NSCLC with EGFR exon 20 insertion alterations that has progressed on or after platinum-based chemotherapy                                                                                                                                     | Common: diarrhea, rash, nausea, stomatitis, vomiting, decreased appetite, paronychia, fatigue, dry skin, musculoskeletal pain, decreased red blood cells, decreased lymphocytes, increased creatinine<br>Black box warning: QTc prolongation, including torsades de pointes<br>Other severe adverse events: ILD/pneumonitis, cardiotoxicity, diarrhea | Patients should take once daily with or without food. Capsules should be swallowed whole. They should not be opened, chewed, or dissolved. If patients miss a dose and it has been more than 6 hours, they should skip the dose and take the next dose at the regularly scheduled time. If patients vomit a dose, they should not take an extra dose. Drug interactions exist with moderate and strong CYP3A inhibitors (including grapefruit) and moderate or strong CYP3A inducers. Avoid use with concomitant drugs that increase QTc interval. Monitor ECG at baseline and periodically during treatment. Correct any abnormalities in sodium, potassium, calcium, and magnesium. Monitor LVEF at baseline and during treatment.                                                                                       |

| Drug                                   | Mechanism of Action                                                                                                                                  | Route | Indications                                                                                                                                                                                                                                                                                              | Side Effects                                                                                                                                                                                                                                                            | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mobocertinib<br>(Exkivity™)<br>(Cont.) |                                                                                                                                                      |       |                                                                                                                                                                                                                                                                                                          |                                                                                                                                                                                                                                                                         | Median time to first onset of diarrhea is approximately 5 days. Monitor electrolytes and advise patients to start an antidiarrheal agent at first episode of diarrhea. Hormonal contraceptives may be ineffective when used concurrently with mobocertinib. Females of reproductive potential and males with female partners should use nonhormonal contraception during treatment and for at least 1 month after completion of therapy. (Takeda Pharmaceuticals, 2021)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Neratinib<br>(Nerlynx®)                | Intracellular kinase inhibitor that binds to and inhibits autophosphorylation of EGFR, HER2, and HER4 and downstream MAPK and Akt signaling pathways | PO    | Early-stage HER2-positive breast cancer, as extended adjuvant treatment following adjuvant trastuzumab-based therapy<br>Advanced or metastatic HER2-positive breast cancer, in combination with capecitabine, in patients who have received 2 or more prior anti-HER2 regimens in the metastatic setting | Common: diarrhea, nausea, abdominal pain, fatigue, vomiting, rash, stomatitis, decreased appetite, muscle spasms, dyspepsia, increased AST/ALT, nail disorder, dry skin, abdominal distension, weight loss, urinary tract infection<br>Severe: diarrhea, hepatotoxicity | Patients should take once daily at approximately the same time with food. Tablets should not be chewed, crushed, or split. If patients miss a dose, they should not replace the missed dose and should resume with the next scheduled daily dose. A two-week dose escalation may be considered to improve tolerability (week 1: 120 mg daily; week 2: 160 mg daily; week 3 and onward: 240 mg daily). Concomitant use with CYP3A4 inhibitors (including grapefruit) or CYP3A4 inducers may alter exposure to neratinib. Concomitant use with P-gp substrates may alter exposure to the P-gp substrate. Avoid concomitant use with PPIs and H <sub>2</sub> antagonists. Separate by 3 hours from antacid dosing. Dose adjustment is required in patients with severe hepatic impairment. Initiate loperamide with the first dose of neratinib and continue during first 2 cycles (56 days) of treatment. Titrate to 1–2 bowel movements per day. Refer to package insert for specific loperamide prophylaxis dosing recommendations. With severe diarrhea, initiate fluids and electrolytes as needed. Women of reproductive potential should use contraception during treatment and for 1 month following completion of therapy. Men should use contraception during treatment and for 3 months following completion of therapy. (Puma Biotechnology, 2021) |

| Drug                    | Mechanism of Action                                                                                 | Route | Indications                                                                                                                                                                                                                                                                                                                                                   | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Nilotinib<br>(Tasigna®) | Inhibits BCR-ABL1 kinase, PDGFR, KIT, CSF1R, and discoidin domain receptor tyrosine kinase 1 (DDR1) | PO    | Newly diagnosed Ph-positive CML in chronic phase in adult and pediatric patients aged ≥1 year<br>Ph-positive CML in chronic or accelerated phase that is resistant or intolerant to prior therapy, including imatinib, in adults<br>Ph-positive CML in chronic phase that is resistant or intolerant to prior TKI therapy, in pediatric patients aged ≥1 year | Common: nausea, rash, headache, fatigue, pruritus, vomiting, diarrhea, cough, constipation, arthralgia, nasopharyngitis, fever, night sweats, thrombocytopenia, neutropenia, anemia<br>Black box warnings: QT prolongation, sudden death<br>Other severe adverse events: myelosuppression, cardiac and arterial vascular occlusive events, pancreatitis and elevated serum lipase, hepatotoxicity, electrolyte abnormalities (hypophosphatemia, hypokalemia, hyperkalemia, hypocalcemia, hyponatremia), TLS, hemorrhage, fluid retention, effects on growth and development in pediatric patients | Patients should take twice daily, 12 hours apart, without food. Patients should avoid food for at least 2 hours before the dose and 1 hour after each dose. Taking with food increases risk for QT prolongation. Capsules should be swallowed whole with water. For patients unable to swallow capsules, the contents may be mixed in 1 teaspoon of applesauce and taken within 15 minutes. Capsules must be crushed in pharmacy. If patients miss a dose, they should not replace the missed dose. They should resume with the next scheduled daily dose. Dose modifications are recommended for patients with baseline hepatic impairment (Child-Pugh A, B, or C). Drug interactions exist with strong CYP3A4 inhibitors (including grapefruit) and strong CYP3A4 inducers. Avoid use of PPIs. Separate antacids from nilotinib by 2 hours. Administer nilotinib 2 hours before or 10 hours after H <sub>2</sub> antagonists. Avoid concomitant use of drugs known to prolong QT interval. Monitor and correct for hypomagnesemia and hypokalemia to reduce risk of QT prolongation. Do not use in patients with hypokalemia, hypomagnesemia, or long QT syndrome. Obtain ECG at baseline, 7 days after initiation, and periodically (including after any dose adjustments) to monitor QTc. Monitor CBC every 2 weeks for the first 2 months and then monthly thereafter. Monitor serum lipase and LFTs monthly. Monitor phosphorus, potassium, calcium, and sodium levels. Monitor lipid panel and glucose periodically during the first year. Monitor patients for unexpected rapid weight gain, swelling, and shortness of breath. Women of reproductive potential should use contraception during treatment and for 14 days following completion of therapy. (Novartis Pharmaceuticals, 2020d) |

**TABLE 8-1. Targeted Therapies (Continued)**

| Drug                 | Mechanism of Action                                                                                      | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Niraparib (Zejula®)  | Inhibits PARP enzymes, which play a role in DNA repair, leading to DNA damage, apoptosis, and cell death | PO    | Maintenance therapy for recurrent epithelial ovarian, fallopian tube, or primary peritoneal cancer in patients who had complete or partial response to first-line, platinum-based chemotherapy<br>Maintenance therapy for recurrent epithelial ovarian, fallopian tube, or primary peritoneal cancer in patients who had a complete or partial response to platinum-based chemotherapy<br>Advanced ovarian, fallopian tube, or primary peritoneal cancer that has been treated with 3 or more prior chemotherapy regimens and is associated with HRD-positive status defined by either a pathogenic or suspected pathogenic <i>BRCA</i> 1/2 alteration or genomic instability and that has progressed more than 6 months after response to previous platinum-based chemotherapy | Common: nausea, thrombocytopenia, anemia, fatigue, constipation, musculoskeletal pain, abdominal pain, vomiting, neutropenia, decreased appetite, leukopenia, insomnia, headache, dyspnea, rash, diarrhea, hypertension, cough, dizziness, acute kidney injury, urinary tract infection, hypomagnesemia<br>Severe: MDS/AML, bone marrow suppression, hypertension and cardiovascular events, posterior reversible encephalopathy allergic reactions to tartrazine | Patients should take once daily at approximately the same time with or without food. Bedtime administration may help with managing nausea.<br>Capsules should not be chewed, crushed, or split.<br>For first-line maintenance treatment, dose is based on weight and platelet count. Nausea and vomiting is very common. Prophylactic antiemetic (i.e., ondansetron) is recommended.<br>If patients miss or vomit a dose, they should skip that dose and take the next dose at the regularly scheduled time.<br>Dose modifications are recommended for patients with moderate hepatic impairment. Monitor CBC weekly for the first month, monthly for next 11 months, and periodically thereafter. Monitor BP and heart rate at least weekly for the first 2 months, monthly for the first year, and periodically thereafter.<br>Women of reproductive potential should use contraception during treatment and for at least 6 months following completion of therapy. (GlaxoSmithKline, 2021) |
| Olaparib (Lynparza®) | Inhibits PARP enzymes, which play a role in DNA repair, leading to DNA damage, apoptosis, and cell death | PO    | Maintenance therapy for advanced epithelial ovarian, fallopian tube, or primary peritoneal cancer with pathogenic or suspected pathogenic germline or somatic <i>BRCA</i> 1/2 alterations (gBRCAm or sBRCAm) in patients who are in complete or partial response to first-line platinum-based chemotherapy<br>Maintenance therapy for recurrent epithelial ovarian, fallopian tube, or primary peritoneal cancer in patients who are in complete or partial response to platinum-based chemotherapy<br>Maintenance therapy in combination with bevacizumab for advanced epithelial ovarian, fallopian tube,                                                                                                                                                                     | Common: anemia, nausea, fatigue, vomiting, diarrhea, dysgeusia, headache, decreased appetite, cough, leukopenia, neutropenia, thrombocytopenia<br>Severe: MDS/AML, pneumonitis, venous thromboembolic events                                                                                                                                                                                                                                                      | Patients should take twice daily with or without food.<br>Tablets should not be chewed, crushed, dissolved, or split.<br>If patients miss a dose, they should skip that dose and take the next dose at the regularly scheduled time.<br>Nausea and vomiting is very common. A prophylactic antiemetic (e.g., ondansetron) is recommended.<br>Dose adjustment is recommended in patients with moderate renal impairment (CrCl 31–50 ml/min). No data are available for use in severe renal impairment (CrCl ≤ 30 ml/min) or severe hepatic impairment.                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Drug                    | Mechanism of Action                                                                             | Route | Indications                                                                                                                                                                                                                                                                                                                                         | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                     | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------|-------------------------------------------------------------------------------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Osimertinib (Tagrisso®) | Inhibits EGFR by binding irreversibly to certain variant forms (T790M, L858R, exon 19 deletion) | PO    | Metastatic EGFR T790M alteration–positive NSCLC that has progressed on or after EGFR TKI therapy<br>Metastatic NSCLC with EGFR exon 19 deletions or exon 21 L858R alteration, as detected by an FDA-approved test, as first-line therapy<br>Adjuvant therapy after tumor resection of NSCLC with EGFR exon 19 deletion or exon 21 L858R alterations | Common: diarrhea, rash, leukopenia, lymphopenia, thrombocytopenia, anemia, neutropenia, musculoskeletal pain, dry skin, nail toxicity, fatigue, cough<br>Severe: ILD/pneumonitis; QTc prolongation; cardiomyopathy, including cardiac failure, chronic cardiac failure, CHF, pulmonary edema, and decreased ejection fraction; keratitis, erythema multiforme and Stevens-Johnson Syndrome, cutaneous vasculitis | <p>Patients should take once daily with or without food.</p> <p>If patients miss a dose, they should skip that dose and take the next dose at the next regularly scheduled time.</p> <p>Adjuvant treatment should be given for up to 3 years.</p> <p>In patients with difficulty swallowing tablets, disperse tablet in 60 ml of noncarbonated water only. Stir until tablet is dispersed into small pieces (the tablet will not completely dissolve) and swallow immediately. Do not crush, heat, or ultrasonicate during preparation. Rinse the container with 120–240 ml water and immediately drink.</p> <p>If administered via nasogastric tube, disperse in 15 ml of water, and use an additional 15 ml to transfer any residue to a syringe. Administer this 30 ml immediately with appropriate water flushes (approximately 30 ml). Use gloves.</p> <p>Drug interactions exist with strong CYP3A4 inducers and other medications that prolong QT intervals.</p> <p>Monitor for signs and symptoms of cardiomyopathy.</p> <p>Assess cardiac status, including LVEF at baseline and during treatment for patients with preexisting cardiac risk factors or patients who develop cardiac signs or symptoms during treatment.</p> <p>Monitor ECG and electrolytes (magnesium and potassium) in patients who have a history or predisposition for QTc prolongation or those taking medications known to prolong QTc interval.</p> <p>Women of reproductive potential should use contraception during treatment and for 6 weeks following completion of therapy. Men with female partners of reproductive potential should use contraception during treatment and for 4 months following completion of therapy.</p> <p>(AstraZeneca Pharmaceuticals, 2020)</p> |

| Palbociclib (Ibrance®)  | Inhibits CDK4 and CDK6, leading to reduced cellular proliferation by blocking the progression of the cell cycle from G <sub>1</sub> into S phase | PO    | HR-positive, HER2-negative, advanced or metastatic breast cancer, in combination with an aromatase inhibitor as initial endocrine-based therapy, in postmenopausal women or men, or in combination with fulvestrant in women with disease progression following endocrine therapy | Common: neutropenia, infections, leukopenia, fatigue, nausea, stomatitis, anemia, diarrhea, alopecia, thrombocytopenia, rash, vomiting, decreased appetite, asthenia, fever<br>Severe: neutropenia, ILD/pneumonitis                                                                                                                             | Patients should take once daily at approximately the same time for 21 days followed by 7 days off treatment.<br>Tablets may be taken with or without food. Capsules should be taken with food. Tablets and capsules should not be crushed, split, chewed, or opened.<br>If patients miss a dose, they should skip that dose and take the next dose at the next regularly scheduled time.<br>Pre/perimenopausal patients should also receive a luteinizing hormone-releasing hormone agonist.<br>Dose modifications are recommended for patients with severe hepatic impairment (Child-Pugh C).<br>Drug interactions exist with strong CYP3A inhibitors (including grapefruit), strong CYP3A inducers, and CYP3A substrates.<br>Neutropenia is very common, but febrile neutropenia is uncommon.<br>Monitor CBC prior to the start and at the beginning of each cycle and day 15 of the first 2 cycles.<br>Women of reproductive potential should use contraception during treatment and for 3 weeks following completion of therapy. Men with female partners of reproductive potential should use contraception during treatment and for 3 months following completion of therapy.<br>Tablets are available as a monthly box containing 3 weekly blister packs of 7 tablets each. (Pfizer, 2019a, 2019b) |
| Panobinostat (Farydak®) | Inhibits HDAC, resulting in increased acetylation of histone proteins, inducing cell cycle arrest and/or apoptosis of cells                      | PO    | Multiple myeloma, in combination with bortezomib and dexamethasone, in patients who have received at least 2 prior regimens, including bortezomib and an immunomodulatory agent                                                                                                   | Common: diarrhea, fatigue, nausea, peripheral edema, decreased appetite, fever, vomiting, hypophosphatemia, hypokalemia, hyponatremia, increased creatinine, thrombocytopenia, lymphopenia, leukopenia, neutropenia, anemia<br>Black box warnings: severe diarrhea, cardiotoxicities<br>Other severe adverse events: hemorrhage, hepatotoxicity | Patients should take every other day for 3 doses per week (days 1, 3, 5, 8, 10, 12) during weeks 1 and 2 of each 21-day cycle.<br>Patients should take at approximately the same time each day with or without food.<br>Capsules should not be opened, crushed, or chewed.<br>If patients miss a dose beyond 12 hours, they should skip the dose and take the usual dose on the following day. If patients vomit a dose, they should skip the dose and take the usual dose on the following day.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Drug                                  | Mechanism of Action | Route | Indications | Side Effects | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------|---------------------|-------|-------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Panobinostat<br>(Farydak®)<br>(Cont.) |                     |       |             |              | <p>Patients should receive 8 cycles with potential for an additional 8 cycles for a total duration of 16 cycles.</p> <p>Dose modifications are recommended in patients with mild to moderate hepatic impairment. Use should be avoided in patients with severe hepatic impairment.</p> <p>Drug interactions exist with strong CYP3A4 inhibitors (including grapefruit), CYP3A4 inducers, sensitive CYP2D6 substrates, and antiarrhythmic/QT-prolonging drugs.</p> <p>Severe diarrhea occurs in approximately 25% of patients. At the first sign of diarrhea, patients should be treated with antidiarrheal medications (e.g., loperamide). Consider prophylactic antiemetics.</p> <p>Monitor CBC at baseline and at least weekly during treatment. Consider monitoring more frequently in patients aged &gt; 65 years due to increased risk of myelosuppression.</p> <p>Monitor LFTs at baseline and regularly during treatment.</p> <p>Perform ECG at baseline and repeat periodically during treatment as clinically indicated.</p> <p>Monitor electrolytes, including magnesium and potassium, and correct values before treatment. Do not initiate in patients with QTcF &gt; 450 msec.</p> <p>Women of reproductive potential should use contraception during treatment and for 3 months following completion of therapy.</p> <p>Males with female partners of reproductive potential should use contraception during treatment and for 6 months following completion of therapy.</p> <p>The drug is available in blister packs containing 6 tablets.</p> <p>(Novartis Pharmaceuticals, 2016)</p> |

**TABLE 8-1.** Targeted Therapies (*Continued*)

| Drug                     | Mechanism of Action                                                                                                                                                                                                                                                     | Route | Indications                                                                                   | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-----------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pazopanib<br>(Votrient®) | Multi-TKI of VEGFR (1, 2, and 3), PDGFR (alpha and beta), FGFR (1 and 3), KIT, interleukin-2 receptor-inducible T-cell kinase (Itk), lymphocyte-specific protein tyrosine kinase (Lck), and CSF1R (c-Fms), interfering with tumor angiogenesis, growth, and progression | PO    | Advanced RCC<br>Advanced soft tissue sarcoma in patients who have received prior chemotherapy | Common: diarrhea, hypertension, hair and skin color changes (depigmentation), nausea, anorexia, vomiting, fatigue, decreased appetite, tumor pain, dysgeusia, headache, musculoskeletal pain, dyspnea<br>Black box warning: hepatotoxicity<br>Other severe adverse events: QTc prolongation (including torsades de pointes), cardiac dysfunction (decreased LVEF, CHF), hemorrhage, arterial and venous thromboembolism, thrombotic microangiopathy (including thrombotic thrombocytopenic purpura and hemolytic uremic syndrome), ILD/pneumonitis, GI perforation, GI fistula formation, posterior reversible encephalopathy hypertension, hypothyroidism, impaired wound healing, TLS, infection, proteinuria | Patients should take once daily without food at least 1 hour before or 2 hours after a meal. Tablets should not be crushed.<br>If a dose is missed beyond 12 hours, patients should skip the dose and take the usual dose on the following day.<br>Dose modifications are recommended in patients with moderate hepatic impairment. Use is not recommended in severe impairment.<br>Drug interactions exist with strong CYP3A4 inhibitors (including grapefruit), strong CYP3A4 inducers, CYP substrates (e.g., CYP3A4, CYP2D6, CYP2C8), simvastatin, and gastric-acid reducing agents.<br>Concomitant use of PPIs or H <sub>2</sub> antagonists is not recommended; consider use of short-acting antacids separated from pazopanib administration by several hours.<br>Concomitant use with simvastatin may increase risk of ALT elevations. Consider weekly monitoring of LFTs.<br>Measure LFTs at baseline and every 2 weeks for cycles 1–2, once monthly for cycles 3–4, then periodically thereafter. Risk of AST/ALT elevation is highest early in treatment.<br>Use with caution in patients with a history of QT prolongation or concomitantly using other drugs that prolong QT interval. Correct electrolyte abnormalities before treatment.<br>Monitor ECG and electrolytes (e.g., calcium, potassium, magnesium) at baseline and as clinically indicated for patients at high risk for developing QTc prolongation.<br>Monitor LVEF at baseline and periodically in patients at risk for cardiac dysfunction, including previous anthracycline exposure.<br>Monitor BP as clinically indicated. Optimize BP before initiating treatment.<br>Monitor thyroid tests at baseline and during treatment.<br>Monitor urinalysis for proteinuria at baseline and periodically during treatment. |

| Pazopanib<br>(Votrient®)<br>(Cont.) |                                                                                                                                |       |                                                                                                                                        |                                                                                                                                                                                                                                                                                                                          | Hold pazopanib at least 7 days prior to planned surgery. Do not administer for at least 2 weeks following major surgery and until adequate wound healing.<br>Women of reproductive potential and males with female partners of reproductive potential should use contraception during treatment and for 2 weeks following completion of therapy. (Novartis Pharmaceuticals, 2020f)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Pemigatinib<br>(Pemazyre®)          | Small molecule kinase inhibitor targeting FGFR1, FGFR2, FGFR3, and FGFR4 to decrease malignant cell proliferation and survival | PO    | Previously treated unresectable locally advanced or metastatic cholangiocarcinoma with a FGFR2 fusion or other rearrangement in adults | Common: hyperphosphatemia, hypophosphatemia, alopecia, diarrhea, nail toxicity, fatigue, dysgeusia, nausea and vomiting, constipation, stomatitis, dry eyes, dry mouth, dry skin, decreased appetite, arthralgia, abdominal pain, back pain<br>Severe: ocular toxicity, hyperphosphatemia and soft tissue mineralization | Patients should take once daily with or without food for 14 days, followed by 7 days off therapy, in 21-day cycles.<br>Tablets should not be crushed, chewed, split, or dissolved.<br>Dose modifications are recommended for patients with severe renal impairment (eGFR 15–29 ml/min/1.73 m <sup>2</sup> ) and severe hepatic impairment (total bilirubin > 3 × ULN).<br>If patients miss a dose, it can be taken within 4 hours on the same day. If more than 4 hours have passed, patients should skip that dose and take the next dose at the next regularly scheduled time.<br>Drug interactions exist with moderate and strong CYP3A inducers and moderate and strong CYP3A inhibitors (including grapefruit).<br>Ophthalmic examination, including optical coherence tomography, should be performed prior to initiation of therapy, every 2 months for the first 6 months of treatment, and every 3 months thereafter and urgently at any time for visual symptoms.<br>Monitor for hyperphosphatemia. Median time to onset is 8 days. Initiate a low phosphate diet when serum phosphate level is > 5.5 mg/dl. If levels > 7 mg/dl, initiate phosphate lowering therapy and hold pemigatinib.<br>Women of reproductive potential and males with female partners of reproductive potential should use effective contraception during treatment and for 1 week after completion of therapy. | Drug                       | Mechanism of Action                                                                                              | Route | Indications                                                                                                                                                         | Side Effects                                                                                                                                                                                                                                                                               | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------|------------------------------------------------------------------------------------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pexidartinib<br>(Turalio™) | TKI that inhibits CSF1R, KIT, and FLT3-ITD alteration, preventing proliferation of cell lines dependent on CSF1R | PO    | Symptomatic tenosynovial giant cell tumor associated with severe morbidity or functional limitations and that is not amenable to improvement with surgery in adults | Common: increased lactate dehydrogenase, increased AST, hair color changes, fatigue, eye edema, increased ALT, decreased ANC, increased cholesterol, increased ALP, decreased lymphocytes, decreased hemoglobin, rash, dysgeusia, decreased phosphate<br>Black box warning: hepatotoxicity | <p>Patients should take twice daily without food at least 1 hour before or 2 hours after a snack or meal.</p> <p>Capsules should not be opened, broken, or chewed.</p> <p>If patients vomit or miss a dose, they should skip the missed dose and take the next dose the following day at its scheduled time.</p> <p>Dose modifications are recommended for patients with mild to severe renal impairment (CrCl 15–89 ml/min).</p> <p>Drug interactions exist with moderate or strong CYP3A inhibitors (including grapefruit), strong CYP3A inducers, UGT inhibitors, CYP3A substrates, acid-reducing agents, and other products that cause hepatotoxicity.</p> <p>Use with PPIs should be avoided. Administer 2 hours prior or 10 hours after H<sub>2</sub> antagonists and space from locally acting antacids by at least 2 hours.</p> <p>Monitor LFTs prior to initiation, weekly for the first 8 weeks, every 2 weeks for the next month, then every 3 months thereafter.</p> <p>Women of reproductive potential should use effective contraception during treatment and for 1 month after completion of therapy.</p> <p>Males with female partners of reproductive potential should use effective contraception during treatment and for 1 week after completion of therapy.</p> <p>The drug is available only through a Risk Evaluation and Mitigation Strategies (REMS) program.</p> <p>Prescribers must be trained and certified.</p> <p>Patients must be enrolled in a registry.</p> <p>Pharmacies must be certified.</p> <p>(Daiichi Sankyo, 2021)</p> |

**TABLE 8-1.** Targeted Therapies (*Continued*)

| Drug                      | Mechanism of Action                                                                          | Route | Indications                                                                                                                                                                                                                                                                                                                                                                        | Side Effects                                                                                                                                                                                                                                                                                                   | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|----------------------------------------------------------------------------------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pralsetinib<br>(Gavreto™) | Kinase inhibitor of RET fusions (CCDC6-RET) and variations (RET V804L, RET V804M, RET M918T) | PO    | Metastatic RET fusion–positive NSCLC in adults<br>Advanced or metastatic RET–altered medullary thyroid cancer in adults and pediatric patients aged ≥ 12 years who require systemic therapy<br>Advanced or metastatic RET fusion–positive thyroid cancer in adult and pediatric patients aged ≥ 12 years who require systemic therapy and who are refractory to radioactive iodine | Common: fatigue, constipation, musculoskeletal pain, hypertension, diarrhea, neutropenia, lymphopenia, anemia, thrombocytopenia, hypophosphatemia, hyponatremia, hypocalcemia, increased ALT/AST/ALP<br>Severe: ILD/pneumonitis, hypertension, hepatotoxicity, hemorrhagic events, TLS, impaired wound healing | <p>Patients should take once daily on an empty stomach with no food at least 2 hours before or 1 hour after.</p> <p>If patients miss a dose, they should take it as soon as possible on the same day. Patients should resume the regular daily dose schedule the next day.</p> <p>If patients vomit, another dose should not be taken. Patients should take the next dose at the regularly scheduled time.</p> <p>Drug interactions exist with strong CYP3A inhibitors (including grapefruit), combined P-gp and strong CYP3A inhibitors, and strong CYP3A inducers. Hormonal contraceptives may be ineffective because of decreased exposure when used concurrently with pralsetinib.</p> <p>Optimize BP prior to initiating pralsetinib. Monitor BP at baseline, after 1 week, at least monthly thereafter, and as clinically indicated.</p> <p>Monitor ALT and AST at baseline, every 2 weeks for the first 3 months, then monthly thereafter.</p> <p>Hold for at least 5 days prior to elective surgery. Do not administer for at least 2 weeks following major surgery and until adequate wound healing.</p> <p>Women of reproductive potential should use a nonhormonal contraceptive during treatment and for 2 weeks after completion of therapy. Male patients with female partners of reproductive potential should use effective contraception during treatment and for 1 week following completion of therapy. (Blueprint Medicines, 2021b)</p> |

**TABLE 8-1.** Targeted Therapies (Continued)

| Drug                    | Mechanism of Action                                                                                                                                                                                  | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                              | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                           | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Regorafenib (Stivarga®) | Inhibits multiple membrane-bound and intracellular kinases involved in oncogenesis, tumor angiogenesis, metastasis, and tumor immunity, including RET, VEGFR, KIT, PDGFR, FGFR, RAF, BRAF, and CSF1R | PO    | Metastatic colorectal cancer previously treated with other therapies, including a fluoropyrimidine, oxaliplatin, irinotecan, anti-VEGF therapy, and anti-EGFR therapy (if RAS wild-type)<br>Locally advanced, unresectable, or metastatic GIST following previous treatment with imatinib and sunitinib<br>HCC previously treated with sorafenib                                                                         | Common: pain (including GI and abdominal pain), hand-foot skin reactions, rash, fatigue, diarrhea, decreased appetite, hypertension, infection, dysphonia, hyperbilirubinemia, fever, mucositis, weight loss, nausea<br>Black box warning: hepatotoxicity<br>Other severe adverse events: infections, hemorrhage, GI perforation or fistula, dermatologic toxicities, hypertension, cardiac ischemia and infarction, RPLS, wound healing complications | Patients should take once daily at the same time each day on days 1–21 of a 28-day cycle. It should be taken with a low-fat meal containing < 600 calories and < 30% fat. Tablets should be swallowed whole. If patients miss a dose, they should skip it and take the usual dose on the following day. Drug interactions exist with strong CYP3A4 inhibitors (including grapefruit), strong CYP3A4 inducers, and BCRP substrates. Monitor LFTs at baseline, every 2 weeks for the first 2 months, then at least monthly thereafter. Monitor BP weekly for the first 6 weeks then at least once per cycle. Hold for at least 2 weeks prior to elective surgery. Do not administer for at least 2 weeks after major surgery and until adequate wound healing. Women of reproductive potential and males with female partners of reproductive potential should use contraception during treatment and for 2 months following completion of therapy. Discard any unused tablets 7 weeks after opening the bottle. (Bayer HealthCare Pharmaceuticals, 2020) |
| Ribociclib (Kisqali®)   | Inhibits CDK4 and CDK6, leading to arrest in the G <sub>1</sub> phase of the cell cycle and reduced cell proliferation                                                                               | PO    | HR-positive, HER2-negative advanced or metastatic breast cancer, in combination with an aromatase inhibitor as initial endocrine-based therapy, in pre- or perimenopausal and postmenopausal women<br>HR-positive, HER2-negative advanced or metastatic breast cancer, in combination with fulvestrant as initial endocrine-based therapy or following disease progression on endocrine therapy, in postmenopausal women | Common: neutropenia, nausea, fatigue, diarrhea, leukopenia, alopecia, vomiting, constipation, headache, rash, cough, infections<br>Severe: ILD/pneumonitis, severe cutaneous adverse reactions, QT interval prolongation, hepatobiliary toxicity, neutropenia                                                                                                                                                                                          | Patients should take once daily (preferably in the morning), on days 1–21 followed by 7 days off (28-day cycle) with or without food. Tablets should be swallowed whole. They should not be broken, cracked, or otherwise not intact. If patients vomit or miss a dose, they should skip the dose and take the usual dose on the following day. Dose modification is required in patients with moderate or severe hepatic impairment (Child-Pugh B and C). Drug interactions exist with strong CYP3A4 inhibitors (including grapefruit), strong CYP3A4 inducers, CYP3A4 substrates, and drugs known to prolong QT interval.                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Ribociclib<br>(Kisqali®)<br>( <i>Cont.</i> ) |                                                                                 |       |                                                                                                 |                                                                                                                                                                                                                                                                                                                                                   | <p>Monitor CBC before initiating treatment and every 2 weeks for the first 2 cycles, at the beginning of each of the 4 subsequent cycles, and as clinically indicated.</p> <p>Monitor ECG at baseline, cycle 1 day 14, and at the beginning of the second cycle. Monitor electrolytes at the beginning of the cycle for 6 cycles and as clinically indicated. Avoid use with tamoxifen due to increased QT prolongation. Do not initiate in patients with QTcF <math>\geq</math> 450 msec.</p> <p>Monitor LFTs at baseline, every 2 weeks for the first 2 cycles, at the beginning of the subsequent 4 cycles, and as clinically indicated.</p> <p>Pre/perimenopausal patients should also receive a luteinizing hormone-releasing hormone agonist.</p> <p>Women of reproductive potential should use contraception during treatment and for 3 weeks following completion of therapy.</p> <p>The drug is available in blister packs containing 14 or 21 tablets.</p> <p>(Novartis Pharmaceuticals, 2020b)</p> |
| Ripretinib<br>(Qinlock®)                     | Inhibits KIT proto-oncogene receptor tyrosine kinase and PDGFR- $\alpha$ kinase | PO    | Advanced GIST in adults previously treated with 3 or more kinase inhibitors, including imatinib | <p>Common: alopecia, fatigue, nausea, abdominal pain, constipation, myalgia, diarrhea, decreased appetite, palmar-plantar erythrodysesthesia, vomiting, increased lipase, decreased phosphate</p> <p>Severe: palmar-plantar erythrodysesthesia, new primary cutaneous malignancies, hypertension, cardiac dysfunction, impaired wound healing</p> | <p>Patients should take once daily at the same time of day with or without food.</p> <p>Tablets should be swallowed whole.</p> <p>If patients miss a dose and if &lt; 8 hours have passed, they should take the missed scheduled dose.</p> <p>If patients vomit a dose, they should skip that dose and resume with next scheduled dose.</p> <p>Drug interactions exist with strong CYP3A inhibitors (including grapefruit) and moderate to strong CYP3A inducers.</p> <p>Optimize BP prior to initiating treatment. Monitor BP throughout treatment.</p> <p>Assess LVEF by echocardiogram or multi-gated acquisition scan prior to initiation and during treatment as indicated.</p> <p>Hold for at least 1 week before elective surgery and for at least 2 weeks after major surgery and until adequate wound healing.</p>                                                                                                                                                                                   |

**TABLE 8-1.** Targeted Therapies (*Continued*)

| Drug                               | Mechanism of Action                                                                                         | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Side Effects                                                                                                                                                                                                                                                                                                                                | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------|-------------------------------------------------------------------------------------------------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Romiplostim (Nplate <sup>®</sup> ) | Binds to and activates the TPO receptor to increase platelet production, a mechanism akin to endogenous TPO | SC    | Thrombocytopenia in patients with chronic immune thrombocytopenic purpura who have had an insufficient response to corticosteroids, immunoglobulins, or splenectomy<br>Immune thrombocytopenic purpura lasting for at least 6 months in pediatric patients aged $\geq 1$ year who have had an insufficient response to corticosteroids, immunoglobulins, or splenectomy<br>Adult and pediatric patients (including term neonates) acutely exposed to myelosuppressive doses of radiation | Common: arthralgia, dizziness, insomnia, myalgia, pain in extremities, abdominal pain, shoulder pain, dyspepsia, paresthesia, headache<br>Severe: increased risk of progression to AML in patients with MDS, thrombotic/thromboembolic complications, formation of neutralizing antibodies, arthralgia resulting in severe thrombocytopenia | Administer once weekly as an SC injection.<br>Adjust dose based on platelet response. Do not exceed the maximum weekly dose of 10 mcg/kg. Do not dose if platelets exceed 400,000/mm <sup>3</sup> .<br>In adults, use actual body weight at initiation of treatment to calculate the initial dose. Future adjustments are based on changes in platelet counts only (not changes in weight).<br>Calculate the dose and reconstitute with the correct volume of sterile water for injection. Gently swirl and invert the vial to reconstitute. Do not shake during reconstitution; protect reconstituted solution from light. Administer reconstituted solution within 24 hours. The administered volume may be very small. Use a syringe with graduations to 0.01 ml. Discard any unused portions of the vial.<br>If the calculated dose is < 23 mcg, dilute with 0.9% sodium chloride injection and sterile water for injection (see package insert for volume).<br>Treatment should only be used in patients whose degree of thrombocytopenia and clinical condition increase the risk for bleeding. Do not use to normalize platelet counts.<br>Obtain CBCs, including platelet counts, weekly during the dose adjustment phase of therapy, then monthly following establishment of a stable dose. Obtain CBCs, including platelet counts, weekly for at least 2 weeks following discontinuation of romiplostim.<br>The drug may cause fetal harm when administered to a pregnant woman.<br>(Amgen, 2021a) |

**TABLE 8-1.** Targeted Therapies (Continued)

| Drug                 | Mechanism of Action                                                                                 | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Side Effects                                                                                                                                                                                                                                                  | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------|-----------------------------------------------------------------------------------------------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Rucaparib (Rubraca®) | Inhibits PARP, which plays a role in DNA repair, resulting in DNA damage, apoptosis, and cell death | PO    | Maintenance treatment for recurrent epithelial ovarian, fallopian tube, or primary peritoneal cancer in a complete or partial response to platinum-based chemotherapy<br>Deleterious BRCA alteration (germline and/or somatic)–associated epithelial ovarian, fallopian tube, or primary peritoneal cancer that has been treated with 2 or more prior lines of chemotherapy<br>Pathogenic BRCA alteration (germline and/or somatic)–associated metastatic castration-resistant prostate cancer who have been treated with androgen receptor-directed therapy and a taxane-based chemotherapy | Common: nausea, fatigue, vomiting, anemia, abdominal pain, dysgeusia, constipation, decreased appetite, diarrhea, dyspnea, increased AST/ALT, thrombocytopenia, neutropenia, stomatitis, nasopharyngitis/upper respiratory infection, rash<br>Severe: MDS/AML | Patients should take twice daily (approximately 12 hours apart) with or without food. If patients miss or vomit a dose, they should skip the dose and take the next scheduled dose.<br>Drug interactions exist with CYP1A2, CYP3A, CYP2C9 (e.g., warfarin), and CYP2C19 substrates.<br>Advise patients to use appropriate sun protection because of increased susceptibility to sunburn.<br>Monitor CBC at baseline and monthly thereafter. Do not start until patients have recovered from hematologic toxicity caused by previous chemotherapy.<br>Patients receiving rucaparib for prostate cancer should also receive a gonadotropin-releasing hormone analog concurrently or should have had bilateral orchiectomy.<br>Women of reproductive potential should use contraception during treatment and for 6 months following completion of therapy. (Clovis Oncology, 2020) |

| Drug                  | Mechanism of Action                                                                                                  | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Side Effects                                                                                                                                                                                                                                                                                          | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|----------------------------------------------------------------------------------------------------------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ruxolitinib (Jakafi®) | Inhibits JAK1 and JAK2, which mediate cytokines and growth factors responsible for hematopoiesis and immune function | PO    | Intermediate- or high-risk myelofibrosis, including primary myelofibrosis, post-polycythemia vera myelofibrosis, and post-essential thrombocythemia myelofibrosis<br>Polycythemia vera in patients with an inadequate response or intolerance to hydroxyurea<br>Steroid-refractory acute GVHD in adult patients and pediatric patients aged $\geq 12$ years<br>Chronic GVHD after failure of 1 or 2 lines of systemic therapy in adult and pediatric patients aged $\geq 12$ years | Common: thrombocytopenia, anemia, bruising, dizziness, headache, edema<br>Severe: thrombocytopenia, anemia, neutropenia, infections (e.g., tuberculosis, herpes zoster, hepatitis B), nonmelanoma skin cancer, hyperlipidemia, risk of symptom exacerbation following interruption or discontinuation | Patients should take twice daily with or without food.<br>If patients miss a dose, they should skip the dose and take the next scheduled dose.<br>If patients are unable to swallow the tablets, ruxolitinib may be administered via nasogastric tube (8 French or greater). Suspend 1 tablet in 40 ml of water and stir for 10 minutes before administration via nasogastric tube, followed by a flush with 75 ml of water. Administer the suspension within 6 hours of preparation.<br>Dose modifications may be necessary in patients with moderate or severe hepatic or renal impairment.<br>Drug interactions exist with strong CYP3A4 inhibitors (including grapefruit) or fluconazole. Avoid use in patients receiving fluconazole doses $> 200$ mg daily, except in patients with acute GVHD.<br>Monitor CBC every 2–4 weeks until the dose is stabilized, then as needed.<br>Based on indication, duration of therapy, and CBC results, doses may be increased or decreased.<br>When discontinuing therapy for reasons other than thrombocytopenia, a gradual taper by 5 mg twice daily each week should occur. Sudden interruption of therapy can lead to symptom exacerbation.<br>Consider tapering the dose after 6 months of treatment in patients with GVHD who have discontinued therapeutic doses of corticosteroids.<br>Perform periodic skin examinations.<br>Assess lipid parameters approximately 8–12 weeks following initiation and as needed. (Incyte, 2020) |

**TABLE 8-1.** Targeted Therapies (Continued)

| Drug                | Mechanism of Action                                                                                                                                                                                                | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Side Effects                                                                                                                                                                                                                                                                                                                                                                     | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Selinexor (Xpovio™) | Inhibits exportin 1 (XPO1), which leads to accumulation of tumor suppressor proteins in the nucleus, reductions in several oncoproteins (e.g., c-myc, cyclin D1), cell cycle arrest, and apoptosis of cancer cells | PO    | <p>Multiple myeloma, in combination with bortezomib and dexamethasone, in patients who have received at least 1 prior therapy</p> <p>Relapsed or refractory multiple myeloma, in combination with dexamethasone, in patients who have received at least 4 prior therapies and whose disease is refractory to at least 2 proteasome inhibitors, at least 2 immunomodulatory agents, and an anti-CD38 monoclonal antibody</p> <p>Relapsed or refractory diffuse large B-cell lymphoma, not otherwise specified, including diffuse large B-cell lymphoma arising from follicular lymphoma, in adults who have received at least 2 lines of systemic therapy</p> | <p>Common: thrombocytopenia, fatigue, nausea, anemia, decreased appetite, decreased weight, diarrhea, vomiting, hyponatremia, neutropenia, leukopenia, constipation, dyspnea, upper respiratory tract infection</p> <p>Severe: thrombocytopenia, neutropenia, GI toxicity (e.g., nausea, vomiting, diarrhea), hyponatremia, serious toxicity, neurologic toxicity, cataracts</p> | <p>Patients should take once to twice weekly depending on the specific regimen. Take at approximately the same time of day. Tablets should be swallowed whole with water and not be crushed, chewed, or split. If patients vomit or miss a dose, they should skip the missed dose and take the usual dose the following day.</p> <p>Monitor CBC, standard blood chemistry, and body weight at baseline and during treatment as clinically indicated. Monitor more frequently during the first 3 months of treatment.</p> <p>Monitor serum sodium levels at baseline, during treatment, and as clinically indicated. Correct for concurrent hyperglycemia and high serum paraprotein levels.</p> <p>Advise patients to avoid taking with other medications that may cause dizziness or confusion because of risk for neurotoxicity. Avoid situations in which dizziness or a confused state may be a problem. Optimize hydration status, CBC, and concomitant medications to avoid dizziness or confusion.</p> <p>Advise patients to take a 5-HT<sub>3</sub> antagonist and/or other antiemetic agents prior to each dose and during treatment.</p> <p>Advise patients to maintain adequate fluid and caloric intake throughout treatment.</p> <p>Women of reproductive potential and males with female partners of reproductive potential should use effective contraception during treatment and for 1 week following completion of therapy.</p> <p>The drug is available as blister packs with various tablet strengths and quantities. (Karyopharm Therapeutics, 2021)</p> |

**TABLE 8-1.** Targeted Therapies (*Continued*)

| Drug                        | Mechanism of Action                        | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                         | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                          | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------|--------------------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Selpercatinib<br>(Retevmo™) | Inhibits RET, as well as VEGFR1 and VEGFR3 | PO    | Metastatic RET fusion–positive NSCLC in adults<br>Advanced or metastatic RET-variant medullary thyroid cancer in adults and pediatric patients aged ≥ 12 years who require systemic therapy<br>Advanced or metastatic RET fusion–positive thyroid cancer in adults and pediatric patients aged ≥ 12 years who require systemic therapy and whose disease is refractory to radioactive iodine (if radioactive iodine is appropriate) | Common: increased ALT/AST, increased glucose, decreased leukocytes, decreased albumin, decreased calcium, dry mouth, diarrhea, increased creatinine, increased ALP, hypertension, fatigue, edema, decreased platelets, increased total cholesterol, rash, decreased sodium, constipation<br>Severe: hepatotoxicity, hypertension, QT interval prolongation, hemorrhage, hypersensitivity, impaired wound healing, TLS | Patients should take twice daily, approximately every 12 hours, with or without food. Take with food if patients are also on a PPI. The dose is based on weight. Capsules should not be crushed or chewed. If patients miss a dose, they should only take it if it is > 6 hours until next scheduled dose. If patients vomit a dose, they should take the next dose at the regularly scheduled time. Dose modification is recommended for patients with severe hepatic impairment. Monitor ALT and AST at baseline, every 2 weeks during the first 3 months, monthly thereafter, and as clinically indicated. Monitor BP after 1 week, monthly thereafter, and as clinically indicated. Optimize BP prior to initiation. Monitor QT interval, electrolytes (e.g., potassium, magnesium, calcium), and thyroid-stimulating hormone at baseline and periodically during treatment. Withhold for at least 7 days before surgery. Do not administer for at least 2 weeks after major surgery and until adequate wound healing. Drug interactions exist with strong and moderate CYP3A inhibitors, strong and moderate CYP3A inducers, CYP2C8 and CYP3A substrates, and acid-reducing agents. If acid-reducing agent cannot be avoided, take PPI with food; take drug 2 hours before or 10 hours after administration of H <sub>2</sub> receptor antagonist or space 2 hours from locally acting antacid. If hypersensitivity occurs, hold drug and start prednisone 1 mg/kg daily or equivalent. Women of reproductive potential and males with female partners of reproductive potential should use effective contraception during treatment and for 1 week after completion of therapy.<br>(Eli Lilly and Company, 2021b) |

| Drug                       | Mechanism of Action    | Route | Indications                                                                                                        | Side Effects                                                                                                                                                                                                                                                                                                          | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------|------------------------|-------|--------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Selumetinib<br>(Koselugo™) | Inhibits MEK1 and MEK2 | PO    | Neurofibromatosis type 1 with symptomatic, inoperable plexiform neurofibromas in pediatric patients aged ≥ 2 years | Common: vomiting, rash, abdominal pain, diarrhea, nausea, dry skin, fatigue, musculoskeletal pain, fever, acneiform rash, stomatitis, headache, paronychia, pruritus<br>Severe: cardiomyopathy, ocular toxicity, GI toxicity, rash, increased CPK and rhabdomyolysis, increased vitamin E levels and risk of bleeding | <p>Patients should take twice daily on an empty stomach. They should not eat food for 2 hours before and 1 hour after each dose. Capsules should not be chewed, dissolved, or opened.</p> <p>If patients miss a dose, they should only take it if it is &gt; 6 hours until the next scheduled dose.</p> <p>If patients vomit a dose, they should take the next dose at the regularly scheduled time. Dose modifications are recommended for patients with moderate hepatic impairment (Child-Pugh B).</p> <p>Drug interactions exist with moderate to strong CYP3A4 inhibitors (including grapefruit), fluconazole, and moderate to strong CYP3A4 inducers.</p> <p>Assess LVEF prior to treatment, every 3 months during the first year, every 6 months thereafter, and as clinically indicated.</p> <p>Monitor for ocular toxicities with ophthalmic assessments prior to treatment, at regular intervals, and with new or worsening visual changes.</p> <p>An antidiarrheal agent (e.g., loperamide) should be initiated immediately after the first episode of loose stool. Patients should increase fluid intake.</p> <p>Monitor CPK prior to therapy, periodically during treatment, and when clinically indicated. Selumetinib capsules contain large quantities of vitamin E. Monitor for bleeding.</p> <p>Women of reproductive potential and males with female partners of reproductive potential should use effective contraception during treatment and for 1 week following completion of therapy.</p> <p>(AstraZeneca Pharmaceuticals, 2021b)</p> |

| Sonidegib<br>(Odomzo®)  | Inhibits Hedgehog pathway by binding to and inhibiting Smoothened, a transmembrane protein involved in Hedgehog signal transduction                                  | PO    | Locally advanced basal cell carcinoma that has recurred following surgery or radiation therapy or in patients who are not candidates for surgery or radiation therapy | Common: musculoskeletal pain, muscle spasms, alopecia, dysgeusia, fatigue, nausea, diarrhea, weight loss, decreased appetite, myalgia, abdominal pain, headache, pain, vomiting, pruritus<br>Black box warning: embryo-fetal toxicity<br>Other severe adverse events: musculoskeletal adverse reactions                                                                                         | Patients should take once daily on an empty stomach at least 1 hour before or 2 hours after a meal.<br>If patients miss a dose, they should resume dosing with the next scheduled dose.<br>Drug interactions exist with moderate to strong CYP3A inhibitors (including grapefruit) and moderate to strong CYP3A inducers.<br>Advise patients to not donate blood for at least 20 months after the final dose.<br>Monitor creatine kinase and SCr levels at baseline, periodically during treatment, and as clinically indicated.<br>The drug may cause embryo-fetal death or severe birth defects when administered to a pregnant woman. Verify pregnancy status prior to starting therapy. Women of reproductive potential should use contraception during treatment and for 20 months following completion of therapy. Males with female partners of reproductive potential should use contraception during treatment and for 8 months following completion of therapy. (Sun Pharmaceutical Industries, 2019) |
| Sorafenib<br>(Nexavar®) | Inhibits multiple kinases (including C-RAF, BRAF, KIT, FLT3, RET, VEGFR, and PDGFR-beta) thought to be involved in tumor cell signaling, angiogenesis, and apoptosis | PO    | Unresectable HCC<br>Advanced RCC<br>Locally recurrent or metastatic, progressive, differentiated thyroid carcinoma refractory to radioactive iodine treatment         | Common: diarrhea, fatigue, infection, alopecia, hand-foot skin reaction, rash, weight loss, decreased appetite, nausea, GI and abdominal pain, hemorrhage, hypertension<br>Severe: cardiac ischemia and/or infarction, hemorrhage, hypertension, dermatologic toxicities, GI perforation, risk of impaired wound healing, QT prolongation, hepatitis, impairment of thyroid-stimulating hormone | Patients should take twice daily without food at least 1 hour before or 2 hours after a meal.<br>Use with carboplatin and paclitaxel is contraindicated in patients with squamous cell lung cancer because of increased mortality risk.<br>Drug interactions exist with CYP3A4 inducers. Sorafenib may increase the activity of warfarin if taken concomitantly. Monitor INR closely. Avoid concomitant medications that prolong QTc interval.<br>Hold for at least 10 days prior to elective surgery. Do not administer for at least 2 weeks following major surgery and until adequate wound healing.<br>Monitor BP weekly for the first 6 weeks then periodically thereafter.                                                                                                                                                                                                                                                                                                                                |

| Drug                | Mechanism of Action                                                                                                                                                          | Route | Indications                                                                                                                                                                                                                                                                    | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sunitinib (Sutent®) | Inhibits multiple receptor tyrosine kinases, including PDGFR, VEGFR, KIT, FLT3, CSF1R, and RET, leading to decreased tumor cell proliferation and reduced tumor angiogenesis | PO    | GIST after disease progression while on imatinib or intolerance to imatinib<br>Advanced RCC<br>Adjuvant treatment of RCC with high risk of recurrence following nephrectomy<br>Progressive, well-differentiated, unresectable, locally advanced, or metastatic pancreatic NETs | Common: fatigue, asthenia, diarrhea, nausea, vomiting, dyspepsia, abdominal pain, hypertension, hand-foot syndrome, altered taste, anorexia, bleeding, mucositis/stomatitis, thrombocytopenia<br>Black box warning: hepatotoxicity<br>Other severe adverse events: cardiovascular events including myocardial ischemia/infarction and left ventricular dysfunction, QT prolongation and torsades de pointes, hypertension, hemorrhagic events, TLS, thrombotic microangiopathy, proteinuria, RPLS, dermatologic toxicities, thyroid dysfunction, hypoglycemia, osteonecrosis of the jaw, impaired wound healing | Patients should take daily with or without food. Schedule for administration varies based on indication.<br>Drug interactions exist with strong CYP3A4 inhibitors (including grapefruit), strong CYP3A4 inducers, and other medications that prolong QTc interval.<br>Consider preventive dentistry prior to treatment. Avoid invasive dental procedures, especially in patients receiving concurrent bisphosphonates. Hold for at least 3 weeks prior to invasive dental procedures.<br>Hold for at least 3 weeks prior to elective surgery. Do not administer for at least 2 weeks following major surgery and until adequate wound healing.<br>Monitor LFTs at baseline, during each cycle, and as clinically indicated.<br>Obtain baseline LVEF at baseline and periodically during treatment, especially in patients with cardiac risk factors.<br>Monitor and correct for hypomagnesemia and hypokalemia to reduce risk of QT prolongation. Consider monitoring ECG for patients at high risk for QTc prolongation.<br>Monitor BP at baseline and as clinically indicated.<br>Monitor urine protein, CBC, thyroid function, and serum glucose at baseline and periodically during treatment.<br>Women of reproductive potential should use effective contraception during treatment and for 4 weeks following completion of therapy. Males with female partners of reproductive potential should use contraception during treatment and for 7 weeks following completion of therapy.<br>(Pfizer, 2020c) |

| Drug                         | Mechanism of Action                                                                                                                                                                                                                              | Route | Indications                                                              | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                        | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|--------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Tebentafusp-tebn (Kimmtrak®) | Bispecific gp100 peptide; human leukocyte antigen (HLA)-A*02:01-directed T-cell receptor CD3 T-cell engager; activates polyclonal T cells to release inflammatory cytokines and cytolytic proteins, which results in direct lysis of tumor cells | IV    | Unresectable or metastatic uveal melanoma in HLA-A*02:01-positive adults | <p>Common: cytokine release syndrome, rash, fever, pruritus, fatigue, nausea, chills, abdominal pain, edema, hypotension, dry skin, headache, vomiting, decreased lymphocyte count, increased creatinine, increased glucose, increased ALT and AST, decreased hemoglobin, decreased phosphate</p> <p>Black box warning: cytokine release syndrome</p> <p>Other severe adverse events: rash, pruritus, cutaneous edema, elevated liver enzymes</p>   | <p>Select patients for treatment based on a positive HLA-A*02:01 genotyping test.</p> <p>Administer IV over 15–20 minutes once weekly. To prevent adsorption of tebentafusp-tebn to the infusion bag, albumin must be added to the bag (volume of albumin varies based on albumin concentration used).</p> <p>Admixture should be prepared in a 100 ml infusion bag containing NS plus albumin. Administer using a low protein binding 0.2-micron in-line filter.</p> <p>Monitor during the infusion and for at least 16 hours following the first 3 infusions. If patients do not experience <math>\geq</math> grade 2 hypotension during or after the third infusion, subsequent doses may be administered in an appropriate ambulatory care setting. Monitor patients for at least 30 minutes after each infusion.</p> <p>Monitor fluid status, vital signs, and oxygenation level. Ensure patients are euvolemic prior to initiating the infusions.</p> <p>Monitor for skin reactions. The median time to onset of skin reactions was 1 day.</p> <p>Monitor ALT, AST, and total bilirubin prior to start of and during treatment.</p> <p>Women of reproductive potential should use contraception during treatment and for 1 week after the final dose.</p> <p>(Immunocore Limited, 2022)</p> |
| Temsirolimus (Torisel®)      | Kinase that inhibits mTOR, resulting in G <sub>1</sub> growth arrest                                                                                                                                                                             | IV    | Advanced RCC                                                             | <p>Common: rash, asthenia, mucositis, nausea, edema, anorexia, anemia, hypertriglyceridemia, hyperglycemia, hyperlipidemia, elevated ALP, increased SCr, lymphopenia, hypophosphatemia, thrombocytopenia, elevated AST, leukopenia</p> <p>Severe: hypersensitivity reaction, hyperglycemia, hyperlipidemia, hepatic impairment, infections (PJP), ILD, bowel perforation, proteinuria/nephrotic syndrome, renal failure, abnormal wound healing</p> | <p>Administer IV over 30–60 minutes once weekly.</p> <p>Premedicate with prophylactic IV diphenhydramine 25–50 mg (or similar antihistamine) approximately 30 minutes before the start of each dose. Hypersensitivity reaction generally occurs early in the first infusion. To treat, stop infusion and administer an antihistamine (such as diphenhydramine) if not previously administered and/or an H<sub>2</sub> antagonist (IV famotidine or ranitidine) approximately 30 minutes before restarting. Temsirolimus may then be initiated at a lower infusion rate (up to 60 minutes) following a 30–60-minute observation period.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Drug                                           | Mechanism of Action | Route | Indications | Side Effects | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------------------|---------------------|-------|-------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Temsirolimus<br/>(Torisel®)<br/>(Cont.)</p> |                     |       |             |              | <p>Vial content must first be diluted with an enclosed diluent before diluting the resultant solution with 250 ml NS. Prepare temsirolimus in polyvinyl chloride (PVC)-free, non-di(2-ethylhexyl) phthalate (DEHP) glass bottles or infusion bags (polypropylene, polyolefin) and use polyethylene-lined tubing. Protect prepared product from excessive room light and sunlight and administer through an in-line filter of &lt; 5 microns within 6 hours after dilution in NS.</p> <p>Dose modifications are required in patients with mild hepatic impairment, and drug is contraindicated in patients with bilirubin &gt; 1.5 × ULN. Drug interactions exist with strong CYP3A4 inhibitors (including grapefruit) and strong CYP3A4/5 inducers.</p> <p>Angioedema has been reported in combination with angiotensin-converting enzyme inhibitors or calcium channel blockers.</p> <p>Monitor glucose and lipid profiles at baseline and during treatment. Hyperglycemia and hyperlipidemia are likely and may require treatment.</p> <p>Patients with CNS tumors or those receiving additional anticoagulation may be at increased risk for bleeding.</p> <p>Because of the risk for abnormal wound healing, use with caution in the perioperative period.</p> <p>Patients should avoid receiving live vaccines and having close contact with those who have received live vaccines.</p> <p>Older adult patients may be more likely to experience certain adverse reactions, including diarrhea, edema, and pneumonia.</p> <p>Monitor renal function and urine protein at baseline and throughout treatment.</p> <p>Women of reproductive potential and males with female partners of reproductive potential should use contraception during treatment and for 3 months following completion of therapy.</p> <p>Follow hazardous drug special handling and disposal.</p> <p>(Pfizer, 2018)</p> |

| Tepotinib<br>(Tepmetko®) | Inhibits MET, including variants with exon 14 skipping, to decrease tumor cell proliferation                                                       | PO    | Metastatic NSCLC with MET exon 14 skipping alterations                           | Common: edema, fatigue, nausea, diarrhea, musculoskeletal pain, dyspnea, decreased lymphocytes, decreased hemoglobin, decreased albumin, decreased sodium, increased gamma glutamyl transferase, increased amylase, increased ALT and AST<br>Severe: ILD/pneumonitis, hepatotoxicity                                                                                                                                           | <p>Patients should take once daily with food. If patients miss a dose, they should take it as soon as possible but not &lt; 8 hours of the next dose.</p> <p>If patients vomit a dose, they should skip the dose and take the next dose at the next regularly scheduled time.</p> <p>Drug interactions exist with strong CYP3A inducers, dual strong CYP3A inhibitors (including grapefruit), P-gp inhibitors, and certain P-gp substrates.</p> <p>Monitor LFTs prior to start of therapy, every 2 weeks for the first 3 months, then once monthly or as clinically indicated.</p> <p>Women of reproductive potential and males with female partners of reproductive potential should use contraception during treatment and for 1 week following completion of therapy.</p> <p>The drug is available in blister cards containing 10 tablets.<br/>(EMD Serono, 2021)</p>                                              |
| Tivozanib<br>(Fotivda®)  | Inhibits VEGFR1, VEGFR2, VEGFR3, and other kinases, including KIT and PDGFR-beta, to inhibit angiogenesis, vascular permeability, and tumor growth | PO    | Relapsed or refractory advanced RCC following 2 or more prior systemic therapies | Common: fatigue, hypertension, diarrhea, decreased appetite, nausea, dysphonia, hypothyroidism, cough, stomatitis, decreased sodium, increased lipase, decreased phosphate<br>Severe: hypertension and hypertensive crisis, cardiac failure, cardiac ischemia, arterial and venous thromboembolic events, hemorrhagic events, proteinuria, thyroid dysfunction, impaired wound healing, RPLS, allergic reactions to tartrazine | <p>Patients should take once daily, with or without food, on days 1–21, followed by 7 days off (28-day cycle).</p> <p>Capsules should be swallowed whole with a glass of water. Capsules should not be opened.</p> <p>If patients miss a dose, they should take the next dose at the regularly scheduled time. They should not take 2 doses at the same time.</p> <p>Dose modifications are recommended for patients with moderate hepatic impairment (total bilirubin &gt; 1.5–3 × ULN).</p> <p>Drug interactions exist with CYP3A inducers. Optimize BP prior to treatment. Monitor BP after 2 weeks of treatment and at least monthly during treatment.</p> <p>Monitor urine protein and thyroid function at baseline and periodically throughout treatment.</p> <p>Hold for at least 24 days before elective surgery. Do not administer for 2 weeks following major surgery and until adequate wound healing.</p> |

| Tivozanib<br>(Fotivda®)<br>(Cont.) |                                                                                                                              |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                          | Women of reproductive potential and males with female partners of reproductive potential should use contraception during treatment and for 1 month following completion of therapy. (Aveo Pharmaceuticals, 2021)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Trametinib<br>(Mekinist®)          | Reversible inhibitor of MEK1 and MEK2, which are upstream regulators of the ERK pathway that promotes cellular proliferation | PO    | <p>Unresectable or metastatic melanoma with <i>BRAF</i> V600E or V600K alteration, as a single agent</p> <p>Unresectable or metastatic melanoma with <i>BRAF</i> V600E or V600K alterations, in combination with dabrafenib</p> <p>Metastatic NSCLC with <i>BRAF</i> V600E alteration, in combination with dabrafenib</p> <p>Adjuvant therapy in combination with dabrafenib, for melanoma with <i>BRAF</i> V600E or V600K alterations and involvement of lymph nodes following complete resection</p> <p>Locally advanced or metastatic anaplastic thyroid cancer with <i>BRAF</i> V600E alteration, in combination with dabrafenib, if no satisfactory locoregional treatment options are available</p> | <p>Common: rash, diarrhea, lymphedema, fever, nausea, chills, vomiting, hypertension, peripheral edema, fatigue, dry skin, anorexia, edema, cough, dyspnea</p> <p>Severe: new primary malignancies (cutaneous and noncutaneous), hemorrhage, colitis and GI perforation, venous thromboembolism, cardiomyopathy, ocular toxicities, ILD/pneumonitis, serious febrile reactions, serious skin toxicity, hyperglycemia</p> | <p>Patients should take once daily on an empty stomach at least 1 hour before or 2 hours after a meal.</p> <p>If patients miss a dose, they should not take it if it is within 12 hours of the next dose.</p> <p>Serious febrile reactions can occur when used with dabrafenib. Hold for fever &gt; 104°F or fever accompanied by hypotension, rigors/chills, dehydration, or renal failure. Following the first febrile reaction, administer antipyretics as second prophylaxis. Administer corticosteroids (e.g., prednisone 10 mg daily) for at least 5 days for second or subsequent development of fever if temperature does not return to baseline within 3 days of onset or associated with complications.</p> <p>Monitor patients for new malignancies prior to initiation, during therapy, and following discontinuation.</p> <p>Monitor LVEF at baseline, after 1 month of treatment, then every 2–3 months thereafter.</p> <p>Perform ophthalmologic evaluation for any visual disturbances.</p> <p>Monitor serum glucose levels at baseline and during treatment in patients with preexisting diabetes or hyperglycemia.</p> <p>The drug may interact with radiation and lead to increased CNS, pulmonary, dermatologic, and visceral toxicity. Consider holding ≥ 3 days before and after fractionated radiation and ≥ 1 day before and after stereotactic radiosurgery.</p> <p>Women of reproductive potential should use contraception during treatment and for 4 months following completion of therapy.</p> <p>Store tablets in refrigerator.</p> <p>(National Comprehensive Cancer Network, 2022; Novartis Pharmaceuticals, 2021b)</p> |

**TABLE 8-1.** Targeted Therapies (*Continued*)

| Drug                   | Mechanism of Action                                                                   | Route | Indications                                                                                                                                                                                                                                       | Side Effects                                                                                                                                                                                                  | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------|---------------------------------------------------------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Tucatinib<br>(Tukysa®) | TKI of HER2, resulting in inhibition of MAPK and Akt signaling and cell proliferation | PO    | Advanced unresectable or metastatic HER2-positive breast cancer, in combination with trastuzumab and capecitabine, in patients who have received one or more prior anti-HER2-based regimens in the metastatic setting, including brain metastasis | Common: diarrhea, palmar-plantar erythrodysesthesia, nausea and vomiting, fatigue, hepatotoxicity, stomatitis, decreased appetite, abdominal pain, headache, anemia, rash<br>Severe: diarrhea, hepatotoxicity | <p>Patients should take twice daily, approximately 12 hours apart, with or without food. Tablets should not be chewed, crush, or split. If patients vomit or miss a dose, they should take the next dose at the regularly scheduled time.</p> <p>Dose modifications are recommended for patients with severe hepatic impairment (Child-Pugh C).</p> <p>Drug interactions exist with moderate to strong CYP3A inducers, moderate CYP2C8 inducers, strong CYP2C8 inhibitors, CYP3A substrates, and P-gp substrates.</p> <p>Administer antidiarrheal medications as indicated. Dose of tucatinib may need to be reduced, or treatment may need to be interrupted.</p> <p>Monitor LFTs at baseline, every 3 weeks during treatment, and as clinically indicated. Increased SCr may occur within the first 21 days and persist throughout treatment but is reversible upon treatment completion. Consider alternative markers of renal function if persistent elevation in SCr is observed.</p> <p>Women of reproductive potential and males with female partners of reproductive potential should use effective contraception during treatment and for 1 week after completion of therapy.</p> <p>(Seattle Genetics, 2020)</p> |

| Umbralisib (Ukoniq™)   | Inhibits multiple kinases, including PI3K-delta and casein kinase CK1-epsilon, to inhibit malignant B-cell proliferation                                                 | PO    | Relapsed or refractory marginal zone lymphoma in patients who have received at least 1 prior anti-CD20-based regimen<br>Relapsed or refractory follicular lymphoma in patients who have received at least 3 prior lines of systemic therapy | Common: increased creatinine, diarrhea/colitis, fatigue, nausea, neutropenia, increased ALT/AST<br>Severe: infections, neutropenia, diarrhea or noninfectious colitis, hepatotoxicity, severe cutaneous reactions, allergic reactions due to tartrazine                                                                                                                                                            | Patients should take once daily with food at the same time each day.<br>Tablets should not be crushed, broken, cut, or chewed.<br>If patients miss a dose, they should take it as soon as possible unless it is < 12 hours until the next scheduled dose.<br>If patients vomit a dose, they should not take an additional dose and continue with the next scheduled dose.<br>Administer PJP prophylaxis during treatment. Consider prophylactic antivirals to prevent CMV infection.<br>Monitor CBC with differential at least every 2 weeks for the first 2 months then at least weekly in patients with ANC < 1,000/mm <sup>3</sup> .<br>Monitor LFTs at baseline and during treatment.<br>Women of reproductive potential and males with female partners of reproductive potential should use effective contraception during treatment and for 1 month after completion of therapy.<br>(TG Therapeutics, 2021) |
| Vandetanib (Caprelsa®) | Inhibits multiple kinase families, including VEGFR and EGFR, interfering with oncogenesis, metastasis, tumor angiogenesis, and maintenance of the tumor microenvironment | PO    | Symptomatic or progressive, unresectable, locally advanced or metastatic medullary thyroid cancer                                                                                                                                           | Common: diarrhea/colitis, rash, acneiform dermatitis, hypertension, nausea, headache, upper respiratory tract infection, decreased appetite, abdominal pain<br>Black box warnings: QT prolongation, torsades de pointes, sudden death<br>Other severe adverse events: severe skin reactions, ILD, ischemic cerebrovascular events, hemorrhage, heart failure, diarrhea, hypertension, RPLS, impaired wound healing | Patients should take once daily with or without food.<br>Tablets should not be crushed. If patients are unable to swallow tablets, tablets can be dispersed in 2 oz of water, stirred for approximately 10 minutes, and then swallowed immediately. Any residue in the glass should be mixed with 4 oz of additional water and swallowed. Tablets will not dissolve completely. Dispersion may be administered through nasogastric or gastric tube. Follow hazardous drug handling precautions.<br>If patients miss a dose, they can take the dose up to 12 hours prior to the next dose.<br>Dose modifications are required for moderate or severe renal impairment (CrCl < 50 ml/min). Do not use in patients with moderate or severe hepatic impairment.                                                                                                                                                       |

| Vemurafenib<br>(Zelboraf®)<br>(Cont.) |                                                                                                                                                                                                                                                             |       |                                                                                                                                                                                                                        |                                                                                                                                                                                                    | <p>Perform dermatologic evaluation at baseline, then every 2 months thereafter until 6 months after discontinuation because of the risk of new primary cutaneous malignancies. Dose modifications are required based on the severity of the adverse reaction. Discontinue in patients unable to tolerate at least 480 mg twice daily.</p> <p>Monitor and correct for hypocalcemia, hypomagnesemia, and hypokalemia to reduce risk of QT prolongation. Monitor ECG and electrolytes (potassium, magnesium, calcium) at baseline, 15 days after the start of treatment, monthly during the first 3 months of treatment, and then at least every 3 months thereafter. Avoid use in patients with a QTc &gt; 500 ms and hold therapy if QTc exceeds this time during treatment.</p> <p>Monitor LFTs at baseline and monthly during treatment.</p> <p>Monitor SCr at baseline and periodically during treatment.</p> <p>The drug increases sensitivity to sun exposure. Instruct patients to avoid sun exposure and wear protective clothing and use broad-spectrum sunscreen and lip balm (SPF ≥ 30) when outdoors.</p> <p>Women of reproductive potential should use contraception during treatment and for 2 weeks following completion of therapy. (Genentech, 2020c)</p> |
| Venetoclax<br>(Venclexta®)            | Inhibits B-cell lymphoma 2 protein, an antiapoptotic product; restores apoptosis by binding to B-cell lymphoma 2 protein, displacing proapoptotic proteins (e.g., Bim), triggering mitochondrial outer membrane permeabilization and activation of caspases | PO    | CLL or SLL<br>Newly diagnosed AML, in combination with azacitidine or decitabine or low-dose cytarabine, in adult patients aged ≥ 75 years or with comorbidities that preclude use of intensive induction chemotherapy | <p>Common: neutropenia, anemia, thrombocytopenia, diarrhea, nausea, upper respiratory tract infection, fatigue, cough, musculoskeletal pain, edema</p> <p>Severe: TLS, neutropenia, infections</p> | <p>Patients should take once daily with a meal and water at approximately the same time each day.</p> <p>Tablets should not be chewed, crushed, or broken.</p> <p>The dose should be increased according to a ramp-up schedule (typically over 5 weeks for CLL/SLL and over 3–4 days for AML).</p> <p>If patients miss a dose, they can take it up to 8 hours from the time it is normally taken. If missed by &gt; 8 hours, they should skip that dose and resume with next scheduled dose.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Drug                                      | Mechanism of Action | Route | Indications | Side Effects | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Venetoclax<br>(Venclexta®)<br>(Cont.)     |                     |       |             |              | <p>If patients vomit a dose, they should take the next scheduled dose, not an additional dose. Dose modifications are recommended for patients with severe hepatic impairment (Child-Pugh C).</p> <p>Drug interactions exist with moderate to strong CYP3A4 inhibitors (including grapefruit), azole antifungals, moderate to strong P-gp inhibitors, moderate to strong CYP3A4 inducers, and P-gp substrates. Take P-gp substrates at least 6 hours before venetoclax.</p> <p>Concurrent use of CYP3A4 inhibitors during the ramp-up phase is contraindicated. Assess patient risk for TLS. Provide prophylactic hydration and antihyperuricemic (e.g., allopurinol) prior to initiation. Patients with high tumor burden are recommended to be admitted for administration of the first dose of weeks 1 and 2.</p> <p>Patients with AML should have a WBC count &lt; 25,000/mm<sup>3</sup> prior to initiation. Cyto reduction prior to treatment may be required. Patients should be well hydrated during the ramp-up phase to prevent TLS (approximately 56 oz water daily). Patients should drink plenty of water starting 2 days before, on the day of the first dose, and each time the dose is increased.</p> <p>Monitor TLS labs frequently during the first treatment cycle (frequency depends on patient's risk for TLS).</p> <p>Monitor CBC with differential regularly during treatment.</p> <p>Do not administer live attenuated vaccines prior to, during, or after treatment.</p> <p>Women of reproductive potential should use contraception during treatment and for 30 days following completion of therapy.</p> <p>Ramp-up cycle for CLL is available as a starting pack with the first 4 weeks of therapy. (Genentech, 2020b)</p> |

**TABLE 8-1.** Targeted Therapies (Continued)

| Drug                      | Mechanism of Action                                                                                                                    | Route | Indications                                                                                                                                                                         | Side Effects                                                                                                                                                                                                                                                                    | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Vismodegib<br>(Erivedge®) | Inhibits the Hedgehog pathway via binding to and inhibiting Smoothed, a transmembrane protein involved in Hedgehog signal transduction | PO    | Metastatic basal cell carcinoma or locally advanced basal cell carcinoma that has recurred following surgery or in patients who are not candidates for surgery or radiation therapy | Common: muscle spasm, alopecia, dysgeusia, weight loss, fatigue, nausea, diarrhea, anorexia, constipation, arthralgia, vomiting, ageusia<br>Black box warning: embryo-fetal toxicity<br>Other severe adverse events: cutaneous adverse reactions, premature fusion of epiphyses | Patients should take once daily with or without food.<br>Capsules should not be crushed or chewed.<br>If patients miss a dose, they should take the next regularly scheduled dose at the usual time.<br>Patients may not donate blood during treatment and for at least 24 months after completing treatment. Men should not donate semen during treatment and for 3 months after therapy.<br>Because of teratogenicity, determine pregnancy status of women of childbearing age within 7 days prior to starting therapy. Inform male patients of fetal risk and instruct on use of contraception during treatment.<br>Women of reproductive potential should use contraception during treatment and for 24 months after completion of therapy. Males with female partners of reproductive potential should use contraception during treatment for 3 months following completion of therapy.<br>(Genentech, 2020a)                                     |
| Vorinostat<br>(Zolinza®)  | Inhibits HDAC, leading to accumulation of acetyl groups on histone lysine residues, resulting in cell cycle arrest and/or apoptosis    | PO    | Cutaneous manifestations of cutaneous T-cell lymphoma in patients who have progressive, persistent, or recurrent disease following 2 systemic therapies                             | Common: fatigue, diarrhea, nausea, thrombocytopenia, anorexia, dysgeusia<br>Severe: pulmonary embolism/deep vein thrombosis, thrombocytopenia, anemia, nausea, vomiting, diarrhea, hyperglycemia, clinical chemistry abnormality (creatinine, magnesium, calcium), GI bleeding  | Patients should take once daily with food.<br>Capsules should not be opened or crushed.<br>Dose modifications are recommended for mild or moderate hepatic impairment.<br>Use with other HDAC inhibitors (e.g., valproic acid) increases the risk for GI bleeding.<br>Use in combination with warfarin may lead to elevated INR. Monitor INR frequently.<br>Patients may require antiemetics, antidiarrheals, fluids, and electrolytes. It is recommended that patients drink 2 L of fluid daily to prevent dehydration.<br>Monitor CBC, glucose, electrolytes, SCr, magnesium, and calcium every 2 weeks for the first 2 months, and monthly thereafter.<br>Women of reproductive potential should use contraception during treatment and for 6 months following completion of therapy. Males with female partners of reproductive potential should use contraception during treatment for 3 months following completion of therapy.<br>(Merck, 2020) |

**TABLE 8-1.** Targeted Therapies (*Continued*)

| Drug                                  | Mechanism of Action                                                                                                                                                                   | Route | Indications                                                                                                                                                                                                        | Side Effects                                                                                                                                                                                                                                                                                            | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Zanubrutinib (Brukinsa <sup>®</sup> ) | Inhibits Bruton tyrosine kinase, which is a signaling molecule of the B-cell antigen receptor and cytokine receptor pathways, leading to inhibition of malignant B-cell proliferation | PO    | Mantle cell lymphoma previously treated with at least 1 prior therapy<br>Waldenström macroglobulinemia<br>Relapsed or refractory marginal zone lymphoma previously treated with at least 1 anti-CD20-based regimen | Common: decreased ANC, lymphocyte, hemoglobin, and platelet counts; upper respiratory tract infection; rash; diarrhea; musculoskeletal pain; increased ALT, increased bilirubin, increased blood uric acid<br>Severe: hemorrhage, infection, cytopenia, second primary malignancies, cardiac arrhythmia | <p>Patients should take once or twice daily (depending on the dose) with or without food.</p> <p>Capsules should be swallowed whole. Capsules should not be opened, broken, or chewed.</p> <p>If patients miss a dose, they should take it as soon as possible on the same day with a return to the normal schedule the following day.</p> <p>Dose modifications are recommended for severe hepatic impairment.</p> <p>Monitor for hemorrhage, infections, cytopenias, second primary malignancies (particularly skin cancer), and cardiac arrhythmia (atrial fibrillation and atrial flutter).</p> <p>Drug interactions exist with moderate or strong CYP3A inhibitors and moderate or strong CYP3A inducers.</p> <p>Monitor CBC regularly during treatment.</p> <p>Asymptomatic lymphocytosis should not be regarded as an adverse effect and patients should continue taking zanubrutinib.</p> <p>Patients should use sun protection.</p> <p>Consider holding 3–7 days presurgery and postsurgery based on risk–benefit analysis.</p> <p>Women of reproductive potential and males with female partners of reproductive potential should use effective contraception for at least 1 week following completion of therapy.</p> <p>(BeiGene, 2021)</p> |

| Drug                       | Mechanism of Action                                                                                                                                                                                    | Route | Indications                                                                                                                                                                   | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ziv-aflibercept (Zaltrap®) | Acts as a soluble receptor and binds to VEGF- $\alpha$ , VEGF- $\beta$ , and placental growth factor (known as PlGF), leading to inhibition of neo-vascularization and decreased vascular permeability | IV    | In combination with 5-fluorouracil, leucovorin, and irinotecan (FOLFIR) for metastatic colorectal cancer that is resistant to or progressive during oxaliplatin-based therapy | Common: leukopenia, neutropenia, thrombocytopenia, diarrhea, proteinuria, stomatitis, increased ALT/AST, fatigue, weight loss, anorexia, epistaxis, abdominal pain, dysphonia, elevated SCr, headache<br>Severe: hemorrhage, GI perforation, impaired wound healing, fistula formation, hypertension, arterial thromboembolic events (e.g., transient ischemic attack, cerebrovascular accident, angina), proteinuria, nephrotic syndrome, thrombotic microangiopathy, neutropenia, infection, diarrhea, dehydration, RPLS | Administer infusions over 1 hour through a 0.2-micron polyethersulfone filter prior to any of the other drugs used in the chemotherapy regimen.<br>Do not use with filters made from polyvinylidene fluoride or nylon.<br>Dilute in NS or 5% dextrose in water to a concentration of 0.6–8 mg/ml.<br>Diluted solution may be stored in refrigeration for up to 24 hours and at room temperature for up to 8 hours.<br>Hold dosing at least 4 weeks prior to elective surgery and do not resume for at least 4 weeks following major surgery and until the wound is fully healed.<br>Monitor BP every 2 weeks during treatment or more frequently as clinically indicated. Hold dosing if recurrent or severe hypertension occurs and restart at a lower dose once BP is controlled.<br>Monitor urine protein and hold dosing if proteinuria > 2 g/24 hours; restart once proteinuria < 2 g/24 hours. Dose reduction is recommended for recurrent proteinuria > 2 g/24 hours.<br>Monitor CBC at baseline and prior to each cycle of treatment.<br>Women of reproductive potential should use contraception during treatment and for 1 month following completion of therapy.<br>(Sanofi-Aventis U.S., 2020) |

Note. For hazardous oral medications, additional precautions should be taken to prevent exposure when handling or manipulating. Refer to Chapter 12. Review package inserts for dosing and prescribing information.

ABL1—Abelson tyrosine-protein kinase 1; ALCL—anaplastic large cell lymphoma; ALK—anaplastic lymphoma kinase; ALL—acute lymphoblastic leukemia; ALP—alkaline phosphatase; ALT—alanine transaminase; AML—acute myeloid leukemia; ANC—absolute neutrophil count; AST—aspartate transaminase; BCR—breakpoint cluster region protein; BCRP—breast cancer resistance protein; BP—blood pressure; BRCA—breast cancer gene; BSA—body surface area; CBC—complete blood count; CD—cluster of differentiation; CDK—cyclin-dependent kinase; CHF—congestive heart failure; CLL—chronic lymphocytic leukemia; CML—chronic myeloid leukemia; CMV—cytomegalovirus; CNS—central nervous system; CPK—creatine phosphokinase; CrCl—creatinine clearance; CSF1R—colony-stimulating factor 1 receptor; CYP—cytochrome P450; ECG—electrocardiogram; EGFR—epidermal growth factor receptor; ERK—extracellular signal-related kinase; EZH2—enhancer of zeste homolog 2; FDA—U.S. Food and Drug Administration; FGFR—fibroblast growth factor receptor; 5-HT<sub>3</sub>—5-hydroxytryptamine-3; FLT—FMS-like tyrosine kinase; GI—gastrointestinal; GIST—gastrointestinal stromal tumor; GVHD—graft versus host disease; HCC—hepatocellular carcinoma; HDAC—histone deacetylase; HER—human epidermal growth factor receptor; HR—hormone receptor; H<sub>2</sub>—histamine receptor 2; HRD—homologous recombination deficiency; IDH—iscitrate dehydrogenase; ILD—interstitial lung disease; INR—international normalized ratio; ITD—internal tandem duplication; IV—intravenous; JAK—Janus kinase; KRAS—Kirsten rat sarcoma viral oncogene homolog; LFTs—liver function tests; LVEF—left ventricular ejection fraction; MAPK—mitogen-activated protein kinase; MDS—myelodysplastic syndrome; MEK—mitogen-activated extracellular signal regulated kinase; MET—mesenchymal-epithelial transition factor; mTOR—mammalian target of rapamycin; NET—neuroendocrine tumor; NS—normal saline; NSCLC—non-small cell lung cancer; NTRK—neurotrophic tyrosine receptor kinase; PARP—poly(ADP-ribose) polymerase; PDGF—platelet-derived growth factor; PDGFR—platelet-derived growth factor receptor; P-gp—P-glycoprotein; Ph—Philadelphia chromosome; PI3K—phosphoinositide 3-kinase; PJP—*Pneumocystis jirovecii* pneumonia; PO—by mouth; PPI—proton pump inhibitor; RCC—renal cell carcinoma; RET—rearranged during transfection kinase; RON—Recepteur d'Origine Nantais; RPLS—reversible posterior leukoencephalopathy syndrome; SC—subcutaneous; SCr—serum creatinine; SLL—small lymphocytic lymphoma; TKI—tyrosine kinase inhibitor; TLS—tumor lysis syndrome; TPO—thrombopoietin; TRK—tropomyosin receptor tyrosine kinase; UGT—uridine diphosphate-glucuronosyltransferase; ULN—upper limit of normal; VEGF—vascular endothelial growth factor; VEGFR—vascular endothelial growth factor receptor

**FIGURE 8-1.** Basic Principles of Tyrosine Kinases

In cancer cells, a metabolic property is present that is not present in healthy cells. This property leads to enhanced activity of various pathways associated with cellular growth and proliferation.

- (1) The mitogen-activated protein kinase (MAPK) signaling pathway plays an important role in cell proliferation and differentiation.
  - (2) Activation of BRAF within the MAPK pathway leads to downstream signaling of MEK1, MEK2, and extracellular signal-regulated kinases (ERKs).
  - (3) Driver variants in the *BRAF* gene lead to constitutive activation of signaling via this pathway.
  - (4) The best-studied driver variant of *BRAF* occurs at codon 600 and is known as V600 (V600E, V600K); it is observed in approximately 50% of patients with melanoma, 25% with anaplastic thyroid cancer, and 2%–8% with non-small cell lung cancer.
  - (5) The use of combination BRAF and MEK inhibitors maximizes inhibition of the MAPK pathway and decreases the development of resistance compared to monotherapy with BRAF inhibitors (Subbiah et al., 2020).
  - (6) Examples of BRAF inhibitors include dabrafenib (oral), vemurafenib (oral), and encorafenib (oral). Examples of MEK inhibitors include cobimetinib (oral), trametinib (oral), and binimetinib (oral).
- d) B-cell receptor pathway inhibitors
- (1) Signaling mediated by B-cell receptors has a key role in the proliferation of B-cell neoplasms.
  - (2) Stimulation of the B-cell receptor leads to activation of spleen tyrosine kinase (SYK) and Lyn kinase, which activates Bruton tyrosine kinase (BTK) and phosphatidylinositol 3-kinase (PI3K).
  - (3) Inhibiting these pathways in B-cell malignancies leads to decreased cell proliferation (Crisci et al., 2019).
  - (4) Examples of BTK inhibitors include zanubrutinib (oral), acalabrutinib (oral), and ibrutinib (oral). Examples of PI3K inhibitors include idelalisib (oral), copanlisib (IV), duvelisib (oral), and umbralisib (oral).
- e) Cyclin-dependent kinase (CDK) inhibitors
- (1) CDKs are regulatory enzymes that control cell cycle transitions and eventual cell division.
  - (2) The transition from G<sub>1</sub> to S phase is controlled by the retinoblastoma protein through binding to *E2F* transcription factors, which halts the cycle cell at this stage. Inactivation of retinoblastoma leads to cell cycle progression.
  - (3) The binding of cyclin D to either CDK4 or CDK6 results in phosphorylation of retinoblastoma protein, release of *E2F* transcription factors, and cell cycle progression.
  - (4) Inhibition of CDK4/6 causes cell cycle arrest in the G<sub>1</sub> phase, leading to decreased cell viability.
  - (5) Estrogen has been shown to increase the rate of progression from the G<sub>1</sub> to S phase; therefore, targeting the CDK4/6 and retinoblastoma protein interaction is beneficial in estrogen receptor–positive breast cancer (Spring et al., 2019).
  - (6) Examples include abemaciclib (oral), palbociclib (oral), and ribociclib (oral).
- f) EGFR inhibitors
- (1) EGFR, a group of four related receptor tyrosine kinases, acts as a key mediator in cell signaling pathways, such as RAS/RAF/MEK, STAT, and PI3K/Akt/mTOR. It promotes cell proliferation, inhibition of apoptosis, angiogenesis, and metastatic spread.
  - (2) Overexpression of EGFR has been associated with many tumors, such as head and neck, breast, lung, colorectal, prostate, kidney, pancreatic, ovarian, and brain cancers.

**FIGURE 8-2.** Epidermal Growth Factor Receptor and Vascular Endothelial Growth Factor Receptor Pathways

Examples of targeted pathways. In these pathways, the extracellular receptor is activated, leading to a cascade of events resulting in enhanced gene expression, cell proliferation, cell survival, and migration.

EGFR—epidermal growth factor receptor; VEGFR—vascular endothelial growth factor receptor

Note. From "Growth Factor Receptors and Apoptosis Regulators: Signaling Pathways, Prognosis, Chemosensitivity and Treatment Outcomes of Breast Cancer," by S. Sarkar and M. Mandal, 2009, *Breast Cancer: Basic and Clinical Research*, 3, p. 52 (<https://doi.org/10.4137/bcbcr.s2492>). Licensed under Creative Commons Attribution 4.0 International License (CC-BY 4.0) (<https://creativecommons.org/licenses/by/4.0>).

- (3) Small molecule EGFR TKIs reversibly compete with adenosine triphosphate (ATP) for binding to the intracellular kinase domain, subsequently inhibiting EGFR autophosphorylation and downstream signaling.
  - (4) EGFR T790M variants lead to tumor resistance against first- and second-generation EGFR TKIs but can be targeted using third-generation TKIs (Ayati et al., 2020).
  - (5) Examples include afatinib (oral), erlotinib (oral), gefitinib (oral), and osimertinib (oral).
- g) Epigenetic mechanisms
- (1) Epigenetics is the study of heritable gene expression changes without changes to the nucleotide sequence of genes.
    - (a) This process is regulated by a variety of chemical-modifying enzymes and recognition proteins, including DNA methyltransferases, histone acetyltransferases, histone deacetylases (HDACs), methyl-binding domain proteins, and others (Zhong et al., 2021).
  - (2) HDAC inhibitors
    - (a) HDACs are epigenetic regulators that remove acetyl groups from the N-acetylated lysine residues of histones and nonhistone substrates.
  - (b) Epigenetic variants in cancer cells modify the structure and stability of the genome to initiate tumor growth and propagate carcinogenesis (Furtado et al., 2019). Available agents of epigenetic targets include HDAC inhibitors, enhancer of zeste homolog 2 (EZH2) inhibitors, and isocitrate dehydrogenase (IDH) inhibitors (Zhong et al., 2021).

- (b) Upregulation of HDAC has been observed in several malignancies, such as T-cell lymphoma and multiple myeloma, and causes alteration of oncogene and tumor suppressor gene transcription.
- (c) Inhibition of HDAC enables histone acetylation to increase by blocking the catalytic sites of HDACs, leading to growth arrest and apoptosis (Furtado et al., 2019).
- (d) Examples include belinostat (oral), panobinostat (oral), romidepsin (parenteral), and vorinostat (oral).
- (3) EZH2 inhibitors
  - (a) EZH2 is a member of a family of polycomb group genes, an important epigenetic regulator that represses transcription.
  - (b) EZH2 regulates cell cycle progression, autophagy, apoptosis, and cell senescence.
  - (c) It is also critical for promoting DNA damage repair.
  - (d) Alterations or abnormal expression of EZH2 may result in cancer initiation, progression, metastasis, metabolism, and drug resistance (Duan et al., 2020).
  - (e) An example is tazemetostat (oral).
- (4) IDH inhibitors
  - (a) The IDH family of enzymes consists of three isoforms (IDH1–IDH3) involved in many important cellular processes, including mitochondrial oxidative phosphorylation, glutamine metabolism, lipogenesis, glucose sensing, and regulation of cellular redox status (Idbaih & Touat, 2016).
  - (b) IDH1 and IDH2 driver variants are found in 20% of acute myeloid leukemia cases and occur more frequently in older individuals.
  - (c) These variants lead to the conversion of alpha-ketoglutarate into an oncogenic metabolite, R-2-hydroxyglutarate (R2HG), which accumulates, causes extensive epigenetic changes, and ultimately impairs cellular differentiation.
  - (d) IDH inhibitors block the activity of variant IDH to lower levels of R2HG, which induces blast differentiation (Alfayez & DiNardo, 2019).
  - (e) Examples include ivosidenib (oral IDH1 inhibitor) and enasidenib (oral IDH2 inhibitor).
- h) Exportin 1 (XPO1) inhibitors
  - (1) Proper cellular function requires the transport of larger molecules (including RNAs and proteins) between the nucleus and cytoplasm by transport receptors.
  - (2) XPO1 is a major transport receptor responsible for transporting multiple RNA species and proteins, including tumor suppressors (p53, BRCA1, BRCA2, and p27) and oncoproteins from the nucleus to the cytoplasm.
  - (3) The mechanism of action of XPO1 inhibitors has not been fully elucidated; however, it is postulated that it involves nuclear export blockade of tumor suppressor proteins (Azizian & Li, 2020).
  - (4) An example is selinexor (oral).
- i) Fibroblast growth factor receptor (FGFR) inhibitors
  - (1) FGFRs are expressed on cell surface membranes and consist of four isoforms (FGFR1–FGFR4).
  - (2) Binding fibroblast growth factors to these receptors promotes embryogenesis, angiogenesis, and tissue regeneration.
  - (3) Alterations of this process, through FGFR genetic substitutions, insertions, deletions, duplications, or fusions, lead to constitutive activation of the receptor through ligand-independent activation, which promotes the oncogenic process.
  - (4) FGFR alterations have been found in various solid tumor malignancies, including urothelial carcinoma, cholangiocarcinoma, endometrial cancer, ovarian cancer, breast cancer, non-small cell lung cancer, head and neck cancer, and glioblastomas (Weaver & Bossaer, 2021).
  - (5) Examples include erdafitinib (oral) and pemigatinib (oral).
- j) FMS-like tyrosine kinase 3 (FLT3) inhibitors
  - (1) FLT3 is a receptor tyrosine kinase expressed typically by hematopoietic stem or progenitor cells. It plays a key role in early-stage myeloid and lymphoid lineage development.
  - (2) Cell proliferation, survival, and differentiation are promoted by the binding of an extracellular ligand and activation of FLT3 signaling pathways, including PI3K, RAS, and STAT5.
  - (3) Alterations in FLT3 occur in approximately 30% of new diagnoses of acute myeloid

leukemia as internal tandem duplications or point variants in the tyrosine kinase domain.

- (4) Both variants lead to constitutive activation of the FLT3 kinase, resulting in proliferation and survival of acute myeloid leukemia (Daver et al., 2019).
  - (5) Examples include midostaurin (oral) and gilteritinib (oral).
- k) Hedgehog pathway inhibitors
- (1) The Hedgehog pathway is critical for embryonic development and tissue regeneration.
  - (2) Activation of the Hedgehog pathway causes the release of ligands that bind and suppress the transmembrane receptor Patched-1. Patched-1 is internalized from the cell membrane and degraded, resulting in the release of a transmembrane transducer known as Smoothened.
  - (3) Active Smoothened ultimately promotes the expression of target genes related to cell proliferation, survival, and differentiation.
  - (4) Abnormal signaling of the Hedgehog pathway can be caused by various mechanisms, including Hedgehog ligand upregulation and Patched-1 and Smoothened variants.
  - (5) The Hedgehog pathway has become a target for cancer therapies because of its close association with oncogenesis and the progression of cancers, including basal cell carcinoma and acute myeloid leukemia (Zhong et al., 2021).
  - (6) Examples include sonidegib (oral), vismodegib (oral), and glasdegib (oral).
- l) Human epidermal growth factor receptor (HER) 2 inhibitors
- (1) HER2, an oncoprotein situated on the long arm of chromosome 17, is part of the EGFR family, which includes EGFR (also known as HER1), HER2, HER3, and HER4.
  - (2) These receptors control cell growth, survival, differentiation, and migration.
  - (3) Overexpression and amplification of these receptors occur in 20%–25% of patients with breast cancer and may also occur in other cancers, such as gastric, lung, and colorectal. This results in dysregulated signaling through the PI3K and MAPK signaling pathways, leading to cell cycle progression and proliferation (Schlam & Swain, 2021).

- (4) Examples include lapatinib (oral), neratinib (oral), and tucatinib (oral).

m) Janus kinase (JAK) inhibitors

- (1) The JAK/STAT signaling pathway regulates many key cellular processes, including innate and adaptive immune responses, cell proliferation, differentiation, and apoptosis.
- (2) Binding of a ligand to transmembrane receptors initiates signaling of this pathway through activation of JAKs, subsequently leading to recruitment of specific signal transducer and activator of transcription (STAT) proteins.
- (3) STATs are phosphorylated by JAKs, resulting in translocation of STATs to the nucleus via importins, which bind to DNA and activate the transcription of target genes.
- (4) Abnormal signaling of the JAK/STAT pathway is primarily caused by variations and polymorphisms in JAK and STAT genes observed in the pathogenesis of several cancers (e.g., myeloproliferative neoplasms, leukemia) and other diseases (e.g., inflammatory skin conditions, autoimmune disorders).
- (5) JAK inhibitors suppress the enzymatic activity of JAK family members, inhibiting this signaling pathway (Moura & Fonseca, 2021).
- (6) Examples include ruxolitinib (oral), fedratinib (oral), and tofacitinib (oral).

n) Kirsten rat sarcoma viral oncogene homolog (KRAS) inhibitors

- (1) *KRAS* is the most frequently altered oncogene in human cancers.
- (2) It encodes for guanosine triphosphatase (GTPase), alternating between active and inactive states to regulate signal transduction.
- (3) These driver variants are typically associated with resistance to targeted therapies and poor treatment outcomes.
- (4) The *KRAS* p.G12C variant occurs in approximately 13% of patients with non-small cell lung cancer and 1%–3% of other solid tumors.
- (5) This oncoprotein enhances the proliferation and survival of tumor cells (Hong et al., 2020).
- (6) An example is sotorasib (oral).

o) Mammalian target of rapamycin (mTOR) kinase inhibitors

- (1) As a dual-specificity protein kinase, mTOR phosphorylates serine/threonine and tyro-

- sine residues to regulate cell growth, survival, metabolism, and immunity.
- (2) It activates multiple targets, such as ribosomal protein S6 kinase B-1, eukaryotic translation initiation factor 4E-binding protein 1, Akt, protein kinase C, and type-1 insulin-like growth factor.
  - (3) Deregulated mTOR activity is associated with various malignancies, including breast, prostate, lung, liver, and renal carcinomas.
  - (4) Upregulation of this signaling contributes to tumor growth and progression by promoting growth factor receptor signaling, angiogenesis, glycolytic metabolism, lipid metabolism, cancer cell migration, and suppression of autophagy.
  - (5) Several mTOR inhibitors with various mechanisms of action have been developed to combat this aberrant pathway (Hua et al., 2019).
  - (6) Examples include everolimus (oral) and temsirolimus (parenteral).
- p) Mediators of apoptosis B-cell lymphoma 2 (BCL2) inhibitors (BH3-mimetics)
- (1) Overexpression of BCL2 protein functions to protect cells from apoptosis through direct binding of the two main cell death effector proteins, BAX and BAK. BCL2 and other prosurvival proteins are naturally antagonized by the proapoptotic BH3-only protein subfamily.
  - (2) The balance of activity between prosurvival proteins and BH3-only proapoptotic proteins determines whether a cell will survive or undergo apoptosis.
  - (3) Malignant cells with upregulated BCL2 are protected from apoptosis despite cellular stresses.
  - (4) BH3-mimetics bind to a prosurvival protein such as BCL2 and inhibit the ability of BCL2 to bind to BAX or BAK, which allows permeability of the mitochondria, release of cytochrome C, and caspase activation, which all lead to apoptosis (Roberts, 2020).
  - (5) Examples include venetoclax (oral).
- q) Mesenchymal-epithelial transition factor (MET) inhibitors
- (1) *MET* is an oncogene encoding a tyrosine kinase receptor involved with embryogenesis, tumor growth, and metastasis.
  - (2) The dysregulation of the MET/hepatocyte growth factor (HGF) pathway is found in various solid tumor malignancies, including non-small cell lung, breast, cervical, stomach, and colon cancers. It is often associated with a poor prognosis (Liang & Wang, 2020).
  - (3) Examples include capmatinib (oral) and tepotinib (oral).
- r) Neurotrophin tyrosine receptor kinase (NTRK) inhibitors
- (1) *NTRK* gene fusions encode for the neurotrophin receptors tropomyosin receptor tyrosine kinase (TRK) A, TRKB, and TRKC and are known oncogenic drivers in many adult and pediatric malignancies.
  - (2) Ligand-binding activation of these receptors activates multiple intracellular pathways, including MAPK, PI3K, and protein kinase C, which ultimately regulate the transcription of genes involved in the differentiation and survival of neurons.
  - (3) Treatment of tumors harboring *NTRK* fusion with a TRK inhibitor inhibits the MAPK, PI3K/Akt, protein kinase C and STAT3 pathways (Cocco et al., 2018).
  - (4) Examples include larotrectinib (oral) and entrectinib (oral).
- s) Poly(ADP-ribose) polymerase (PARP) inhibitors
- (1) The PARP family of proteins primarily functions to repair damaged DNA.
  - (2) In response to single-strand DNA break, PARP1 recruits proteins to repair the DNA.
  - (3) In the absence of PARP, these single-strand breaks progress to double-strand breaks, which may be poorly repaired, especially in tumors with germline or somatic pathogenic variants in *BRCA1* or *BRCA2*.
  - (4) The combination of a double-stranded break in a *BRCA1/BRCA2*-altered cell and PARP inhibition results in the cell's inability to repair the damaged DNA, leading to cell death.
  - (5) Cells with *BRCA1/BRCA2* pathogenic variants are inherently more susceptible to PARP inhibition than wild-type cells; however, patients with wild-type *BRCA1/BRCA2* have benefited from PARP inhibition in some clinical trials (Hennes et al., 2020).
  - (6) Examples include olaparib (oral), rucaparib (oral), niraparib (oral), and talazoparib (oral).
- t) Proteasome inhibitors
- (1) Proteasomes are necessary for healthy cellular functions and to degrade misfolded or altered proteins.

- (2) The ubiquitin/proteasome pathway regulates fundamental processes, including apoptosis, cell growth and proliferation, DNA repair, unfolded protein response, and immune response.
  - (3) It removes damaged and misfolded proteins by first targeting the protein for degradation through ubiquitination. The protein then passes through the 20S proteasome, where it is degraded into small oligopeptides.
  - (4) Proteasome inhibitors prevent the degradation of ubiquitinated proteins. By inhibiting the translocation of the misfolded proteins out of the endoplasmic reticulum, the cell is under stress leading to cell cycle arrest and subsequent apoptosis (Fricker, 2020).
  - (5) Examples include bortezomib (subcutaneous or IV), carfilzomib (IV), and ixazomib (oral).
- u) Rearranged during transfection (RET) kinase inhibitors
- (1) The *RET* proto-oncogene encodes for a transmembrane receptor tyrosine kinase that plays a role in healthy embryonic development.
  - (2) Fusions between sequences that encode the kinase domain result in constitutively active, ligand-independent signaling and oncogenesis.
  - (3) RET fusions are typically mutually exclusive from other cancer drivers and lead to the dependence of the tumor cell on the oncogenic kinase.
  - (4) These fusions have been identified in 1%–2% of patients with non-small cell lung cancer and are associated with a high risk of developing brain metastases (Drilon et al., 2020).
  - (5) Examples include selpercatinib (oral) and pralsetinib (oral).
- v) ROS proto-oncogene 1 (ROS1) inhibitors
- (1) *ROS1* is a proto-oncogene related to the ALK, leukocyte receptor tyrosine kinase, and insulin receptor families.
  - (2) Rearrangements in *ROS1* are estimated to occur in 1%–2% of non-small cell lung cancers.
  - (3) Fusion of the ROS1 kinase with a partner leads to constitutive activation of the ROS1 kinase domain and phosphorylation and activation of downstream signaling through the MAPK/ERK, STAT3, and Akt pathways.
  - (4) Inhibition of ROS1 has been shown to decrease phosphorylation of these signals.
  - (5) Targeted agents against ALK fusions often also inhibit ROS1 due to the structural similarity of the kinase domains of the ROS1 and ALK proteins (Giustini & Bazhenova, 2020).
  - (6) Examples include crizotinib (oral), ceritinib (oral), cabozantinib (oral), entrectinib (oral), and lorlatinib (oral).
- w) Thrombopoietin (TPO) receptor agonists
- (1) TPO is the key cytokine that stimulates platelet production.
  - (2) TPO agonists bind to the TPO receptor, leading to conformational changes and JAK2/STAT5 pathway activation.
  - (3) Activation of this pathway increases megakaryocyte progenitor proliferation and platelet production.
  - (4) Available agonists in this class share the same mechanism of action; however, romiplostim is a peptibody that binds directly and competitively at the TPO binding site, whereas eltrombopag, a small molecule, binds at a transmembrane site.
  - (5) Examples include romiplostim (IV) and eltrombopag (oral).
- x) VEGF inhibitors
- (1) The VEGF pathway is an essential component of angiogenesis, the recruitment of new blood vessels to a tumor as it grows.
  - (2) This process is initiated by binding VEGF to receptors on the surface of endothelial cells.
  - (3) Angiogenesis holds an important role in cancer progression through generating new blood vessels to supply tumors with oxygen and nutrients necessary for growth and metastases.
  - (4) Angiogenesis inhibitors interfere with this process by binding to VEGF and its receptor or other proteins in the downstream signaling pathway to block activation of this pathway (National Cancer Institute, 2018).
  - (5) Examples include axitinib (oral), lenvatinib (oral), pazopanib (oral), sorafenib (oral), sunitinib (oral), and ziv-aflibercept (IV).
- y) Multiple kinase targets
- (1) These agents target multiple kinase pathways, leading to alterations in cell proliferation. The exact primary target is unknown.
  - (2) Examples include cabozantinib (oral) and regorafenib (oral).

### B. Adverse effects of targeted therapies

1. In contrast to cytotoxic agents, targeted therapies interfere with specific pathways in cancer cells, with little or no effect on healthy tissues. Consequently, they have a nontraditional side effect profile compared to cytotoxic agents (National Cancer Institute, 2018).
2. Table 8-1 and Figure 8-3 include notable side effects for the different targeted agents. These include acneiform rash, diarrhea, cardiotoxicity, hepatotoxicity, hypertension, metabolic abnormalities (e.g., hyperglycemia, hyperlipidemia), and others.

### C. Drug–drug interactions

1. Cytochrome P450 (CYP) enzymes are expressed primarily in the liver and are responsible for the metab-

olism of drugs. Although more than 50 of these enzymes exist, six metabolize most drugs—CYP1A2, CYP2C9, CYP2C19, CYP2D6, CYP3A4, and CYP3A5.

2. Drugs can inhibit or induce these enzymes, leading to drug–drug interactions. The clinical outcome of these interactions can be adverse reactions or therapy failures from overexposure or underexposure to the intended medication. For example, ritonavir is a strong inhibitor of CYP3A4. Many TKIs are metabolized by CYP3A4; therefore, coadministration with ritonavir or another strong inhibitor may decrease TKI metabolism and increase toxicity. Inducers of CYP3A4, such as rifampin, carbamazepine, and St. John's wort, can increase TKI metabolism and decrease efficacy (Rimassa et al., 2019).
3. Many TKIs undergo metabolism via CYP pathways, leading to a high propensity for drug–drug interactions. Table 8-1 includes specifics to avoid interactions.

**FIGURE 8-3.** Potential Side Effects and Toxicities of Targeted Therapy by System

GI—gastrointestinal; LFTs—liver function tests; SIADH—syndrome of inappropriate antidiuretic hormone secretion

## CHAPTER 9

# Principles of the Immune System

### A. Overview of immunology

1. Current advances in immunotherapy use immune pathways and cellular mechanisms as a therapeutic approach to the treatment and prevention of cancer. Basic knowledge of the immune system and immune response to tumor cells is essential to understanding the clinical application of immunotherapy.
2. The immune system is a highly specialized and adaptive system of barriers, organs, cells, and molecules that guard an individual by providing the following (Abbas et al., 2019; see Figure 9-1):
  - a) Protection: defense against foreign pathogens (i.e., bacteria, viruses, fungi, and parasites)
  - b) Homeostasis: elimination of damaged or dead cells and initiation of tissue repair
  - c) Surveillance: identification of foreign or nonself substances; inhibition of tumor growth

### B. Types of immune response (see Figure 9-2)

1. An immune response is the reaction of the immune system against a foreign substance or antigen (e.g., bacteria).
2. The immune system consists of two types of immunity: innate and adaptive (Abbas et al., 2019; see Table 9-1).
  - a) Innate immunity (natural or native immunity)
    - (1) Innate immunity is the first line of defense and is essential for inducing a nonspecific response to a pathogen or foreign substance (Sompayrac, 2019). It does not generate immunologic memory.
    - (2) Components of innate immunity (Frizinsky et al., 2019)
      - (a) Physical barriers (e.g., skin, mucous membranes)
      - (b) Mechanical barriers (e.g., coughing, sneezing, blinking)
      - (c) Chemical barriers (e.g., tears, acidic pH, sweat)
      - (d) Inflammatory barriers (e.g., vascular fluid leakage)

- (e) Complement activation (e.g., plasma proteins mark pathogens for destruction)
- (f) Acute-phase protein production (e.g., recruiting phagocytes to the site of infection or tissue injury)
- (g) Large granular lymphocyte production (e.g., kill and digest pathogens)

### b) Adaptive or acquired immunity

**FIGURE 9-1.** Primary and Secondary Lymphoid Organs

**FIGURE 9-2.** The Innate and Adaptive Immune Response

The innate immune response functions as the first line of defense against infection. It consists of soluble factors, such as complement proteins, and diverse cellular components including granulocytes (basophils, eosinophils and neutrophils), mast cells, macrophages, dendritic cells, natural killer (NK) cells, and innate lymphoid cells (ILCs). The adaptive immune response is slower to develop but manifests as increased antigenic specificity and memory. It consists of antibodies, B cells, T lymphocytes, and effector T cells.

Note. From *Basic Immunology: Functions and Disorders of the Immune System* (6th ed., p. 20), by A.K. Abbas, A.H. Lichtman, and S. Pillai, 2019, Elsevier. Copyright 2019 by Elsevier. Reprinted with permission.

- (1) Adaptive immunity is often considered the second line of defense and involves immunologic memory, specificity, and collaboration of B and T cells (Medina, 2016).
- (2) Three types of adaptive immunity
  - (a) Humoral immunity is mediated by B cells and plasma cells, resulting in the production of immunoglobulins (Igs) or antibodies (Sompayrac, 2019).
  - (b) Cell-mediated immunity is mediated primarily by T cells and cytokine products. The cytotoxic T cells and helper T cells (type 1 or 2) react to self-antigens or a foreign pathogen through T-cell receptor signaling (Butcher & Zhu, 2021; Sompayrac, 2019; Wu et al., 2020).
  - (c) Regulatory T cells, formerly known as suppressor T cells, limit the activity of other immune effector cells (Zhao et al., 2017).
- i. Their primary role is to prevent the onset of immunity to healthy tissue (autoimmune disease) and limit the inflammatory response that can occur with infections.
- ii. Absence of regulatory T cells may trigger inflammatory disorders primarily involving the bowel, skin, and liver.
- C. Organs of the immune system (Abbas et al., 2019; Ruddle, 2020; Thapa & Farber, 2019)
  1. The immune system consists of primary and second (peripheral) lymphoid organs.
  2. Primary lymphoid organs are bone marrow and thymus. They are sites of lymphocyte development and differentiation.
  3. Second (peripheral) lymphoid organs include lymph nodes, spleen, Peyer patches, adenoids, tonsils, and mucosa-associated lymphoid tissue. They are sites of antigen-driven proliferation and lymphocyte maturation.

**TABLE 9-1.** Adaptive and Innate Immune Responses

| Immune Response | Mechanism of Action                                 | Cells Primarily Involved                                                                                        |
|-----------------|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| Innate          | Primary line of defense<br>Nonspecific<br>No memory | Neutrophils<br>Monocytes<br>Macrophages<br>Dendritic cells<br>Large granular lymphocytes (natural killer cells) |
| Adaptive        | Secondary line of defense<br>Specific memory        | B lymphocytes (in humoral immunity)<br>T lymphocytes (in cell-mediated immunity)                                |

Note. Based on information from Abbas et al., 2019.

#### D. Cells of the immune system (see Figure 9-3)

1. The immune response involves the intricate interaction of several cells and proteins. Cells are widely categorized by their progenitor bone marrow cell lines (Sompayrac, 2019).
2. Myeloid cells arise from the myeloid stem cell line, giving rise to red blood cells and platelets (Weiskopf et al., 2016).
  - a) Myeloid cells involved in the immune system include monocytes, macrophages, dendritic cells, granulocytes, and mast cells.
  - b) Granulocytes are composed of four subsets: neutrophils, eosinophils, basophils, and mast cells. Neutrophils are the first responders, phagocytosing infection and initiating inflammation.
3. Lymphocytes arise from the lymphoid stem cell line and include effector cells, which are short-lived naïve cells activated during an immune response.
  - a) Effector cells include T cells (cytotoxic T cells and helper T cells), which produce cytotoxic molecules, and B cells (plasma cells), which produce antibodies that function to eliminate antigens (Abbas et al., 2019).
    - (1) T cells
      - (a) Helper T cells coordinate the immune response and cell-mediated immunity; they are required to maintain cytotoxic T-cell responses and express cluster of differentiation (CD) 4, which assists in stimulating macrophages, B cells, and CD8-positive T-cell production.
        - i. Type 1 helper T cells are necessary for activating macrophages and are involved in producing specific antibody isotypes.

- ii. Type 2 helper T cells are effective activators of B cells, particularly in primary responses.

(b) Cytotoxic T cells kill foreign cells, virally infected cells, or cells with new surface antigens.

- i. Cytotoxic T cells express CD8.
- ii. T cells secrete cytokines such as tumor necrosis factor and interferon gamma.
- iii. Additionally, CD8 functions as a co-receptor for T-cell receptors and T-cell signaling, regulating cell proliferation, differentiation, survival, and cytokine production.

(c) Regulatory T cells

- i. These cells interfere with the development of an immune reaction when recognizing an antigen.
- ii. Their primary role is to modulate the severity of inflammation produced by infection and prevent autoimmunity; they may be involved in malignancy.

(d) Memory T cells recognize specific antigens and induce recall responses.

(2) B cells involved in mediated immunologic memory give rise to plasma cells and memory B cells (Sompayrac, 2019).

(a) Plasma cells manufacture antibody molecules specific to a target antigen.

- i. The function of the plasma cell is to enhance effector cell functions. Most peripheral blood antibodies are IgG, which enhances the phagocytosis of antigens by macrophages, monocytes, polymorphonuclear cells, and some lymphocytes.
- ii. IgM is the first antibody produced in response to an antigen.
- iii. IgA is present in body secretions and helps prevent infections at sites where the environment interacts with the body, such as the nose and lungs.
- iv. IgD is present in small amounts in normal serum. The exact biologic function is unclear; however, IgD may have some antibody function for penicillin, diphtheria, and insulin.

**FIGURE 9-3.** Cells of the Immune System

Note. Image courtesy of iStock. Used with permission.

v. IgE exists in trace amounts in normal serum and is associated with immediate hypersensitivity reactions. IgE antibodies are generated when combined with specific antigens, thus activating histamine release from mast cells.

(b) Memory B cells recognize a specific antigen and can survive for an extended period after clearance of the primary infestation. They can quickly produce antigen-specific antibodies upon re-exposure (Abbas et al., 2019).

b) Natural killer (NK) cells

(1) NK cells are effector lymphocytes of the innate immune system. They are important because of their ability to induce cell death in tumor cells and virally infected

autologous cells by producing substances that can bind to and destroy foreign invaders without identifying a specific antigen.

(2) NK cells identify foreign substances by their lack of identifying surface molecules (Abel et al., 2018).

c) NK T cells have both NK and T-cell markers and produce cytokines without differentiating into effector cells or having prior sensitization (Abel et al., 2018).

#### E. Immune system proteins and receptors

1. Cells of the immune system evaluate structures (antigens) on membranes of circulating cells as a critical step in immune response (Actor, 2019; Gonzalez et al., 2018; Jhunjhunwala et al., 2021).
2. Receptor tyrosine kinases (RTKs) are membrane-bound molecules that, when stimulated, send intracellular signals to the DNA, culminating in cell proliferation and migration (Keith & Abueg, 2015).

- a) RTKs can often be variated or overexpressed in malignant tumors. RTK variants may result in changes in cellular pathways that affect intracellular signal activation in the absence of the appropriate extracellular growth signal, resulting in unregulated tumor growth.
  - b) The epidermal growth factor receptor family (EGFR1, EGFR2, EGFR3, and EGFR4) of RTKs is widely distributed in healthy tissue. EGFR is a known driver of carcinogenesis in breast cancer, lung cancer, melanoma, glioblastoma, and gastrointestinal tumors.
  - c) Other major RTKs implicated in oncogenesis include platelet-derived growth factor receptor (PDGFR), ROS oncogene 1 (ROS1), anaplastic lymphoma kinase (ALK), and mesenchymal-epithelial transition factor (MET).
3. CD markers are surface-bound proteins that act as receptors and ligands to neighboring cells (Shahrabi et al., 2020).
- a) Diagnostic immunophenotyping assays use CD antigens to sort, identify, and measure cells based on the molecules present on the cell surface.
  - b) The CD nomenclature and numbering system is a standardized protocol used to identify these molecules (see Table 9-2).
4. RTKs and CDs are common targets of immunotherapy.
- a) Some monoclonal antibodies target the surface-bound RTKs, inducing immune-mediated cellular toxicity and halting cell signal transduction.
  - b) Small molecule tyrosine kinase inhibitors disrupt the interaction between molecules of the cell signal transduction pathways.
5. Inhibitory and regulatory proteins limit autoimmunity.
- a) Autoimmunity occurs when the immune system mounts anti-self B-cell and T-cell reactions after mistaking healthy self-tissues as foreign (National Cancer Institute, n.d.).
  - b) Regulatory T cells suppress exaggerated immune responses and reactions to self-molecules (Rocamora-Reverte et al., 2021).
  - c) Immune checkpoint molecules inhibit T-cell responses, protecting the host from self-attack (Ohue & Nishikawa, 2019; Seidel et al., 2018; Zhang et al., 2018).
    - (1) Cytotoxic T-lymphocyte antigen 4 (CTLA-4) ligands bind to antigen-presenting cells, downregulating T-cell activity.
      - (a) CTLA-4 expression decreases the activation of T cells and sends inhibitory signals to the T cell.
      - (b) CTLA-4 is expressed by activated CD8-positive cells, but the primary

**TABLE 9-2.** Cluster of Differentiation Cell Expression

| Cluster of Differentiation Cell | Normal Expression                                                                                  | Increased Expression                                       |
|---------------------------------|----------------------------------------------------------------------------------------------------|------------------------------------------------------------|

CD—cluster of differentiation; NK—natural killer

Note. Based on information from National Cancer Institute, 2021; Shahrabi et al., 2020.

role of CTLA-4 is diminishing activity of helper T cells and enhancing the immunosuppressive activity of regulatory T cells (Rowshanravan et al., 2018).

- (2) Programmed cell death protein 1 (PD-1)
    - (a) PD-1 is a membrane-bound inhibitory receptor on T cells, B cells, and NK cells.
    - (b) PD-1 interaction with programmed cell death-ligand 1 (PD-L1) inhibits T-cell proliferation and cytotoxic function and induces T-cell regulatory function and apoptosis.
  - (3) Tumors may overexpress PD-L1, shielding them from an immune response. Diagnostic assays measure PD-L1 expression and have been used as a predictive biomarker for sensitivity to checkpoint inhibitor therapy in some cancers (Davis & Patel, 2019).
6. Immune cell communication is coordinated by cytokines.
- a) Cytokines
    - (1) Cytokines are glycoprotein products of immune cells, such as lymphocytes and macrophages.
    - (2) Cytokines are produced in response to T-cell activation and mediate effector defense functions.
    - (3) Cytokines coordinate an immune response that can be cytotoxic (e.g., interleukins, interferon) (Berraondo et al., 2019; Korbecki et al., 2020; Morein et al., 2020; Nagarsheth et al., 2017).
  - b) Chemokines, or chemotactic cytokines, are protein molecules that regulate leukocyte migration and are essential organizers of cell distribution in immune and inflammatory responses (Battle & Massagué, 2019; Berraondo et al., 2019; Korbecki et al., 2020; Wang et al., 2020).
  - c) In the tumor microenvironment, tumors manipulate cytokine and chemokine expression to suppress the immune response and promote tumor proliferation and migration.
  - d) Exogenous administration of chemokines and cytokines can be used in anticancer therapies.

#### F. Phases of immune response (Abbas et al., 2019; Sompayrac, 2019)

1. Antigen recognition: Circulating antibodies recognize a foreign antigen, which activates the immune system.
  - a) Antigens are molecular structures that are recognized by and can stimulate the immune system. Tumor antigens are either cell surface molecules

that function as targets for antibody responses or intracellular molecules presented within the context of major histocompatibility complex molecules capable of T-cell recognition (Jongsma et al., 2021).

- b) Antigen-presenting cells (e.g., macrophages, B cells, dendritic cells) efficiently present the antigen to T cells; only dendritic cells can initiate a primary immune response.
  - c) Antigen presentation must occur in the presence of inflammatory factors to generate an immune response. Antigen presentation in the absence of a noninflammatory environment can result in immune tolerance.
2. Lymphocyte activation: B or T cells are activated to proliferate and differentiate into effector lymphocytes.
  3. Effector phase: Foreign antigen is inactivated or destroyed.
  4. Contraction: During this phase, T-cell expansion is inhibited or activated cells are eliminated by apoptosis, facilitating the immune system's return to a resting state and limiting tissue damage and chronic inflammation.
  5. Memory: Lymphocytes that survive the immune response become memory cells that can recognize a former antigen and initiate a rapid response.

#### G. Tumor escape mechanisms

1. Immune surveillance refers to the process “whereby the immune system identifies cancerous and/or pre-cancerous cells and eliminates them before they can cause harm” (Swann & Smyth, 2007, p. 1137). Cancer cell formation occurs when immune surveillance fails (Swann & Smyth, 2007).
2. Theories of tumor escape mechanisms (Bates et al., 2018; Cornel et al., 2020; Friedrich et al., 2019; Mortezaee, 2020; Shembrey et al., 2019)
  - a) Tumors manipulate antigen presentation as a mechanism of tumor escape (altered immunogenicity). Alterations to antigen presentation weaken immune recognition and dampen immune response (Jhunjhunwala et al., 2021; Jongsma et al., 2021; Seliger, 2019).
    - (1) Tumors express surface antigens also expressed on self-cells, then evade the immune system.
    - (2) Neoantigens are products of acquired gene variants resulting in altered antigen expression on the tumor cell surface, allowing the antigen to go unrecognized by the humoral immune system (Zhang et al., 2021).
    - (3) Major histocompatibility complex molecule loss or alteration blunts cell-mediated

- immune response. The peptide epitope (antigen) that binds to the major histocompatibility complex molecule and is recognized by T cells is lost or mutated.
- (4) Antibodies produced as part of the immune response cause antigens to enter the tumor cell or leave it entirely. This further limits the immune cells' ability to recognize the tumor cell as nonself.
- b) Acquired deficiencies in immune sensitivity (Hong et al., 2019)
- (1) These include age- and disease-associated alterations, such as decreased or increased apoptosis and signaling defects of T cells.
  - (2) Immunologic aging or immunosenescence causes the following:
    - (a) Decreased number of naïve T cells; decreased generation of cytotoxic T cells, hematopoietic stem cells, phagocytes, and NK cells
    - (b) Decreased production of interleukin-2
    - (c) Decreased signal transduction of lymphocytes
    - (d) Decreased humoral immunity
    - (e) Decreased antigen response and proliferation, increased memory T cells, and a potentially decreased number of functional regulatory T cells
- c) Tumors develop adaptive mechanisms to evade immune detection (Baghban et al., 2020; Giraldo et al., 2019; Mortezaee, 2020).
- (1) Tumors hijack the expression of immune checkpoints (e.g., CTLA-4, PD-1, lymphocyte activation gene 3 [known as *LAG3*]), which inhibit usual T-cell activity.
  - (2) High levels of PD-L1 expression promote immune system tolerance and allow for unchecked tumor growth (Davis & Patel, 2019).
    - (a) Tumors fail to give off inflammatory warning signals to stimulate an immune response. T-cell interaction in the absence of inflammatory signals results in sustained immune tolerance.
    - (b) Tumors recruit regulatory T cells that suppress T-cell activity.
    - (c) The tumor itself produces substances that alter or inhibit the body's immune response. Examples include transforming growth factor-beta, interleukin-10, and adenosine, which limit T-cell toxicity functions.
  - d) Immunoediting is the development of an immune-resistant tumor mass resulting from a prior immune attack. Three phases lead to its development (Batlle & Massagué, 2019; O'Donnell et al., 2019; Swann & Smyth, 2007; Teng et al., 2013).
    - (1) In the elimination phase, cellular and humoral immune cells eliminate highly immunogenic tumor cells. Cells with low immunogenicity survive.
    - (2) Tumor cells with low immunogenicity are ignored by a tolerant immune system during the equilibrium phase.
    - (3) The tumor mass is allowed to grow and spread unchecked in the escape phase.
3. Angiogenesis (Al-Ostoot et al., 2021; Loizzi et al., 2017; Saman et al., 2020; Teleanu et al., 2020; Zuazo-Gaztelu & Casanovas, 2018)
- a) Angiogenesis is the development of new blood vessels. It is a complex, multistep process required for many healthy functions, including wound healing, tissue repair, reproduction, growth, and development.
- (1) Healthy angiogenesis occurs in response to physiologic demands, such as hypoxia, wound healing, growth, or acidosis.
  - (2) Healthy angiogenesis is tightly controlled by the balance of vascular mediators that ensure blood vessel growth is limited to physiologic needs.
  - (3) Vascular endothelial growth factor is expressed on endothelial cells and is an important mediator of angiogenesis.
  - (4) Other angiogenic mediators include hypoxia-inducible factor-1 angiopoietins, platelet-derived growth factor, fibroblast growth factor, granulocyte-colony-stimulating factor, interleukin-8, matrix metalloproteases, hepatocyte growth factor, tumor necrosis factor, transforming growth factor, epidermal growth factor, interferons (alpha, beta, and gamma), and endostatin.
- b) Tumor angiogenesis is the development of new blood vessels within a tumor (Loizzi et al., 2017; Lugano et al., 2020).
- (1) Angiogenic switch occurs when the balance of angiogenic mediators is disrupted, leading to tumor angiogenesis.
  - (2) Endothelial cells line the vasculature of healthy tissues. In a resting state, they provide a homeostatic barrier that prevents the uncontrolled extravasation of intravascular components and inhibits coagulation.

- (3) Tumors produce an overabundance of angiogenic factors that stimulate receptors on endothelial cells.
  - (4) Stimulated endothelial cells secrete enzymes (matrix metalloproteinases) that digest the basement membrane, stimulating the release of proangiogenic factors from neighboring endothelial cells.
  - (5) Stimulated endothelial cells then sprout new capillaries that grow toward the source of the proangiogenic factors (the tumor).
  - (6) Poorly formed, leaky tumor vasculature excretes proangiogenic factors that further stimulate the cycle of tumor vascular growth. Leaky tumor vasculature hampers the delivery of chemotherapy to the tumor site.
  - (7) Blood flow in tumors is sluggish, thus inducing hypoxia and acidosis, further triggering angiogenesis.
- c) Angiogenesis inhibitors (antiangiogenics) are therapeutic agents that block angiogenesis.

## CHAPTER 10

# Immunotherapy

### A. Overview

1. *Immunotherapy* is a broad term that refers to many different therapies. It harnesses the body's immune system to eradicate cancer cells.
2. Multiple modalities exist in which immunotherapy is administered, including cytokines, vaccines, immune checkpoint inhibitors, oncologic viral therapies, monoclonal antibodies (e.g., radioimmunotherapy), and chimeric antigen receptor (CAR) T-cell therapy (Abbott & Ustoyev, 2019).

### B. Modalities of immunotherapy

#### 1. Immune checkpoint inhibitors

##### a) Pathophysiology

- (1) The immune system uses inhibitory and stimulatory pathways to regulate the cells and the immune response process to identify and eliminate abnormal cells. It has been found that some cancers disrupt these pathways and avoid recognition (Bayer et al., 2017).
- (2) Stimulation of select immune checkpoints blocks the proteins and receptors that help moderate immune response and prevent T lymphocytes from recognizing and killing cancer cells. Immune checkpoint inhibitors help block the stimulation of these regulatory signals that inhibit T cells, and T cells are released and can elicit an immune response against cancer cells.
- (3) Several immune checkpoint inhibitors have been approved for the treatment of cancer, including anti-cytotoxic T-lymphocyte antigen 4 (CTLA-4), anti-programmed cell death protein 1 (PD-1), and anti-programmed cell death-ligand 1 (PD-L1) (Postow et al., 2018).
- (4) Currently, clinical trials are using several drugs that target other immune checkpoints.

##### b) Mechanism of action

- (1) CTLA-4 is a first-in-class target for immune checkpoint inhibitors. It is a receptor found on T cells and engaged by its ligand B7 to prevent overactivation. Blockade of CTLA-4 allows for continued T-cell activation, thus enhancing antitumor responses (Bayer et al., 2017). An example includes ipilimumab.
  - (2) PD-1 is an inhibitory pathway present on activated T cells. It binds to the PD-L1 and PD-L2 ligands. Stimulation of the PD-1 pathway leads to disruption of immune surveillance and antitumor response. Immune checkpoint inhibitors targeting PD-1 can disrupt this process, allowing for continued T-cell activation and tumor surveillance and elimination (Mahoney et al., 2015). Examples include nivolumab, pembrolizumab, cemiplimab, and dostarlimab.
  - (3) PD-L1 can be found on cancer cells. It has an affinity for binding to PD-1 and B7 receptors, which initiates a pathway that inhibits T-cell activation. Blocking PD-L1 can help restore immune activity (Chen et al., 2012; Mahoney et al., 2015). Examples include atezolizumab, avelumab, and durvalumab.
- c) Applications and indications: Since the introduction of immune checkpoint inhibitors in 2011, the U.S. Food and Drug Administration (FDA)-approved indications and clinical applications have markedly expanded and include solid tumor and hematologic malignancies. These agents are used as a single-agent therapy and combined with other anticancer therapies to treat a variety of cancers. As of the date of publication, indications by agent are presented in Table 10-1.
- d) Administration: Immune checkpoint inhibitors are administered via IV infusion.

**TABLE 10-1.** Immunotherapy Agents

| Classification          | Mechanism of Action                                                                                                                                                                                                                                                                                           | Drug                                                                          | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Side Effects                                                                                                                                                                                                                                                                                             | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Antibody-drug conjugate | Chimeric monoclonal antibody targeting CD30, attached to anti-microtubule agent MMAE; binds to CD30-expressing cells, resulting in internalization and intracellular cleaving of the conjugate, releasing MMAE, which disrupts the cellular microtubule network, resulting in cell cycle arrest and apoptosis | Brentuximab vedotin (anti-CD30 antibody; Adcetris <sup>®</sup> ) <sup>a</sup> | IV    | <p>Previously untreated stage III or IV cHL, in combination with chemotherapy</p> <p>cHL at high risk for relapse after autologous HSCT</p> <p>cHL after the failure of autologous HSCT or after the failure of at least 2 prior chemotherapy regimens</p> <p>Previously untreated CD30-expressing peripheral T-cell lymphoma, in combination with chemotherapy</p> <p>Systemic anaplastic large cell lymphoma after the failure of at least 1 prior chemotherapy regimen</p> <p>Primary cutaneous anaplastic large cell lymphoma or CD30-expressing mycosis fungoides in patients who have received prior systemic therapy</p> | Peripheral neuropathy, fatigue, rash, neutropenia, anemia, upper respiratory tract infection, cough, fever, infusion-related reactions, nausea, constipation, vomiting, alopecia, decreased weight, abdominal pain, stomatitis, thrombocytopenia, lymphopenia, mucositis, renal toxicity, hepatotoxicity | <p>Previously untreated stage III or IV cHL: Recommended dosage is 1.2 mg/kg IV (maximum 120 mg) over 30 minutes every 2 weeks until a maximum of 12 doses, disease progression, or unacceptable toxicity.</p> <p>Other indications: Recommended dosage is 1.8 mg/kg IV (maximum 180 mg) over 30 minutes every 3 weeks.</p> <p>Do not administer as an IV push or bolus.</p> <p>In patients who have experienced a prior infusion-related reaction, premedication may include acetaminophen, an antihistamine, and a corticosteroid.</p> <p>Reduce dose in patients with mild hepatic or renal impairment.</p> <p>Monitor liver enzymes and bilirubin.</p> <p>Monitor CBC prior to each dose. Monitor more frequently for patients with grade 3–4 neutropenia. Monitor patients for fever. If grade 3–4 neutropenia develops, consider dose delays, reductions, discontinuation, or G-CSF prophylaxis with subsequent doses.</p> <p>Advise patients to report symptoms of pulmonary toxicity, hepatotoxicity, and dermatologic toxicity.</p> <p>Store reconstituted vials or diluted solutions at 2°C–8°C and use within 24 hours.</p> <p>Monitor for TLS in patients with a rapidly proliferating tumor or high tumor burden.</p> <p>Start primary prophylaxis with G-CSF beginning with cycle 1 for patients who receive brentuximab vedotin in combination with chemotherapy for previously untreated stage III or IV cHL or previously untreated peripheral T-cell lymphoma.</p> <p>Serious infections and opportunistic infections have been observed. Monitor for bacterial, fungal, and viral infections.</p> <p>(Seagen, 2020)</p> |

| Antibody-drug conjugate<br>( <i>Cont.</i> ) |                                                                                                                                                                                                                                                                                                                                                                               | Polatuzumab vedotin-piiq (Polivy®)<br>( <i>Cont.</i> ) |       |                                                                                                                                                                                              |                                                                                                                                                                                                                                                                                                                                                                 | Concomitant use with strong CYP3A4 inhibitors or inducers may affect dose. This medication contains warnings for reproduction or lactation. Refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring. (Genentech, 2020c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                                             | Afucosylated monoclonal antibody directed against BCMA, attached to anti-microtubule agent MMAF; binds to BCMA-expressing cells, resulting in internalization and intracellular cleaving of the conjugate, releasing MMAF, which disrupts the cellular microtubule network, resulting in cell cycle arrest and apoptosis; also induces tumor cell lysis through ADCC and ADCP | Belantamab mafodotin-blmf (Blenrep™)                   | IV    | Relapsed or refractory multiple myeloma in adults who have received at least 4 prior therapies, including an anti-CD38 monoclonal antibody, proteasome inhibitor, and immunomodulatory agent | Black box warning: ocular toxicity, including changes in vision, severe vision loss, and corneal ulcer<br>Ocular changes, keratopathy (corneal epithelium change on eye exam), dry eyes, blurred vision, fever, nausea, infusion-related reactions, fatigue, myelosuppression, increased creatinine, increased gamma-glutamyltransferase, embryo-fetal toxicity | Administer 2.5 mg/kg IV over 30 minutes once every 3 weeks.<br>Conduct ophthalmic exams at baseline (within 3 weeks of the first dose), prior to each dose (between 1 week after the previous dose and within 2 weeks of the next dose), and promptly for worsening symptoms.<br>Advise patients to use preservative-free lubricant eye drops at least 4 times a day, starting with the first infusion and continuing until the end of treatment.<br>Instruct patients to avoid wearing contact lenses unless directed by an ophthalmologist.<br>Vision changes may be associated with difficulty reading or driving. Advise patients to use caution when driving or operating machinery.<br>Monitor CBC at baseline and during treatment as clinically indicated.<br>Monitor patients for infusion-related reactions. Interrupt infusion and reduce the rate or permanently discontinue based on the severity of the reaction.<br>Belantamab mafodotin-blmf is available only through the Blenrep REMS program.<br>This medication contains warnings for reproduction or lactation. Refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring. (GlaxoSmithKline, 2020) |

**TABLE 10-1.** Immunotherapy Agents (*Continued*)

| Classification                              | Mechanism of Action                                                                                                                                                                                                                                                                                      | Drug                                 | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Side Effects                                                                                                                                                                                                                                                                           | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Antibody-drug conjugate<br>( <i>Cont.</i> ) | Humanized monoclonal antibody targeting HER2, attached to anti-microtubule agent DM1; binds to HER2-expressing cells, resulting in internalization and intracellular cleaving of conjugate, releasing DM1, which disrupts the cellular microtubule network, resulting in cell cycle arrest and apoptosis | Ado-trastuzumab emtansine (Kadcyla®) | IV    | HER2-positive early breast cancer, as a single agent, in patients with residual invasive disease following neoadjuvant taxane and trastuzumab-based treatment<br>HER2-positive metastatic breast cancer, as a single agent, in patients who previously received trastuzumab and a taxane and have either received prior therapy for metastatic disease or experience disease recurrence during adjuvant therapy or within 6 months of completing adjuvant therapy | Fatigue, nausea, musculoskeletal pain, arthralgia, peripheral neuropathy, headache, increased transaminases, constipation, thrombocytopenia, bleeding, epistaxis, cardiotoxicity<br>Reactions such as erythema, swelling, irritation, and pain have been observed after extravasation. | Administer 3.6 mg/kg IV over 90 minutes on day 1 of a 21-day cycle.<br>If well-tolerated, subsequent infusions may be administered over 30 minutes.<br>Do not mix or infuse with other products.<br>Do not administer as an IV push or bolus.<br>Administer with an 0.2- or 0.22-micron in-line PES filter.<br>Observe patients during infusion and for at least 90 minutes following the initial dose and 30 minutes following subsequent doses for fever, chills, or other infusion-related reactions.<br>Patients may require dose modifications for increased transaminases, hyperbilirubinemia, thrombocytopenia, or cardiotoxicity (e.g., left ventricular dysfunction).<br>Monitor LVEF at baseline and at regular intervals during treatment.<br>Discontinue therapy for symptomatic congestive heart failure, ILD, pneumonitis, or nodular regenerative hyperplasia.<br>Do not substitute trastuzumab for or with ado-trastuzumab emtansine.<br>Monitor for infiltration during administration.<br>The drug is classified as an irritant (usually) or a vesicant (rarely). Apply cold for extravasation; refer to Chapter 13 for additional information.<br>This medication contains warnings for reproduction or lactation. Refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring.<br>(Genentech, 2020a) |

**TABLE 10-1.** Immunotherapy Agents (*Continued*)

| Classification                              | Mechanism of Action                                                                                                                                                                                                                                                                           | Drug                                       | Route | Indications                                                                                                                                                                                                                                                                                            | Side Effects                                                                                                                                                                                                                                                                                | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Antibody-drug conjugate<br>( <i>Cont.</i> ) | Humanized monoclonal antibody targeting HER2 attached to topoisomerase I inhibitor DXd; binds to HER2-expressing cells and is internalized with the subsequent release of DXd, which prevents religation of topoisomerase I-induced single-strand DNA breaks and damage, leading to apoptosis | Fam-trastuzumab deruxtecan-nxki (Enhertu®) | IV    | Unresectable or metastatic HER2-positive breast cancer in adults who have received 2 or more prior anti-HER2-based regimens in the metastatic setting<br>Locally advanced or metastatic HER2-positive gastric or GEJ adenocarcinoma in adults who previously received a trastuzumab-containing regimen | Black box warning: ILD (pneumonitis, cough, dyspnea, fever, worsening respiratory status), embryo-fetal toxicity<br>Nausea, fatigue, vomiting, alopecia, constipation, decreased appetite, anemia, diarrhea, leukopenia, cough, thrombocytopenia, neutropenia, left ventricular dysfunction | Administer 5.4 mg/kg IV once every 3 weeks. The first dose is administered over 90 minutes; subsequent doses are administered over 30 minutes.<br>Assess for LVEF prior to initiation and at regular intervals throughout therapy. Monitor and manage signs and symptoms of LVEF. Interrupt at LVEF of 40%–45% and an absolute decrease from baseline of 10%–20%, or if LVEF < 40% with an absolute decrease > 20%, which requires permanent discontinuation if confirmed. Discontinue treatment in patients with symptomatic congestive heart failure.<br>Discontinue treatment in all patients with ≥ grade 2 ILD.<br>Monitor CBC prior to initiation and for each subsequent dose. Interrupt treatment in the presence of grade 3–4 neutropenia. Resume at ≤ grade 2 at the same dose for grade 3 and at a reduced dose for grade 4 or with the presence of febrile neutropenia.<br>Do not substitute drug for trastuzumab or ado-trastuzumab emtansine.<br>This medication contains warnings for reproduction or lactation. Refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring.<br>(Daiichi Sankyo, 2021) |

| Antibody-drug conjugate<br>( <i>Cont.</i> ) | Human monoclonal antibody targeting CD19, attached to alkylating agent SG3199; binds to CD19-expressing cells, resulting in internalization and intracellular cleaving of the conjugate, releasing SG3199, which induces DNA inter-strand crosslinks, resulting in cell cycle arrest and apoptosis | Loncastuximab tesirine-lpyl (Zynlonta <sup>®</sup> ) | IV    | Relapsed or refractory large B-cell lymphoma (including DLBCL not otherwise specified, transformed DLBCL, and high-grade B-cell lymphoma) in adults after 2 or more lines of systemic therapy | Myelosuppression, pleural effusion, pericardial effusion, ascites, edema, infection, cutaneous reactions including rash and photosensitivity, increased GGT, hyperglycemia, elevated LFTs, nausea, musculoskeletal pain | <p>Administer at 0.15 mg/kg IV every 3 weeks for 2 cycles, then 0.075 mg/kg IV every 3 weeks for subsequent cycles.</p> <p>Administer infusion over 30 minutes on day 1 of each 3-week cycle.</p> <p>Use adjusted body weight for dosage if patients have a body mass index <math>\geq 35</math> kg/m<sup>2</sup>: adjusted body weight in kg = <math>35 \text{ kg/m}^2 \times (\text{height in meters})^2</math>.</p> <p>Premedicate with dexamethasone 4 mg twice daily for 3 days starting the day before treatment.</p> <p>Administer using 0.2- or 0.22-micron filter.</p> <p>Hold therapy for neutropenia, thrombocytopenia, edema, or effusions of grade 2 or higher.</p> <p>The drug is classified as an irritant (usually) or a vesicant (rarely). Apply cold for extravasation; refer to Chapter 13 for additional information.</p> <p>Advise pregnant women of the potential risk to a fetus.</p> <p>This medication contains warnings for reproduction or lactation. Refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring.</p> <p>(ADC Therapeutics America, 2021)</p> |

| Classification                              | Mechanism of Action                                                                                                                                                                                                                                                                                      | Drug                                   | Route | Indications                                                                                                                                                                                         | Side Effects                                                                                                                                                                                    | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Antibody-drug conjugate<br>( <i>Cont.</i> ) | Humanized monoclonal antibody targeting Trop-2, attached to topoisomerase I inhibitor SN-38; binds to Trop-2-expressing cells and is internalized with the subsequent release of SN-38, which prevents religation of topoisomerase I-induced single-strand DNA breaks and damage that leads to apoptosis | Sacituzumab govitecan-hziy (Trodelvy™) | IV    | Unresectable locally advanced or metastatic triple-negative breast cancer in adults who have received at least 2 prior therapies, at least one for metastatic disease<br>Advanced urothelial cancer | Nausea, neutropenia, diarrhea, fatigue, anemia, vomiting, alopecia, constipation, rash, decreased appetite, abdominal pain, infusion-related reactions, hypersensitivity, embryo-fetal toxicity | <p>The recommended dose is 10 mg/kg once weekly on days 1 and 8 of continuous 21-day treatment cycles until disease progression or unacceptable toxicity. The first infusion is administered over 3 hours. Subsequent infusions can be administered over 1–2 hours if prior infusions were tolerated. Observe for 30 minutes after infusions.</p> <p>Prolonged neutropenia and febrile neutropenia may require dose adjustment and G-CSF support.</p> <p>Premedicate for prevention of infusion reactions with antipyretics and H<sub>1</sub> and H<sub>2</sub> antagonists. Add corticosteroids if patients have a history of infusion-related reactions. Monitor during infusion and for at least 30 minutes after completion. Permanently discontinue if severe or life-threatening reactions occur.</p> <p>Premedicate for nausea and vomiting with a 2–3 drug combination regimen, such as dexamethasone with a 5-HT<sub>3</sub> receptor antagonist or a neurokinin-1 receptor antagonist.</p> <p>Patients who are homozygous for the UGT1A1*28 allele are at increased risk for neutropenia following initiation of sacituzumab govitecan-hziy treatment.</p> <p>This medication contains warnings for reproduction or lactation. Please refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring. (Immunomedics, 2020)</p> |

| Antibody-drug conjugate<br>( <i>Cont.</i> ) | Humanized monoclonal antibody targeting CD22, attached to calicheamicin, an agent that binds to DNA and causes direct DNA damage; binds to CD22-expressing cells, resulting in internalization and intracellular cleaving of the conjugate, releasing calicheamicin, which induces double-strand DNA breaks, resulting in cell cycle arrest and apoptosis | Inotuzumab ozogamicin (Besponsa®)               | IV    | Relapsed or refractory B-cell precursor ALL in adults                                                                                                                                  | Black box warning: hepatotoxicity, including sinusoidal obstruction syndrome, increased risk of HSCT non-relapse mortality. Myelosuppression, infusion-related reactions, QT interval prolongation, embryo-fetal toxicity, fatigue, fever                                                                                         | Administer IV over 1 hour:<br>• Day 1: 0.8 mg/m <sup>2</sup><br>• Day 8: 0.5 mg/m <sup>2</sup><br>• Day 15: 0.5 mg/m <sup>2</sup><br>If patients achieve complete response or clinical response with incomplete count recovery, doses for subsequent cycles are adjusted to 0.5 mg/m <sup>2</sup> on days 1, 8, and 15. Dose interruptions may be necessary in subsequent cycles for neutropenia, thrombocytopenia, and elevated LFTs. Premedicate with corticosteroid, antipyretic, and antihistamine prior to administration. Monitor for at least 1 hour after infusion for infusion-related reactions. For patients with circulating lymphoblasts, administer cyto reduction to a peripheral blast count ≤ 10,000/mm <sup>3</sup> prior to infusion. Protect from light; do not freeze. This medication contains warnings for reproduction or lactation. Refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring. (Wyeth Pharmaceuticals, 2018) |
| Radioimmunoconjugate                        | IgG1 kappa murine monoclonal antibody targeting CD20, conjugated to yttrium-90 ( <sup>90</sup> Y); beta radiation from <sup>90</sup> Y induces cellular damage by the formation of free radicals in the target and neighboring cells.                                                                                                                     | <sup>90</sup> Y-ibritumomab tiuxetan (Zevalin®) | IV    | Relapsed or refractory follicular B-cell or low-grade non-Hodgkin lymphoma<br>Follicular lymphoma in patients who achieved a complete or partial response with first-line chemotherapy | Black box warnings: serious infusion-related reactions, prolonged and severe cytopenias, cutaneous and mucocutaneous reactions, maximum radiation dosage 32 mCi (1,184 MBq)<br>Hematologic toxicity is a major side effect. Onset may be delayed and duration prolonged. Cytopenias have persisted 12 weeks after administration. | <sup>90</sup> Y-ibritumomab tiuxetan is administered on a specific regimen that includes “pre-targeting” of the tissues with rituximab first, followed by the radiolabeled isotope. Patients receive rituximab 250 mg/m <sup>2</sup> on day 1. On day 7, 8, or 9, a second dose of rituximab 250 mg/m <sup>2</sup> is administered, followed by <sup>90</sup> Y-ibritumomab tiuxetan. If platelet count ≥ 150,000/mm <sup>3</sup> , within 4 hours after rituximab infusion, administer <sup>90</sup> Y-ibritumomab tiuxetan 0.4 mCi/kg (14.8 MBq/kg) IV. If platelet count ≥ 100,000/mm <sup>3</sup> but ≤ 149,000/mm <sup>3</sup> in patients with relapsed or refractory disease, within 4 hours after rituximab infusion, administer                                                                                                                                                                                                                                                                                     |

| CD22-directed cytotoxin<br>( <i>Cont.</i> ) |                     | Moxetumomab pasudotox-tdfk (Lumoxiti®)<br>( <i>Cont.</i> ) |       |             |              | <p>For drug dilution, add IV solution stabilizer to the infusion bag prior to adding the medication solution. IV solution stabilizer is packaged separately. Obtain a 50 ml 0.9% sodium chloride injection USP (normal saline) bag. Add 1 ml IV solution stabilizer to the infusion bag. Gently invert the bag to mix the solution. Do not shake. Withdraw the required volume of medication solution from the reconstituted vial(s). Inject medication into the infusion bag. Gently invert the bag to mix the solution. Do not shake. Discard partially used or empty vials of medication and IV solution stabilizer.</p> <p>After dilution, store at room temperature for up to 4 hours and refrigerated (36°F–46°F) for 24 hours. Protect from light. Do not freeze or shake. If refrigerated, allow the solution to come to room temperature for no more than 4 hours prior to administration. Administer within 24 hours of reconstitution.</p> <p>Maintain hydration during treatment. Administer 1 L of isotonic solution over 2–4 hours before and after each infusion; if patient weighs less than 50 kg, administer 500 ml.</p> <p>Monitor serum electrolytes prior to each dose and on day 8 of each cycle.</p> <p>Encourage patients to hydrate with up to 3 L of oral fluids over 24 hours on days 1–6 of every 28-day cycle. If patients weigh less than 50 kg, 2 L is recommended.</p> <p>Consider low-dose aspirin for thromboprophylaxis on days 1–8 of each 28-day cycle.</p> <p>Premedicate (30–90 minutes prior to infusion) with acetaminophen, an antihistamine (hydroxyzine or diphenhydramine), and an H<sub>2</sub> antagonist (ranitidine, famotidine, or cimetidine) prior to all infusions.</p> |

| Classification                              | Mechanism of Action | Drug                                                      | Route | Indications | Side Effects | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------------|---------------------|-----------------------------------------------------------|-------|-------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CD22-directed cytotoxin<br>( <i>Cont.</i> ) |                     | Moxetumomab pasudotox-tdfk (Lumoxiti)<br>( <i>Cont.</i> ) |       |             |              | <p>Post-infusion medication includes oral antihistamines and antipyretics for up to 24 hours following infusion. An oral corticosteroid is recommended to decrease nausea and vomiting. Patients should maintain adequate oral fluid intake.</p> <p>If patients have a <math>\geq</math> grade 2 creatinine increase (<math>&gt; 1.5 \times</math> baseline or ULN), delay administration. Resume medication when creatinine recovers to grade 1 (<math>1-1.5 \times</math> baseline or between the ULN and <math>1.5 \times</math> the ULN).</p> <p>For patients with <math>\geq</math> grade 3 creatinine increase, delay dosing and resume when recovers to baseline grade or lower.</p> <p>Not recommended in patients with severe renal impairment (creatinine clearance <math>\leq 29</math> ml/min)</p> <p>Monitor for capillary leak syndrome before each treatment; monitor weight, blood pressure, and laboratory tests, including albumin if suspected). For grade 2 capillary leak syndrome (symptomatic), treat medically and delay dosing until recovery of symptoms. For grade 3 (severe symptoms), treat medically and discontinue the medication. For grade 4 (life-threatening), provide urgent intervention and discontinue the medication. Most cases of capillary leak syndrome occur within the first 8 days of a treatment cycle but can occur throughout the cycle. The median time to resolution was 12 days.</p> <p>Monitor for hemolytic uremic syndrome before each treatment; monitor hemoglobin, platelet count, and creatinine; maintain adequate hydration. If patients develop hemolytic uremic syndrome, discontinue medication and treat with appropriate supportive measures. Most cases occur within the first 9 days of a treatment cycle but can occur throughout the cycle. The median time to resolution was 11.5 days.</p> |

Treatment may be held or discontinued based on the severity of the immune-related adverse effects.<br>This medication contains warnings for reproduction or lactation. Please refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring.<br>(AstraZeneca Pharmaceuticals, 2020)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| CAR T-cell immunotherapy                           | CD19-directed, genetically modified, autologous T-cell immunotherapy that binds to CD19-expressing cancer cells and healthy B cells. CD19 cellular binding results in CD28 and CD3-zeta costimulatory domains, which activate downstream signaling cascades that lead to T-cell activation, proliferation, and acquisition of effector functions and secretion of inflammatory cytokines and chemokines, leading to the killing of CD19-expressing cells. | Axicabtagene ciloleucel<br>(Yescarta®)      | IV    | <p>Relapsed or refractory large B-cell lymphoma, after 2 or more lines of systemic therapy, including:</p> <ul style="list-style-type: none"> <li>• DLBCL not otherwise specified or arising from follicular lymphoma</li> <li>• Primary mediastinal large B-cell lymphoma</li> <li>• High-grade B-cell lymphoma</li> </ul> <p>Relapsed or refractory follicular lymphoma in adults after 2 or more lines of systemic therapy</p> <p>Not indicated for the treatment of patients with primary central nervous system lymphoma</p> | Black box warning: CRS, neurotoxicity<br>Fever, hypotension, encephalopathy, tachycardia, fatigue, headache, decreased appetite, chills, diarrhea, febrile neutropenia, infections, nausea, vomiting, hypoxia, tremor, cough, dizziness, constipation, cardiac arrhythmias, hypersensitivity reactions, prolonged cytopenias, secondary malignancies, hepatitis B virus reactivation | <p>Administer after lymphodepleting regimen per package insert.</p> <p>Axicabtagene ciloleucel is for autologous use only. Confirm patient identity prior to administration.</p> <p>Premedicate with acetaminophen 650 mg PO and diphenhydramine 12.5 mg PO or IV 1 hour prior to infusion; confirm availability of tocilizumab before infusion.</p> <p>Avoid prophylactic use of systemic corticosteroids.</p> <p>Do not use a lymphodepleting filter.</p> <p>Central venous access is recommended for administration.</p> <p>Prime tubing with normal saline prior to administration.</p> <p>Infuse the entire contents of the bag within 30 minutes by gravity or peristaltic pump. The bag may be gently agitated to prevent clumping.</p> <p>Rinse tubing with normal saline and infuse at the same rate of infusion to ensure all cells are delivered.</p> <p>The bag is stable for up to 3 hours after thawing.</p> <p>Monitor patients for hypersensitivity during infusion and for signs and symptoms of CRS and neurotoxicity, which may be life threatening.</p> |

| Classification                      | Mechanism of Action | Drug                                           | Route | Indications | Side Effects | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------------|---------------------|------------------------------------------------|-------|-------------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CAR T-cell immunotherapy<br>(Cont.) |                     | Axicabtagene ciloleucel (Yescarta®)<br>(Cont.) |       |             |              | <p>CRS may occur with a median time to onset of 2 days. Provide symptomatic support, including antipyretics, oxygen, IV fluids, or vasopressors.</p> <p>Tocilizumab (an IL-6 receptor antagonist) IV over 60 minutes may be administered to manage severe or life-threatening CRS associated with CAR T-cell therapy. It may be used with corticosteroids.</p> <p>Neurotoxicity may occur with a median time to onset of 4–6 days (depending on indication) and may occur concurrent with, following the resolution of, or independent of CRS. Assess patients for headache, encephalopathy, delirium, anxiety, sleep disorders, dizziness, tremor, peripheral neuropathy, seizures, mutism, and aphasia.</p> <p>Neurotoxicity may be managed with supportive care and steroids.</p> <p>Advise patients to not drive or operate heavy machinery for up to 8 weeks following treatment.</p> <p>Axicabtagene ciloleucel can only be administered at a certified healthcare facility; patients should be monitored at least daily during the first week following infusion for signs and symptoms of CRS and neurotoxicity; patients should remain in proximity to the center for 4 weeks after infusion for follow-up and toxicity monitoring.</p> <p>Manage increased infection risk with Ig replacement therapy and antibiotic prophylaxis.</p> <p>Treatment is available only through the Yescarta and Tecartus REMS programs.</p> <p>This medication contains warnings for reproduction or lactation. Refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring.</p> <p>(Kite Pharma, 2021b)</p> |

| Classification                               | Mechanism of Action                                                                                                                                                                                                                                                                                                                                                                                                                                       | Drug                                  | Route | Indications                                           | Side Effects                                                                                                                                                                                                                                                                                                                                                                                    | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|-------|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CAR T-cell immunotherapy<br>( <i>Cont.</i> ) | CD19-directed, genetically modified, autologous T-cell immunotherapy that binds to CD19-expressing cancer cells and healthy B cells. CD19 cellular binding results in CD28 and CD3-zeta costimulatory domains, which activate downstream signaling cascades that lead to T-cell activation, proliferation, and acquisition of effector functions and secretion of inflammatory cytokines and chemokines, leading to the killing of CD19-expressing cells. | Brexucabtagene autoleucel (Tecartus®) | IV    | Relapsed or refractory mantle cell lymphoma in adults | Black box warning: CRS, neurotoxicity<br>Fever, myelosuppression, hypersensitivity reactions, hypotension, encephalopathy, fatigue, tachycardia, arrhythmia, infection, chills, hypoxia, cough, tremor, musculoskeletal pain, headache, nausea, edema, motor dysfunction, constipation, diarrhea, decreased appetite, dyspnea, rash, insomnia, pleural effusion, aphasia, hypogammaglobulinemia | Administer after lymphodepleting regimen per package insert.<br>Brexucabtagene autoleucel is for autologous use only. Confirm patient identity prior to administration.<br>Premedicate with acetaminophen and diphenhydramine 30–60 minutes prior to infusion; avoid prophylactic use of systemic corticosteroids.<br>Confirm availability of tocilizumab before infusion.<br>Do not use a lymphodepleting filter.<br>Central venous access is recommended for administration.<br>Prime tubing with normal saline prior to administration.<br>Infuse the entire contents of the bag within 30 minutes by gravity or peristaltic pump. The bag may be gently agitated to prevent clumping.<br>Rinse tubing with normal saline and infuse at the same rate of infusion to ensure all cells are delivered.<br>The bag is stable for up to 3 hours after thawing.<br>Monitor patients for hypersensitivity during infusion and for signs and symptoms of CRS and neurotoxicity, which may be life threatening.<br>CRS may occur with a median time to onset of 3 days. Provide symptomatic support, including antipyretics, oxygen, IV fluids, or vasopressors.<br>Tocilizumab (an IL-6 receptor antagonist) IV over 60 minutes may be administered to manage severe or life-threatening CRS associated with CAR T-cell therapy. It may be used with corticosteroids.<br>Neurotoxicity may occur with a median time to onset of 6 days and may occur concurrent with, following the resolution of, or independent of CRS. Assess patients for |

| CAR T-cell immunotherapy<br>( <i>Cont.</i> ) | CD19-directed, genetically modified, autologous CD4 and CD8 T-cell immunotherapy that binds to CD19-expressing cancer cells and healthy B cells. CD19 cellular binding results in CD28 transmembrane, 4-1BB (CD137), and CD3-zeta costimulatory domains, which activate downstream signaling cascades that lead to T-cell activation, proliferation, and acquisition of effector functions and secretion of inflammatory cytokines and chemokines, leading to the killing of CD19-expressing cells. | Lisocabtagene maraleucel (Breyanzi®) | IV    | <p>Relapsed or refractory large B-cell lymphoma in adults after 2 or more lines of systemic therapy, including:</p> <ul style="list-style-type: none"> <li>• DLBCL not otherwise specified (including transformed DLBCL)</li> <li>• High-grade B-cell lymphoma</li> <li>• Primary mediastinal large B-cell lymphoma</li> <li>• Follicular lymphoma grade 3B</li> </ul> <p>Not indicated for the treatment of primary CNS lymphoma</p> | <p>Black box warnings: CRS, neurotoxicity</p> <p>Fevers, hypersensitivity reactions, infection, prolonged cytopenias, hypogammaglobulinemia, second primary malignancy, fatigue, musculoskeletal pain, nausea, vomiting, headache, encephalopathy, decreased appetite, diarrhea, hypotension, tachycardia, dizziness, cough, constipation, abdominal pain, edema</p> | <p>Administer after lymphodepleting regimen per package insert. Administer 2–7 days after completion of lymphodepleting therapy. Lisocabtagene maraleucel is for autologous use only. Confirm patient identity prior to administration.</p> <p>Premedicate with acetaminophen 650 mg PO and an H<sub>1</sub> antagonist 30–60 minutes prior to infusion; confirm availability of tocilizumab before infusion. Avoid the use of systemic corticosteroids.</p> <p>Keep vials of CD8 and CD4 components separate. Prepare the syringes of the CD8 component first.</p> <p>The volume to be drawn up and infused may differ for each component; do not draw up the excess volume. Gently invert vials to mix cell product until evenly resuspended. Once drawn into syringes, administer as soon as possible.</p> <p>Lisocabtagene maraleucel should be administered within 2 hours of the start of thawing.</p> <p>Do not use a lymphodepleting filter.</p> <p>Prime tubing with normal saline prior to administration and after each CD8 or CD4 component administration.</p> <p>Administer the CD8 component first. Infuse the entire contents of the syringe at 0.5 ml/min, using the closest port or Y-arm. Administer each syringe consecutively without any time between syringes.</p> <p>After CD8 component administration, flush the entire tubing with normal saline.</p> <p>Administer the CD4 component immediately after saline flush.</p> <p>Flush entire tubing with normal saline when complete.</p> <p>Monitor patients for hypersensitivity during infusion and for signs and symptoms of CRS and neurotoxicity, which may be life threatening.</p> |

|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CAR T-cell immunotherapy<br>( <i>Cont.</i> ) | <p>BCMA-directed, genetically modified autologous T-cell immunotherapy.</p> <p>The CAR construct includes an anti-BCMA single-chain variable fragment-targeting domain for antigen specificity, a transmembrane domain, a CD3-zeta activation domain, and a 4-1BB (CD137) costimulatory domain. CD3-zeta signaling initiates activation and anti-tumor activity, while 4-1BB signaling enhances T-cell expansion. Antigen-specific activation of idecabtagene vicleucel results in CAR T-cell proliferation, cytokine secretion, and subsequent cytolytic killing of BCMA-expressing cells.</p> | Idecabtagene vicleucel (Abecma®) | IV    | Relapsed or refractory multiple myeloma in adults after 4 or more prior lines of therapy, including an immunomodulatory agent, a proteasome inhibitor, and an anti-CD38 monoclonal antibody | <p>Black box warnings: CRS, neurotoxicity, hemophagocytic lymphohistiocytosis/macrophage activation syndrome, prolonged cytopenia</p> <p>Fevers, infection, fatigue, musculoskeletal pain, hypogammaglobulinemia, diarrhea, nausea, encephalopathy, edema, cough, headache, decreased appetite, neutropenia, leukopenia, thrombocytopenia, anemia</p> | <p>Administer after lymphodepleting regimen per package insert. Administer 2–9 days after completion of lymphodepleting therapy. Idecabtagene vicleucel is for autologous use only. Confirm patient identity prior to administration.</p> <p>Premedicate with acetaminophen 650 mg PO and an H<sub>1</sub> antagonist 30–60 minutes prior to infusion; confirm availability of tocilizumab before idecabtagene vicleucel infusion. Avoid the use of systemic corticosteroids.</p> <p>Idecabtagene vicleucel should be administered within 1 hour of the start of thawing and is stable for 2 hours once thawed. Do not use a lymphodepleting filter. Prime tubing with normal saline prior to administration.</p> <p>Infuse entire contents of the bag within 1 hour by gravity or peristaltic pump. The bag may be gently agitated to prevent clumping.</p> <p>Rinse tubing with 30–60 ml normal saline and infuse at the same rate of infusion to ensure all cells are delivered.</p> <p>If more than one infusion bag has been received, administer all bags as directed. Do not initiate thaw of the next bag until infusion of the previous bag is complete.</p> <p>Monitor patients for hypersensitivity during infusion and for signs and symptoms of CRS and neurotoxicity, which may be life threatening.</p> <p>CRS may occur with a median time to onset of 1 day. Provide symptomatic support, including antipyretics, oxygen, IV fluids, or vasopressors.</p> <p>Tocilizumab (an IL-6 receptor antagonist) IV over 60 minutes may be administered to manage severe or life-threatening CRS associated with CAR T-cell therapy. It may be used with corticosteroids.</p> |

|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CAR T-cell immunotherapy<br>( <i>Cont.</i> ) | CD19-directed, genetically modified, autologous T-cell immunotherapy that binds to CD19-expressing cancer cells and healthy B cells. CD19 cellular binding results in 4-1BB (CD137) and CD3-zeta costimulatory domains, which activate downstream signaling cascades that lead to T-cell activation, proliferation, and acquisition of effector functions and secretion of inflammatory cytokines and chemokines, leading to the killing of CD19-expressing cells. | Tisagenlecleucel (Kymriah®) | IV    | B-cell precursor ALL in individuals aged 25 years or younger<br>Relapsed or refractory large B-cell lymphoma in adults after 2 or more lines of systemic therapy | Black box warning: CRS and neurotoxicity<br>Fever, hypotension, encephalopathy, tachycardia, fatigue, headache, decreased appetite, chills, febrile neutropenia, infections, hepatitis B virus reactivation, hypoxia, tremor, cough, nausea, vomiting, diarrhea, constipation, dizziness, cardiac arrhythmias, hypersensitivity reactions, prolonged cytopenias, hypogammaglobulinemia, second primary malignancies, bleeding episodes | Administer after lymphodepleting regimen per package insert.<br>Lymphodepleting chemotherapy may be omitted in adults with relapsed or refractory DLBCL if white blood cell count is $\leq 1,000/\text{mm}^3$ within 1 week prior to tisagenlecleucel infusion.<br>Tisagenlecleucel is for autologous use only. Confirm patient identity prior to administration.<br>Premedicate with acetaminophen and an $H_1$ antagonist 30–60 minutes prior to infusion; confirm availability of tocilizumab before infusion. Avoid prophylactic use of systemic corticosteroids.<br>Administer as an IV infusion at 10–20 ml/min (adjusted by age and volume).<br>The volume in the infusion bag ranges 10–50 ml.<br>Do not use a lymphodepleting filter.<br>Prime tubing with normal saline prior to administration.<br>Infuse the entire contents of the bag within 30 minutes by gravity or peristaltic pump.<br>The bag may be gently agitated to prevent clumping.<br>Rinse tubing with 10–30 ml of normal saline and infuse at the same infusion rate to ensure all cells are delivered.<br>Monitor patients for hypersensitivity during infusion and for signs and symptoms of CRS and neurotoxicity, which may be life threatening.<br>CRS may occur with a median time to onset of 3 days. Provide symptomatic support, including antipyretics, oxygen, IV fluids, or vasopressors.<br>Tocilizumab (an IL-6 receptor antagonist) IV over 60 minutes may be administered to manage severe or life-threatening CRS associated with CAR T-cell therapy. It may be used with corticosteroids. |

**TABLE 10-1.** Immunotherapy Agents (*Continued*)

| Classification                      | Mechanism of Action                                                                                                                                                                                                       | Drug                     | Route | Indications                                                                                                                                                                                         | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                         | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cytokines: IFNs<br>( <i>Cont.</i> ) | Binds to cell surface receptors and is classified as a type 2 IFN; enhances oxidative metabolism of macrophages, ADCC, activation of NK cells, and expression of Fc receptors and major histocompatibility antigens       | IFN gamma (Actimmune®)   | SC    | To reduce the frequency and severity of serious infections associated with chronic granulomatous disease<br><br>To delay time to disease progression in patients with severe malignant osteoporosis | Common: flu-like symptoms, fever, chills, myalgia, fatigue, neutropenia, thrombocytopenia, liver enzyme elevation, rash, diarrhea, vomiting, nausea, arthralgia<br><br>Serious: exacerbations of underlying cardiac disease, hepatic insufficiency, pancreatitis with death, asthenia, chest pain, upper respiratory tract infection, muscle spasm, pain, confusion, depression, hallucination, mental status decrease, atopic dermatitis, urticaria | Administer 50 mcg/m <sup>2</sup> SC in patients with body surface area > 0.5 m <sup>2</sup> and 1.5 mcg/kg SC in patients with body surface area ≤ 0.5 m <sup>2</sup> three times weekly.<br>Monitor CBC, chemistries, LFTs, and urinalysis prior to treatment and every 3 months following treatment.<br>Assess for signs and symptoms of infection. Report new symptoms immediately. Symptoms will be most intense at the beginning of treatment and can wane in intensity as treatment continues.<br>(Horizon Therapeutics, 2021)                                                                             |
| Cytokines: ILs                      | Human recombinant IL-2; exact mechanism unknown, but causes induction of lymphokine-activated killer cells, NK cells, and IFN gamma production; inhibits tumor growth by stimulating growth and activity of T and B cells | Aldesleukin (Proleukin®) | IV    | Metastatic melanoma<br>Metastatic renal cell carcinoma                                                                                                                                              | Black box warnings: cardiopulmonary disease, CNS toxicity, capillary leak syndrome, infections<br><br>Common: hypotension, peripheral edema, tachycardia, vasodilation, pruritus, rash, diarrhea, loss of appetite, nausea, vomiting, anemia, thrombocytopenia, hyperbilirubinemia, asthenia, confusion, somnolence, oliguria, elevated serum creatinine, dyspnea, fever, infections, malaise, shivering                                             | Dosing is based on patient weight. Administer 600,000 IU/kg (0.037 mg/kg) IV every 8 hours for 14 doses.<br>Repeat administration after a rest period of 9 days.<br>The drug must be administered in a center with cardiac monitoring capability and intensive care if needed.<br>Administer under the supervision of a qualified physician.<br>Monitor for acute signs of infection and side effects.<br>Monitor weight, urine output, bowel movements, blood pressure, heart rate, temperature, respiratory rate, and oxygen saturation during therapy.<br>Administer supportive medications for side effects. |

| Classification                                         | Mechanism of Action                                                                                | Drug                    | Route | Indications                                                         | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------|-------------------------|-------|---------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Miscellaneous:<br>Immunomodulators<br>( <i>Cont.</i> ) | Not fully understood; possesses immunomodulatory, anti-inflammatory, and antiangiogenic properties | Thalidomide (Thalomid®) | PO    | Newly diagnosed multiple myeloma, in combination with dexamethasone | <p>Black box warning: teratogenicity, thromboembolic events</p> <p>Common: fatigue, hypocalcemia, edema, constipation, peripheral neuropathy, dyspnea, muscle weakness, leukopenia, neutropenia, rash/desquamation, confusion, anorexia, nausea, anxiety/agitation, asthenia, tremor, fever, weight loss, thrombosis/embolism, motor neuropathy, weight gain, dizziness, dry skin</p> <p>Serious: ischemic heart disease in patients treated in combination with dexamethasone, dizziness and orthostatic hypotension, neutropenia, thrombocytopenia, bradycardia, SJS, TEN, seizures, TLS, hypersensitivity reaction, increased HIV viral load</p> | <p>Dosage is 200 mg once daily in combination with dexamethasone 40 mg/day on days 1–4, 9–12, and 17–20 of a 28-day cycle. Doses should be taken once daily with water, preferably at bedtime and at least 1 hour after a meal.</p> <p>The drug is available in 50, 100, 150, and 200 mg capsules.</p> <p>Examine patients every 3 months for signs of peripheral neuropathy.</p> <p>The drug is only available through a REMS program.</p> <p>Patients must not donate blood during treatment and for 1 month following treatment.</p> <p>The drug is teratogenic; avoid use in pregnant women and women of childbearing potential.</p> <p>This medication contains warnings for reproduction or lactation. Refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring. (Celgene, 2021b)</p> |

**TABLE 10-1.** Immunotherapy Agents (*Continued*)

| Classification                   | Mechanism of Action                                                                                                                                                | Drug                            | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Side Effects                                                                                                                                                                                                                                                                                                                                         | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Monoclonal antibody:<br>Chimeric | Blocks the binding of ligands to EGFR, resulting in the inhibition of cell growth and induction of apoptosis; also mediates ADCC against certain human tumor types | Cetuximab (Erbix <sup>®</sup> ) | IV    | <p><i>KRAS</i> wild-type EGFR-expressing metastatic colorectal cancer in combination with chemotherapy; not indicated when results of the <i>RAS</i> variation tests are unknown</p> <p>Recurrent or metastatic squamous head and neck cancer after platinum-based chemotherapy failure</p> <p>Locally or regionally advanced squamous head and neck cancer in combination with radiation therapy</p> <p>Locoregional or metastatic squamous head and neck cancer in combination chemotherapy</p> | <p>Black box warning: cardiopulmonary arrest, infusion-related reactions</p> <p>Fatigue, pain, peripheral neuropathy, headache, insomnia, weight loss, skin toxicities (e.g., acneiform rash, nail changes), hypomagnesemia, dehydration, GI toxicities, elevated LFTs, weakness, dyspnea, cough, fever, pharyngitis, infusion-related reactions</p> | <p>Administer 400 mg/m<sup>2</sup> initial dose as a 120-minute IV infusion.</p> <p>The maintenance dosage is 250 mg/m<sup>2</sup> weekly over 60 minutes. The maximum infusion rate is 10 mg/min.</p> <p>Initiate cetuximab 1 week prior to the start of radiation therapy.</p> <p>Complete cetuximab 1 hour prior to platinum-based therapy with a 5-fluorouracil and FOLFIRI regimen.</p> <p>Administer with a 0.22-micron in-line filter.</p> <p>Premedicate with antihistamine.</p> <p>Treatment for anaphylactic reactions should be available as needed during and for 1 hour after infusion.</p> <p>Monitor serum electrolytes (e.g., magnesium, potassium, calcium) during and up to 8 weeks after treatment.</p> <p>Monitor for dermatologic toxicities and advise patients to wear sunscreen. Monitor for preexisting cardiac disease or worsening or new cardiac symptoms.</p> <p>Do not administer as an IV push or bolus.</p> <p>This medication contains warnings for reproduction or lactation. Refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring.</p> <p>(Eli Lilly and Company, 2021)</p> |

| Classification                                       | Mechanism of Action                                                                                                                                                                                                                        | Drug                        | Route | Indications                                                                                                                                                                                                                                                                                                                           | Side Effects                                                                                                                                                          | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Monoclonal antibody:<br>Chimeric<br>( <i>Cont.</i> ) | Chimeric monoclonal antibody directed against CD38 expressed on multiple myeloma cells; exerts antitumor activity via ADCC, CDC, and ADCP; activates NK cells in the absence of CD38+ target cells and suppresses CD38+ regulatory T cells | Isatuximab-irfc (Sarclisa®) | IV    | Multiple myeloma, in combination with pomalidomide and dexamethasone, in adults who have received at least 2 prior therapies, including lenalidomide and a proteasome inhibitor<br>Relapsed or refractory multiple myeloma, in combination with carfilzomib and dexamethasone, in adults who have received 1–3 prior lines of therapy | Neutropenia, myelosuppression, infusion-related reactions, pneumonia, upper respiratory tract infection, diarrhea, second primary malignancies, embryo-fetal toxicity | Administer 10 mg/kg IV every week for 4 weeks followed by every 2 weeks, in combination with pomalidomide and dexamethasone or in combination with carfilzomib and dexamethasone.<br>Premedicate with dexamethasone, acetaminophen, H <sub>2</sub> antagonists, and diphenhydramine.<br>If a reaction occurs, treat patients as indicated. Discontinue treatment permanently for grade 3–4 reactions.<br>Monitor patients with neutropenia for signs of infection. Colony-stimulating factors may be needed for the improvement of neutrophil count.<br>Monitor patients for the development of second primary malignancies.<br>The drug can interfere with serologic testing (indirect antiglobulin test). Type and screen patients prior to starting treatment and inform the blood bank that patients have received isatuximab-irfc.<br>The drug may interfere with the assays used to monitor myeloma protein, affecting the determination of complete response.<br>This medication contains warnings for reproduction or lactation. Refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring.<br>(Sanofi-Aventis U.S., 2021) |

| Classification                                       | Mechanism of Action                                                                                                                               | Drug                                                                                                  | Route | Indications                                                                                  | Side Effects                                                                                                                                                                                                                                                                                           | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|-------|----------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Monoclonal antibody:<br>Chimeric<br>( <i>Cont.</i> ) | Binds to the anti-gen CD20 on B cells, leading to B-cell lysis                                                                                    | Rituximab (Rituxan®), Rituximab-abbs (Truxima®), Rituximab-arrx (Riabni™), Rituximab-pvvr (Ruxience®) | IV    | CD20-positive CLL<br>CD20-positive non-Hodgkin lymphoma                                      | Black box warnings: infusion-related reactions within 24 hours of infusion, TLS<br>Severe mucocutaneous reactions, progressive multifocal leukoencephalopathy<br>Adverse reactions: fatigue, chills, neuropathy, nausea, lymphocytopenia, anemia, infection, weakness, infusion-related reactions, TLS | For non-Hodgkin lymphoma, administer 375 mg/m <sup>2</sup> IV according to schedule for specific diagnosis (see prescribing information).<br>For CLL, administer 375 mg/m <sup>2</sup> in cycle 1 and 500 mg/m <sup>2</sup> in cycles 2–6.<br>With first administration in patients with high disease burden, consider stepped-up dosing: 50 mg on day 1, 150 mg on day 2, and the remainder of the 375 mg/m <sup>2</sup> on day 3.<br>Do not administer as an IV push or bolus.<br>Premedicate with acetaminophen and an antihistamine prior to each infusion.<br>Adjust dose for adverse effects. Treatment may be held or discontinued based on the severity of the adverse effects.<br>Monitor hepatitis B serologies. If patients have a history of hepatitis B, advise them to report any signs or symptoms of an active infection.<br>Advise patients to avoid vaccines. Administration of non-live vaccines should take place at least 4 weeks prior to 2-week treatment.<br>Instruct patients to report any skin toxicities.<br>This medication contains warnings for reproduction or lactation. Refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring.<br>(Amgen, 2020a; Genentech, 2020d, 2021f; Pfizer; 2020; Teva Pharmaceuticals, 2019b; Winkler et al., 1999) |
|                                                      | Binds to the antigen CD20 and is combined with hyaluronidase. Hyaluronidase increases permeability of the SC tissue by depolymerizing hyaluronan. | Rituximab and hyaluronidase (Rituxan Hycela®)                                                         | SC    | CD20-positive CLL<br>CD20-positive non-Hodgkin lymphoma<br>CD20-positive follicular lymphoma | Black box warnings: hepatitis B virus reactivation, severe mucocutaneous reactions, progressive multifocal leukoencephalopathy<br>Adverse effects: neutropenia, anemia,                                                                                                                                | All patients receive at least one full dose of rituximab IV before receiving the SC dose of rituximab and hyaluronidase.<br>For CLL, administer 1,600 mg rituximab and 26,800 units hyaluronidase SC over 7 minutes.<br>For non-Hodgkin lymphoma and follicular lymphoma, administer 1,400 mg rituximab and 23,400 units hyaluronidase SC over 5 minutes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**TABLE 10-1.** Immunotherapy Agents (*Continued*)

| Classification                  | Mechanism of Action                                                                                                                                                                                                  | Drug                                                  | Route | Indications                                                                                                                                                                                                                                                                                                                                                                  | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Monoclonal antibodies:<br>Human | Binds to CD38, resulting in apoptosis via Fc-mediated cross-linking and immune-mediated tumor cell death by CDC, ADCC, and ADCP                                                                                      | Daratumumab (anti-CD38 antibody; Darzalex®)           | IV    | Newly diagnosed, relapsed, or refractory multiple myeloma in adults<br>Newly diagnosed multiple myeloma, in combination with other therapy<br>Relapsed or refractory multiple myeloma, as monotherapy or in combination with other therapy<br>Newly diagnosed light-chain amyloidosis, in combination with bortezomib, cyclophosphamide, and dexamethasone                   | Fatigue, nausea, lymphocytopenia, neutropenia, anemia, back pain, cough, fever, infusion-related reactions, asthenia, diarrhea, constipation, decreased appetite, vomiting, muscle spasms, arthralgia, fever, chills, dizziness, insomnia, cough, dyspnea, peripheral edema, peripheral sensory neuropathy, bronchitis, pneumonia, upper respiratory tract infection<br>Potential treatment-related toxicities, including anaphylactic infusion-related reactions, interference with crossmatching and blood cell antibody screening, thrombocytopenia | The drug interferes with serologic testing. Obtain a type and screen prior to treatment. Daratumumab binds to CD38 on RBCs and results in a positive indirect Coombs test. Positive Coombs test may occur up to 6 months after final administration. Notify the transfusion center that patients have received daratumumab. Administer 16 mg/kg based on actual body weight. Titrate per package insert based on volume and dose. Use a 0.22- or 0.2-micron in-line, nonpyrogenic, low-protein-binding PES filter. Do not administer as an IV push or bolus. Administer weekly for 8 doses (weeks 1–8), then every 2 weeks (weeks 9–24), and then every 4 weeks (starting week 25) until disease progression. Premedicate with PO or IV dexamethasone 20 mg, PO antipyretic, and PO or IV antihistamine. Educate patients to report symptoms of infection and easy bruising or bleeding. (Janssen Biotech, 2020a) |
|                                 | Binds to CD38, resulting in apoptosis via Fc-mediated cross-linking and immune-mediated tumor cell death by CDC, ADCC, and ADCP. Hyaluronidase increases permeability of the SC tissue by depolymerizing hyaluronan. | Daratumumab and hyaluronidase-fihj (Darzalex Faspro®) | SC    | Newly diagnosed multiple myeloma, in combination with bortezomib, melphalan, and prednisone, in patients who are ineligible for autologous HSCT<br>Newly diagnosed multiple myeloma, in combination with lenalidomide and dexamethasone, in patients who are ineligible for autologous HSCT<br>Relapsed or refractory multiple myeloma, in combination with lenalidomide and | Fatigue, nausea, lymphocytopenia, neutropenia, anemia, back pain, cough, hypersensitivity and other administration reactions (skin reactions at or near the injection site), asthenia, diarrhea, constipation, decreased appetite, vomiting, muscle spasms, arthralgia, fever, chills, dizziness, insomnia, cough,                                                                                                                                                                                                                                     | The drug interferes with serologic testing. Daratumumab binds to CD38 on RBCs and results in a positive indirect Coombs test. Obtain a type and screen prior to the start of treatment. Positive Coombs test may occur up to 6 months after the final dose. Notify the transfusion center that patients have received daratumumab. Drug combination allows for SC dosing of daratumumab. Premedicate with a corticosteroid, acetaminophen, and an H <sub>1</sub> antagonist. Premedication may be discontinued after the first three doses if no major systemic administration-related reactions occur.                                                                                                                                                                                                                                                                                                           |

| Classification                                      | Mechanism of Action                                 | Drug                                                                   | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Side Effects                                                                                                                                                                                                                                                                           | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------------|-----------------------------------------------------|------------------------------------------------------------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Monoclonal antibodies:<br>Human<br>( <i>Cont.</i> ) |                                                     | Daratumumab and hyaluronidase-fihj (Darzalex Faspro® ( <i>Cont.</i> )) |       | dexamethasone, in patients who have received at least 1 prior therapy<br>Multiple myeloma, in combination with bortezomib and dexamethasone, in patients who have received at least one prior therapy<br>Multiple myeloma, as monotherapy, in patients who have received at least 3 prior lines of therapy, including a proteasome inhibitor and an immunomodulatory agent, or in patients who are double refractory to a proteasome inhibitor and an immunomodulatory agent | dyspnea, peripheral edema, peripheral sensory neuropathy, bronchitis, pneumonia, upper respiratory tract infection<br>Potential treatment-related toxicities, including anaphylactic reaction, interference with crossmatching and blood cell antibody screening, and thrombocytopenia | The dosage is 1,800 mg daratumumab and 30,000 units hyaluronidase SC, according to the recommended schedule. The schedule is dependent on whether treatment is a combination or monotherapy.<br>Inject 15 ml of the drug into the SC tissue of the abdomen, approximately 3 in. (7.5 cm) to the right or left of the navel, over approximately 3–5 minutes. No data are available on injecting other sites of the body.<br>Rotate injection sites for successive injections.<br>Never inject into areas where the skin is red, bruised, tender, or hard or areas with scars. Pause or slow delivery rate if patients experience pain. In the event pain is not alleviated by pausing or slowing down the delivery rate, a second injection site may be used on the opposite side of the abdomen to deliver the remainder of the dose.<br>Skin reactions at or near the injection site can occur. Symptoms may include itching, swelling, bruising, or redness. These reactions can occur more than 24 hours after an injection.<br>Patients should be monitored after the first and second SC dose if they have never received IV daratumumab. The median time to onset of a systemic administration-related reaction is 3.7 hours.<br>Educate patients to report symptoms of infection and easy bruising or bleeding. (Janssen Biotech, 2020b) |

| Classification                                      | Mechanism of Action                               | Drug                                         | Route | Indications                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Side Effects                                                                                                                                                                                                                                                                                                                                                 | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------------------------|---------------------------------------------------|----------------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Monoclonal antibodies:<br>Human<br>( <i>Cont.</i> ) | Blocks the binding of ligands to EGFR             | Panitumumab (anti-EGFR antibody; Vectibix®)  | IV    | Metastatic wild-type <i>KRAS</i> colorectal cancer                                                                                                                                                                                                                                                                                                                                                                                                            | Black box warning: Dermatologic toxicities<br>Adverse effects: Fatigue, skin toxicity (acneiform dermatitis, pruritus, erythema, rash, exfoliation, paronychia, dry skin, fissures), ocular toxicity, nausea, diarrhea, vomiting, dyspnea, pulmonary fibrosis/ILD, infusion-related reactions                                                                | Administer 6 mg/kg as IV infusion every 14 days. If dose < 1,000 mg, infuse over 60 minutes. If dose > 1,000 mg, infuse over 90 minutes.<br>Do not administer as an IV push or bolus. Administer using a low-protein-binding 0.2-micron or 0.22-micron in-line filter. Refer to prescribing information for titration instructions.<br>Use the diluted solution within 6 hours of dilution if stored at room temperature. Adjust dose for adverse effects. Treatment may be held or discontinued based on the severity of adverse effects.<br>Monitor electrolytes, ocular toxicities (keratitis or ulcerative keratitis), and dermatologic toxicities.<br>Advise patients to limit sun exposure. This medication contains warnings for reproduction or lactation. Refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring. (Amgen, 2015) |
|                                                     | Binds to VEGFR2 and prevents ligands from binding | Ramucirumab (anti-VEGFR2 antibody; Cyramza®) | IV    | Gastric or GEJ adenocarcinoma, as a single agent or in combination with paclitaxel, for advanced or metastatic disease that has progressed on or after prior fluoropyrimidine- or platinum-containing chemotherapy.<br>NSCLC<br>• In combination with docetaxel for metastatic disease with progression on or after platinum-based chemotherapy; progression of disease with EGFR or ALK genomic tumor aberrations on FDA-approved therapy prior to treatment | Hypertension, proteinuria, infusion-related reactions, impaired wound healing, risk of hemorrhage<br>Worsening of preexisting hepatic impairment, particularly hepatic encephalopathy, and hepatorenal syndrome for individuals with Child-Pugh A liver cirrhosis<br>See prescribing information for most common adverse reactions with combination therapy. | For gastric cancer, administer 8 mg/kg every 2 weeks as a single agent or in combination with weekly paclitaxel.<br>For NSCLC, administer 10 mg/kg on day 1 of a 21-day cycle prior to docetaxel.<br>For colorectal cancer, administer 8 mg/kg every 2 weeks prior to FOLFIRI.<br>For hepatocellular carcinoma, administer 8 mg/kg every 2 weeks.<br>Administer IV infusion over 60 minutes; schedule is specific to cancer type. Administer with normal saline only.<br>Administer with a protein-sparing 0.22-micron filter.<br>Premedicate with IV H <sub>1</sub> antagonist. If patients have had a prior grade 1 or 2 infusion-related reaction, also premedicate with dexamethasone and acetaminophen.                                                                                                                                                                                                       |

| Classification                                        | Mechanism of Action                                                                                                       | Drug                       | Route | Indications                                                                                                                                                                                                                                                       | Side Effects                                                                                                                                                                                                                                                                                                                                                  | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|----------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Monoclonal antibody:<br>Humanized<br>( <i>Cont.</i> ) | Binds to ganglioside GD2 that is overexpressed on neuroblastoma cells; induces complement-dependent cytotoxicity and ADCC | Naxitamab-gqgk (Danyelza®) | IV    | Neuroblastoma, in combination with GM-CSF, in adult and pediatric patients aged > 1 year with relapsed or refractory high-risk disease in the bone or bone marrow that has demonstrated a partial response, minor response, or stable disease after prior therapy | Black box warnings: infusion-related reactions; neurotoxicity, including posterior leukoencephalopathy syndrome<br>Adverse effects: peripheral neuropathy, pain, infusion-related reactions, edema, fatigue, fever, cough, nausea, vomiting, diarrhea, headache, somnolence, neurologic eye disorders, infection, electrolyte abnormalities, myelosuppression | Administer 3 mg/kg/day on days 1, 3, and 5 of each cycle.<br>Repeat cycles every 4 weeks until complete response or partial response, then 5 additional cycles every 4 weeks.<br>Further cycles may be every 8 weeks.<br>Administer GM-CSF 250 mcg/m <sup>2</sup> /day as SC injection on days –4 to 0. Administer GM-CSF 500 mcg/m <sup>2</sup> /day as SC injection on days 1–5.<br>Administer IV corticosteroids (e.g., methylprednisolone 2 mg/kg up to 80 mg or equivalent) 30 minutes to 2 hours prior to infusion.<br>Administer an antihistamine, H <sub>2</sub> antagonist, acetaminophen, and antiemetic 30 minutes prior to infusion.<br>Administer the first cycle over 60 minutes. Subsequent cycles can be administered over 30–60 minutes, as tolerated.<br>Observe patients for a minimum of 2 hours following each infusion.<br>Administer naxitamab as an IV infusion only. GM-CSF should be administered at least 1 hour prior to naxitamab on days 1, 3, and 5 of a cycle.<br>Beginning 5 days prior to the first infusion, initiate a 12-day course of prophylactic medication for neuropathic pain (e.g., gabapentin).<br>Adjust dose for adverse effects. Treatment may be held, adjusted, or discontinued based on the severity of the adverse effects.<br>Monitor for infusion-related reactions.<br>Monitor for neurotoxicity, including peripheral neuropathy.<br>Monitor blood pressure before and during treatment.<br>This medication contains warnings for reproduction or lactation. Refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring.<br>(Y-mAbs Therapeutics, 2020) |

| Classification                                        | Mechanism of Action                                                                                                                                                                                                                                                                                                               | Drug                                                      | Route | Indications                                                                                                                                                                                                                                                                                                                                                                      | Side Effects                                                                                                                                                                                                                                                                            | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Monoclonal antibody:<br>Humanized<br>( <i>Cont.</i> ) | Targets HER2 on breast cancer cells resulting in cell growth arrest and apoptosis; also causes ADCC                                                                                                                                                                                                                               | Pertuzumab (Perjeta®)                                     | IV    | HER2-positive breast cancer, in the neoadjuvant, adjuvant, or metastatic setting, in combination with trastuzumab and chemotherapy                                                                                                                                                                                                                                               | Black box warning: left ventricular dysfunction, embryo-fetal toxicity<br><br>Adverse effects: weakness, myalgias, neutropenia, anemia, diarrhea, nausea, vomiting, alopecia, rash, fatigue, headache, left ventricular cardiac dysfunction, infusion-related reactions                 | Administer the initial dose of 840 mg IV over 60 minutes.<br>Administer subsequent doses of 420 mg over 30–60 minutes.<br>Do not administer as an IV push or bolus.<br>Adjust dose for adverse effects. Treatment may be held or discontinued based on the severity of the adverse effects.<br>Monitor LVEF prior to and during therapy.<br>See prescribing information for schedule.<br>Monitor for infusion-related reactions.<br>This medication contains warnings for reproduction or lactation. Refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring.<br>(Genentech, 2021e)                                                                                                                                                                                                                                                                     |
|                                                       | Pertuzumab and trastuzumab target HER2. Hyaluronidase (recombinant human) is an endoglycosidase used to increase the dispersion and absorption of SC coadministered drugs; it is a glycosylated single-chain protein produced by mammalian cells containing a DNA plasmid encoding for a soluble fragment of human hyaluronidase. | Pertuzumab, trastuzumab, and hyaluronidase-zzxf (Phesgo™) | SC    | Neoadjuvant treatment for HER2-positive locally advanced, inflammatory, or early-stage breast cancer<br>Neoadjuvant treatment for HER2-positive early-stage breast cancer at high risk for recurrence<br>HER2-positive metastatic breast cancer, in combination with docetaxel, in patients who have not received prior anti-HER2 therapy or chemotherapy for metastatic disease | Black box warnings: cardiomyopathy, embryo-fetal toxicity, pulmonary toxicity<br><br>Adverse effects: alopecia, nausea, diarrhea, anemia, asthenia, neutropenia, fatigue, rash, peripheral neuropathy, pulmonary toxicity, cardiomyopathy, hypersensitivity, infusion-related reactions | The initial dose is 1,200 mg pertuzumab, 600 mg trastuzumab, and 30,000 units hyaluronidase SC over approximately 8 minutes into the thigh only.<br>Subsequent doses are 600 mg pertuzumab, 600 mg trastuzumab, and 20,000 units hyaluronidase SC over 5 minutes, administered every 3 weeks.<br>For SC administration, use in the thigh only. Do not administer via IV.<br>Adjust dose for adverse effects. Treatment may be held or discontinued based on the severity of the adverse effects.<br>Monitor for cardiac symptoms, including hypertension, arrhythmias, and left ventricular dysfunction.<br>Conduct a comprehensive cardiac assessment, including history, physical examination, and multigated acquisition scan, prior to beginning therapy, at regular intervals, and with cardiac symptoms.<br>Monitor for signs of pulmonary toxicity, including anaphylaxis, angioedema, interstitial pneumonitis, or ARDS. |

**TABLE 10-1.** Immunotherapy Agents (Continued)

| Classification                         | Mechanism of Action                                                                                                                                                                                                                              | Drug                                                    | Route | Indications                                                                                                                                                                           | Side Effects                                                                                                                                                                                                                                                                                                                                                                    | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Monoclonal antibody: Humanized (Cont.) | Trastuzumab is a mediator of ADCC for HER2-overexpressing cancer cells. Hyaluronidase increases permeability of the SC tissue by depolymerizing hyaluronan and increases the absorption rate of a trastuzumab product into systemic circulation. | Trastuzumab and hyaluronidase-oysk (Herceptin Hylecta™) | SC    | HER2-positive breast cancer, as adjuvant therapy in combination with chemotherapy or as a single agent<br>HER2-positive metastatic breast cancer, in combination or as a single agent | Black box warnings: cardiomyopathy, pulmonary toxicity, embryo-fetal toxicity<br>Adverse effects: fatigue, arthralgia, diarrhea, injection site reaction, upper respiratory tract infection, rash, myalgia, nausea, headache, edema, flushing, fever, cough, extremity pain<br>May contribute to the exacerbation of chemotherapy-induced neutropenia and embryo-fetal toxicity | Administer trastuzumab 600 mg and hyaluronidase 10,000 units SC over 2–5 minutes once every 3 weeks.<br>If a dose is missed, administer the next dose as soon as possible, with the interval between doses < 3 weeks.<br>Administer SC only.<br>Alternate administration between left and right thigh, giving the injection at least 2.5 cm from the previous site and only to healthy skin without redness, bruising, tenderness, hardness, moles, or scars.<br>Adjust dose for adverse effects. Treatment may be held or discontinued based on the severity of the adverse effects.<br>Monitor for hypersensitivity and administration-related reactions, especially with the first dose.<br>Assess LVEF at baseline and every 3 months during treatment and at completion.<br>Refer to prescribing information for LVEF assessments.<br>Discontinue in the presence of cardiomyopathy, anaphylaxis, angioedema, interstitial pneumonitis, or ARDS.<br>This medication contains warnings for reproduction or lactation. Refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring.<br>(Genentech, 2019) |

| Bispecific antibody                            | Binds to EGFR and MET receptor, disrupting EGFR and MET signaling functions through blockage and degradation of receptor; allows for targeting of tumor cells by immune effector cells, with NK cells causing ADCC and macrophages causing trogocytosis                                                                | Amivantamab-vmjw (Rybrevant®) | IV    | Locally advanced or metastatic NSCLC with EGFR exon 20 insertion variations that has progressed on or after platinum-based chemotherapy, in adults                                                | Infusion-related reactions, ILD/pneumonitis, acneiform dermatitis, TEN, ocular toxicity, embryo-fetal toxicity, rash, paronychia, musculoskeletal pain, dyspnea, nausea, vomiting, fatigue, edema, stomatitis, cough, constipation, decreased lymphocytes, hypokalemia, hyponatremia | Dose is based on baseline body weight: <ul style="list-style-type: none"> <li>• &lt; 80 kg: 1,050 mg</li> <li>• ≥ 80 kg: 1,400 mg</li> </ul> Premedicate with acetaminophen and antihistamine prior to all doses. Administer corticosteroid prior to initial doses on days 1 and 2 of week 1 of treatment. Infusion rates are dependent on dose, infusion schedule, and observed infusion-related reactions. See prescribing information for infusion rate table and adjustments for infusion reactions. Administer using 0.2-micron PES filter. Hold and discontinue therapy for presumed and confirmed ILD and severe dermatologic adverse events. This medication contains warnings for reproduction or lactation. Refer to the prescribing information for additional details on the risk and product-specific guidance in avoidance or monitoring. (Janssen Biotech, 2021)                                                 |
| Bispecific T-cell engaging monoclonal antibody | Bispecific CD19-directed CD3 T-cell engager; binds to CD19 expressed on the surface of cells of B-lineage origin and CD3 expressed on the surface of T cells, which activates endogenous T cells by connecting CD3 in the T-cell receptor complex with CD19 on benign and malignant B cells; upregulates cell adhesion | Blinatumomab (Blinxyto®)      | IV    | CD19-positive B-cell precursor ALL in first or second complete response with MRD ≥ 0.1% in adults and children<br>CD19-positive relapsed or refractory B-cell precursor ALL in adults or children | Black box warning: CRS, neurotoxicity<br>Edema, hypertension, neurotoxicity, headache, rash, hypokalemia, nausea, vomiting, abdominal pain, anemia, thrombocytopenia, neutropenia, leukopenia, febrile neutropenia, elevated serum ALT, infection, fever, infusion-related reactions | For MRD-positive disease: <ul style="list-style-type: none"> <li>• Each treatment cycle consists of 4 weeks of continuous infusion followed by a 2-week treatment-free interval.</li> <li>• Therapy involves 1 induction cycle followed by up to 3 additional cycles for consolidation (a total of up to 4 cycles).</li> <li>• Administer 15 mcg/m<sup>2</sup>/day dose for weight &lt; 45 kg and flat dose 28 mcg/day for weight ≥ 45 kg.</li> <li>• Dosage is based on weight and cycle.</li> <li>• Premedicate with dexamethasone or prednisone 1 hour prior to the first dose of each cycle and if restarting after interruption of ≥ 4 hours in the first cycle.</li> </ul> For relapsed/refractory disease: <ul style="list-style-type: none"> <li>• The treatment course consists of up to 2 cycles for induction, followed by 3 additional cycles of consolidation, and up to 4 cycles of continued therapy.</li> </ul> |

**TABLE 10-1.** Immunotherapy Agents *(Continued)*

| Classification                                                     | Mechanism of Action                                                                                                                                             | Drug                                         | Route | Indications | Side Effects | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|-------|-------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bispecific T-cell engaging monoclonal antibody<br>( <i>Cont.</i> ) | molecules, production of cytolytic proteins, the release of inflammatory cytokines, and proliferation of T cells, which results in lysis of CD19-positive cells | Blinatumomab (Blincyto®)<br>( <i>Cont.</i> ) |       |             |              | <ul style="list-style-type: none"> <li>Dosing is based on weight and cycle, with an mcg/m<sup>2</sup>/day dose for weight &lt; 45 kg and a flat mcg/day dose for weight ≥ 45 kg.</li> <li>Premedicate with dexamethasone or prednisone 1 hour prior to the first dose of each cycle, prior to a step dose (such as cycle 1, day 8), and when restarting after interruption ≥ 4 hours.</li> </ul> <p>Administer as a continuous IV infusion for the daily dose; confirm infusion rate based on compounded infusion.</p> <p>Do not administer as an IV push or bolus. Instruct patients to refrain from driving while receiving blinatumomab infusion.</p> <p>Hospitalization is recommended for the first 9 days of the first cycle and the first 2 days of the second cycle.</p> <p>For MRD, hospitalization is recommended for the first 2 days of each cycle.</p> <p>Patients should be aware of the neurotoxicity effects and avoid activities that require mental alertness or coordination for the first dose. Instruct patients to report neurotoxicity, as well as symptoms of infection and pancreatitis.</p> <p>Advise patients not to change pump settings and to alert a healthcare worker immediately if the pump malfunctions.</p> <p>Do not flush the blinatumomab infusion line or IV catheter, especially when changing infusion bags. Flushing when changing bags or at the completion of the infusion can result in excess dosage and complications. Blinatumomab should be infused through a dedicated lumen of a vascular access catheter.</p> <p>CRS can occur and may be life-threatening or fatal. Interrupt or discontinue blinatumomab and treat with corticosteroids as recommended by the provider.</p> <p>(Amgen, 2021a)</p> |

| Oncolytic viral therapy | Replicates within tumors to produce the immune-stimulatory protein GM-CSF, causing tumor lysis and promoting an anti-tumor response | Talimogene laherparepvec (Imlygic®) | Intrale-sional injection | Unresectable cutaneous, SC, and nodal lesion melanoma that is recurrent after initial surgery | Immune-mediated events: glomerulo-nephritis, vasculitis, pneumonitis, worsen-ing psoriasis, vitiligo<br>Fever, fatigue, chills, nausea, vomiting, headache, flu-like symptoms, elevated liver enzymes, injection site pain | <p>Starting dose is up to a maximum of 4 ml at a concentration of 1 million PFU/ml.</p> <p>Subsequent doses should be up to 4 ml at a concentration of 100 million PFU/ml.</p> <p>Clean lesion and surrounding area with an alcohol swab and let dry.</p> <p>Administer topical or local anesthetic. Do not inject into the lesion.</p> <p>Inject talimogene laherparepvec into cutaneous, SC, or nodal lesions that are visible, palpable, or detectable by ultrasound guidance.</p> <p>Using a single insertion point, inject along multiple tracks as far as the radial reach of the needle to achieve complete dispersion.</p> <p>Multiple insertion points are permitted for larger lesions.</p> <p>Inject by pulling the needle back without exiting the lesion.</p> <p>If withdrawing, remove slowly to prevent leakage at the insertion point.</p> <p>Use a new needle each time the needle is completely removed from a lesion, and a different lesion is treated.</p> <p>Monitor the injection site for necrosis or ulceration, cellulitis, and infection.</p> <p>Keep injection site covered for at least 1 week after each treatment.</p> <p>Wear personal protective equipment when administering.</p> <p>Clean all surfaces that may have come into contact with the product using a virucidal agent.</p> <p>Immunocompromised individuals should <i>not</i> administer the drug, change dressings, or have contact with patient body fluids.</p> <p>Caregivers should wear protective gloves when assisting patients in applying or changing occlusive dressings.</p> <p>Dispose of dressings and cleaning materials used for the site in a sealed plastic bag and dispose of in household waste.</p> |

ADCC—antibody-dependent cell-mediated cytotoxicity; ADCP—antibody-dependent cellular phagocytosis; ALK—anaplastic lymphoma kinase; ALL—acute lymphoblastic leukemia; ALT—alanine aminotransferase; AML—acute myeloid leukemia; ARDS—acute respiratory distress syndrome; AST—aspartate aminotransferase; BCMA—B-cell maturation antigen; CAR—chimeric antigen receptor; CBC—complete blood count; CCR4—C-C chemokine receptor type 4; CD—cluster of differentiation; CDC—complement-dependent cytotoxicity; cHL—classical Hodgkin lymphoma; CLL—chronic lymphocytic leukemia; CMV—cytomegalovirus; CRS—cytokine release syndrome; CYP—cytochrome P450; DLBCL—diffuse large B-cell lymphoma; dMMR—mismatch repair deficient; EGFR—epidermal growth factor receptor; Fc—fragment crystallizable; FDA—U.S. Food and Drug Administration; FOLFIRI—leucovorin, 5-fluorouracil, and irinotecan; 5-HT<sub>3</sub>—5-hydroxytryptamine-3; G-CSF—granulocyte-colony-stimulating factor; GEJ—gastroesophageal junction; GGT—gamma-glutamyltransferase; GI—gastrointestinal; GM-CSF—granulocyte macrophage-colony-stimulating factor; HER2—human epidermal growth factor receptor 2; Hgb—hemoglobin; HSCT—hematopoietic stem cell transplantation; IFN—interferon; Ig—immunoglobulin; IL—interleukin; ILD—interstitial lung disease; IM—intramuscular; IV—intravenous; LFTs—liver function tests; LVEF—left ventricular ejection fraction; MMAE—monomethyl auristatin E; MMAF—monomethyl auristatin F; MRD—minimal residual disease; MSI-H—microsatellite instability-high; NK—natural killer; NSCLC—non-small cell lung cancer; PAP—prostatic acid phosphatase; PD-L1/2—programmed cell death-ligand 1/2; PD-1—programmed cell death protein 1; PES—polyethersulfone; PFU—plaque-forming unit; PO—by mouth; RANK—receptor activator of nuclear factor kappa-B; RANKL—receptor activator of nuclear factor kappa-B ligand; RBC—red blood cell; REMS—risk evaluation and mitigation strategy; SC—subcutaneous; SCLC—small cell lung cancer; SJS—Stevens-Johnson Syndrome; SLAMF7—signaling lymphocytic activation molecule family member 7; TEN—toxic epidermal necrolysis; TLS—tumor lysis syndrome; Trop-2—trophoblast cell-surface antigen 2; UGT1A1—uridine diphosphate-glucuronosyl transferase 1A1; VEGF—vascular endothelial growth factor; ULN—upper limit of normal; USP—U.S. Pharmacopeia; VEGFR2—vascular endothelial growth factor receptor 2

e) Toxicities: Based on the mechanism of action, the most common toxicities associated with checkpoint inhibitors are immune-related adverse events (irAEs). These events are thought to be driven by an inflammatory response to immune-mediated activity, resulting in inflammation within one or more organ systems (Gordon et al., 2017; Postow et al., 2018; Villadolid & Amin, 2015). The extent of inflammation can range from mild to severe, and the onset of irAEs can range from immediately after treatment initiation to months after initiation (Thompson et al., 2019).

(1) Safe and effective management of irAEs necessitates a thorough baseline assessment and early recognition and may require supportive care and immunosuppressive agents. Patients and caregivers should be educated on irAEs, including signs and symptoms of toxicities, the importance of communication with the healthcare team, and management strategies.

(2) Most commonly observed irAEs (see Figure 10-1)

- (a) Gastrointestinal (e.g., diarrhea, colitis)
- (b) Pulmonary (e.g., pneumonitis)
- (c) Dermatologic (e.g., rash, pruritus)
- (d) Endocrine (e.g., hypophysitis, hyperthyroidism, hypothyroidism)
- (e) Renal (e.g., nephritis)
- (f) Rheumatologic (e.g., arthralgias, myalgias)

(3) Several organizations, such as the American Society of Clinical Oncology, National Comprehensive Cancer Network (NCCN), Society for Immunotherapy of Cancer, and European Society for Medical Oncology, have published clinical guidelines for checkpoint inhibitor-related irAEs (Brahmer et al., 2018; Haanen et al., 2017; NCCN, 2022). General recommendations include the following (these may be different for specific manifestations of an irAE) (Brahmer et al., 2018):

- (a) Grade 1 toxicities can generally be managed with supportive care and close monitoring during immune checkpoint inhibitor therapy. An exception is made for certain irAEs, including neurologic and hematologic toxicities.
- (b) Grade 2 toxicities generally require holding immune checkpoint inhib-

**FIGURE 10-1.** Potential Side Effects and Toxicities of Immunotherapy by System

itors until grade 1 or lower toxicity levels are achieved. Corticosteroids may be introduced for toxicity management. Of note, dose reduction of immune checkpoint inhibitors is not recommended.

- (c) Grade 3 toxicities require the immune checkpoint inhibitors to be held. High-dose corticosteroid therapy is recommended over six weeks. Response to the therapy determines the duration of corticosteroid or other immunosuppression. The decision to rechallenge with an immune checkpoint inhibitor after the resolution of a grade 3 irAE is an indi-

vidualized decision depending, in part, on the adverse event. Additional immunosuppression may be indicated with refractory symptoms. Referrals to organ-specific specialists should be considered for many irAEs.

(d) Grade 4 toxicities typically require permanent discontinuation of checkpoint inhibitors.

f) Education (Bayer et al., 2017)

- (1) Patients should be educated prior to and throughout therapy about the potential toxicities associated with immunotherapy.
- (2) Patients should be educated about the importance of contacting their care team, how to manage irAEs associated with therapy, and when to present to the hospital or emergency department for further assessment.

## 2. CAR T-cell immunotherapy

a) Pathophysiology

- (1) CAR T cells are genetically modified with a specific protein receptor that binds to a specific cancer antigen and causes cancer cell death.
- (2) This therapy uses CAR T cells with tumor-specific antigen recognition to target specific malignancies.
- (3) The T cells are generated through genetic modification of the patient's autologous T cells or from an allogeneic donor through leukapheresis (Ragoonanan et al., 2021). The cells are then expanded in a laboratory setting (Callahan et al., 2017).
- (4) Prior to the infusion of CAR T cells, patients will undergo lymphodepletion chemotherapy and subsequently have CAR T cells reinfused (Nair & Westin, 2020).
- (5) CAR T cells, through activation of T-cell memory, target malignant cells. This, along with the persistence of the CAR, allows for durable memory and improved relapse-free survival (June & Sadelain, 2018).

b) Mechanism of action

- (1) FDA-approved CAR T cells include tisagenlecleucel, axicabtagene ciloleucel, lisocabtagene maraleucel, idecabtagene vicleucel, and brexucabtagene autoleucel.
- (2) FDA initially approved four CAR T cells that target cluster of differentiation (CD)19 antigens present in most B-cell

leukemias and lymphomas. These include tisagenlecleucel, axicabtagene ciloleucel, lisocabtagene maraleucel, and brexucabtagene autoleucel (Sadelain et al., 2013).

- (3) FDA recently approved idecabtagene vicleucel, which targets B-cell maturation antigen (BCMA), for multiple myeloma (U.S. FDA, 2021).
- (4) All products currently on the market require a Risk Evaluation and Mitigation Strategy (REMS) from manufacturers to ensure the benefits outweigh the risks.

c) Indications

(1) Tisagenlecleucel

- (a) Approved for pediatric and young adult relapsed or refractory B-cell acute lymphoblastic leukemia
- (b) Patients up to age 25 years with B-cell precursor acute lymphoblastic leukemia that is refractory or in a second or later relapse
- (c) Adult relapsed or refractory diffuse large B-cell lymphoma (DLBCL) or relapsed or refractory large B-cell lymphoma after two or more lines of systemic therapy, including DLBCL, high-grade B-cell lymphoma, and DLBCL arising from follicular lymphoma
- (d) Excludes primary central nervous system lymphoma (Novartis Pharmaceuticals, 2021)

(2) Axicabtagene ciloleucel

- (a) Adults with relapsed or refractory large B-cell lymphoma after two or more lines of systemic therapy, including DLBCL, primary mediastinal large B-cell lymphoma, high-grade B-cell lymphoma, and DLBCL arising from follicular lymphoma
- (b) Excludes primary central nervous system lymphoma (Kite Pharma, 2021b)
- (c) Adults with relapsed or refractory follicular lymphoma after two or more lines of systemic therapy (Kite Pharma, 2021b)

(3) Lisocabtagene maraleucel

- (a) Adults with relapsed or refractory large B-cell lymphoma after two or more lines of systemic therapy, including DLBCL, DLBCL arising from indolent lymphoma, high-grade B-cell lymphoma, primary medi-

- astinal large B-cell lymphoma, and follicular lymphoma grade 3B (Bristol-Myers Squibb, 2021)
- (b) Excludes primary central nervous system lymphoma (Bristol-Myers Squibb, 2021)
- (4) Idecabtagene vicleucel: adults with relapsed or refractory multiple myeloma after four or more prior lines of therapy, including an immunomodulatory agent, a proteasome inhibitor, and an anti-CD38 monoclonal antibody (Celgene, 2021a)
- (5) Brexucabtagene autoleucel
  - (a) Adults with relapsed or refractory mantle cell lymphoma
  - (b) This product received accelerated approval based on its response rate. Continued approval is dependent on confirmatory trial results (Kite Pharma, 2021a).
- d) Collaborative management
  - (1) Administration
    - (a) Emergency equipment, including a code cart and hypersensitivity kit, should be available during CAR T-cell infusion.
    - (b) Neurotoxicity is a common toxicity of CAR T-cell therapy. It is important to have a baseline neurologic examination and ensure patients are on seizure prophylaxis medication (Neelapu et al., 2019).
    - (c) Central venous access is recommended for IV administration of current CAR T-cell therapies.
    - (d) Nursing care includes administration of fluids and premedications as ordered, careful assessment for signs and symptoms of infusion reactions, and documentation of the specific product administered in the medical record (Halton et al., 2017).
  - (2) Monitoring
    - (a) Monitoring after the cell infusion is important for the early identification of any toxicities.
    - (b) Vital signs should be monitored minimally every four hours and more frequently based on clinical assessment.
    - (c) Changes in clinical status and symptoms, such as pain, infection, neurologic changes, laboratory inflammatory biomarkers and coagulopathies, and organ toxicities, should be monitored following the infusion and as clinically necessary.
  - (d) Monitoring fluid status may include daily weights, intake and output, and symptoms of edema. Neurologic assessments should occur every shift and more often if any changes are noted.
  - (e) Daily review of laboratory results, organ systems, neurologic assessments, and physical examination should be performed.
- (3) Assessment
  - (a) Early recognition of changes could lead to earlier intervention for more severe side effects, such as cerebral edema and severe cytokine release syndrome (CRS).
  - (b) Bedside nurses are in key positions for assessment, as they will likely be the first to recognize any changes and can promptly notify the oncology provider for further management.
- (4) Follow-up
  - (a) Patients will need routine follow-up with an oncology provider for several weeks after infusion to assess the onset of toxicities, hematologic recovery, and overall health.
  - (b) Follow-up of disease status may include bone marrow aspirate, biopsies, and radiologic imaging appropriate for the disease.
  - (c) Patients who received CAR T-cell therapy in a clinical trial may be asked to participate in long-term follow-up to monitor the persistence of the CAR T cells, adverse events, disease relapse, or other autoimmune or hematologic disorders (McConville et al., 2017).
- e) Toxicities
  - (1) Intensive monitoring, accurate grading, and prompt management of toxicities with aggressive supportive care have reduced the morbidity and mortality associated with CAR T-cell therapy (Neelapu et al., 2019).
  - (2) The location for toxicity management is determined by the severity of toxicity, the status of the patient, and the resources available at the treatment site. Some care may require more intensive monitoring. An intensive care unit may be considered

for those with severe toxicities who need a higher level of care.

- (3) Other toxicities seen with CAR T cells include tumor lysis syndrome, cytopenias, and sequelae such as infections, which are medically managed per standard of care.
- (4) A grading system is important for managing toxicities. Since the approval of the first CAR T-cell therapies, many grading systems have been used for symptoms like CRS. The American Society for Transplantation and Cell Therapy published a consensus grading tool to assess the severity and management of CRS, organ toxicity, and neurotoxicity (D.W. Lee et al., 2019).
- (5) CRS
  - (a) CRS is a common toxicity of CAR T-cell therapy. The hallmark of CRS is elevated inflammatory cytokines caused by immune system activation, with patients demonstrating dramatic increases in the cytokine interleukin (IL)-6 levels following CAR T-cell infusion.
  - (b) CRS symptoms include myalgias, headaches, fever, fatigue, nausea, hypotension, and capillary leak.
  - (c) Supportive care only can be considered for mild CRS management. Moderate to severe cases require the addition of corticosteroids, tocilizumab, and standard medical management for constitutional symptoms.
  - (d) CRS may have a delayed onset, rarely beyond 14 days, and should be carefully evaluated for other causes outside this window (D.W. Lee et al., 2019).
  - (e) Tocilizumab is approved for the treatment and management of severe CRS. The administration of tocilizumab, an IL-6 inhibitor, leads to an almost immediate reversal of CRS (Bonifant et al., 2016).
    - i. The tocilizumab dose is weight based.
    - ii. The recommended dose for patients who weigh less than 30 kg is a 12 mg/kg IV infusion over 60 minutes. The dose is 8 mg/kg in patients who weigh 30 kg or more.
    - iii. Depending on CRS severity, some patients may require

repeat dosing. The interval between consecutive doses should be at least eight hours apart with a maximum 800 mg IV infusion (Genentech, 2021a).

- (6) Immune effector cell-associated neurotoxicity syndrome (ICANS)
  - (a) Mild to potentially fatal neurotoxicity is associated with CAR T-cell therapy. Neurologic assessment is imperative.
  - (b) The immune cell-associated encephalopathy (ICE) score and the American Society for Transplantation and Cellular Therapy ICANS consensus grading for children or adults aids in determining the severity and management of neurotoxicity (D.W. Lee et al., 2019).
  - (c) Neurotoxicity hallmark signs are confusion, aphasia, and seizures.
- (7) Hemophagocytic lymphohistiocytosis/macrophage-activation syndrome (HLH/MAS)
  - (a) HLH/MAS is a life-threatening hyperinflammatory syndrome with high mortality that can occur after CAR T-cell therapy.
  - (b) It can be difficult to diagnose in the context of CRS, as both are on the spectrum of systemic hyperinflammatory disorders. New criteria for diagnosing HLH/MAS after CAR T-cell therapy are needed, as non-specific traditional diagnostic criteria are also used for CRS diagnosis.
  - (c) The occurrence of HLH/MAS requires additional management, as it does not respond to the corticosteroids or tocilizumab strategies used for CRS. Therefore, if no improvement is seen after 48 hours, etoposide treatment or intrathecal cytarabine for neurotoxicity must be considered (Neelapu et al., 2019).
- (8) B-cell aplasia
  - (a) B-cell aplasia is the mass death of B cells.
  - (b) CD19 and BCMA are expressed in healthy B cells responsible for producing antibodies that kill pathogens. These healthy B cells are also killed by infused CAR T cells that target CD19 and BCMA antigens. Patients must subsequently receive

immunoglobulin therapy to fight off infections (Maude et al., 2015; Wang et al., 2021).

*f) Education*

- (1) Nurses should initiate patient education prior to CAR T-cell therapy.
- (2) Important topics include caregiver requirements, financial implications, infection prevention, and emergency management.
- (3) Written and verbal education should be provided to patients and caregivers about the treatment, signs and symptoms of toxicities, toxicity management, and the importance of prompt reporting of toxicities to the oncology provider. Education should be provided and documented prior to and throughout treatment (Halton et al., 2017).
- (4) Patients should be educated about adherence to long-term follow-up once discharged from direct patient care. Patients enrolled in clinical trials may be asked to participate in long-term follow-up to monitor for the persistence of the CAR T cells, adverse events, disease relapse, or other autoimmune or hematologic disorders (e.g., B-cell aplasia) (McConville et al., 2017).

**3. Cytokines**

*a) Pathophysiology:* Cytokines are small protein molecules released by different cells throughout the body, aiding with communication between the cells of the immune system via stimulator or suppressor signals (S. Lee & Margolin, 2011; Silk & Margolin, 2019).

- (1) They can be further classified based on the proximity of the signaling cell to the target cell (Owen et al., 2013).
  - (a) Endocrine action requires the cytokine to transmit its signal via the blood circulation to its distant target.
  - (b) Paracrine action is when the cytokine signal must diffuse through tissue fluids across an immunologic synapse.
  - (c) Autocrine action is when a cell receives a signal from a cytokine within its membrane receptors.
- (2) Cytokines generally are activated by a stimulus and induce responses by binding to specific receptors (Owen et al., 2013).
  - (a) Cells expressing receptors for specific cytokines can be activated or inhibited,

altering the immune effector function.

(b) Some cytokines are pleiotropic. They can induce different outcomes based on the nature of the target cell.

*b) Mechanism of action* (S. Lee & Margolin, 2011; Owen et al., 2013)

- (1) Cytokines affect the growth, differentiation, and function of white blood cells, red blood cells, platelets, and other cells that regulate immune and inflammatory responses within the body.
  - (2) Cytokines may enhance the cytotoxic activity of the cells of the immune system and secrete additional cytokines, resulting in amplification or suppression of the immune response.
    - (a) An enhanced immune response may include proliferation or activation and recruitment of additional immune effector cells.
    - (b) This is also known as the cascade effect, in which one cytokine reaches its receptor on the target cell, and then that cell produces one or more additional cytokines.
  - (3) Select cytokines can exact proinflammatory, anti-inflammatory, and regulatory functions in the immune system, such as hematopoiesis and wound healing.
  - (4) Select cytokines can send signals that inhibit or promote cell death.
  - (5) Select cytokines include a variety of chemokines—a small group of cytokines that help mobilize immune cells toward specific sites in the body.
  - (6) Cytokines regulate antibody production, the functions of B and T cells, and interactions with antigen-presenting cells and natural killer cells.
- c) Indications:* Cytokines have diverse indications based on categories grouped as follows (Becker et al., 2020):
- (1) Hematopoietic growth factors
    - (a) Hematopoietic growth factors stimulate growth, differentiation, and maturation of target cells.
    - (b) The stimulating growth factors commonly used in patients with cancer are isolated to stimulate red blood cells, platelets, and white blood cells. Table 10-1 lists current FDA-approved drugs. Examples include epoetin alfa and filgrastim (Baldo, 2016).

- (c) Biosimilars have been FDA approved for some growth factors. They have no clinically meaningful difference from the reference product. Biosimilars will have the same amino acid sequence, but “differences can be seen in the 3-dimensional structure, glycosylation site, isoform profiles, and the level of protein aggregation” (Becker et al., 2020, p. 15). Biosimilar use is regulated by FDA approval but may be determined by factors in a practice site or payer.
- (2) Interferons (IFNs) (Parker et al., 2016)
  - (a) IFNs are currently used as anti-neoplastic and antiviral therapies. This chapter focuses on the current FDA-approved antitumor treatments.
  - (b) IFN is part of the cell’s defense mechanism against viruses and other foreign substances. It was discovered in the 1950s when scientists saw that it interfered with viral replication and growth.
  - (c) IFN inhibits B-lymphocyte (B-cell) activation, enhances T-lymphocyte (T-cell) activity, and increases the cellular destruction capability of natural killer cells.
  - (d) Three forms of IFNs exist—alpha, beta, and gamma. IFN alpha and beta can be produced by any cell exposed to the virus, whereas IFN gamma is only secreted by natural killer cells and T lymphocytes (Owen et al., 2013). Examples include IFN alfa-2b, peginterferon alfa-2b (alpha), IFN beta, and IFN gamma.
- (3) ILs
  - (a) ILs are naturally occurring proteins secreted by cells in response to a stimulus, such as an infection. Once ILs are bound to a receptor, a cascade effect is created of signals that regulate the growth, differentiation, and motility of cells (Ardolino et al., 2015).
  - (b) ILs were discovered in the 1970s and named as such because it appeared they were made by leukocytes and acted on other leukocytes. Further discoveries revealed they are created by many different cells and provide a variety of functions (Owen et al., 2013).
  - (c) Currently, 40 known ILs exist, and each functions differently with receptors on various cells (Justiz-Vaillant & Qurie, 2021). Examples include aldesleukin (IL-2) and oprelvekin (IL-11).
  - (4) Current research is exploring the combined therapy of cytokines with other immunotherapies, such as immune checkpoint inhibitors, but none are FDA approved. The current FDA-approved cytokines for cancer therapy are IFN alfa and IL-2 (Rahimi Kalateh Shah Moham-mad et al., 2020; Runbeck et al., 2021).
- d) Collaborative management
  - (1) Administration: Cytokines have diverse administration routes.
  - (2) Monitoring
    - (a) IFNs: Monitor laboratory values, specifically white blood cells, hemoglobin, platelets, and kidney and liver function. Assess for injection site redness versus infection or cellulitis.
    - (b) ILs: Monitor laboratory values, including complete blood count and kidney and liver function (Clinigen, 2019).
- e) Toxicities: Cytokine toxicities vary by agent.
- f) Education
  - (1) Patients might be reluctant to discuss side effects because they are concerned about dose reductions or delays. Ask specific questions related to drug therapy so that management can occur quickly and appropriately.
  - (2) Educate patients and caregivers to report new symptoms to their provider immediately.
    - (a) IFNs: Nausea, vomiting, loss of appetite, weight loss, hair loss, dry skin/rash, and fatigue are anticipated side effects. Notify providers of any depression and suicidal thoughts or plans. Avoid alcohol use (Merck, 2015, 2019).
    - (b) ILs: Possible side effects include diarrhea, worsening rash with or without itching, cough, shortness of breath, swelling of the extremities, chest pain, tachycardia, yellowing of the skin and eyes, bloated feeling, abdominal distension, loss of appetite, and headache (Clinigen, 2019).
      - i. Use unscented, dye-free creams to help with the rash.

- ii. Document weight daily while on therapy and notify the healthcare team of a 10% loss or gain.
  - (3) Be aware that some immunotherapy, especially agents that stimulate cytokines, can cause ongoing overstimulation of the immune system. These side effects might require lifelong management.
  - (4) Counsel patients to avoid getting pregnant during all therapies. Include information on reliable contraception methods, such as intrauterine devices, oral contraceptive pills, condoms, and spermicide.
- 4. Immunomodulators
  - a) Pathophysiology
    - (1) Immunomodulators are a class of agents used to modify immune response activity. These agents may have antiangiogenic or antineoplastic properties.
    - (2) Immunomodulators are used in various diseases, including Crohn disease and cancers, and primarily target pathways related to multiple myeloma (e.g., thalidomide). *IMiD* is a common term to describe the immunomodulatory drugs used to treat myeloma.
  - b) Mechanism of action
    - (1) IMiDs
      - (a) Cereblon, a human protein encoded by the *CRBN* gene, has recently been identified as the primary target for this class of agents, where binding to *CRBN* occurs. The breakdown of transcription factors IKZF1 and IKZF3 occurs, resulting in the upregulation of IL-2 expression in T cells (Asatsuma-Okumura et al., 2019). Examples include pomalidomide and thalidomide.
      - (b) Additionally, CK1a degradation results in effective cell death mediated by the action of *TP53* (Asatsuma-Okumura et al., 2019). An example includes lenalidomide.
    - (2) Topical immunomodulatory agents: Modulation of monocytes, macrophages, and dendritic cells occurs with some immunomodulators that act on natural killer cells, T cells, and B cells (Mahatma et al., 2020). An example includes imiquimod.
  - c) Indications
    - (1) Indications for immunomodulators include primarily hematologic malignancies.
    - (2) Other indications include topical use to manage skin conditions, such as basal cell carcinoma, when patients are poor surgical candidates (e.g., imiquimod).
  - d) Collaborative management
    - (1) Administration: Routes include oral and topical administration. This class of agents is highly teratogenic when given orally; therefore, safe handling by providers, patients, and caregivers is essential.
    - (2) Monitoring: Prior to therapy, pregnancy screening (two tests) in women of child-bearing potential is imperative.
  - e) Toxicities: Reproductive toxicities, nerve damage, myelosuppression, and blood clots can occur. Patients can experience flu-like symptoms while taking IMiDs.
  - f) Education: Appropriate contraception should be used up to four weeks before and after treatment.
- 5. Monoclonal antibodies (mAbs)
  - a) Pathophysiology
    - (1) The mAbs are highly specific antibodies produced by a clone of a single hybridoma cell. They are produced in living cells and are laboratory substances.
    - (2) An antigen-specific plasma cell is produced and fused with a cancerous immune cell for immortality. This is followed by the cell being cloned to produce numerous daughter clones that continuously produce the desired mAb.
    - (3) The mAbs can restore, enhance, or mimic the immune system's ability to attack cancer cells (Rhyman & Meibohm, 2017). The currently marketed immune checkpoint inhibitors are mAbs.
    - (4) The mAbs bind with proteins and antigens.
    - (5) Classification by source (see Figure 10-2)
      - (a) Murine means made from mice (suffix: *-omab*). An example includes blinatumomab.
      - (b) Chimeric means part mouse and part human (suffix: *-ximab*). Examples include brentuximab, cetuximab, and rituximab.
      - (c) Humanized means small portions of mouse antibodies are attached to human antibodies (suffix: *-zumab*). Examples include emtansine, alemtuzumab, bevacizumab, elotuzumab, gemtuzumab, ozogamicin, obinutuzumab, pertuzumab, and trastuzumab.
      - (d) Human means completely human antibodies (suffix: *-umab*). Examples

**FIGURE 10-2.** Types of Monoclonal Antibodies

Comparison of monoclonal antibodies (dark—human, light—nonhuman):

- Top row: mouse, chimeric
- Bottom row: humanized, chimeric/humanized, human

The subtypes according to the nomenclature of monoclonal antibodies are shown below each antibody.

Note. From "Chimeric and Humanized Antibodies," by Anypodetos, 2010. Retrieved from [https://en.wikipedia.org/wiki/File:Chimeric\\_and\\_humanized\\_antibodies.svg#file](https://en.wikipedia.org/wiki/File:Chimeric_and_humanized_antibodies.svg#file). This work has been released into the public domain by its author, Anypodetos at English Wikipedia. Anypodetos grants anyone the right to use this work for any purpose, without any conditions, unless such conditions are required by law.

include daratumumab, denosumab, necitumumab, ofatumumab, panitumumab, and ramucirumab.

- (6) Classifications may be determined by the mAb target. Examples include CD20-targeted, SLAMF7-targeted, HER2-targeted, CD38-targeted, IL-6-targeted, PD-1-targeted, and CD5-targeted agents.

*b) Mechanism of action*

- (1) The mAbs can function in several manners (Bayer, 2019).

*(a) Direct tumor cell death*

- This method involves the mAbs ability to bind to cancer cells that contain tumor antigens. The antigens then prompt apoptosis (unconjugated antibodies).
- The mAbs also can bind to a receptor, blocking any antigens that would fuel cancer growth (unconjugated antibodies).

*(b) Cell death by immune mediation*

- This method involves the immune system seeking out cancer cells and destroying them.
- This is prompted by several mechanisms that can include phagocytosis, inhibition of T-cell inhibitory receptors, and complement activation.

(c) Antibodies can be conjugated to an element toxic to cancer cells (e.g., chemotherapy, radiation, another toxin). These antibodies can then be used to destroy tumor cells (conjugated antibodies). Examples include ado-trastuzumab and enfortumab vedotin.

- (2) Unconjugated antibodies (American Cancer Society, 2019)

(a) Unconjugated antibodies are the most common mAbs available in the United States used for cancer treatment.

(b) The antibodies function by themselves, whereas conjugated antibodies join with a drug or particle.

(c) Unconjugated antibodies work by binding to cancer cells and mimicking a marker so that the immune system will destroy it. An example is alemtuzumab, which can be used to treat chronic lymphocytic leukemia. This mAb binds to CD52 antigens on hematopoietic cells, thus drawing the immune cells to destroy them.

(d) Other mAbs can work by blocking the antigens on cancer cells that can help cancer spread. An example is trastuzumab, which can be used to treat HER2-positive breast cancer. This mAb binds to the HER2 protein, impairing its functionality.

- (3) Antibody-drug conjugates (Criscitiello et al., 2021)

(a) These conjugates work by merging the selectivity of mAbs with the cell-killing properties of chemotherapy. Antibodies incorporated are mainly humanized antibodies.

(b) These conjugates directly transport cytotoxic drug into the tumor space, thus transforming chemotherapy into a targeted agent.

(c) Examples include trastuzumab deruxtecan (targeting HER2), sacituzumabgovitecan (targeting Trop2),

and enfortumab vedotin (targeting Nectin4).

(4) Conjugated antibodies (American Cancer Society, 2019)

(a) The antibodies work by combining with a chemotherapy agent or radioactive particle.

- i. The mAbs deliver the conjugated agent straight to cancer cells in the body. An example is ado-trastuzumab emtansine, which can be used to treat breast cancer. It is attached to DM1, a microtubule inhibitor, and targets the HER2 protein.
- ii. The mAbs attach directly to cancer cell surface antigens so that the conjugated agent can be directly delivered.
- iii. Similar to trastuzumab, ado-trastuzumab emtansine inhibits HER2 receptor signaling.

(b) Targeted radionuclide therapy and radioimmunotherapy

- i. Pathophysiology: Radiolabeled antibodies have small radioactive particles attached to a mAb. The mAb and radiation are delivered directly to the target cells because the mAb attaches to the target while the radiation affects the target and nearby cells to a certain extent (American Cancer Society, 2019).
  - $^{90}\text{Y}$ -Ibritumomab tiuxetan is an antibody against the CD20 antigen bound to yttrium-90. The antibody delivers radioactivity directly to cancer cells and is made of a mAb (ibritumomab) and radioactive substance (yttrium-90) (American Cancer Society, 2019).
  - Radioimmunotherapy is a form of targeted radionuclide therapy that uses mAbs conjugated to therapeutic radionuclides.
  - This is an attempt to augment the single-agent efficacy by conjugating thera-

peutic radionuclides to the mAbs to optimize radiation delivery to the tumor while minimizing total body exposure to radiation (Sachpedkidis et al., 2019).

ii. Mechanism of action (Sachpedkidis et al., 2019)

- The action involves a combination of the antibody-stimulated cytotoxicity and induction of apoptosis.
- Ionizing radiation emitted from the radioisotope leads to free radicals and subsequent cellular damage.
- Adjacent tumor cells that do not bind to the antibody may still be killed through the radiation crossfire effect.

iii. Targeted radionuclide therapy with external beam radiation therapy (Gill et al., 2017)

- Synergy arises because external beam radiation therapy acts locally on the primary tumor, whereas the targeted radionuclide therapy can also target beyond the radiation field.
- Another interaction between these two methods is the effect of radiation therapy on blood flow and vessel permeability, leading to enhanced intratumor accumulation of the targets radionuclides as a result of the vasculature perturbation after the radiation therapy takes place.

(5) Bispecific mAbs (American Cancer Society, 2019).

(a) Bispecific mAbs comprise two different mAbs attaching to two different proteins simultaneously. By binding to both protein targets, the drugs bring the cancer cells and immune cells together, causing the immune system to attack the cancer cell.

(b) Blinatumomab is an example of a bispecific engager used to treat some types of leukemia. One part attaches to the CD19 protein, and another attaches to CD3.

c) Indications: Indications for mAbs include solid tumor and hematologic malignancies. These agents are used alone and in combination with other anticancer therapies.

- (1) Radioimmunotherapy is administered to treat hematologic tumors.
- (2) The mAbs are used in various diseases beyond cancer.

d) Collaborative management

- (1) The mAb administration is determined by the drug product. Some mAbs are given via IV infusion, and others are given subcutaneously.

(a) Some agents have been tested for safety as treatment during pregnancy and may have the potential for harm during fetal development. Treatment in pregnant women should be determined by the agent and clinical situation (Sarno et al., 2013).

(b) Radioimmunotherapy is administered on a specific regimen, including pretargeting tissues with an unconjugated mAb (e.g., rituximab) followed by the radiolabeled isotope. Pretargeting is a strategy to decrease toxicity to healthy tissue while enhancing the radiation dose to the tumor. This is achieved by separating the tumor antigen targeting phase from the radioisotope delivery phase (Patra et al., 2016).

i.  $^{90}\text{Y}$ -ibritumomab tiuxetan can safely be administered in the outpatient setting with few discharge instructions and minimal risk of radiation exposure to others.

ii. Because the primary route of elimination for  $^{90}\text{Y}$ -ibritumomab tiuxetan is through the kidneys, urine and other body fluids should be flushed down the toilet and any spills cleaned up. Linens contaminated with body fluids should be washed separately. Handwashing should be emphasized.

- (2) Monitoring for radioimmunotherapy

(a) Complete blood count, urinalysis, thyroid function testing, pregnancy testing, and cardiovascular and pulmonary assessment are rec-

ommended prior to therapy (Gharwan & Groninger, 2016).

(b) Monitor for acute infusion reactions.

(c) Monitor for acute and long-term system-related toxicities, including cardiac, renal, and dermatologic toxicities; myelosuppression; and thromboembolic events (Gharwan & Groninger, 2016).

e) Toxicities

(1) CRS can be accompanied by nausea, headache, fever, rash, tachycardia, and dyspnea. More severe side effects can include hypotension, seizures, and psychotic symptoms (Posner et al., 2019).

(2) Common side effects include allergic-type reactions (e.g., hives, pruritus) and flu-like symptoms (e.g., fatigue, headache, muscle ache, chills, fever, nausea, vomiting, diarrhea) (Gharwan & Groninger, 2016).

(3) Hypersensitivity reactions can include rash, fever, urticaria, and angioedema (Posner et al., 2019).

(4) Fully human mAbs are considered less immunogenic than humanized or chimeric mAbs. However, even fully human proteins can elicit an unwanted immune response (Picard & Galvão, 2017).

(5) Allergic reactions with murine mAbs are common when used in humans and often result in the induction of antidrug antibodies (Bayer, 2019).

(6) Almost all patients with an immediate reaction can be safely reexposed through desensitization or challenge, depending on the severity of the initial reaction (Picard & Galvão, 2017).

(7) Toxicities are also related to the specific target.

f) Education

(1) Patients should use precautions to prevent pregnancy during and following treatment according to drug-specific recommendations.

(2) Additional education should be provided based on the specific mAb being administered.

g) Radioimmunotherapy-specific considerations

(1) Administration

(a) As with many oncologic therapies, radioimmunotherapy involves an interprofessional and coordinated approach to achieve the desired patient outcomes.

- (b) Radiation safety precautions will depend on the specific isotope used.
    - (c) For clinicians, safety precautions include standard universal precautions with the addition of acrylic shielding during administration.
    - (d) For safe and effective use of radioimmunotherapy, accurate dose planning should be emphasized (Evans-Axelsson et al., 2016).
  - (2) Monitoring: Monitor for any signs of infusion or allergic reaction, such as urticaria, respiratory or cardiac abnormalities, and any symptoms of extravasation during the infusion.
  - (3) Education
    - (a) Additional education should be provided based on the specific therapies being administered.
    - (b) The ability to generate an immune response to any vaccine following the <sup>90</sup>Y-ibritumomab tiuxetan regimen has not been studied. Additionally, live viral vaccines should not be administered to patients who have recently received <sup>90</sup>Y-ibritumomab tiuxetan (Acrotech Biopharma, 2019).
    - (c) Females of reproductive potential and males with female partners of reproductive potential should use effective contraception during treatment and for a minimum of 12 months after the final dose. Fetal harm can occur, as can harm through lactation (Acrotech Biopharma, 2019).
6. Oncolytic viral therapies
- a) Pathophysiology: Oncolytic viral immunotherapy is a viral-targeted therapy that directly kills cancer cells by causing tumor death and producing tumor-toxic cytokines or antitumor host immune responses. The two oncolytic viral immunotherapies are nonpathogenic (harmless to humans) and pathogenic (requiring genetic modification for use) (Abd-Aziz & Poh, 2021; Prestwich et al., 2008).
  - b) Mechanism of action
    - (1) The only FDA-approved agent is talimogene laherparepvec (Andtbacka et al., 2015).
    - (2) The two primary processes by which oncolytic viruses destroy cancer is direct cell lysis and induction of antitumor immunity (Goradel et al., 2021). The four mechanisms of action thought to exist with oncolytic viral immunotherapies include the following (Abd-Aziz & Poh, 2021; Goradel et al., 2021; Wollmann et al., 2012):
      - (a) Viral cell receptor responses target viral-specific cell surface receptors overexpressed in cancer cells.
      - (b) Cytokine release is seen with double-stranded RNA viruses that cause antiviral cellular activation of cytokines that promote apoptosis (e.g., influenza).
      - (c) Nuclear replication of cancer cells can be disrupted by certain double-stranded DNA viruses that have been genetically modified to target tumor DNA synthesis.
      - (d) Innate immune response is activated by introducing specific synergistic viruses to kill cancer cells. Tumor lysis subsequently aids in the release of tumor-associated antigens.
  - c) Indications: Oncolytic viral immunotherapies, including adenoviruses, poliovirus, coxsackievirus, herpes simplex virus 1, measles virus, Newcastle disease virus, reovirus, vaccinia virus, and vesicular stomatitis virus, are being investigated in clinical trials across a wide array of cancer types (Abd-Aziz & Poh, 2021; Eager & Nemunaitis, 2011; Msaouel et al., 2013). However, the only FDA-approved indication for use at the time of this publication is the genetically modified herpes simplex virus 1 to treat metastatic melanoma (Andtbacka et al., 2015).
  - d) Collaborative management
    - (1) Administration: intralesional injection for metastatic melanoma
      - (a) Safe handling (Hoffner et al., 2016)
        - i. Change the needle after each injection to avoid infection.
        - ii. Apply sterile gauze to the site for at least 30 seconds after injection.
        - iii. Discard gloves immediately after injection and perform hand hygiene. After donning a new set of gloves, apply an absorbent pad and dry occlusive dressing to the site. Wipe the surface of the occlusive dressing with an alcohol swab to remove any surface virus that has shed.

- (b) Immunocompromised and pregnant individuals (e.g., caregivers) should not handle, administer, or care for the injection site of the drug (Amgen, 2019).
  - (2) Monitoring: Monitor for injection site pain, redness, infection, and irritation.
  - e) Toxicities: Fever, malaise, chills, nausea, vomiting, headache, elevated liver enzymes, injection site pain, and autoimmune vitiligo are toxicities.
  - f) Education
    - (1) Patients should be in contact isolation for seven days. This is important if they have subsequent visits to a clinic or a planned procedure (Amgen, 2019).
    - (2) Counsel patients and caregivers on using standard precautions when changing dressings, including safe disposal (placing soiled dressings in a sealed bag).
    - (3) To prevent possible viral infections, counsel patients on avoiding young children, pregnant women, and immunocompromised individuals during treatment (Amgen, 2019).
- C. General patient and family education
1. Convey to patients and families that immunotherapy is not chemotherapy and works differently within the body (Brahmer et al., 2018).
  2. Inform patients and families that some immunotherapies, such as immune checkpoint inhibitors, have an immune response that may continue after drug discontinuation (Brahmer et al., 2018).
  3. Instruct patients to inform their provider of any new medications or dietary supplements introduced during therapy (Bayer et al., 2017).
  4. Educate patients about side effects and potential toxicities unique to immunotherapies (Bayer et al., 2017).
  5. Educate patients on the importance of communication with the healthcare team and when to seek medical management (e.g., hospital or emergency department for toxicity management) (Bayer et al., 2017).
  6. Encourage patients to carry a card to identify the type of immunotherapy they receive. This can be useful when presenting for care in an emergency department, clinic, or another primary provider outside the cancer care setting (Brahmer et al., 2018; see Figure 10-3).
  7. Educate patients and caregivers about the importance of follow-up to monitor late-term effects, as the healthcare community has yet to know the long-term effects of newer therapies (Buitrago et al., 2019).

## SECTION IV

---

# Treatment Administration and Safety

Chapter 11. Administration Considerations

Chapter 12. Safe Handling of Hazardous Drugs

Chapter 13. Infusion-Related Complications

## CHAPTER 11

# Administration Considerations

### A. Components of safe and effective administration of cancer therapies

1. Comprehensive pretreatment assessment
2. System safeguards to prevent errors and manage emergencies
3. Dose calculations and verification processes
4. Evidence-based practices for all routes of chemotherapy, targeted therapy, and immunotherapy administration
5. Refer to Chapter 1 for nursing scope and standards, professional education, policy and procedure requirements, and an overview of antineoplastic medication safety. Chapter 12 reviews safe handling precautions for hazardous drugs (HDs). Chapter 13 discusses infiltration, extravasation, and infusion-related complications.

### B. Pretreatment

1. A thorough assessment of the patient, patient history, and cancer treatment plan, including orders and treatment notes, with proactive interventions can prevent adverse reactions and errors.
  - a) The assessment should be performed for all routes of chemotherapy, targeted therapy, and immunotherapy, including those given orally.
  - b) Assess information specific to the agent (see Tables 6-1, 7-1, 8-1, and 10-1) and route of administration.
  - c) Identify questions and concerns that require discussion or collaboration with the patient's provider.
2. Before the administration of a new treatment regimen, review the patient's medical record for the following elements (Neuss et al., 2016):
  - a) Cancer diagnosis, stage, and current cancer status (e.g., progression)
  - b) Cancer treatment plan, including goals of therapy, medications, and duration of treatment
    - (1) Goals include chemoprevention, cure, control, or palliation. Electronic documentation systems often have a location for the

prescriber to document goals on the treatment plan. Some informed consent documents include goals of treatment.

- (a) Compare the goals of therapy documented with the patient's understanding.
    - (b) Discuss discrepancies with the provider.
  - (2) For curative therapy, the duration of treatment is often a set number of cycles. However, for metastatic disease, treatment may continue until disease progression, unacceptable toxicity, or the decision to decline or terminate treatment.
- c) Planned frequency of office visits and patient monitoring appropriate for the treatment plan
  - (1) The National Comprehensive Cancer Network (NCCN, [www.nccn.org](http://www.nccn.org)) has disease-specific guidelines and chemotherapy order templates that include suggested patient monitoring for cancer type and stage (e.g., type and timing of imaging) and treatment regimen.
  - (2) See Appendix C for an example of a chemotherapy order template.
- d) Allergies, risk, and history of infusion-related reactions (see Chapter 13)
  - (1) Risk factors for hypersensitivity reactions include multiple allergies, cardiovascular disease, asthma, older age, and previous exposure to the agent (Shaker et al., 2020).
  - (2) Patients are at the highest risk for infusion-related reactions and cytokine release syndrome at the initiation of the first dose of monoclonal antibodies. Patients with B-cell lymphomas and leukemias with high circulating blast counts (greater than 25,000/mm<sup>3</sup>) or who have bulky disease are at increased risk for reactions with the initiation of treatment with

- anti-cluster of differentiation 20 (CD20) antibodies (e.g., rituximab) (Genentech, 2021b).
- (3) Review the grade (severity), symptoms, onset, course of progression, interventions, patient response, and time to resolution of symptoms for past infusion-related reactions. A thorough history is an essential risk assessment tool when administering chemotherapy or immunotherapy (Andrews, 2017).
    - (a) Documentation tools and grading systems should be integrated into electronic health records to identify patients who have had reactions (Andrews, 2017; see Chapter 13).
    - (b) For many agents, the grade of the previous reaction is used to order future premedications, infusion rates, and infusion volumes. It is also used to determine if patients can receive medication over a shorter period in the future or via the subcutaneous (SC) route (Genentech, 2021b, 2021c).
    - (c) Previous reactions may require a change in treatment location for future treatments (inpatient vs. outpatient), desensitization protocols, and an increased nurse-to-patient ratio.
  - (4) Verify that emergency equipment and supplies are available, not expired, functional, and that staff are aware of their location. Ensure that treatment chairs can change to the supine position if needed and that oxygen tanks are not empty.
- e) Risk factors for adverse reactions related to disease and treatment history
- (1) Patients with rapidly growing cancers, such as small cell lung cancer, aggressive forms of lymphoma, and acute leukemia, have an increased risk for tumor lysis syndrome at the initiation of treatment (NCCN, 2021a, 2021b, 2021f, 2022a).
  - (2) Hematologic malignancy or bone marrow involvement increases the risk for myelosuppression from chemotherapy (NCCN, 2021a, 2022a).
  - (3) A patient's cancer treatment history can contribute to toxicities for the planned therapy.
    - (a) Radiation recall, characterized by an acute inflammatory reaction confined to previously irradiated sites, can be triggered by the administration of some agents (e.g., doxorubicin) and can occur months to years after radiation (I.C. Liu et al., 2020).
    - (b) Prior treatment with an anthracycline antitumor antibiotic can increase the risk of congestive heart failure if other cardiotoxic therapies are planned (Polonsky & DeCara, 2019). Review cumulative doses of all drugs in this category. See Table 6-1 for cumulative dose information for each anthracycline drug and Chapter 16 for information on cardiotoxicity.
    - (c) Concurrent chemotherapy and radiation therapy can increase toxicity. For example, concurrent therapy for non-small cell lung cancer increases the risk and severity of esophagitis versus radiation therapy alone (Or et al., 2021).
- f) Comorbidities and noncancer treatments
- (1) Comorbidities and treatments should be assessed for potential adverse effects on patient outcomes.
  - (2) Comorbidity index scoring systems capture complexity and assign a score (Charlson et al., 1987; Wass et al., 2016). Multiple comorbidities can negatively affect cancer therapies and patient outcomes (Sarfati et al., 2016).
  - (3) Comorbidities that can affect cancer therapies include the following:
    - (a) Congestive heart failure
      - i. Congestive heart failure can preclude treatment with anthracycline antitumor antibiotics and HER2 receptor antibodies (NCCN, 2021g).
      - ii. Patients with congestive heart failure are at risk for fluid overload with hydration that is often needed to prevent nephrotoxicity from cisplatin or hemorrhagic cystitis from cyclophosphamide and ifosfamide.
    - (b) Diabetes
      - i. Poor glycemic control in patients with cancer has been associated with neutropenia, infections, and mortality (Arreskov et al., 2019; Storey et al., 2021).
      - ii. Blood glucose can be more challenging to control in patients receiving steroids as

part of a chemotherapy treatment plan, as steroids can increase blood glucose (Hershey & Hession, 2017; see Figure 22-1).

- iii. Patients with complications from diabetes have been found to have more than twice the risk for chemotherapy-related neuropathy (Hershman et al., 2016).

(c) Liver disease

- i. Liver disease can alter hepatic drug metabolism and cause high or prolonged drug levels with increased toxicity and worsening liver function (Kasi et al., 2015).
- ii. All patients should be asked if they have a personal history of hepatitis B (Hwang et al., 2020).
- iii. Patients who are hepatitis B positive and receiving chemotherapy or immunotherapy are at an increased risk for hepatitis B reactivation at the initiation of treatment (Hwang et al., 2020).

(d) Renal failure

- i. Many chemotherapies, targeted therapies, and immunotherapy agents are excreted primarily by the kidneys. Impaired renal function can lead to alterations in pharmacokinetics, elevated blood levels of drugs, and increased toxicity (Krens et al., 2019).
- ii. Hemodialysis can remove some chemotherapy and immunotherapy agents from the blood.
- iii. Collaboration with a nephrologist, oncologist, and pharmacist can determine if dose adjustments are needed and the appropriate timing to avoid drug removal from dialysis.

(e) Plasmapheresis

- i. Patients with cancer sometimes require plasmapheresis for hyperviscosity syndrome and leukocytosis.
- ii. Plasmapheresis can remove some medications from the

plasma, lowering serum concentration and affecting therapeutic levels.

- iii. Typically, drugs with high plasma protein binding affinity (greater than 80%) and low volumes of distribution (less than 0.2 L/kg) remain in the intravascular compartment and are most vulnerable to influences from plasmapheresis (Chen et al., 2017).

g) Medications

- (1) Review the patient's current medications.
- (2) Verify that the patient has been prescribed supportive medications.
- (3) Verify that the patient understands the purpose, dosing, administration instructions, and schedule of all medications.
  - (a) Provide the patient with written and verbal information and a calendar (as appropriate).

(b) Examples of supportive medications

- i. Antibiotics, antifungals, and antiviral agents: NCCN (2021e) has published guidelines for infection prophylaxis for various regimens based on the risk for infection.
- ii. Antidiarrheal agents: Patients receiving capecitabine, 5-fluorouracil, irinotecan, and other agents with an increased risk for diarrhea should be prescribed antidiarrheal agents such as loperamide (Krishnamurthi & Macaron, 2021).
- iii. Antiemetics

- Several studies have indicated that adherence to post-chemotherapy antiemetics, especially dexamethasone, is low and results in an increased incidence of nausea and vomiting (Mellin et al., 2018).
- Patient education has improved adherence and decreased the incidence of nausea and vomiting (Hendricks, 2015; Mellin et al., 2018).
- Clear communication between patients and nurses as to when the patient took

- prechemotherapy oral antiemetics is imperative to ensure that the antiemetics have time to take effect before infusions are initiated.
- iv. High-dose methotrexate
    - Administration of oral agents such as sodium bicarbonate and acetazolamide before patient admission for high-dose methotrexate successfully increases urine pH and prevents renal toxicity (Clemmons et al., 2021; Kramer et al., 2021).
    - Administration of oral medications before hospitalization can decrease the length of hospital stay by allowing earlier administration of methotrexate (Clemmons et al., 2021; Kramer et al., 2021).
    - Oral administration allows treatment when parenteral shortages of sodium bicarbonate occur.
    - Oral administration of agents to increase urine pH facilitates outpatient administration of high-dose methotrexate (NCCN, 2020).
- (4) Drug interactions: Assess for antineoplastic drug–drug interactions and food–drug interactions. Online resources such as Lexicomp provide details on these interactions (<https://online.lexi.com/lco/action/login>; login required). Examples of potential interactions include the following (Parsad & Ratain, 2017):
- (a) CYP3A4 inhibitors and inducers: Some antineoplastic agents are metabolized through the cytochrome P450 enzymes in the liver, especially CYP3A4. Many medications and herbs can inhibit or induce this enzyme and affect drug levels.
    - i. CYP3A4 inducers decrease the level of the drug, making it less effective.
    - ii. CYP3A4 inhibitors increase the concentration of the drug and contribute to increased toxicities.
    - iii. Strong CYP3A4 inducers and inhibitors should be avoided in patients if that pathway metabolizes the antineoplastic agent. When avoidance is not possible, some medications have specific dosing recommendations that should be followed.
    - iv. A significant interaction can occur when antineoplastic agents that are CYP3A4 inhibitors are used with opioids that are also CYP3A4 inhibitors (e.g., fentanyl) (Janssen Biotech, 2021). Fatal overdoses of fentanyl have been reported. This also can occur when antineoplastic agents that are CYP3A4 inducers are discontinued.
  - (b) QT-prolonging medications: Prolonged QT intervals can place patients at risk for life-threatening ventricular arrhythmias such as torsades de pointes. Risk is increased in patients receiving more than one QT-prolonging agent and those with an underlying prolonged QT or an electrolyte imbalance (Duan et al., 2018).
    - i. Examples of antineoplastic agents that can prolong QT intervals include arsenic trioxide, capecitabine, crizotinib, dasatinib, eribulin, dasatinib, lapatinib, and sunitinib (Duan et al., 2018).
    - ii. Significant nonantineoplastic medications that can prolong QT intervals include antipsychotics, 5-hydroxytryptamine-3 (5-HT<sub>3</sub>) antagonist antiemetics, antibiotics, antifungals, and antiarrhythmics (Farzam & Tivakaran, 2021).
    - iii. Methadone, an analgesic frequently used in cancer, can also prolong QT intervals (Farzam & Tivakaran, 2021).
  - (c) Nephrotoxic medications: Nonsteroidal anti-inflammatory drugs can potentiate renal toxicity in patients receiving nephrotoxic chemotherapy (e.g., cisplatin) (Sato et

- al., 2016). Caution should be used when administering nonsteroidal anti-inflammatory drugs to patients with mild to moderate renal insufficiency receiving pemetrexed (Eli Lilly and Company, 2017).
- (d) Steroids and immunotherapy: Poorer outcomes were reported in patients who received corticosteroids of greater than 10 mg of prednisone equivalent per day with an immune checkpoint inhibitor. Adverse effects on overall survival were not recorded when steroids were used for symptom control during treatment with immune checkpoint inhibitors. (Petrelli et al., 2020). Collaboration with the oncologist, pharmacist, and rheumatologist (if indicated) should occur to determine a plan for patients requiring steroids for comorbidities such as autoimmune diseases.
- h) Immunizations: Before initiating therapy, assess patient immunization status.
- (1) Patients with hematologic and solid tumor malignancies should receive the inactivated influenza virus vaccine annually (Centers for Disease Control and Prevention, 2022; Rubin et al., 2014).
  - (2) Inactivated vaccines can be administered safely to people with altered immunocompetence (Centers for Disease Control and Prevention, 2022; Rubin et al., 2014).
  - (3) Live vaccines should be avoided (Centers for Disease Control and Prevention, 2022; Rubin et al., 2014). If a patient recently received a live virus, contact the provider.
  - (4) Vaccination recommendations should be reviewed thoroughly, as instructions change frequently.
  - (5) Except for the inactivated influenza vaccine, vaccination during chemotherapy or radiation therapy should be delayed, if possible, because antibody response might be suboptimal (Centers for Disease Control and Prevention, 2022; Rubin et al., 2014).
  - (6) Information for COVID-19 vaccine and patients receiving antineoplastics (NCCN, 2022e):
    - (a) Immunization is recommended for all eligible patients, including patients with cancer undergoing treatment and cancer survivors six months of age and older, based on U.S. Food and Drug Administration–approved indications or emergency use authorization (EUA).
    - (b) To maximize vaccine efficacy, the vaccination should be delayed for at least three months following hematopoietic cell transplantation or engineered cellular therapy (e.g., chimeric antigen receptor T-cell therapy).
    - (c) For patients with hematologic cancers receiving intensive chemotherapy (e.g., cytarabine- or anthracycline-based induction regimens for acute myeloid leukemia), vaccination should be delayed until absolute neutrophil count recovery.
    - (d) For patients with solid tumor malignancies undergoing major surgery, separate the date of surgery from the vaccination by at least a few days.
    - (e) Caregivers, household members, and close contacts should be immunized.
    - (f) The NCCN committee prefers the use of mRNA vaccines for the primary series and boosters.
- i) Complementary and alternative therapies: Review the use of complementary and alternative therapies and assess for any interactions with planned treatment. See the Office of Cancer Complementary and Alternative Medicine website for more information (<https://cam.cancer.gov>).
- (1) Alternative care refers to nontraditional treatment interventions used in place of conventional medicine. Although there may be anecdotal evidence addressing the benefits, this care has not been subjected to the type of rigorous testing for safety and efficacy.
  - (2) Complementary health approaches refer to diverse medical and healthcare systems, practices, and products used with conventional medicine or usual care. They are not used as an alternative or in place of conventional medicine unless as part of a clinical trial.
  - (3) Examples include natural products (e.g., herbs/botanicals, vitamins, minerals), essential oils (e.g., aromatherapy), and mind–body practices (e.g., acupuncture, acupressure, chiropractic and osteopathic manipulation, healing touch, hypnotherapy, massage, meditation, movement therapies). The Office of Cancer Complementary and Alternative Medicine provides a

helpful workbook to help patients talk to healthcare providers about complementary and alternative medicine ([https://cam.cancer.gov/health\\_information/talking\\_about\\_cam.htm](https://cam.cancer.gov/health_information/talking_about_cam.htm))

- (4) Potential interactions and adverse reactions to herbs, vitamins, minerals, and other supplements should be monitored.

j) Age

- (1) The patient's age should be recorded to determine potential issues associated with various age groups.
- (2) Challenges regarding dosing for older patients include inadequate representation in oncology clinical trials, higher risk of treatment-related toxicity, increased risk of drug interactions with multiple medications, and physiologic effects of the natural aging process (e.g., decreased bone marrow reserves) (Lichtman et al., 2016; Parikh, 2018).

(a) Many chemotherapy toxicity prediction tools for older adults are available on the American Society of Clinical Oncology (ASCO) website ([www.asco.org](http://www.asco.org)).

(b) Chronologic age may not correlate with physiologic impairment and decline in functional reserve, which vary substantially among individuals. Therefore, treatment for older adults should focus on the extent of comorbidity and functional status (NCCN, 2021d).

(c) Cognitive impairment or decline may affect comprehension and adherence to therapies (NCCN, 2021d; Whitman et al., 2021).

(d) Polypharmacy is more common in older adult patients and increases the risk for drug interactions (Whitman et al., 2021).

- (3) Pediatric oncology: Safe administration of chemotherapy in pediatric patients requires a specialized knowledge set. The Association of Pediatric Hematology/Oncology Nurses provides resources for pediatric oncology nurses ([www.aphon.org](http://www.aphon.org)).

k) Physical examination

- (1) A complete physical examination should be documented in the patient's medical record.
- (2) It should be reviewed prior to initiating a new therapy.

- (3) Any abnormalities should be noted and used as a comparison for future assessments.

l) Pregnancy

- (1) Pregnancy testing is recommended prior to treatment. Few formal guidelines are available regarding pregnancy screening protocols, and a lack of consensus exists regarding the frequency of testing (Association for Clinical Oncology, 2020; Berger et al., 2019; Neuss et al., 2016).

(a) Institutions should develop pregnancy screening protocols that have inclusion criteria (e.g., age 12–55 years, menstrual status), exclusion criteria (e.g., hysterectomy, laboratory tests confirming menopause), time of testing (e.g., within seven days of treatment) and frequency of testing (e.g., every 30 days). Additional factors to consider are intrauterine devices and tubal ligations. If applicable, declaration forms should be considered to document that patients understand the potential harm to a developing fetus and agree to proceed without testing.

(b) Use of prechemotherapy checklists and orders for point-of-care pregnancy tests has been found to improve pregnancy screening rates (Rogers et al., 2017).

- (2) Consensus guidelines for cancer chemotherapy during pregnancy have been developed (Amant et al., 2019).

(a) Patients should be managed by an interprofessional team, including the oncologist, maternal-fetal medicine team, and psychological, social, and spiritual support team members, as indicated or requested.

(b) Risk to the fetus is dependent on the gestational age and the planned agents to be administered.

(c) Chemotherapy is contraindicated during the first trimester because of the increased risk of spontaneous abortions, fetal death, and major congenital malformation (Amant et al., 2019).

(d) Fetal benefit of treatment delay until the second trimester should be balanced against maternal risk (Amant et al., 2019). After 14 weeks of gesta-

tion, administration of several chemotherapy drugs is feasible, including taxanes, platinum agents, anthracyclines, etoposide, and bleomycin (Amant et al., 2019).

- (e) Chemotherapy is not recommended beyond a gestational age of 35 weeks because a three-week window between the last cycle of chemotherapy and delivery is important to allow maternal and fetal bone marrow recovery (Amant et al., 2019).

*m) Gender identity*

- (1) Gender identity should be assessed, and the potential impact on drug dosing and other issues surrounding chemotherapy and immunotherapy should be considered.
  - (a) Gender-affirming hormone therapy can impact renal clearance and ideal body weight (Webb et al., 2020).
  - (b) Webb et al. (2020) recommended that medications be dosed on creatinine clearance and ideal body weight calculations consistent with gender identity after patients have been on hormone therapy for six months or longer.
- (2) Electronic health record systems may calculate creatinine clearance for patients who identify as transgender on admission (Webb et al., 2020). The formula to be used should be clarified with the provider and pharmacist.

*n) Initial psychosocial assessment*

- (1) Standardized tools are used to assess psychosocial concerns (Neuss et al., 2016; Pirl et al., 2013).
- (2) The American College of Surgeons Commission on Cancer (2022) requires distress screening as accreditation criteria.
- (3) Distress has been defined as “a multifactorial unpleasant experience of a psychological (i.e., cognitive, behavioral, emotional), social, spiritual, and/or physical nature that may interfere with one’s ability to cope effectively with cancer, its physical symptoms, and its treatment” (NCCN, 2022c, p. DIS-1).
- (4) The NCCN Distress Thermometer is a tool used to screen for distress (NCCN, 2022c; see Appendix F).
  - (a) Patients are asked to rate distress on a 0–10 scale, with 0 representing no

distress and 10 representing extreme distress.

- (b) If clinical evidence of moderate or severe stress exists or if the score exceeds 4, a clinician trained in distress screening should evaluate the cause of distress and ensure that a referral to a clinician qualified to address distress is completed (NCCN, 2022c).
- (5) Regardless of the tool used for distress screening, the following should be assessed:
  - (a) Family structure and dynamics, living conditions, and caregivers
  - (b) Transportation, financial, or insurance issues: Patients receiving sedating premedications or opioids will need transportation to and from treatment.
  - (c) Religious beliefs or spiritual concerns that may affect dietary and other requirements or restrictions
- o) Comprehension of the disease and planned treatment (see Chapter 3)*
  - (1) Teach-back strategies can assess comprehension (Agency for Healthcare Research and Quality, 2020).
  - (2) Teach-back is a method to assess understanding by asking patients to state, in their own words, the information they have been taught.
  - (3) Using teach-back strategies for assessing comprehension in patients receiving oral chemotherapy has improved patient adherence to treatment (Bellomo, 2016).
- p) Informed consent:* Verify that the informed consent document has been completed and is accurate and current (see Chapter 2). Confirm that issues related to biosimilar substitution have been addressed in the consent process.
- 3. At each clinical encounter related to treatment (e.g., office visit prior to treatment, hospitalization for inpatient treatment, infusion visit), assess the following (Neuss et al., 2016):
  - a) Performance status:* Performance status measures the patient’s functional capacity, including the ability to perform activities of daily living (Neuss et al., 2016).
    - (1) Performance status is used to predict patient tolerance and response to treatment (Jang et al., 2014).
    - (2) Different tools used to assess performance status include the Eastern Cooperative Oncology Group Performance Sta-

- tus Scale and the Karnofsky Performance Status Scale (see Chapter 4).
- (3) The literature reports conflicting data regarding the reliability of performance status measurements, with variable levels of inter-rater reliability (Chow et al., 2020).
- b) Vital signs
- (1) Monitor vital signs before each treatment.
  - (2) Assess for abnormal vital signs (e.g., increased temperature, which could indicate an infection) and adverse reactions to previous doses (e.g., bevacizumab can cause hypertension).
- c) Height and weight: Monitor the patient's height and weight at least weekly when present in the healthcare setting (Neuss et al., 2016). The following are recommended by the Institute for Safe Medication Practices [ISMP] (2022).
- (1) Accurately measured height and weight are imperative for correct dosing of weight-based drugs.
  - (2) One of the most commonly reported medication errors related to dose is inaccurate height and weight.
  - (3) Avoid using stated or estimated height or weight from a previous encounter.
  - (4) Measure and document weight in metric units.
  - (5) Place a conversion chart near all scales so that patients and caregivers can be told the weight in pounds when requested.
  - (6) If purchasing scales, buy scales that measure in kilograms or can be locked out to measure in metric units only.
  - (7) Computer screens and IV infusion pumps should prompt patient weight in metric units only.
- d) Physical examination: Perform an assessment prior to each treatment.
- (1) Assessment should include but not be limited to orientation, level of consciousness, signs of infection, nutritional status, indicators of pain, toxicities from previous doses, and any change that may preclude patients from treatment (e.g., new onset of tachycardia, arrhythmia, shortness of breath, syncope).
  - (2) Perform a focused assessment based on the potential adverse reactions of the agents to be administered.
  - (3) For patients with vascular access devices, assess patency, including a blood return, and for signs of complications.
- (4) Notify the provider of any signs of infection.
    - (a) The treatment plan and assessment findings are considered when deciding to hold or continue therapy when a patient has a fever.
    - (b) For example, the provider may elect to proceed with treatment in a patient with an uncomplicated urinary tract infection receiving a non-myelosuppressive agent.
- e) Symptom assessment: Assess symptoms using an evidence-based patient-reporting tool.
- (1) Patient-reported outcomes are recommended as the preferred method to screen for symptoms because of underdetection of symptoms by healthcare providers. These outcomes are defined as any report of a health condition that comes directly from the patient without interpretation by the clinician (Pirschel, 2017).
  - (2) The Oncology Nursing Society (ONS) has established criteria for patient-reported outcome assessment tools and lists instruments that meet these criteria on its website ([www.ons.org/explore-resources?display=results&source=1476](http://www.ons.org/explore-resources?display=results&source=1476))
- f) Toxicity grading: Grade toxicities found during the physical examination and symptom assessment (Neuss et al., 2016).
- (1) Grading is used to standardize communication among healthcare providers. Toxicity grades can be included as parameters to withhold, delay, or dose-reduce treatment. They are also included as part of clinical trials.
  - (2) The National Cancer Institute Cancer Therapy Evaluation Program's Common Terminology Criteria for Adverse Events tool (v.5.0) is available at [https://ctep.cancer.gov/protocoldevelopment/electronic\\_applications/docs/CTCAE\\_v5\\_Quick\\_Reference\\_5x7.pdf](https://ctep.cancer.gov/protocoldevelopment/electronic_applications/docs/CTCAE_v5_Quick_Reference_5x7.pdf). Different versions of the tool exist, making it essential to verify the current version of the literature.
- g) Laboratory values: Review laboratory values prior to each treatment.
- (1) Laboratory tests are specific for the agent, regimen, and individual patient. They may be ordered to calculate doses (e.g., serum creatinine for carboplatin), assess for toxicities from prior treatments (e.g., myelosuppression), and ensure that the agent will be adequately metabolized and excreted.

- (2) Determine if the values meet predetermined parameters, which can be included on the treatment orders or listed in a policy or procedure. Parameters to hold the agent or reduce the dose depend on therapy, regimen, and patient goals.
- (3) Examples of laboratory tests
  - (a) Complete blood count and differential: Evaluate results to determine if the dose should be delayed or reduced.
    - i. Parameters for holding therapy should be defined by the practice or prescriber. This can be done based on the individual patient via a specific provider order or a regimen guideline approved for a specific diagnosis. For example, in patients with solid tumors, a parameter to hold treatment or clarify with the prescriber might be an absolute neutrophil count of less than  $1,500/\text{mm}^3$  and a platelet count less than  $100,000/\text{mm}^3$ .
    - ii. Red blood cell count, hemoglobin, and hematocrit should be evaluated to determine if the patient is anemic; however, anemia is usually not an indication to hold chemotherapy.
  - (b) Serum creatinine and creatinine clearance
    - i. Serum creatinine and creatinine clearance are used to calculate doses of carboplatin.
    - ii. Many agents are excreted renally, such as carboplatin, cisplatin, cyclophosphamide, and pemetrexed (Krens et al., 2019). These agents require dose reduction for impaired renal function because renal impairment can cause delayed excretion and increased toxicities.
    - iii. Renal function is also monitored to assess for nephrotoxicity from agents such as cisplatin, high-dose methotrexate, and mitomycin C (Krens et al., 2019).
    - iv. Immune checkpoint inhibitors can cause renal damage, including tubule-interstitial nephritis and immune complex glomerulonephritis (NCCN, 2021c).
  - (c) Total bilirubin and liver function tests
    - i. Many agents are metabolized and cleared from the body by the liver; therefore, dose reductions may be needed for patients with impaired liver function (Krens et al., 2019).
    - ii. Some chemotherapy and immunotherapy agents can also cause hepatotoxicity (Krens et al., 2019). Immune checkpoint inhibitors can cause autoimmune hepatitis with elevated alanine transaminase and aspartate transaminase (NCCN, 2021c).
  - (d) Electrolytes (e.g., calcium, magnesium, potassium): Nephrotoxic agents such as cisplatin can cause electrolyte wasting (Workeneh et al., 2021). The most common laboratory abnormality reported with cisplatin is hypomagnesemia, with incidences reported as high as 91.8% (Workeneh et al., 2021).
  - (e) Hepatitis B testing: Patients with cancer receiving chemotherapy or immunotherapy who are hepatitis B positive are at increased risk for hepatitis B reactivation with the initiation of chemotherapy and immunotherapy (Hwang et al., 2020).
    - i. The risk of hepatitis B reactivation among patients with solid tumors is less than for patients with hematologic malignancies, particularly those receiving anti-CD20 therapies or who have received a stem cell transplant (Hwang et al., 2020).
    - ii. Guidelines for screening hepatitis B and testing
      - The Centers for Disease Control and Prevention recommends prechemotherapy hepatitis B screening for all patients receiving cytotoxic or immunosuppressive therapy (Weinbaum et al., 2008).
      - ASCO (Hwang et al., 2020) recommends that all patients

with cancer anticipating systemic anticancer therapy should be tested for hepatitis B with the following tests: hepatitis B surface antigen (HBsAg), hepatitis B core antibody (anti-HBc) total immunoglobulin (Ig) or IgG, and antibody to hepatitis B surface antigen (anti-HBs) prior to or at the beginning of systemic anticancer therapy.

- The American Gastroenterological Association recommends screening (HBsAg and anti-HBc, followed by a sensitive hepatitis B virus DNA test if positive) in patients at moderate or high risk who are receiving immunosuppressive drug therapy. They suggest against routinely screening patients who will receive immunosuppressive agents at low risk (Reddy et al., 2015).
- All patients receiving anti-CD20 monoclonal antibodies should be screened for hepatitis B (Hwang et al., 2020; Reddy et al., 2015). Anti-CD20 monoclonal antibodies include obinutuzumab, ofatumumab, and rituximab.

(f) Thyroid function tests: Immune checkpoint inhibitors, such as nivolumab, ipilimumab, and pembrolizumab, can cause endocrinopathies, such as hypothyroidism. NCCN (2021c) guidelines recommend a thyroid-stimulating hormone and free thyroxine ( $T_4$ ) every four to six weeks during immune checkpoint inhibitor therapy and then every 12 weeks as indicated.

(g) Serum cortisol tests (morning preferred) are recommended prior to each treatment or every four to six weeks in patients receiving specific immune checkpoint inhibitors, including ipilimumab (NCCN, 2021c).

h) Diagnostic tests: Review diagnostic tests pertinent to the specific agent.

## (1) Cardiac testing

### (a) Echocardiogram

- i. Echocardiographic imaging is crucial for managing patients treated with cardiotoxic anti-neoplastic agents.
- ii. Left ventricular ejection fraction is the most commonly used parameter for identifying left ventricular dysfunction before, during, and after cancer therapy.
- iii. A complete echocardiogram and strain imaging echocardiogram measure left ventricular dysfunction. A strain imaging echocardiogram also measures global longitudinal strain, which measures cardiac contractile function, an early marker of cardiotoxicity (J.E. Liu et al., 2020).
- iv. Patients receiving anthracycline antitumor antibiotics (e.g., doxorubicin) should have a baseline echocardiogram to evaluate left ventricular ejection fraction (Lexicomp, 2021b). Recommendations to repeat echocardiograms are dependent on the agent and cumulative dose.
- v. In the adjuvant setting, product labeling for trastuzumab recommends an echocardiogram at baseline, every three months during treatment, and every six months for two years following treatment (Genentech, 2021a). If trastuzumab is held because of decreased left ventricular ejection fraction, patients should have repeat monitoring four weeks after discontinuation (Genentech, 2021a).

(b) Electrocardiogram: A baseline electrocardiogram should be performed before starting agents with the potential to prolong QT intervals (Duan et al., 2018). The frequency of follow-up electrocardiograms varies with the agent. The corrected QT, known as QTc, considers the patient's heart rate.

- (2) Pulmonary testing
    - (a) Pulmonary function tests may be ordered prior to initiating bleomycin and at intervals throughout treatment; however, effectiveness in detecting changes from bleomycin is controversial (Roncolato et al., 2016). Spirometry and diffusing capacity for carbon monoxide are typically ordered.
    - (b) Some recommendations advocate chest x-rays or computed tomography scans at intervals throughout bleomycin treatment (Khan et al., 2016).
    - (c) Chest computed tomography scans are recommended to detect interstitial pneumonitis, which can be caused by numerous agents, including immune checkpoint inhibitors (NCCN, 2021c).
    - (d) Pulmonary function tests may be indicated prior to and during other cancer treatment regimens and in patients with preexisting pulmonary issues.
  - i) Psychosocial concerns: Assess psychosocial concerns at each visit.
    - (1) NCCN recommends completion of distress screening at medical visits, including chemotherapy and immunotherapy treatments (NCCN, 2022c; see Appendix F).
    - (2) ASCO/ONS Chemotherapy Administration Safety Standards recommend psychosocial assessment with each cycle and more frequently as indicated (Neuss et al., 2016).
    - (3) At a minimum, distress screening should occur at the initial visit, at appropriate intervals, and as clinically indicated (e.g., changes in disease status, such as recurrence and progression) (NCCN, 2022c).
  - j) Allergies and previous treatment-related reactions should be reviewed and updated at each visit.
  - k) The medication list should be reviewed and updated at each visit.
- C. Chemotherapy, targeted therapy, and immunotherapy dosing
1. Dose calculation includes the calculation methodology, variables used to calculate the dose, frequency at which the variables are reevaluated, and changes in the values that prompt confirmation of dosing (Neuss et al., 2016).
  2. Different dosing methods may be used to calculate doses, depending on the agent and regimen ordered.
    - a) Fixed dosing (flat dosing) is not based on the patient's height or weight.
      - (1) Many oral agents are prescribed in fixed doses. Be aware of agents that may be ordered as fixed doses or based on body surface area (BSA) (e.g., bleomycin fixed dose of 30 units or BSA dose of 10 units/m<sup>2</sup>). Confirm with a reference if the agents in the regimen are a fixed dose or based on BSA or weight alone.
      - (2) According to an ASCO consensus panel, except for bleomycin, no data support the use of fixed dosing for cytotoxic agents (i.e., traditional chemotherapy agents). The practice of limiting vincristine doses to 2 mg in clinical trial protocols is not supported by existing data. Refer to the consensus statement for additional details and clarifications (Griggs et al., 2022).
    - b) Weight-based dosing is expressed as drug dose per unit of body weight (e.g., mg/kg).
    - c) Most chemotherapy agents are dosed using the patient's BSA (m<sup>2</sup>).
      - (1) BSA is a function of height and weight. It can be calculated using a variety of formulas, including the Du Bois and Du Bois formula and the Mosteller formula (see Figure 11-1). ASCO recommends that BSA be calculated using standard formulas. No evidence supports one formula for calculating BSA over another (Griggs et al., 2021).
      - (2) The calculated BSA is then multiplied by the dose in mg/m<sup>2</sup>, mcg/m<sup>2</sup>, or g/m<sup>2</sup> to determine the total dose of the agent to be administered. To prevent errors, institutions should standardize milligrams (mg) or grams (g) in orders and pump error prevention programming (i.e., methotrexate should not appear in milligrams in the order set but in grams in the pump error prevention program).
      - (3) The underlying assumption for dosing based on BSA is that BSA is a more reliable indicator than using weight alone for predicting pharmacokinetics. However, BSA dosing does not consider factors such as gender and age.
      - (4) In most situations, no significant difference exists between doses calculated using different BSA formulas (Faisal et al.,

**FIGURE 11-1.** Calculating Chemotherapy Dose Using Body Surface Area**Formulas to calculate estimated body surface area (BSA)**

- Du Bois and Du Bois:  $BSA (m^2) = \text{Weight (kg)}^{0.425} \times \text{Height (cm)}^{0.725} \times 0.007184$
- Mosteller (metric):  $BSA (m^2) = \sqrt{[(\text{Height (cm)} \times \text{Weight (kg)}) / 3,600]}$

**To calculate the total dose of chemotherapy or immunotherapy**

Calculated BSA ( $m^2$ )  $\times$  dose in  $mcg/m^2$ ,  $mg/m^2$ , or  $g/m^2$  = total dose of chemotherapy

**Example**

The patient is 157.48 cm tall and weighs 60 kg. She is scheduled to receive paclitaxel 80  $mg/m^2$  IV.

- Using the Mosteller formula, calculate the BSA.
  - Multiply height and weight using metric units.  
 $157.48 \text{ cm} \times 60 \text{ kg} = 9,448.8$
  - Divide the total by 3,600.  
 $9,448.8 / 3,600 = 2.6246$
  - Using a calculator, determine the square root.  
Square root =  $1.62 \text{ m}^2$
- Calculate the total dose by multiplying the BSA by the dose ordered in  $mg/m^2$ .  
 $1.62 \text{ m}^2 \times 80 \text{ mg/m}^2 = 129.6 \text{ mg}$

Note. Based on information from Du Bois & Du Bois, 1916; Mosteller, 1987.

2016). However, different formulas may produce different results for patients with extremes in height or weight (Faisal et al., 2016; Fancher et al., 2016).

- (5) The Mosteller formula can be easily performed using any calculator with a square root function.
  - (6) If the electronic health record calculates BSA, verify the formula and use it when recalculating doses during order verification.
- d) Carboplatin is dosed using area under the curve (AUC)-based dosing, which refers to the amount of drug exposure or total drug concentration in plasma over time.
- (1) AUC dosing considers age, gender, weight, and renal function.
  - (2) Carboplatin drug clearance is strongly correlated with renal function.
  - (3) Carboplatin doses are determined by first calculating the creatinine clearance and then calculating the total dose of carboplatin by using the Calvert formula (see Figure 11-2). AUC is prescribed in the treatment plan and usually ranges from 2 (low dose) to 6 (higher dose).
    - (a) To calculate creatinine clearance, estimated creatinine clearance is often used rather than an actual glomerular filtration rate (24-hour urine for creatinine clearance).
    - (b) Many formulas are used to calculate creatinine clearance, with the

Cockcroft-Gault being the most common in the United States.

- (c) To calculate creatinine clearance using the Cockcroft-Gault formula, the patient's age, gender, weight in kilograms, and recent serum creatinine are obtained (see Figure 11-3). The formula may not be accurate in patients with rapidly changing serum creatinine levels (Gaguski & Karcheski, 2011).
- (d) The National Cancer Institute (2010) recommends capping estimated serum creatinine clearance at 125 mL/min to prevent overdosing and dose capping carboplatin based on AUC (see Figure 11-4).
- (e) Additional considerations in carboplatin calculations (NCCN, 2020)
  - i. Consider using an adjusted body weight for patients characterized as overweight or obese (body mass index

**FIGURE 11-2.** Calculating Carboplatin Dose Using the Calvert Formula

Dose of carboplatin (mg) = (target AUC)  $\times$  (GFR + 25)

Total dose calculated is in mg, not  $mg/m^2$ .

AUC—area under the plasma concentration versus-time curve; GFR—glomerular filtration rate

Note. Based on information from Calvert et al., 1989.

**FIGURE 11-3.** Calculating Glomerular Filtration Rate Using the Cockcroft-Gault Formula**Males**

$$\text{estCrCl (ml/min)} = \frac{(140 - \text{age}) \times (\text{weight in kg})}{72 \times \text{serum creatinine (mg/dl)}}$$

**Females**

$$\text{estCrCl (ml/min)} = \frac{(140 - \text{age}) \times (\text{weight in kg}) \times (0.85)}{72 \times \text{serum creatinine (mg/dl)}}$$

estCrCl—estimated creatinine clearance

Note. Based on information from Cockcroft &amp; Gault, 1976.

greater than or equal to 25 kg/m<sup>2</sup>): adjusted body weight (kg) = ideal body weight + 0.4 × (total body weight – ideal body weight).

- ii. For patients with abnormally low serum creatinine, including older adults or cachectic patients, consider using a minimum serum creatinine of 0.7 mg/dl to avoid overestimated creatinine clearance.

- iii. Consider using ethylenediaminetetraacetic acid or 24-hour urine testing to measure creatinine clearance (not Cockcroft-Gault or another formula) when dosing AUC greater than 6 or when using an uncapped creatinine clearance.

- (f) If variance exists between the prescribed dose and the recalculated dose, clarify with the prescriber whether the actual, adjusted, or ideal

weight was used when calculating creatinine clearance and whether an adjusted serum creatinine was used.

## 3. Dosing and obesity

- a) Controversy exists regarding dosing for patients characterized as obese. Concerns voiced include fears of toxicity versus compromising disease-free survival in the curative setting (Furlanetto et al., 2016). ASCO has developed formalized guidelines for this population (Griggs et al., 2021).

- (1) Full, weight-based cytotoxic chemotherapy doses should be used to treat obese adults with cancer.
- (2) An adult with a body mass index of 30 kg/m<sup>2</sup> or greater is considered obese.
- (3) Fixed dosing of chemotherapy should be limited to selected agents (e.g., bleomycin).
- (4) U.S. Food and Drug Administration prescribing information for immune checkpoint inhibitors should be used in all patients regardless of obesity status.
- (5) Clinicians should follow the same dose reduction guidelines for patients characterized as obese and nonobese.

- b) Actual body weight is recommended for BSA and weight-based dosing; however, NCCN (2020) recommends using adjusted body weight for overweight or obese patients (body mass index greater than or equal to 25 kg/m<sup>2</sup>) when calculating creatinine clearance for carboplatin dosing.

## 4. Dosing and underweight patients

- a) No formal guidelines exist addressing the dosing of underweight patients, those with low body mass index, or those with low skeletal mass (Griggs et al., 2021).
- b) Preterm termination of chemotherapy is associated with lower body mass index (Grabowski et al., 2018).

## 5. Dose rounding

- a) Institutional dose-rounding policies and practices should be followed when calculating and verifying doses.
- b) These policies often allow dose rounding at 5%–10% of the prescribed therapy. Policies may also differentiate between chemotherapy and immunotherapy doses, the intent of therapy (cure vs. palliation), and whether doses can be rounded up, down, or both. Some institutions may not allow dose rounding for pediatric patients. Clinical trials may specify the accepted percentage for dose rounding.
- c) Hematology/Oncology Pharmacy Association (2017) dose-rounding recommendations

**FIGURE 11-4.** Calculating Carboplatin Dose Capping Using Estimated Creatinine Clearance

$$\text{Dose of carboplatin (mg)} = (\text{target AUC}) \times (\text{estCrCl} + 25)$$

estCrCl capped at 125 ml/min

Maximum doses for sample target AUCs

- Target AUC 6:  
Maximum carboplatin dose = 6 × (125 + 25) = 900 mg
- Target AUC 5:  
Maximum carboplatin dose = 5 × (125 + 25) = 750 mg
- Target AUC 4:  
Maximum carboplatin dose = 4 × (125 + 25) = 600 mg

AUC—area under the plasma concentration versus-time curve; estCrCl—estimated creatinine clearance

Note. Based on information from Calvert et al., 1989.

- (1) For monoclonal antibodies, other immunotherapies, and traditional cytotoxic chemotherapy, round the dose to the nearest vial size within 10% of the prescribed dose.
- (2) For monoclonal antibodies with conjugated (attached) cytotoxic agents, apply dose rounding to the cytotoxic component of the agent. It can be rounded to the nearest vial size within 10% of the prescribed dose.
- (3) For oral chemotherapy, use one dose strength and round the final dose, when possible, to simplify dosing for patients.
- (4) Dose rounding can be used for curative and palliative therapy if the rounding does not influence clinical safety or effectiveness.

#### D. Verification

1. The healthcare setting should have established processes for verification and clearly defined steps to take when discrepancies arise (Neuss et al., 2016). Verification refers to determining the accuracy of the prescribed therapy, prepared medication, patient identification, and pump settings (if applicable).
2. Verification should occur prior to administration for all chemotherapy, targeted therapy, and immunotherapy routes, including the oral route.
  - a) Independent dual verification (i.e., independent double-check) is a process in which a second person conducts an independent verification of the accuracy of the prescribed therapy without telling their findings to the other verifier until both have completed the process (ISMP, 2019).
  - b) Numerous studies have demonstrated that independent double-checks of medication can detect up to 95% of errors (Alsulami et al., 2012). Checklists may help promote a consistent process (see Appendix D).
3. Verification step 1: Verify the accuracy of the treatment plan (chemotherapy orders).
  - a) Verify a minimum of two patient identifiers per institutional policy, such as name, date of birth, and medical record number. Do not use room or chair numbers as patient identifiers (Neuss et al., 2016).
  - b) Compare the treatment plan with a reference for doses, routes, and schedule. For example, orders for doxorubicin 60 mg/m<sup>2</sup> IV and cyclophosphamide 600 mg/m<sup>2</sup> IV every two weeks for four cycles are compared with a reference. This confirms the doses, routes, and schedule. Never verify accuracy by comparing previous patient doses, as they may have been changed because of toxicities or weight change.
- c) Confirm the accuracy of the treatment plan cycle and day number.
  - (1) Compare the date on the orders, date of planned therapy, and previously administered doses. For example, the patient is scheduled for cycle 12 of weekly paclitaxel, but the nurse notes from the medical record that the patient has received 10 doses.
  - (2) Confirm that the appropriate interval has occurred between treatments (e.g., seven days between paclitaxel doses).
- d) Compare the height and weight on the treatment plan with the current measured height and weight.
- e) BSA-dosed medications
  - (1) Recalculate the BSA based on the current measured height and weight. Compare the recalculated BSA with the one on the treatment plan.
  - (2) Recalculate the total dose and compare it with the prescribed dose.
- f) For carboplatin, recalculate the patient's creatinine clearance. Recalculate the total dose using the Calvert formula. Compare the recalculated dose with the prescribed dose.
- g) For weight-based medications, recalculate the total dose.
- h) For fixed-dose medications, compare the prescribed dose with a reference.
- i) Institutional policy and procedure should define changes in values that prompt a call to the provider to determine if recalculation or dose adjustment is needed (Association for Clinical Oncology, 2020). For example, an institutional policy may state that a 10% change in weight would prompt a call to the provider to determine if the dose should be changed to reflect the weight change. Some electronic health records will alert the provider to identified changes in weight or BSA.
- j) Verify the route of administration, sequence of administration, and the duration of infusion, if applicable.
  - (1) The sequence in which chemotherapy and immunotherapy are given may affect the pharmacokinetics and pharmacodynamics of the agents and thus, efficacy and toxicity.
  - (2) Lehman et al. (2019) developed a sequencing table to guide staff when evidence for sequencing exists.
  - (3) If sequencing data are not available, institutions should follow the original sequence in the clinical trial.

- (4) For administration through peripheral IVs, vesicant status should also be considered in sequencing, as venous integrity decreases over time.
  - k) Verify the compatibility of any IV solutions and medications used during administration.
  - l) Confirm that supportive care treatments are ordered and are appropriate to the regimen (e.g., premedications, hydration, growth factors, rescue agents, medications to manage infusion reactions).
  - m) Clarify any discrepancies with the prescriber before initiating treatment. Common discrepancies include inaccurate height and weight and different formulas for calculating BSA or creatinine clearance.
4. Verification step 2: Check the prepared medication.
  - a) Compare the medication and label with the treatment plan (orders) and verify the following:
    - (1) Patient name, date of birth, and any other identifier established in institutional policy
    - (2) Medication name and total dose
    - (3) Diluent type and total volume (as appropriate)
    - (4) Expiration date and time
  - b) Assess the appearance and physical integrity of the medication and medication container (e.g., clarity, leaking).
  - c) Check any special labeling (e.g., HDs, for IV use only, protect from light).
  - d) Verify that the correct type of tubing and filter is attached, if applicable.
  - e) Confirm the presence of a closed-system drug-transfer device (CSTD) on parenteral preparations.
5. Verification step 3: Verify the patient, medication, and pump programming at the bedside (or chair-side).
  - a) Prior to placing an identification band or label on the patient, always confirm the patient's stated name and birthdate with the identification band or label.
    - (1) Do not assume that the patient's identification band is correct without patient verification.
    - (2) For non-English-speaking patients, an interpreter should be used to confirm patient identity prior to wrist band application.
  - b) Immediately prior to administration, the following should be verified by two practitioners approved by the healthcare setting:
    - (1) Compare the patient's stated name, birthdate, and any other institutional identifiers on the patient's identification band or sticker and the medication label.
  - (2) Compare the medication name, dose, route, and schedule on the label with the treatment plan.
  - (3) Where scanning is available, scan the patient's wristband with the medication label. Scanning does not eliminate the action of verifying the patient's stated name and birthdate.
    - (a) No studies exist investigating the accuracy of scanning replacing two-practitioner bedside verification.
    - (b) Numerous studies and recommendations support barcoding and scanning for medication administration (Seibert et al., 2014). Advantages reported included increased accuracy, elimination of the need to find another practitioner who may be busy, improvement in verification time, and elimination of bias.
    - (c) Limitations of barcode scanning
      - i. Failure to detect the incorrect route of administration
      - ii. Poor practices involving using scanning identification barcodes not attached to patients
      - iii. Possibility of incorrect barcodes
      - iv. Overreliance on technology (Michalek & Carson, 2020)
      - v. Barcode scanning not detecting an error if the wrong patient identification band or label is applied to patients
  - c) Verify any infusion pump programming with the treatment plan and reference (Neuss et al., 2016).
6. Include the patient as part of the verification process.
  - a) Involve patients and families in the medication verification process by providing them with the medication names, schedule, potential adverse reactions, and indications of when to notify the healthcare provider.
  - b) Encourage patients to alert their nurse to clarify any possible discrepancies (e.g., "I thought today was my last chemotherapy, not next week," "Is it OK for me to get my 5-fluorouracil if I have diarrhea six to eight times a day?") (Agency for Healthcare Research and Quality, 2021; Hartkopf Smith, 2009a; Schwappach et al., 2018).
  - c) Individuals with limited English fluency are at high risk for medical errors and serious adverse

events (Perez et al., 2016; Wasserman et al., 2014). The use of medical interpreters, including video services, has decreased these errors (Nápoles et al., 2015).

#### E. Routes of chemotherapy, immunotherapy, and targeted therapy administration

##### 1. Oral route

*a)* Oral cancer treatments have experienced a rapid increase over the past 10 years with new cytotoxic agents, small molecule inhibitors, and other targeted therapies. The oral route presents unique challenges for oncology nurses and patients as treatment shifts from clinician-administered therapy in a healthcare setting to self-administration.

*b)* Pretreatment assessment (in addition to the general pretreatment assessment) (Multinational Association of Supportive Care in Cancer, 2016; Neuss et al., 2016; ONS, 2016)

- (1) Financial/insurance coverage for the medication and available pharmaceutical company assistance programs
- (2) Method or location the patient will obtain the medication (e.g., specialty pharmacy, drop shipment)
- (3) The patient's ability to swallow and retain pills (e.g., dysphagia, strictures, presence of gastrostomy or jejunostomy tube, mucositis, esophageal strictures, vomiting)
- (4) The patient's ability to read labels, instructions, and calendars
- (5) The patient's ability to open medication bottles or packages
- (6) The patient's ability to comprehend instructions regarding dosing, schedules, and indications to hold medication and notify the healthcare provider
- (7) Possible food–drug interactions, drug–drug interactions, and supplement–drug interactions

*c)* System safeguards to prevent errors and manage emergencies (see Chapters 1, 12, and 13)

- (1) Independent practitioners qualified by the healthcare setting should sign oral chemotherapy, targeted therapy, and immunotherapy orders to treat cancer (Neuss et al., 2016).
- (2) Information to include in prescriptions or orders for oral chemotherapy, targeted therapies, and immunotherapy (Neuss et al., 2016; ONS, 2016)
  - (a)* Patient name, date of birth, and any institution-specific identifiers

*(b)* Full generic name of the medication

*(c)* Drug dose and calculation methodology (e.g., mg/m<sup>2</sup>)

*(d)* Schedule of administration

*(e)* Drug quantity to be dispensed and the number of refills, with zero as the acceptable default value; a time limitation to refills helps ensure appropriate evaluation at predetermined intervals.

*(f)* Any special instructions

(3) Institutional policies should address the process for continuing oral chemotherapy, targeted therapy, and immunotherapy when patients are admitted to the hospital.

*(a)* In many settings, patients may be admitted by a hospitalist or other non-oncologist. The potential for error exists if the therapy is continued as part of a home medication list; however, it may be contraindicated for the patient's current condition (Booth et al., 2011; Schleisman & Mahon, 2015).

*(b)* Prior to giving an oral chemotherapy, targeted therapy, or immunotherapy agent in the inpatient setting as a continuation of home therapy, verify that the agent was ordered by a licensed independent practitioner qualified by the healthcare setting and that the therapy is appropriate to continue and at the same dose.

*d)* Dosing: When possible, one dose strength of pill should be used and rounded to the final dose (Hematology/Oncology Pharmacy Association, 2017).

*e)* Verification (see section D)

*f)* Administration

(1) Do not crush hazardous oral antineoplastics outside of a containment primary engineering control. If the patient cannot take oral medication, discuss an alternative route with the oncologist or use strategies for safe administration (Polovich & Olsen, 2018; see Chapter 12).

(2) For intact oral tablets, capsules, or pills designated as hazardous, wear one pair of gloves tested for use with HDs. A mask with a face shield and double gloves should be worn if the potential for sprays, aerosols, or splattering of the agent exists, such as with liquid oral HDs (Polovich & Olsen, 2018).

*g)* Other considerations

- (1) The institution or practice should determine a process to assess and track patient adherence to oral cancer therapy (Neuss et al., 2016; ONS, 2016).
  - (2) Strategies to encourage adherence include calendars or daily medication checklists, pill diaries, electronic reminders, and text messages (Burhenn & Smuddle, 2015; ONS, 2016; Rodriguez et al., 2017; Spoelstra & Sansoucie, 2015; see Chapter 4).
  - (3) Set up routine appointments to monitor patient response to therapy, including follow-up laboratory testing.
  - (4) Information to include in patient education (ONS, 2016)
    - (a) Drug name, dose, and schedule, including calendar as appropriate
    - (b) How the drug will be obtained
    - (c) Potential side effects, management, and indications for when to notify the healthcare provider
    - (d) Safe storage and handling
    - (e) Disposal of unused medication (e.g., drug drop-off sites that accept HDs)
    - (f) Food, drug, and supplement interactions
    - (g) Plan for missed doses
    - (h) Schedule of appointments for monitoring
    - (i) Process for refills
2. SC and intramuscular (IM) routes
- a) Few chemotherapy, targeted, and immunotherapy agents are administered via the SC or IM route. Select hormone agents used as antineoplastics are administered via these routes. See Tables 6-1, 7-1, 8-1, and 10-1 for a listing of drugs given via these routes.
  - b) Pretreatment assessment (in addition to the general pretreatment assessment)
    - (1) Assess for adequate SC or muscle sites.
    - (2) Review any coagulation values and other risks for bleeding and bruising.
  - c) System safeguards to prevent errors and manage emergencies (see Chapters 1, 12, and 13): Never administer vesicants by the SC or IM route.
  - d) Dosing: The medication may have to be divided into several syringes, depending on the total volume of the syringe.
    - (1) The maximum volume for IM injections varies according to muscle mass and the muscle used, with the deltoid muscle ranging 0.5–2 ml, the dorsogluteal 4 ml, and the vastus lateralis 5 ml (Hopkins & Arias, 2013).
    - (2) The maximum volume for SC injections varies according to the amount of SC muscle and the injection location, with a volume range of 2–3 ml (Ferruccio et al., 2016).
      - (a) Exceptions include preparations that include hyaluronidase. The addition of hyaluronidase, an enzyme that increases the distribution and absorption of locally injected substances, permits the large volume of SC injection. An example is rituximab and hyaluronidase human, for which the total volume of SC injection is 11.7 ml or 13.4 ml, depending on the dose (Genentech, 2021c).
      - (b) Care must be taken to ensure this formulation is not given via IV.
- e) Verification (see section D)
- f) Administration
- (1) For SC and IM medications designated as hazardous (Polovich & Olsen, 2018)
    - (a) Wear two pairs of gloves, tested for use with HDs, and a gown. Wear a mask with face protection if splashing is possible (see Chapter 12).
    - (b) Use CSTDs attached between the syringe and needle when possible (Polovich & Olsen, 2018).
    - (c) If air bubbles are noted in the syringe, do not express unless in a containment primary engineering control (Polovich & Olsen, 2018; see Chapter 12).
  - (2) Use the smallest gauge needle possible.
  - (3) Review product literature for any specific instructions regarding the site of SC or IM injection. For example, instructions for bortezomib specify injection into the thigh or abdomen (Millennium Pharmaceuticals, 2019). Rituximab hyaluronidase is recommended for abdomen administration only (Genentech, 2021c).
  - (4) Avoid scarred areas.
  - (5) Rotate sites.
  - (6) Clean the site with antiseptic and allow to dry completely prior to injection.
  - (7) For IM injections (Sisson, 2015)
    - (a) Usual sites for delivering an IM injection include the deltoid, vastus lateralis, ventrogluteal, and dorsogluteal muscles.
    - (b) The deltoid, vastus lateralis, and ventrogluteal sites are recommended

because these sites are distant from major blood vessels and nerves. Aspiration is not required for these sites.

- (c) Aspiration is still advised when injecting into the dorsogluteal muscle because of its proximity to the gluteal artery.
  - (8) Consider using the Z-track method to administer agents designated as irritants (Hopkins & Arias, 2013).
  - (9) Inject medication at the prescribed rate.
  - (10) Dispose of any unused supplies in an appropriate waste container.
  - (11) Following administration, assess for pain, swelling, induration, hemorrhage, erythema, pruritus, and rash.
3. IV route
- a) IV administration is one of the most common routes of administration. Medications can be administered depending on the agent and regimen and include IV push, short-term infusion, or continuous IV infusion.
  - b) Pretreatment assessment (in addition to the general pretreatment assessment)
    - (1) Evaluate the patient's venous access. Determine if it is appropriate or adequate for the prescribed therapy.
      - (a) Consider the agents to be administered; their vesicant, irritant, or non-vesicant properties; the prescribed method of administration; and the overall duration of therapy.
      - (b) Refer to ONS's *Access Device Standards of Practice for Oncology Nursing* (Camp-Sorrell & Matey, 2017) and the Infusion Nurses Society's (2021) *Infusion Therapy Standards of Practice*.
      - (c) Long peripheral IVs are sometimes used when the vein is difficult to visualize or palpate, and ultrasound is indicated for placement in deep tissue (Infusion Nurses Society, 2021).
        - i. Do not use long peripheral IVs for continuous infusions of antineoplastic vesicants (Infusion Nurses Society, 2021).
        - ii. Signs and symptoms of extravasation may go undetected due to deep placement.
      - (d) Midline catheters are inserted peripherally into the basilic, brachial, or cephalic vein with the tip in the upper arm at the level of the axilla (Infusion Nurses Society, 2021). Midline catheters are considered peripheral IVs (Infusion Nurses Society, 2021).
        - i. Do not use midlines for continuous infusions of vesicants (Infusion Nurses Society, 2021).
        - ii. Caution is recommended with midlines because of the risk of undetected extravasation, as the vein may be deeper than a traditional short peripheral IV (Camp-Sorrell & Matey, 2017). Further research is needed to establish the safety of using midline catheters for intermittent vesicant therapy (e.g., IV push, intermittent infusion) (Infusion Nurses Society, 2021).
    - (e) Central venous catheters include peripherally inserted central lines, implanted ports, tunneled catheters, and nontunneled catheters.
      - i. The appropriate tip location of a central venous catheter is in the lower third of the superior vena cava or near the cavoatrial junction (Infusion Nurses Society, 2021).
      - ii. Central venous access devices are indicated for continuous infusions of vesicants, vesicants greater than or equal to 30 minutes in duration (excluding medications categorized as irritants with vesicant potential; see Chapter 13), home infusions via ambulatory pumps, and with poor venous access where peripheral access is not possible.
  - (2) Identify risk factors for extravasation if the treatment regimen includes a vesicant (see Chapter 13).
  - (3) Priming IV tubing
    - (a) During the preparation of infusions, IV tubings are most often primed with a compatible fluid rather than the antineoplastic agent itself (see Chapter 12).
    - (b) For medications that require rate increases (e.g., rituximab, carboplatin desensitizations), the tubing should

be primed with the antineoplastic medication and a CSTD attached to the end of the tubing.

- i. Laudati et al. (2018) found that the incidence of infusion reactions with rituximab was significantly less when the line was primed with medication rather than the mainline IV solution.
  - ii. If medication is primed to the end of the IV tubing, strategies to prevent exposure to HDs should be implemented, such as priming the IV line under a biosafety cabinet, labeling the IV tubing as “primed with hazardous medication,” and using a CSTD on the end of the tubing (see Chapter 12).
  - iii. Priming paxlitaxol tubing with drug is also a common practice; however, titration may increase the risk of reaction (refer to Chapter 13).
- c) System safeguards to prevent errors and manage emergencies (see Chapters 1, 12, and 13)
- (1) The institution or practice should define a process to manage the overfill of IV bags (ISMP, 2021).
    - (a) To ensure accurate infusion rates and delivery of the entire medication dose, medication labeling or institutional guidelines should provide the total volume to infuse on the label, including overfill and any additives (ISMP, 2021).
    - (b) Lack of a clear identification of the total volume in the bag can lead to administering the agent too quickly, too slowly, or incompletely.
  - (2) Strategies should be implemented to prevent errors from inadvertent administration of vinca alkaloids into the cerebrospinal fluid (ISMP, 2020b; NCCN, 2016).
    - (a) Administer vinca alkaloids in a minibag (IV piggyback). Never administer using an IV pump when administering through a peripheral IV catheter. Do not administer in a syringe in facilities where intrathecal medications are administered.
    - (b) Label all vinca alkaloid bags “FOR INTRAVENOUS USE ONLY—FATAL IF GIVEN BY OTHER ROUTES.”
    - (c) Never dispense vinca alkaloids to an area where intrathecal medications are administered.
    - (d) Never give vinca alkaloids in the same treatment room as intrathecal medications.
- (3) Ambulatory infusion pumps
- (a) To prevent errors, prescribers should order 5-fluorouracil and other continuous infusion antineoplastics in single daily doses with directions to infuse continuously over a specific number of days (e.g., 750 mg/m<sup>2</sup> IV over 24 hours on days 1–5) (ISMP, 2015a).
  - (b) Numerous errors have been reported regarding home infusions of 5-fluorouracil and are often related to prescribing and pump programming. A common but potentially fatal error is confusing the daily dose with the total dose (ISMP, 2015a, 2015b).
  - (c) Infusion pumps should be used with dose error reduction software when possible (ISMP, 2020).
  - (d) The information the pharmacist or nurse needs to program the pump should be displayed clearly on the medication label (ISMP, 2015a, 2015b).
  - (e) Information to include in patient and caregiver education (ISMP, 2015a)
    - i. Total dose, the length of time the infusion should last, and instruction to routinely check that the pump is not infusing too fast or slow
    - ii. Troubleshooting alarms and infusion pump malfunction
    - iii. Steps to follow if tubing becomes disconnected, a spill occurs, or a port needle becomes dislodged
    - iv. 24-hour contact information for questions and problems
  - (f) The institution or practice should establish a process to address patients who present to emergency departments and inpatient areas with ambulatory infusion pumps with antineoplastic. Often, healthcare providers in these areas are not familiar with certain ambulatory pumps, and patients who use these devices may be ill-informed, leading to severe errors (ISMP, 2015a, 2015b).

- (4) To ensure that premedications and IV hydration have sufficient time to work, administer at the prescribed interval before giving the antineoplastic agent (e.g., diphenhydramine 30 minutes [not 10 minutes] prior to the start of paclitaxel).
- d) Dosing (see section C)
- e) Verification (see section D)
- (1) Verify any infusion pump programming with another provider (Neuss et al., 2016).
  - (2) For continuous infusions in inpatient settings, if another nurse initiated an infusion, the nurse assuming patient care should verify the infusion during shift handoff to prevent the possible propagation of a previous error.
  - (3) When chemotherapy is administered in the home by a healthcare provider, a second identifier, such as a driver's license, should be used to confirm the patient's identity (Neuss et al., 2016).
- f) Administration
- (1) Equipment
    - (a) IV tubing selection
      - i. Standardize the use of IV tubings.
      - ii. Use IV tubings with Luer-lock connections. For HDs, use CSTDs (Polovich & Olsen, 2018; see Chapter 12). Some manufacturers incorporate these devices as part of the IV tubing.
      - iii. Select IV tubing and setups that provide minimal waste of antineoplastic remaining in the IV tubing. This provides the maximum dose to the patient with minimal HD disposal. The primary goal of antineoplastic drug administration should be to ensure patients receive the total dose prescribed.
        - Secondary IV tubings (often called IV piggyback tubing) are short tubings with Y-sites above the pump. The mainline infusion (e.g., 0.9% normal saline, primary IV) automatically shuts off during the infusion and turns back on once completed. Harding et al. (2020) recommended short secondary tubings as the best practice for delivering small-volume intermittent IV infusions. After the HD is administered, the back prime method can be repeated to flush out the drug to ensure full medication delivery (ISMP, 2021; see Chapter 12). Short primary tubing can also be used.
  - (2) Long primary IV tubings used to administer antineoplastics are run on their own pump channel and use a Y-site into a mainline IV below the level of the IV pump, often into the Y-site closest to the patient. The mainline infusion continues during the medication. A large drug volume is often left in the IV tubing despite flushing. Drug loss can be significant, especially if the medication volume is 100 ml or less (Hartkopf Smith & Tanner, 2019; ISMP, 2021). A method must be employed to ensure the drug is not wasted in the tubing. If flushing is done from the HD bag, a CSTD should be used to minimize exposure. The HD bag should never be unspiked to flush.
  - (3) Short primary IV tubings use a Y-site into the mainline IV at a level immediately below the IV pump and run on their own pump channel. Advantages of using short primary tubing include the ability to infuse the mainline IV at the same time as the antineoplastic agent and the minimal amount of waste (less than 1 ml) remaining in the IV tubing after the infusion (Hartkopf Smith & Tanner, 2019). The mainline IV can flush the remaining drug to the patient without any breaks in tubing connections.

- Additional interventions to decrease drug waste in tubing include using microbore tubing and flushing after the medication with the mainline IV solution (ISMP, 2021).
  - Select IV tubing and setups that permit the least amount of system manipulation, thus decreasing the risk of infection for the patient and HD exposure for the healthcare provider.
  - Use IV tubings and setups that allow for emergency response if administering a drug that can cause hypersensitivity reaction or anaphylaxis.
  - The mainline IV should contain a compatible carrier solution that can be turned on immediately after discontinuing the medication causing the reaction.
  - Some medications require DEHP (di[2-ethylhexyl] phthalate)-free tubing (see Tables 6-1, 8-1, and 10-1).
  - DEHP is a plasticizer added to polyvinyl chloride plastic to make it flexible.
  - Some medications cause leaching of DEHP, which may be harmful to patients.
  - Medications may require an in-line filter (see Tables 6-1, 8-1, and 10-1 and drug package inserts).
  - The addition of an antisiphon valve to the end of the IV tubing has been found to minimize bubbles and decrease air alarms in continuous chemotherapy infusions, such as EPOCH (etoposide, prednisone, vincristine, cyclophosphamide, and doxorubicin) (Meade et al., 2019).
  - The antisiphon valve must be manually primed with a syringe or IV pump because it cannot be primed by gravity. Blood return with this setup must be checked from below (distal to) the valve.
  - For designated HDs, wear two pairs of gloves, tested for use with HDs, and a gown. Wear a mask with face protection if splashing is possible (Polovich & Olsen, 2018; see Chapter 12).
- (b) Use IV pumps with dose error reduction software in inpatient and outpatient settings to administer infusions of chemotherapies, targeted therapies, and immunotherapies, excluding peripheral administration of vesicants (ISMP, 2020). Refer to the ISMP (2020) *Guidelines for Optimizing Safe Implementation and Use of Smart Infusion Pumps*.
- i. Do not rely on pump alarms to detect IV infiltration or extravasation.
  - ii. IV pumps with dose error reduction software are preferred because they include medication dosing guidelines, concentrations, dose limits, and advisories (Infusion Nurses Society, 2021; ISMP, 2020).
  - iii. Infusion interoperability is the ability of an infusion pump to receive and transmit information in near real time with the electronic health record. Medication orders and parameters automatically program the infusion pump. The pump can then send infusion status and history to the electronic health record.
- (2) Peripheral venous access
- (a) Do not use peripheral IV sites to administer vesicants given as continuous infusions. When administering vesicants via a peripheral IV site, limit the infusion time to less than or equal to 30 minutes and remain with the patient during the entire infusion. See Chapter 13 for more information on the administration of drugs with vesicant potential.
- (b) Venipuncture

- i. Avoid using established IV sites that are more than 24 hours old.
  - ii. No clear evidence exists to support the use of a new venipuncture site versus one less than 24 hours old for the administration of vesicants. Regardless, thoroughly assess the site for patency, including blood return before, during, and after administration.
  - iii. Avoid topical anesthetics if peripheral vesicant chemotherapy is planned.
  - iv. Choose veins that are large, smooth, and pliable.
  - v. Sites to avoid
    - Joints and areas near joints
    - Ventral surface of the hand
    - Antecubital fossa
    - Lower extremities
    - Areas distal to a recent venipuncture, including laboratory draws
    - Areas with decreased sensation (e.g., peripheral neuropathy)
    - Areas of impaired circulation or lymph node drainage (e.g., axillary lymph node dissection)
  - vi. No definitive guidelines exist regarding venipuncture in the involved arm of patients who have had a sentinel lymph node biopsy.
  - vii. Ultrasound-guided peripheral catheter insertion in deep veins in the upper arms may be associated with an increased incidence of undetected infiltration and extravasation. Staff skilled in ultrasound-guided IV insertion must ensure sufficient catheter length is threaded into the vein to prevent catheter dislodgment during patient movement. Nurses should assess the vein frequently for signs and symptoms of infiltration (Infusion Nurses Society, 2021).
  - viii. Avoid using metal needles, as they may increase the risk of infiltration or extravasation (Camp-Sorrell & Matey, 2017).
  - ix. Perform venipuncture according to institutional policy and procedure. If unsuccessful, restart IV using a different site on the opposite arm or proximal to the previous puncture site.
  - x. Apply a transparent dressing to the insertion site and secure the catheter. Ensure visualization of peripheral IV entrance site.
  - xi. Ensure securement of the peripheral IV to help prevent dislodgment. In a study examining 673 vesicant extravasations and irritant infiltrations, one of the most common etiologies was patient movement and subsequent dislodgment (Jackson-Rose et al., 2017).
  - xii. Educate patients to report unusual tugging on tubing or IV, discomfort, swelling, or pain during administration.
  - xiii. Before starting chemotherapy administration, flush the IV with a 5–10 ml normal saline syringe and confirm and document a positive blood return. Confirm and document the absence of signs and symptoms of infiltration. Do not administer vesicants in the absence of a blood return or if other signs or symptoms of infiltration are present.
  - xiv. Observe for swelling, pain, burning, tightness, cool skin, skin color change, and changes in flow rate. If infiltration occurs, immediately stop the infusion.
- (3) Central venous access devices include percutaneous subclavian or jugular catheters, tunneled catheters, peripherally inserted central catheters, and implanted ports.
- (a) For newly placed central lines, confirm tip placement prior to use. The central venous access tip should be located in the lower third of the superior vena cava or at or near the

cavoatrial junction (Infusion Nurses Society, 2021).

- (b) Prior to each use, always confirm that the implanted venous port tip is in the vascular system and not intraperitoneal or intra-arterial. Venous implanted ports are sometimes placed over a lower rib and may be incorrectly identified as intraperitoneal or intra-arterial.
- (c) Prior to administration of cancer therapy, assess for signs and symptoms of malposition or occlusion. Do not proceed and contact the provider if any of the following are present (Infusion Nurses Society, 2021):
  - i. Absent or sluggish blood return
  - ii. Change in color and or pulsatility of blood from lumens
  - iii. Difficulty flushing or IV does not flow freely off of the IV pump
  - iv. Atrial or ventricular arrhythmias
  - v. Pain, edema, or strange sensations in the neck, shoulder, chest, or back
  - vi. Gurgling or rushing sound on the side of the central venous access device, which could indicate tip malposition in the jugular vein
  - vii. New neurologic changes or paresthesias
- (d) Follow institutional guidelines for troubleshooting and declogging procedures and dye studies.
- (e) For implanted ports, access the port with a noncoring needle. Select the appropriate needle length based on the depth of the port. Stabilize the needle with tape and transparent dressing or a securement device to help prevent dislodgment and possible infiltration during medication administration. Inspect the insertion site for evidence of needle dislodgment, including absent or sluggish blood return, leakage of IV fluid, edema, and discomfort or pain.
- (f) For all central venous access devices, use a transparent dressing to ensure visualization of the site during administration. Gauze may be used

to stabilize the needle wings as long as the insertion site is not covered (Infusion Nurses Society, 2021).

- (4) IV push method
  - (a) Refer to institutional guidelines and drug references for the recommended rate of administration. In addition, consider the status of the veins or type of venous access.
  - (b) Although limited published evidence exists supporting the superiority of the side-arm technique method for IV push over other methods, the side-arm technique allows for constant dilution of vesicant during administration, which may decrease the severity of an extravasation injury.
  - (c) Side-arm technique for administration of IV push
    - i. Hang a mainline IV line with a solution compatible with the IV push medications.
    - ii. Allow the mainline IV solution to run freely without using an infusion pump.
    - iii. Prior to attaching the chemotherapy syringe, flush the IV line with a prefilled saline syringe (5–10 ml). Confirm blood return and flush to verify there are no signs or symptoms of infiltration.
    - iv. Attach the antineoplastic syringe to the injection port (Y-site) closest to the patient on the mainline IV tubing (e.g., 0.9% sodium chloride). A CSTD should be attached to the end of the syringe (Polovich & Olsen, 2018). Some systems require a CSTD adaptor attached to the Y-site on the mainline IV tubing.
    - v. Slowly administer the medication. Allow the mainline IV solution to run continuously during the IV push to dilute the medication. Do not pinch the mainline IV tubing while pushing the antineoplastic medication. Keep a thumb on the plunger of the syringe to prevent primary IV fluid from backing up into the syringe.

- vi. Assess for blood return every 2–5 ml. Blood return can be checked by slowly pulling back on the antineoplastic syringe.
  - vii. Continuously assess the site for signs and symptoms of infiltration or extravasation. Patency checks should include blood return, the appearance of the IV site, patient reports, and the ability of the primary IV to run freely off of the pump.
  - viii. If multiple medications are administered, flush with the mainline IV solution between each drug and after the infusion.
  - ix. Discontinue administration immediately for signs or symptoms of infiltration or extravasation. (e.g., pain, burning, redness, edema, leaking at IV site, any patient-reported discomfort). It is essential to distinguish between extravasation and flare reaction (see Chapter 13).
- (5) Intermittent/minibag infusion (IV piggyback)
- (a) Hang a mainline IV compatible with the medications to be administered.
  - (b) Flush the IV line with a prefilled saline syringe (5–10 ml). Use the injection port (Y-site) on the mainline IV tubing closest to the patient.
  - (c) Assess for blood return and other signs of patency (e.g., no pain, burning, redness, edema, leaking at IV site, any patient-reported discomfort).
  - (d) Nonvesicant short-term/minibag (IV piggyback) infusions
    - i. Insert the medication tubing into the Y-site above or below the IV pump, depending on the agent or institutional procedure. A CSTD should be attached to the end of the HD IV tubing. (Polovich & Olsen, 2018). Some systems require a CSTD adaptor attached to the Y-site on the mainline IV tubing.
    - ii. Infuse as ordered or per institutional guidelines or drug reference.
- iii. Assess for signs and symptoms of infiltration.
  - iv. If multiple agents are administered, flush with the mainline IV solution between each agent and after the infusion.
- (e) Vesicant short-term/minibag infusions
- i. Peripheral IV administration
    - Remain with the patient during the entire infusion, as extravasation is a risk for peripheral lines.
    - Use a transparent dressing to visualize the IV site.
    - A CSTD should be attached to the end of the HD IV tubing (Polovich & Olsen, 2018). Some systems require a CSTD adaptor attached to the Y-site on the mainline IV tubing.
    - Administer by gravity through a free-flowing mainline IV. Do not use an infusion pump to administer vesicants through a peripheral IV.
    - Limit administration to 30 minutes or less.
    - Infuse as ordered or per institutional guidelines or drug reference.
    - Verify blood return before, every five minutes during, and after the infusion is complete. Assess for signs and symptoms of infiltration.
    - If multiple agents are administered, flush with the mainline IV solution between each agent and after the infusion.
    - See Chapter 13 for more information on taxane administration.
  - ii. Central venous catheter administration
    - Remain with the patient during the entire infusion, as extravasation is a risk for central and peripheral lines.
    - Use a transparent dressing to visualize the central line site.

- Insert the medication tubing into the Y-site above or below the IV pump, depending on the agent or institutional procedure.
  - Limit administration to 30 minutes or less.
  - Infuse as ordered or per institutional guidelines or drug reference.
  - Verify blood return before, every five minutes during, and after the infusion is complete. Assess for signs and symptoms of infiltration.
  - If multiple agents are administered, flush with the mainline IV solution between each agent and after the infusion.
  - See Chapter 13 for more information on taxane administration.
- iii. Administer all vinca alkaloids as a short-term/minibag infusion (IV piggyback) (ISMP, 2016; NCCN, 2016; Neuss et al., 2016).
- iv. Studies have indicated the risk of extravasation is less than 0.05% when vinca alkaloids are administered using the following method (Gilbar & Carrington, 2006; Hartkopf-Smith & Hughes-McNally, 2012; Nurgat et al., 2015):
- Vinca alkaloids should be prepared as a minibag infusion (e.g., 25–50 ml).
  - Do not use an IV pump when administering vesicants through a peripheral IV.
  - Administer by gravity through a free-flowing primary IV line using a CSTD (Polovich & Olsen, 2018).
  - Remain with the patient during the entire infusion.
  - Use a transparent dressing to visualize the IV site.
  - Infuse over 5–15 minutes.
  - Assess for blood return during any vesicant administration via a short-term infusion before, every five minutes during, and after the infusion is complete.
  - Closely monitor for signs and symptoms of extravasation, such as swelling, loss of blood return, and patient-reported pain or burning sensation.
  - Discontinue administration immediately for signs and symptoms of infiltration and extravasation.
  - See Chapter 13 for management of vesicant extravasation.
- (6) Continuous infusions
- (a) Assess for blood return and other signs of patency prior to, during, and after drug administration according to institutional policy (e.g., pain, burning, redness, edema, leaking at the IV site, patient-reported discomfort).
- (b) Hang a mainline IV tubing with a solution compatible with the medications to be administered (excluding home infusions using ambulatory infusion pumps).
- (c) Use an IV pump. Administer via a programmable infusion pump using dose error-reduction software in inpatient and outpatient areas (ISMP, 2022).
- (d) Connect antineoplastic tubing into primary IV per institutional policy. Use a CSTD to administer HDs. Configure the mainline IV tubing and antineoplastic tubing so that the tubing does not need to be disconnected each time a blood return is checked. Use a CSTD for blood return checks to reduce exposure to HDs (Polovich & Olsen, 2018).
- (e) Infuse as ordered or per institutional guidelines or drug reference.
- (f) Assess for signs and symptoms of infiltration.
- (g) Continuous infusions of vesicants
- i. Always infuse through a central venous access device with positive blood return and tip location confirmed as central.
  - ii. Assess for blood return and other signs and symptoms of

extravasation prior to initiating the infusion, at periods specified by institutional policy (e.g., every four hours), and after the infusion.

- iii. Check for blood return and other signs and symptoms of extravasation if there are any indications that the pump is not flowing (e.g., pump alarm for occlusion, infusion rate appears to be too slow).
- iv. Use a transparent dressing over the site to visualize signs and symptoms of extravasation.
- v. Discontinue administration immediately for signs and symptoms of infiltration and extravasation. See Chapter 13 for management of vesicant extravasation.

#### 4. Intraperitoneal

a) Intraperitoneal chemotherapy is the administration of chemotherapy directly into the peritoneal cavity via an external catheter or port.

- (1) It is most frequently used for ovarian cancer, as the most common route of spread for this cancer is within the peritoneal cavity (NCCN, 2022d).
- (2) Compared with IV chemotherapy, intraperitoneal administration permits a several-fold increase in drug concentration within the abdominal cavity (Dedrick et al., 1978).
  - (a) Intraperitoneal therapy in conjunction with IV chemotherapy is indicated for patients with optimally debulked stage III and IV ovarian cancer (i.e., patients with no or minimal residual disease after surgical cytoreduction) (NCCN, 2022d).
  - (b) The penetration of chemotherapy into tumor tissue is limited to a few millimeters of tumor on the peritoneal surface layers (NCCN, 2022d).
- (3) The most commonly administered intraperitoneal agents for ovarian cancer are cisplatin and paclitaxel (NCCN, 2022d).

b) Pretreatment assessment (in addition to the general pretreatment assessment)

- (1) Verify the type of device (implanted intraperitoneal port vs. external intraperitoneal catheter) and catheter tip location in intraperitoneal space by reviewing operative notes or imaging.

(2) Assess for signs and symptoms of access device complications (Camp-Sorrell & Matey, 2017).

- (a) Exit site infection (e.g., fever, chills, drainage, erythema, tenderness at site)
- (b) Tunneled catheters (e.g., tunnel infection, inflammation appearing along the tunnel line)
- (c) Leakage, bleeding, drainage at the exit site
- (d) Presence or absence of ascites: If patients have ascites, discuss with the prescriber if ascites should be drained prior to chemotherapy to promote comfort and tolerance (Camp-Sorrell & Matey, 2017).

(3) Baseline respiratory status: Note any shortness of breath.

(4) Signs and symptoms of peritonitis (e.g., fever, chills, abdominal pain): If positive, notify the provider and anticipate orders for peritoneal fluid cultures.

- (a) Peritoneal fluid cultures may not be possible to draw if patients do not have ascites.
- (b) Peritonitis is diagnosed by confirming clinical features consistent with peritonitis (i.e., abdominal pain or cloudy dialysis effluent); dialysis effluent white cell count greater than 100/mm<sup>3</sup> (after a dwell time of at least two hours), with greater than 50% polymorphonuclear; and a positive dialysis effluent culture (Li et al., 2016).

(5) Abdominal pain, cramping, diarrhea

(6) Peripheral neuropathy from previous doses of platinum or taxane chemotherapy: Report any peripheral neuropathy. Intraperitoneal chemotherapy may be held for worsening peripheral neuropathy.

(7) Renal function: Check serum creatinine and creatinine clearance prior to cisplatin.

c) System safeguards to prevent errors and manage emergencies (see Chapters 1, 12, and 13)

- (1) Clearly label lines as intraperitoneal and IV to prevent accidental administration of medications via the incorrect route.
- (2) When administering medications and fluids, trace all catheters and lines from the access site into the patient's body.
- (3) Route IV tubing and intraperitoneal tubing to different sides of the bed or chair.

- (4) Infuse intraperitoneal fluids through tubing without injection ports (Y-sites) to prevent the accidental administration of IV medications (Camp-Sorrell & Matey, 2017).
  - (5) Intraperitoneal administration of paclitaxel and cisplatin can cause hypersensitivity reactions, including anaphylaxis. Ensure that emergency medications are available and that patients have patent venous access.
  - (6) Always have peripheral venous access in place for potential emergencies.
- d) Dosing: Intraperitoneal dosing is based on the disease, regimen, patient-specific factors, and presence of toxicities. Care must be taken to verify the dosing of intraperitoneal and IV chemotherapy when administered in the same regimen.
- e) Verification: Immediately prior to administration, verify that the agent to be administered is intraperitoneal and that the tubing and line it is connected to is the intraperitoneal access device (see section D).
- f) Administration
- (1) Ask patients to void prior to starting the procedure and to report difficulty with voiding or a lack of urine output.
  - (2) Obtain IV access for administration of IV fluids and premedications (e.g., prior to administration of intraperitoneal cisplatin).
  - (3) Access the intraperitoneal port.
    - (a) Apply topical anesthetic, if requested.
    - (b) Use a strict sterile technique and maximum barrier precautions when accessing an intraperitoneal port (Camp-Sorrell & Matey, 2017).
    - (c) Instruct patients to lie flat for port access, if possible.
    - (d) Use a noncoring needle. A longer needle may be needed (e.g., 1.5 in) due to the port's location.
    - (e) A blood return should not occur if aspiration is attempted, as the tip of the catheter is in the peritoneal space. If patients have ascites, peritoneal fluid may be withdrawn (often straw-colored, sometimes blood-tinged). Often, intraperitoneal ports will not yield a specimen (Camp-Sorrell & Matey, 2017).
    - (f) Flush with 10–20 ml normal saline. Assess for signs and symptoms of infiltration, including pain, burning, and leaking of fluid (Camp-Sorrell & Matey, 2017).
    - (g) Apply a sterile transparent dressing.
  - (4) Place patients in a semi-Fowler position. A flat position during infusion may increase pressure on the diaphragm, causing respiratory compromise and gastrointestinal upset.
  - (5) Administer IV premedications and hydration as ordered.
  - (6) No definitive recommendations can be made regarding the warming of intraperitoneal fluid prior to administration (Rogers et al., 2017).
    - (a) Patients may tolerate warmed or room-temperature fluids better than cold (BC Renal, 2018).
    - (b) If fluids are warmed, dry heat sources should be used (BC Renal, 2018). U.S. Food and Drug Administration–approved fluid warming cabinets are an example of dry heat.
    - (c) Water baths should not be used for heating solutions due to the potential of waterborne organism contamination to the system (BC Renal, 2018).
    - (d) Do not microwave fluids for intraperitoneal use. This can create “hot spots” and potential burns (BC Renal, 2018). Although intraperitoneal chemotherapy is not mixed in dialysis solution, manufacturers of peritoneal dialysis solutions do not recommend heating using a microwave (Baxter Healthcare, 2015). If intraperitoneal solutions are warmed, temperature regulation should ensure that solutions are heated to 37°C ( $\pm 0.5^\circ\text{C}$ ) (BC Renal, 2018).
    - (e) If fluids are warmed with dry heat, it should be used as soon as possible once removed from the warmer. Fluids should not be exposed to a heat source for an extended period. Extended heating can lead to a breakdown of dextrose, leading to a brown color (BC Renal, 2018).
  - (7) Wear personal protective (PPE) equipment, which includes a gown tested for use with chemotherapy. If unavailable, use a lint-free gown made of a low-permeability fabric, such as polypropylene or other laminate materials, and two pair of gloves tested for use with HDs. Mask and face protection should also be used.

- (8) Chemotherapy is often mixed in one liter of fluid followed by an additional liter of normal saline. If the patient experiences discomfort and fullness, the second liter of intraperitoneal fluid (normal saline) is often discontinued (Anastasia, 2012).
- (9) Infuse intraperitoneal fluids by gravity as rapidly as the patient will tolerate (Anastasia, 2012; Potter & Held-Warmkessel, 2008).
  - (a) Do not use an IV pump, as it has been associated with needle dislodgment and infiltration (Potter & Held-Warmkessel, 2008).
  - (b) Do not use a pressure bag to infuse fluids through an intraperitoneal port.
  - (c) The fluid should flow freely and is often infused over 60–180 minutes. If the infusion will not run within this period, notify the prescriber, as the catheter may be malpositioned, have a fibrin sheath, or the tip may be located in a pocket formed from bowel adhesions in the intraperitoneal cavity (Anastasia, 2012; Camp-Sorrell & Matey, 2017; Potter & Held-Warmkessel, 2008). Check for port needle dislodgment.
  - (d) Slow the intraperitoneal infusion for complaints of abdominal discomfort, cramping, or dyspnea (Anastasia, 2012; Camp-Sorrell & Matey, 2017; Potter & Held-Warmkessel, 2008).
  - (e) Discontinue the infusion for signs and symptoms of infiltration at the port site.
- (10) Although commonly implemented, no evidence supports patient turning.
- (11) When the infusion is complete, disconnect the tubing. Flush with a minimum of 20 ml normal saline and discontinue the port needle. No definitive recommendations can be made regarding the use of heparin (Camp-Sorrell & Matey, 2017).
- (12) The infused fluid is not drained and will absorb over several days to a week (Potter & Held-Warmkessel, 2008).
- (13) Assess for the following throughout the intraperitoneal infusion and after completion (Anastasia, 2012; Camp-Sorrell & Matey, 2017; Potter & Held-Warmkessel, 2008):
  - (a) Signs and symptoms of a hypersensitivity reaction
    - (b) Signs and symptoms of fluid overload
    - (c) Dyspnea
    - (d) Abdominal pain or discomfort
    - (e) Failure of the intraperitoneal fluids to infuse freely by gravity (Anastasia, 2012; Camp-Sorrell & Matey, 2017)
      - i. Line placement and patency may need to be confirmed by a dye study with fluoroscopy.
      - ii. The procedure may indicate complications such as adhesions, retrograde dye flow along the catheter into the port pocket (due to a fibrin sheath), and dye entering the gastrointestinal tract (Markman & Olawaiye, 2021).
    - (f) Leaking around the port needle site or external catheter exit site (Anastasia, 2012; Camp-Sorrell & Matey, 2017)
      - i. Verify needle placement.
      - ii. Excessive pressure from ascites can cause leaking around the catheter or needle.
    - (g) In the event of extravasation (evidenced by abdominal pain and delayed erythema, often due to port malfunction or flipping) or intraperitoneal port malfunction, discontinue intraperitoneal therapy and notify the authorized prescriber immediately.
    - (h) For patients on cisplatin, monitor magnesium levels, and administer replacement as ordered.
    - (i) For patients with significant nausea or vomiting who cannot self-hydrate, consider scheduling return visits for IV hydration.
- g) Other considerations
  - (1) Heated intraperitoneal chemotherapy (HIPEC) is the intraoperative delivery of heated chemotherapy into the intraperitoneal space. It is administered following cytoreductive surgery to eradicate microscopic disease. Hyperthermia is used to increase the uptake of chemotherapy into cancer cells (Goodman et al., 2016).
  - (2) HIPEC has been used for various intraperitoneal cancers, including appendiceal, ovarian, peritoneal mesothelioma, and colon cancer (Goodman et al., 2016).
  - (3) Agents used during HIPEC include carboplatin, cisplatin, 5-fluorouracil, irinotecan,

mitomycin C, and oxaliplatin (Goodman et al., 2016).

- (4) The HIPEC procedure is performed after the cytoreductive surgery. The surgeon places intraperitoneal catheters and temperature probes into the intraperitoneal space. The chemotherapy is heated by a perfusion machine and continuously circulates throughout the intraperitoneal cavity, often for two hours.
  - (5) All personnel who administer HDs via the intraperitoneal route must wear two pairs of gloves tested for use with HDs. Personnel must also wear a gown during IV administration and a mask with face protection if the potential for spilling, splashing, or aerosols exists (Polovich & Olsen, 2018; see Chapter 12).
  - (6) Patients are often rocked back and forth during the procedure. After the procedure, the chemotherapy is drained, and the catheters are removed.
  - (7) Patients are then transferred to the intensive care unit and usually hospitalized until recovery.
  - (8) Complications from the procedure include nausea, vomiting, pain, bleeding, ileus, anastomotic leaks, bowel perforations, and infection (Piso et al., 2019).
  - (9) In many institutions, perfusionists in surgery work with the surgeon to administer HIPEC. Although nurses do not administer the chemotherapy intraoperatively, they play an important role in preventing and managing related complications.
5. Intrathecal via lumbar puncture
- a) Intrathecal chemotherapy is the administration of chemotherapy directly into the intrathecal space by a lumbar puncture. The goal of intrathecal chemotherapy is the prophylaxis or treatment of malignant cells within sites that cannot be reached by systemic chemotherapy because of the blood–brain barrier (NCCN, 2021a, 2021b, 2022a).
    - (1) Indications for prophylactic intrathecal chemotherapy include acute lymphoblastic leukemia (NCCN, 2022a) and Burkitt lymphoma (NCCN, 2021b).
    - (2) Intrathecal chemotherapy is also used for leptomeningeal metastasis (meningeal carcinomatosis) that can occur from the spread of leukemia, lymphoma, and solid tumors, such as breast, lung, and gastrointestinal cancers (NCCN, 2021a, 2021b, 2021f, 2022a).
      - (a) The leptomeninges are two tissue linings, the arachnoid and pia mater, covering the brain and spinal cord. The layers encase the arachnoid space, which contains cerebrospinal fluid.
      - (b) Cancer cells can enter the cerebrospinal fluid by numerous routes, including the blood, the meninges, and extension from spinal metastases.
  - (3) Few chemotherapy agents can safely be given into the intrathecal space. The most commonly used agents are cytarabine and methotrexate (Gabay et al., 2012).
  - b) Pretreatment assessment (in addition to the general pretreatment assessment)
    - (1) Assess the patient's risk for bleeding. Increased bleeding increases the risk of an epidural hematoma and possible paralysis from the lumbar puncture (Balaban et al., 2016; Nair, 2016).
      - (a) Review the patient's laboratory values for bleeding risk (e.g., platelets, coagulation studies) and follow institutional guidelines. Many institutional guidelines are extrapolated from epidural guidelines. Dodd et al. (2018) developed guidelines specifically for lumbar puncture.
      - (b) Review the medication list. Determine if the patient has been on any anticoagulants or nonsteroidal anti-inflammatory drugs.
        - i. Obtain information regarding the dose, route, date, and time of the last administration.
        - ii. The American Society of Regional Anesthesia and Pain Medicine, European Society of Regional Anaesthesia and Pain Therapy, American Academy of Pain Medicine, International Neuromodulation Society, North American Neuro-modulation Society, and World Institute of Pain have established guidelines for procedures involving the spine (e.g., lumbar puncture) for patients on antiplatelet and anticoagulant medications (Narouze et al., 2018). The guidelines include specific details about when anticoagulants should be held and restarted concerning a lumbar puncture.

- (2) Review if the patient has any abnormalities of the lumbar vertebrae or would have difficulty maintaining the position required for the procedure.
  - (3) Clarify whether cerebrospinal fluid specimens should be drawn and sent to the prescriber (e.g., cytology, cell count, glucose, protein, biomarkers).
  - (4) Conduct a neurologic assessment to establish baseline orientation, level of consciousness, presence or absence of headaches, history of seizures, and numbness, tingling, or pain in lower extremities.
- c) System safeguards to prevent errors and manage emergencies: This section applies to both the intrathecal and intraventricular routes (see Chapters 1, 12, and 13).
- (1) Establish institutional policies and procedures related to anticoagulants, coagulation studies, and lumbar puncture.
  - (2) Work with an interprofessional team to prevent fatal chemotherapy errors related to the inadvertent administration of vinca alkaloids into the cerebrospinal fluid (Clement & Holle, 2017; Hartkopf Smith, 2009b; ISMP, 2020b). The institution should establish policies and procedures for intrathecal chemotherapy that radiologists give in interventional radiology or other radiology areas, as personnel in these areas are typically not familiar with the safe handling of HDs and the required safety checks prior to administration (Clement & Holle, 2017; Hartkopf Smith, 2009a).
    - (a) Since the approval of vincristine in the 1960s, more than 125 deaths have been reported from the accidental administration of vinca alkaloids into the intrathecal space (ISMP, 2020b; NCCN, 2016).
    - (b) Many patients receive IV vincristine as part of their chemotherapy regimen, including chemotherapy given into the intrathecal or intraventricular space. In most reports of accidental intrathecal administration, the syringe of vincristine was accidentally administered into the cerebrospinal fluid instead of the intended medication.
    - (c) Administration of vinca alkaloids, such as vincristine, given via this route can cause severe neurologic toxicity, including coma and death (ISMP, 2020b; Reddy et al., 2011).
- (d) More than 20 years ago, the U.S. Pharmacopeial Convention developed requirements for manufacturers and pharmacies to label doses of vincristine with warnings (Schulmeister, 2007). However, accidental injection of vincristine, vinblastine, vinorelbine, and bortezomib continues to occur. The U.S. Food and Drug Administration (2022) updated vinca alkaloid labeling for preparation in IV infusion bags only.
- (e) Strategies to prevent errors (ISMP, 2020b; NCCN, 2016)
- i. Vincristine and other vinca alkaloids must only be given via IV in a minibag (e.g., IV piggyback).
  - ii. Never dispense vinca alkaloids to an area where intrathecal or intraventricular medications are administered.
  - iii. Never give vinca alkaloids in the same treatment room as intrathecal or intraventricular medications.
  - iv. Healthcare providers who prescribe, prepare, and administer intrathecal or intraventricular chemotherapy must receive specialized educational programs that include the safe handling of HDs.
  - v. Institutions should establish a list of drugs that can be given intrathecally or intraventricularly.
  - vi. Orders for intrathecal chemotherapy should be separate from IV chemotherapy orders.
  - vii. Order and deliver intrathecal or intraventricular chemotherapy as close as possible to the time of administration.
  - viii. Package and transport intrathecal and intraventricular chemotherapy separately from IV and other drugs.
  - ix. Intrathecal and intraventricular chemotherapy should not be stored in patient care areas.
  - x. Time-out procedures should be conducted immediately preceding intrathecal and intraventricular chemotherapy administration.

- d) Dosing: A agent may be administered up to three times a week, depending on the regimen. The duration and frequency of treatment often depend on whether the goal is prophylaxis or treatment.
- e) Verification (see section D)
- (1) Verify that the patient's coagulation studies meet institutional parameters for a lumbar puncture.
  - (2) Verify that the patient is not receiving anticoagulants or that they have been discontinued for the necessary amount of time before the lumbar puncture per institutional standards.
  - (3) Immediately preceding the procedure
    - (a) Perform a time-out procedure.
    - (b) Verify with the practitioner performing the procedure (e.g., oncologist, radiologist, advanced practice provider) the following information:
      - i. The medication to be administered is safe via the intrathecal route.
      - ii. The medication is not a vinca alkaloid or bortezomib.
      - iii. The medication is mixed with preservative-free normal saline.
- f) Administration
- (1) Intrathecal chemotherapy via a lumbar puncture may be administered at the bedside, at an ambulatory care center, during interventional radiology, or with fluoroscopy, depending on the healthcare setting.
  - (2) It may be administered by an oncology physician, a radiologist, an advanced practice provider, or a physician assistant. Refer to state and institutional policies regarding the role of advanced practice nurses in administering intrathecal chemotherapy by a lumbar puncture.
  - (3) All personnel who administer HDs via this route must wear two pairs of gloves tested for use with HDs (outer gloves are sterile), a gown, and a mask with face protection (see Chapter 12). A plastic-backed absorbent pad should be placed under the site where the needle enters the spine and the syringe connection (Polovich & Olsen, 2018).
  - (4) Use strict sterile technique and sterile barrier precautions (e.g., mask, sterile field, sterile gloves).
    - (a) A mask also decreases the transfer of *Streptococcus salivarius* bacteria that can cause meningitis to the treatment field (Shewmaker et al., 2010).
- (b) Position the patient in the lateral recumbent or prone positions or sitting upright. The lateral recumbent or prone positions are preferred over the upright position because they allow a more accurate measurement of the opening pressure (Johnson & Sexton, 2021). The prone position is generally used for lumbar punctures performed under fluoroscopic guidance (Johnson & Sexton, 2021).
- (c) Cleanse the skin prior to needle puncture with an antiseptic and let dry completely to ensure that it adequately kills organisms and does not enter the cerebrospinal fluid. Refer to the type of antiseptic to determine the duration of the scrub and dry time.
- i. The choice of antiseptic is controversial (Al Dweikat, 2020).
  - ii. Current package labeling for chlorhexidine gluconate states to avoid contact with the meninges (i.e., do not use on lumbar puncture sites) due to reports of meningitis (Lexicomp, 2021a; Sviggum et al., 2012).
  - iii. Proponents of chlorhexidine use over povidone-iodine cite a more rapid onset of action, extended duration of effect, rare drug resistance, and little evidence to support its role in developing meningitis (Al Dweikat, 2020; Sviggum et al., 2012).
- (d) If the outside of the chemotherapy syringe is not sterile when dispensed, special procedures must be followed to maintain sterility during lumbar puncture (Aiello-Laws & Rutledge, 2008; Elledge, 2017). If the syringe containing the medication is sterile, the label on the medication must also be sterile (Aiello-Laws & Rutledge, 2008). For nonsterile syringes, the provider should access the cerebrospinal fluid with sterile gloves and administer intrathecal medication without touching the sterile access site (Polovich & Olsen, 2018).

- (e) The needle and infusion syringe and tubing should be discarded in an appropriate HD container (Polovich & Olsen, 2018).
- g) Other considerations: Post-lumbar puncture headache is a common complication of lumbar punctures and has been observed in 3.5%–33% of patients (Cognat et al., 2021). It is characterized by a headache that appears when the patient is in a standing position and resolves with lying down. Intracranial hypotension occurs due to a leakage of cerebrospinal fluid through a tear in the meninges. A systematic review assessed the efficacy of prolonged bedrest versus immediate ambulation and found a lack of evidence to support routine bedrest after lumbar puncture (Cognat et al., 2021). In addition, the use of atraumatic, noncutting needles was found to be the most effective intervention for post-lumbar puncture headache prevention (Cognat et al., 2021).
- 6. Intraventricular (e.g., Ommaya reservoir)
  - a) Intraventricular chemotherapy is the administration of chemotherapy into the lateral ventricle of the brain—a network of communicating cavities filled with cerebrospinal fluid.
    - (1) Intraventricular administration is an alternative to administering intrathecal chemotherapy by lumbar puncture and has the advantage of ease of access for repeated chemotherapy administration and cerebrospinal fluid blood sampling.
    - (2) Disadvantages include the need for surgical placement of the catheter, possible body image concerns, risk for infection, and catheter malposition (Wilson et al., 2018).
      - (a) Administration of vinca alkaloids, such as vincristine, given via this route can cause severe neurologic toxicity, including coma and death (Reddy et al., 2011).
      - (b) Ventricular reservoirs (Ommaya reservoirs) consist of a silicone dome and catheter. A neurosurgeon surgically places the dome under the scalp (SC), and the catheter is threaded into the lateral ventricle of the brain (Volkov et al., 2017).
        - i. The reservoir volume of the dome is 1.5–2.5 ml (Elledge, 2017). The catheter length varies, as it is trimmed to fit within the frontal horn of the lateral ventricle of the brain (Elledge, 2017).
        - ii. Ventricular reservoirs can be used to administer medications (i.e., chemotherapy) and sample cerebrospinal fluid.
        - iii. Some ventricular reservoirs have an attached shunt with an on-off flushing reservoir. Finger pressure on a specific device component can open and close the shunting system, thus controlling the flow of cerebrospinal fluid (Palejwala et al., 2014; Volkov et al., 2017). These reservoirs drain cerebrospinal fluid, usually into the peritoneal space. When chemotherapy is administered, the shunting system is closed. After a set time (e.g., four hours), the shunt is reopened (Volkov et al., 2017). These recommendations do not address the administration and management of patients with ventricular reservoirs with an attached shunt with on-off flushing reservoirs.
  - b) Pretreatment assessment (in addition to the general pretreatment assessment)
    - (1) Prior to accessing and using a ventricular reservoir, verify it is within scope of practice by the state board of nursing and institutional policy.
    - (2) Confirm that postoperative imaging was completed to confirm reservoir placement (e.g., magnetic resonance imaging, computed tomography scan), flow patency, and cerebrospinal fluid flow (as indicated) (Elledge, 2017). Flow studies identify areas of obstruction that could prevent chemotherapy from being distributed equally, with resultant increased toxicity and decreased efficacy.
    - (3) Discuss with the provider when the ventricular access can be used. Practices vary from the day of placement to multiple days after placement (Elledge, 2017).
    - (4) Verify the type of ventricular access. Although typically called Ommayas (after its inventor Ayub Ommaya), various manufacturers make ventricular reservoirs, and the products are named differently. The different types of ventricular reservoirs can vary in reservoir volume.

- (5) Ensure that consent has been completed per institutional guidelines (see Chapter 2).
- (6) Assess laboratory values, including a complete blood count and differential. Discuss with the provider any altered coagulation values. The small gauge needle used typically causes minimal bleeding in patients with thrombocytopenia.
- (7) Clarify whether specimens should be drawn and sent to the prescriber (e.g., cytology, cell count, glucose, protein, biomarkers).
- (8) Clip (do not shave) the hair over the ventricular reservoir.
- (9) Assess vital signs.
- (10) Assess neurologic history and status to serve as a baseline, including but not limited to orientation, level of consciousness, headaches, and seizures.
- (11) Assess for signs of infection over the ventricular reservoir.
- c) System safeguards to prevent errors and manage emergencies: Follow system safeguards listed for the intrathecal route (refer to 5c; see Chapters 1, 12, and 13).
- d) Dosing: An agent may be administered up to three times a week, depending on the regimen. The duration and frequency of treatment often depend on whether the goal is prophylaxis or treatment.
- e) Verification (see section D)
  - (1) Perform the time-out procedure and pretreatment verification listed in section D.
  - (2) Verify the following information with another nurse deemed competent to administer antineoplastic therapy, a pharmacist, or a physician:
    - (a) The medication to be administered is safe via the intraventricular route.
    - (b) The medication is not a vinca alkaloid or bortezomib.
    - (c) The medication is mixed with preservative-free normal saline.
- f) Administration
  - (1) No consensus can be made regarding the patient's position during the procedure.
  - (2) All personnel who administer HDs via this route must wear two pairs of gloves tested for use with HDs (outer gloves are sterile), a gown, and a mask with face protection (see Chapter 12).
  - (3) Use strict sterile technique and sterile barrier precautions (e.g., mask, sterile field, sterile gloves).
    - (a) A mask also decreases the transfer of *Streptococcus salivarius* bacteria that can cause meningitis to the treatment field (Shewmaker et al., 2010).
    - (b) If the outside of the chemotherapy syringe is not sterile when dispensed, special procedures must be followed to maintain sterility during lumbar puncture (Aiello-Laws & Rutledge, 2008; Elledge, 2017). If the syringe containing the medication is sterile, the label on the medication must also be sterile (Aiello-Laws & Rutledge, 2008). For nonsterile syringes, the provider should access the cerebrospinal fluid with sterile gloves and administer intrathecal medication without touching the sterile access site (Polovich & Olsen, 2018).
  - (4) Cleanse the reservoir prior to needle puncture with an antiseptic and let dry completely to ensure that it adequately kills organisms and does not enter the cerebrospinal fluid. Refer to the type of antiseptic to determine the duration of the scrub and dry time.
    - (a) Current package labeling for chlorhexidine gluconate states to avoid contact with the meninges (i.e., do not use on lumbar puncture sites) due to reports of meningitis (Lexi-comp, 2021a; Sviggum et al., 2012).
    - (b) Proponents of chlorhexidine use over povidone-iodine cite a more rapid onset of action, extended duration of effect, rare drug resistance, and little evidence to support its role in developing meningitis (Al Dweikat, 2020; Sviggum et al., 2012).
  - (5) Use a 25-gauge or smaller butterfly needle and attach extension tubing to an empty syringe (equal to the volume of the chemotherapy syringe) (Aiello-Laws & Rutledge, 2008; Elledge, 2017; Integra Life-Sciences, 2014).
  - (6) Some practices recommend using a stopcock, with the empty syringe for aspiration and the chemotherapy syringe attached to different ports of the stopcock. The stopcock is connected to the tubing on the butterfly needle. Never use a vacutainer (Aiello-Laws & Rutledge, 2008).
  - (7) Palpate the reservoir.
  - (8) Insert the butterfly at a 90° angle into the ventricular reservoir. Once it is inside the

- dome of the reservoir, decreased resistance should be felt.
- (9) Slowly aspirate. If blood is present, stop and withdraw the needle. If blood is not present, slowly withdraw cerebrospinal fluid equal to the volume of chemotherapy to be administered (Aiello-Laws & Rutledge, 2008; Elledge, 2017).
  - (10) Examine the cerebrospinal fluid. If it is cloudy or bloody, do not proceed with chemotherapy until you have discussed the findings with the provider. Anticipate orders to send a specimen for testing. Proceed if the cerebral spinal fluid is clear.
  - (11) Disconnect the syringe with cerebrospinal fluid (pinch tubing or close the stopcock first). Save the cerebrospinal fluid syringe if specimens are ordered or indicated. Attach the chemotherapy syringe (unpinch tubing or open the stopcock to the chemotherapy syringe) and slowly administer the chemotherapy.
  - (12) Flush with preservative-free normal saline (Aiello-Laws & Rutledge, 2008; Camp-Sorrell & Matey, 2017).
  - (13) Remove the needle.
  - (14) Apply pressure with sterile gauze.
  - (15) Apply a sterile dressing.
  - (16) Postprocedure care
    - (a) No consensus can be made regarding the patient's position following the procedure.
    - (b) Take vital signs.
    - (c) Assess for complications, including headaches, nausea, vomiting, seizures, and changes in neurologic status.
      - i. Acute neurotoxicity due to intrathecal chemotherapy can present within 24–48 hours as chemical arachnoiditis with headache, nuchal rigidity, back pain, vomiting, fever, and seizures (Jacob et al., 2015).
      - ii. Catheter migration or location too close to a vital structure can cause neurologic symptoms, such as headaches, seizures, and nausea, during or immediately after the procedure (Mauler et al., 2020). A computed tomography scan, magnetic resonance imaging, or flow study can help rule out catheter migration.
- (d) If specimens are ordered, label and send per institutional policy and procedure.
- g) Patient education
    - (1) Instruct patients to notify the healthcare provider if headache, nausea, vomiting, neck stiffness, or other neurologic symptoms develop.
    - (2) Instruct patients to avoid trauma to the ventricular reservoir site.
- ## 7. Intravesical (bladder)
- a) Intravesical chemotherapy is the regional administration of chemotherapy directly into the bladder. The medication is administered through a catheter and can be done intraoperatively, immediately postoperatively, and weekly in the outpatient area.
    - (1) Indications include superficial, nonmuscle invasive bladder cancer and selected patients who are not candidates for cystectomy (NCCN, 2022b).
    - (2) Commonly used agents include bacillus Calmette-Guérin (BCG), docetaxel, epirubicin, gemcitabine, mitomycin C, and valrubicin (NCCN, 2022b).
    - (3) BCG contains live attenuated mycobacteria. Because of the potential risk for transmission, it should be prepared, handled, and disposed of as a biohazard material (National Institute for Occupational Safety and Health [NIOSH], 2016). BCG preparation is performed using sterile technique and is not prepared in areas where other parenteral medications are prepared (NIOSH, 2016). BCG treatment contains live bacteria. Patients are instructed to not use public toilets for six hours after treatment and to sit down on the toilet to avoid splashing. They should add 2 cups of undiluted bleach to the toilet, close the lid, and wait 15 minutes before flushing. These precautions may prove difficult to maintain in a busy oncology infusion clinic, and risk to other patients should be considered if implementing this treatment outside of a urology clinic.
    - (4) Intravesical chemotherapy is sometimes given sequentially on the same day (Steinberg et al., 2015). The first medication is instilled and left in for a designated dwell time. The medication is then drained, the catheter flushed with normal saline, and a second medication is instilled, held for a designated dwell time, and then drained.

b) Pretreatment assessment (in addition to the general pretreatment assessment)

- (1) Measure baseline vital signs.
- (2) Verify any allergies to latex, tape, and antiseptic.
- (3) Review medications, as some antibiotics (e.g., fluoroquinolones) may decrease the effectiveness of BCG (Lexicomp, 2021b).
- (4) Treatment is contraindicated in women who are pregnant or breastfeeding.
- (5) If signs and symptoms of a bladder infection (e.g., fever, burning, urgency, frequency, gross hematuria) are present, hold treatment and notify the provider. A routine screening urinalysis is no longer included in the American Urological Association and Society of Urologic Nurses and Associates (2020) guidelines for intravesical treatments. Send a urine culture as ordered. Discuss results with the provider.
- (6) An anticholinergic may be given before the procedure for patients with a history of bladder spasms.
- (7) A special catheter or topical anesthetic may be indicated for patients with a history of difficult or painful catheterization.
- (8) Assess for signs and symptoms of urinary frequency and inability to hold urine.
- (9) Because BCG is a live attenuated form of *Mycobacterium tuberculosis*, assess for the following contraindications to treatment (American Urological Association & Society of Urologic Nurses and Associates, 2020):
  - (a) Within 14 days following bladder or prostatic surgery, including biopsy
  - (b) Within 14 days following traumatic catheterization
  - (c) Traumatic catheterization or gross hematuria on the day of treatment
  - (d) Active tuberculosis: Lexicomp (2021b) recommends a purified protein derivative (PPD) test prior to starting BCG therapy. Patients with a positive PPD test should be further assessed for signs and symptoms of active or latent tuberculosis. The American Urological Association and Society of Urologic Nurses and Associates (2020) guidelines do not include a PPD test as part of the pretreatment assessment.
  - (e) Immunosuppressed patients with congenital or acquired immune defi-

ciency, whether due to concurrent disease (e.g., AIDS, leukemia, lymphoma), cancer therapy (e.g., cytotoxic drugs, radiation), or immunosuppressive therapy (e.g., corticosteroids)

- (f) Symptomatic urinary tract infection
- (g) Fever

c) System safeguards to prevent errors and manage emergencies (also see Chapters 1, 12, and 13)

d) Dosing: The dosing, duration, and frequency are dependent on individual patient factors and the regimens prescribed. The dosing of the different brands of intravesical BCG vary.

e) Verification (see section D)

f) Administration (American Urological Association & Society of Urologic Nurses and Associates, 2020; Hartkopf-Smith, 2020)

- (1) For postoperative patients, obtain an order to discontinue any continuous bladder irrigation for a minimum of one hour before treatment.
- (2) Wear PPE, which includes a gown tested for use with chemotherapy. If unavailable, use a lint-free gown made of a low-permeability fabric, such as polypropylene or other laminate materials, and two pair of gloves tested for use with chemotherapy. Mask and face protection should also be used.
- (3) Place the patient in a supine position and place a plastic-backed pad under the patient's hips.
- (4) If the patient has had difficult or painful catheterizations in the past, apply a topical anesthetic as ordered.
- (5) Using a sterile technique, place a urethral catheter and completely drain the bladder.
  - (a) Using a Foley catheter with an attached drainage bag is preferred, as it allows for a closed system for administration and drainage and prevents spills of HDs. Ensure that the Foley tubing has a port compatible with the CSTD on the end of the syringe or chemotherapy tubing.
  - (b) A straight catheter with a CSTD adaptor can be used if the patient can hold their urine for the designated dwell time without leaking and a bathroom for single use during treatment is close.
    - i. After draining urine, place a CSTD catheter adaptor at the end of the catheter. The slip tip fits into the end of the catheter.

- ter. A cap is attached to the slip tip. The CSTD at the end of the medication syringe or tubing can be attached to the cap on the adaptor for bladder instillation of HDs.
- ii. If BCG is given, the patient's bathroom must be closed for 15 minutes after the patient voids. Two cups of bleach are placed in the toilet and must remain there for 15 minutes to effectively kill BCG.
- (6) Medications may be mixed in a Luer lock syringe or an IV bag with attached short tubing. Some medications (e.g., valrubicin) come with tubing; however, these may not be compatible with CSTDs. Assess to determine if a short IV tubing can be used instead.
  - (7) Syringes or IV tubings should have an attached CSTD.
  - (8) Inject or infuse the chemotherapy or immunotherapy at the prescribed rate. Slow the injection or infusion if the patient reports discomfort or bladder spasms. If using a Foley catheter, the tubing should be clamped (using a smooth clamp) so that the medication does not drain into the Foley bag during the dwell time. If using a straight catheter, the catheter and CSTD adaptor with cap should remain in place.
  - (9) Instruct the patient to hold the medication and not void for one to two hours (American Urological Association & Society of Urologic Nurses and Associates, 2020).
  - (10) No evidence supports having the patient turn from side to side and then lie on their back to ensure the medication comes in contact with the bladder (American Urological Association & Society of Urologic Nurses and Associates, 2020).
  - (11) After one to two hours, the medication may be drained.
    - (a) If the patient has a Foley catheter in place, unclamp the tubing and let the urine and medication drain into the bag. Remove the catheter with the attached bag. Always use safe handling precautions.
    - (b) If the patient has a straight catheter in place, remove it using a plastic-backed absorbent pad under the area in case of leakage. The patient can then void.
    - (c) Instruct male patients to sit while voiding for six hours following the administration of the agent. This prevents splashing of the medication (American Urological Association & Society of Urologic Nurses and Associates, 2020).
  - (12) Assess for pain, burning, spasms, and difficulty retaining urine for two hours. A rare side effect is extravasation during the administration of a vesicant agent, which can result in severe pelvic pain (Elmamoun et al., 2014; Nieuwenhuijzen et al., 2003).
  - (13) Dispose of items, including the catheter, in a designated HD container. If a Foley catheter and drainage bag were used, contain the entire intact urinary drainage system in sealable bags and place it in the designated HD container.
- g) Patient education (American Urological Association & Society of Urologic Nurses and Associates, 2020)
- (1) Restrict intake of fluid, caffeine, and diuretics beginning four hours before the procedure.
  - (2) Following the procedure
    - (a) Sit when voiding for six hours following the procedure to prevent splashing.
    - (b) Avoid using public toilets. Do not void outside.
    - (c) Increase fluid to dilute the urine.
    - (d) Wash any splashing on skin with soap and water. Wash glans or perineum after voiding.
    - (e) Wear a condom during intercourse until therapy is completed.
    - (f) For BCG, place two cups of bleach in the toilet after each void for six hours following the procedure. Let the bleach sit in the toilet for 15 minutes. Cover the toilet, and flush twice.
    - (g) Common side effects include low-grade fever, urinary frequency and urgency, bladder spasms, burning with urination, and fatigue.
    - (h) Remove clothes if contaminated with urine and wash separately.
8. Percutaneous nephrostomy infusions (e.g., renal pelvis, ureters)
- a) Percutaneous nephrostomy infusion is the regional administration of chemotherapy or immunotherapy directly into the renal pelvis or ureter using a nephrostomy tube or other percutaneous catheter. The medication is adminis-

tered through a catheter and can be given in the outpatient area.

- (1) The role of immunotherapy and chemotherapy for upper urinary tract cancer is not firmly established; however, the most established practice is the treatment of carcinoma in situ or small solitary tumors that are completely resected (Carmignani et al., 2013; Metcalf & Pierorazio, 2020).
  - (2) The most commonly used agents include BCG and mitomycin C (Metcalf & Pierorazio, 2020).
  - (3) BCG contains live attenuated mycobacteria. Because of the potential risk for transmission, it should be prepared, handled, and disposed of as a biohazard material (NIOSH, 2016).
- b) Pretreatment assessment (in addition to the general pretreatment assessment)
- (1) The location of the tip of the catheter should be documented in the patient's chart. Check the operative or radiology report.
  - (2) Assess the nephrostomy tube for kinks, tears, or leaks. The nephrostomy tube may have a cap (e.g., needleless connector) on the end rather than a bag.
  - (3) Check for nephrostomy tube patency by flushing with 10 ml normal saline. Do not proceed and notify the provider if resistance is met.
  - (4) Assess for urinary incontinence. If the patient reports incontinence, consider placing a Foley catheter, as the medication will be voided after the procedure.
  - (5) Assess for signs and symptoms of infection.
    - (a) Assess vital signs, including temperature.
    - (b) Check the nephrostomy tube exit site for redness, swelling, and drainage.
    - (c) Check for signs and symptoms of urinary tract infection.
    - (d) If an infection is suspected, do not proceed and notify the provider.
    - (e) Send a urine culture as ordered. Some providers will order a urine culture and IV antibiotic prior to each treatment (Herr, 1985).
  - (6) Medications. Some antibiotics (e.g., fluoroquinolones) may decrease the effectiveness of BCG (Lexicomp, 2021b).
  - (7) Because BCG is a live attenuated form of tuberculosis and some of the BCG drains into the bladder, assess for the following contraindications to treatment (American Urological Association & Society of Urologic Nurses and Associates, 2020; Lexicomp, 2021b):
    - (a) Within 14 days following bladder or prostatic surgery, including biopsy
    - (b) Within 14 days following traumatic catheterization
    - (c) Traumatic catheterization or gross hematuria on the day of treatment
    - (d) Active tuberculosis: Lexicomp (2021b) recommends a PPD test prior to starting BCG therapy. Patients with a positive PPD test should be further assessed for signs and symptoms of active or latent tuberculosis. The American Urological Association and Society of Urologic Nurses and Associates (2020) guidelines do not include a PPD test as part of the pretreatment assessment.
    - (e) Immunosuppressed patients with congenital or acquired immune deficiency, whether due to concurrent disease (e.g., AIDS, leukemia, lymphoma), cancer therapy (e.g., cytotoxic drugs, radiation), or immunosuppressive therapy (e.g., corticosteroids)
  - (8) Instruct the patient to void before and not during the procedure.
- c) System safeguards to prevent errors and manage emergencies (see Chapters 1, 12, and 13)
- (1) Clearly label lines as nephrostomy tube and IV (if ordered for an antibiotic) to prevent accidental administration of medications via the wrong route.
  - (2) When administering medications and fluids, trace all catheters and lines from the access site into the patient's body.
  - (3) Route IV tubing and nephrostomy tubing to different sides of the bed or chair.
  - (4) Infuse nephrostomy tube fluids through IV tubing without injection ports.
- d) Dosing: The dosing, duration, and frequency are dependent on individual patient factors and the regimens prescribed.
- e) Verification: Verify the location of the catheter tip by reviewing imaging or operative reports. Confirm that the catheter is in the ureter or renal pelvis (see section D).
- f) Administration
- (1) Detailed evidence-based information regarding administration is scarce in the literature.

- (a) In 1985, the first case of adjuvant topical immunotherapy BCG was described by Herr.
  - i. The procedure used was based on the instillation of citric acid, glucono-delta-lactone, and magnesium carbonate to dissolve kidney stones and involved monitoring renal pressures using a manometer, daily urine cultures, and prophylactic antibiotics.
  - ii. The underlying premise was to prevent high renal pressure and kidney damage, as a kidney stone was causing an obstruction.
  - iii. Although pressure monitoring continues to be mentioned in most reviews, detailed discussions regarding renal pressure in patients with urinary tract cancer were not found.
- (b) *European Association of Urology Guidelines on Upper Urinary Tract Urothelial Cell Carcinoma* states that the antegrade instillation of BCG or mitomycin C in the upper urinary tract by percutaneous nephrostomy via a three-valve system open at 20 cm (after complete tumor eradication) is feasible (Rouprêt et al., 2015). Other studies and research reviews also describe this procedure (Giannarini et al., 2011; Studer et al., 1989). Draganski et al. (2017) did not include interventions to maintain low pressures in the renal pelvis.
- (c) Assemble equipment for administration.
  - i. For administration and monitoring pressure using a manometer, the medication should be mixed in a minibag (e.g., 50 ml) rather than a syringe. The use of microbore tubing decreases drug waste in the IV tubing and ensures the patient will obtain the maximum amount of the medication. The tubing should have a roller clamp and CSTD.
  - ii. The medication, IV tubing, and three-way stopcock should be connected to a manometer and an additional extension tubing. The tubing, stopcock, and manometer should be primed with normal saline prior to attaching to the medication.
  - iii. The manometer can be secured to the IV pole at the level of the patient's kidneys.
  - iv. The medication should hang no more than 20–30 cm above the level of the patient's kidney (Giannarini et al., 2011; Studer et al., 1989).
  - v. Do not use an IV pump.
  - vi. Wear PPE, which includes a gown tested for use with chemotherapy. If unavailable, use a lint-free gown made of a low-permeability fabric, such as polypropylene or other laminate materials, and two pair of gloves tested for use with chemotherapy. Mask and face protection should also be used. Place the patient in a supine position or on their side with the nephrostomy tube side up (Giannarini et al., 2011; Studer et al., 1989).
  - vii. Place a plastic-backed pad under the patient's hips.
  - viii. Cleanse the cap on the nephrostomy tube with an antiseptic per hospital policy. Scrub for 15 seconds. Let dry. If a needleless connector is used for the cap, the IV tubing can be screwed into this. If not, remove the cap and connect it to the IV tubing.
  - ix. Before starting the infusion, check renal pressure using the manometer. To do this, turn the stopcock off in the direction of the medication. Document the number. Do not proceed and notify the provider if the renal pressure exceeds 20 mm Hg (Giannarini et al., 2011; Studer et al., 1989). Check the pressure every 15 minutes and after the end of the infusion.
  - x. Open the stopcock so that the medication flows to the nephrostomy tube.
  - xi. Administer over one to two hours as ordered.
  - xii. Discontinue the infusion if the renal pressure exceeds 20 mm

- Hg or the patient complains of discomfort. Notify the provider.
  - xiii. After the infusion, disconnect the IV tubing. Use personal protective equipment.
  - xiv. Replace the nephrostomy cap. Clean with antiseptic per hospital policy and flush the nephrostomy tube with 10–20 ml normal saline. Replace the nephrostomy tube dressing if needed.
  - xv. Dispose of supplies and personal protective equipment in the appropriate HD container.
- g) Patient education following the procedure (American Urological Association & Society of Urologic Nurses and Associates, 2020)
- (1) Sit when voiding for six hours following the procedure to prevent splashing.
  - (2) Avoid using public toilets. Do not void outside.
  - (3) Increase fluid to dilute the urine.
  - (4) Wash any splashing on skin with soap and water. Wash glans or perineum after voiding.
  - (5) Wear a condom during intercourse until therapy is completed.
  - (6) For BCG, place two cups of bleach in the toilet after each void for six hours following the procedure. Let the bleach sit in the toilet for 15 minutes. Cover the toilet, and flush twice.
  - (7) Common side effects include low-grade fever, urinary frequency and urgency, bladder spasms, burning with urination, and fatigue.
  - (8) Remove clothes if contaminated with urine and wash separately.
- ### 9. Intra-arterial
- a) Intra-arterial chemotherapy delivers high concentrations of medication directly to the tumor with decreased systemic exposure. It has been used for the following procedures:
- (1) Hepatic arterial infusions
    - (a) Liver metastases derive greater than 80% of their blood supply from the hepatic arterial circulation, whereas healthy hepatocytes obtain blood from the portal circulation (Breedis & Young, 1954). Administration of chemotherapy into the hepatic artery allows selective delivery of the drug to cancer cells while sparing healthy cells.
- (b) Floxuridine is rapidly metabolized by the liver by a first-pass effect, leading to higher levels of drug exposure and decreased systemic side effects (Datta et al., 2019).
- (c) Hepatic arterial infusions may be administered using temporary percutaneous catheters, intra-arterial ports, and implantable, programmable pumps.
- i. Transhepatic arterial chemoembolization (TACE) involves the insertion of a temporary arterial catheter into the femoral artery with the tip location in the hepatic artery. It is indicated for some cases of hepatocellular carcinoma and liver metastasis (Young & Savio, 2021).
    - A radiologist injects chemotherapy into the arterial catheter, usually in the interventional radiology suite. The chemotherapy may be mixed with lipiodol (a contrast agent), and an embolization agent or drug-eluting beads are mixed with the chemotherapy. The beads slowly release the chemotherapy. The catheter is discontinued after the procedure, and the patient is monitored for post-procedure complications.
    - Postprocedure care involves assessing circulation in the extremity, bleeding, management of pain and nausea, and postprocedure chemical hepatitis (often delayed) (Yane et al., 2013).
  - ii. Intra-arterial ports used for hepatic artery infusions consist of an implanted port connected to an arterial catheter threaded into the hepatic artery.
  - iii. Implanted programmable pumps are connected to a catheter threaded into the hepatic artery.
- (2) Isolated limb perfusion
- (a) Isolated limb perfusion has been used for melanomas and sarcomas (Broman & Zager, 2019; Neuwirth et al., 2017).

- (b) Depending on the procedure, hyperthermia techniques or tourniquets may be used while administering chemotherapy (Broman & Zager, 2019; Neuwirth et al., 2017).
  - (c) Complications include bleeding, thrombosis, discomfort, and compartment syndrome (Broman & Zager, 2019; Neuwirth et al., 2017).
- (3) Brain tumors
  - (a) Intra-arterial chemotherapy has been used for various brain tumors, including glioblastomas and primary central nervous system lymphomas (Huang et al., 2020; Su et al., 2016). Agents used include carmustine and cisplatin.
  - (b) A temporary arterial catheter is placed in surgery or interventional radiology, and chemotherapy is infused by a physician.
  - (c) Blood–brain barrier and blood–tumor barrier disruption (using medications such as mannitol or bradykinin) may be used to increase the direct entry of medications into the tumor (Huang et al., 2020; Su et al., 2016).
  - (d) Complications from carotid and vertebral infusions reported include severe vascular toxicity and neurotoxicity. Patients with primary glioblastomas or anaplastic astrocytomas receiving intra-arterial cisplatin can experience a significant loss in high-frequency hearing, decreased visual acuity, and irreversible encephalopathy (Huang et al., 2020; Su et al., 2016).
- (4) Retinoblastoma
  - (a) A catheter is introduced through the femoral arterial and advanced to the ostium of the ophthalmic artery (Manjandavida et al., 2019; Rishi et al., 2020). Chemotherapy is then administered in a pulsatile manner over approximately 30 minutes by a physician.
  - (b) Examples of agents used include carboplatin, melphalan, and topotecan (Manjandavida et al., 2019; Rishi et al., 2020).
  - (c) The procedure is performed under general anesthesia.
  - (d) Side effects include local effects on the eye (e.g., edema, hemorrhage, vision changes) and systemic effects (e.g., stroke, ischemia) (Manjandavida et al., 2019; Rishi et al., 2020).
- b) Pretreatment assessment (in addition to the general pretreatment assessment)
  - (1) Prior to placing an arterial catheter, an angiogram or similar dye study is performed to confirm location and arterial blood flow and assess for complications.
  - (2) When temporary percutaneous catheters are used, assess the peripheral circulation of the affected extremity to serve as a baseline (e.g., color, pulse, temperature).
  - (3) Review any laboratory values as indicated for the procedure, such as complete blood count and differential, coagulation studies, liver function tests, and renal function tests.
- c) System safeguards to prevent errors and manage emergencies (see Chapters 1, 12, and 13)
  - (1) Clearly label external lines as intra-arterial and IV to prevent accidental administration of medications via the wrong route.
  - (2) When administering medications and fluids, trace all catheters and lines from the access site into the patient's body.
  - (3) Route intra-arterial tubing and IV tubing to different sides of the bed or chair.
  - (4) Infuse any intra-arterial fluids through tubing without Y-sites so that other medications cannot accidentally be injected or infused (Camp-Sorrell & Matey, 2017).
  - (5) Immediately prior to administration, verify the medication administration route.
  - (6) Use Luer-lock connections on tubing and tape all connections securely (Camp-Sorrell & Matey, 2017).
  - (7) For temporary percutaneous catheters, immobilize the extremity as indicated to prevent accidental catheter dislodgment (Camp-Sorrell & Matey, 2017).
- d) Dosing: The dosing, duration, and frequency are dependent on individual patient factors and the regimens prescribed.
- e) Verification: Verify the location of the catheter tip by reviewing imaging or operative reports (see section D).
- f) Administration
  - (1) Wear PPE, which includes a gown tested for use with chemotherapy. If unavailable, use a lint-free gown made of a low-permeability fabric, such as polypropylene or other laminate materials, and two pair of gloves tested for use with chemotherapy. Mask and face protection should also be used.

- (2) Temporary percutaneous catheters
  - (a) Temporary percutaneous catheters have been used for regional limb perfusions, carotid artery infusions, and hepatic artery infusions (Camp-Sorrell & Matey, 2017).
  - (b) They are often placed in radiology. The catheter may remain in place for minutes, hours, or several days.
  - (c) The most common insertion sites are the brachial and femoral arteries.
  - (d) Depending on the location and duration of infusion, the patient may have activity restrictions and limb immobilization.
  - (e) Place infusions on a pump.
  - (f) Assess vital signs, circulation, and for hematoma during the infusion and for at least two hours after the catheter is discontinued.
- (3) Intra-arterial ports
  - (a) The portal body is placed subcutaneously, and the port catheter is threaded into the designated artery.
  - (b) Ambulatory infusion pumps have been used to deliver medication.
  - (c) Currently, no ports manufactured in the United States are specifically designed for intra-arterial administration of chemotherapy.
  - (d) The port is accessed per the same procedure as an IV port.
  - (e) All tubings and connections must be secured to prevent disconnection and possible hemorrhage.
- (4) Programmable implanted intra-arterial pumps: Hepatic artery infusion pumps are used to administer chemotherapy for colon cancer that has metastasized to the liver (Parks & Routt, 2015).
  - (a) The chemotherapy commonly infused through an intra-arterial pump is 5-fluorodeoxyuridine. The pump is connected to an arterial catheter threaded into the hepatic artery.
  - (b) At the time of this publication, the only implanted pump approved for hepatic artery infusions in the United States is the Intera 3000™ (Intera Oncology, n.d.). The pump is connected to an arterial catheter that is threaded into the hepatic artery. The pump rate is constant and cannot be programmed to a different rate. To change the dose of medication, the concentration is changed.
  - (c) Multiple specialists are needed to care for patients who receive this complex treatment. Care involves surgically implanting the port, proper dosing of drugs, administering drugs using trained and competent staff, and monitoring for toxicities and catheter-related complications (Napier et al., 2021).
    - i. Always verify the type and model of the pump before administering chemotherapy.
    - ii. Pump insertion (Napier et al., 2021)
      - The pump is inserted in surgery or interventional radiology. It is placed in an SC pocket, and the catheter is threaded into the hepatic artery.
      - Pump delivery rates are specific for the brand of pump. Some pumps have a constant rate and cannot be programmed. The concentration is changed to change the dose of medication. However, other pumps have a changeable rate programmed with an external computer.
      - The surgeon will verify the tip of the catheter is appropriately placed; this is usually confirmed with a dye study at the time of placement.
      - Always verify the rate of administration by reviewing the product information. The rate varies with the pump model and individual patient characteristics.
      - Always verify the reservoir volume before administering medication. The volume varies with the model.
      - Pumps generally must be refilled every two weeks; refer to the provider order. A common schedule is two weeks of chemotherapy and

then two weeks of heparinized saline.

- A special straight noncoring needle is used to access the septum in the pump. Refer to specific pump instructions for more information on the procedure.

#### 10. Intrapleural

a) Intrapleural chemotherapy is used to manage malignant pleural effusions using pleurodesis.

(1) Pleurodesis is performed by draining pleural fluid and instilling an irritant (sclerosing agent) through a chest tube. The agent causes inflammation and fibrosis, leading to adhesions between the two pleural membranes. The adhesions prevent pleural fluid from accumulating in the pleural space.

(2) Chemotherapy agents that have been used for pleurodesis include bevacizumab, bleomycin, cisplatin, cytarabine, doxorubicin, etoposide, 5-fluorouracil, and mitomycin C (Heffner, 2020).

b) Physicians and advanced practice providers typically perform pleurodesis. Prior to performing pleurodesis, verify it is within scope of practice by the state board of nursing and institutional policy.

c) Pretreatment assessment (in addition to the general pretreatment assessment)

(1) Assess the volume of pleural fluid in the chest tube drainage system. The daily drainage should be less than 150 ml/24 hours to perform pleurodesis, ensuring that the sclerosis agent has maximum contact with the pleura (Cope, 2018; Heffner, 2020; Hospira, 2021). The literature suggests that successful pleurodesis is partly dependent on complete drainage of the pleural fluid and reestablishment of negative intrapleural pressure prior to the instillation of a sclerosing agent (Cope, 2018).

(2) Perform a baseline respiratory assessment, including rate, depth, and breath sounds.

d) System safeguards to prevent errors and manage emergencies: Intrapleural chemotherapy administration must be performed by an authorized prescriber (see Chapters 1, 12, and 13).

e) Dosing: The sclerosing agent is dissolved in 100–150 ml of normal saline (Heffner, 2020; Hospira, 2021).

f) Verification: Trace all lines to their point of origin (see section D).

#### g) Administration

(1) Premedicate the patient with analgesics if indicated. Some providers instill lidocaine into the chest tube prior to the sclerosing agent (Heffner, 2020).

(2) Wear PPE, which includes a gown tested for use with chemotherapy. If unavailable, use a lint-free gown made of a low-permeability fabric, such as polypropylene or other laminate materials, and two pair of gloves tested for use with chemotherapy. Mask and face protection should also be used.

(3) Use a CSTD on the chemotherapy if compatible with the chest tube system.

(4) Aseptic technique should be maintained throughout the procedure. Any access ports on the tubing should be cleansed with antiseptic per hospital policy.

(5) Chest tube suction should be turned off during the instillation and dwell time. Any stopcocks or clamps should be closed between the site of medication instillation and the chest tube drainage system.

(6) The medication should be administered slowly as per patient tolerance.

(7) Allow the agent to remain for the prescribed dwell time if tolerated. Some references recommend that the patient rotate side to side to distribute the medication, although no evidence supports this practice (Heffner, 2020; Hospira, 2021).

#### h) Postprocedure

(1) After the dwell time is completed or if the patient cannot tolerate the procedure, allow the medication to drain into the chest tube collection system.

(2) Observe during and after the procedure for signs and symptoms of respiratory distress, pneumothorax, infection, and pain.

(3) Dispose of personal protective equipment and supplies in the appropriate HD container.

(4) A chest x-ray may be ordered 24 hours after the procedure. If the chest x-ray indicates no buildup of pleural fluid, the chest tube may be discontinued.

(5) When the chest tube is discontinued or the collection system is changed, do not drain the fluid from the container. Securely wrap the container in an HD bag and dispose of it in the appropriate container.

## CHAPTER 12

# Safe Handling of Hazardous Drugs

### A. Safe handling and disposal of hazardous drugs (HDs)

1. Many drugs used to treat cancer are hazardous to healthcare workers. HDs require special handling because occupational exposure may cause adverse health effects. These effects occur because of the inherent toxicities of the drugs (American Society of Health-System Pharmacists [ASHP], 2006; National Institute for Occupational Safety and Health [NIOSH], 2004).
2. According to the Occupational Safety and Health Administration (OSHA, 2016), a safe level of occupational exposure to HDs is unknown. Healthcare workers who handle HDs may be at risk for exposure to multiple agents on any given day, and no reliable method for monitoring work-related exposure exists.
3. Therefore, those who work with HDs must adhere to practices designed to minimize occupational exposure.

### B. Definition

1. In 1990, ASHP (then known as the American Society of Hospital Pharmacists) provided the first definition of HDs.
2. ASHP's initial list included four characteristics in determining if a drug is hazardous. Two additional characteristics were later added (NIOSH, 2004).
  - a) Carcinogenicity
  - b) Teratogenicity or developmental toxicity in a fetus
  - c) Reproductive toxicity
  - d) Organ toxicity at low doses
  - e) Genotoxicity
  - f) New drugs similar in structure or toxicity to drugs classified as hazardous using the preceding criteria

### C. Antineoplastic drugs

1. Antineoplastic drugs are also referred to as chemotherapy or cytotoxic drugs used to treat cancer. NIOSH also classifies most antineoplastic drugs as HDs (NIOSH, 2017).

2. Potential adverse health effects of occupational exposure to antineoplastic drugs include increased incidence of cancer in exposed nurses and other healthcare workers.

- a) Published evidence regarding cancer among occupationally exposed nurses and other healthcare workers is limited because of the failure to connect exposure to health outcomes (Blair et al., 2001; Ekpanyaskul & Sangrajrang, 2018; Hansen & Olsen, 1994; Levin et al., 1993; Martin, 2005; Petralia et al., 1999).

- b) In 2019, the National Toxicology Program (NTP) reviewed available studies on cancer. It cited low confidence that occupational exposure to antineoplastic drugs is associated with cancer due to the limited studies of any one cancer site, limited ability to reach level-of-evidence conclusions, and risk-of-bias concerns (NTP, 2019).

- c) The International Agency for Research on Cancer (2022) publishes independent assessments of the carcinogenic risks of chemicals. It has identified 11 antineoplastic drugs and several combination chemotherapy regimens as known human carcinogens. Other antineoplastic agents are classified as probable or possible carcinogens (see Table 12-1).

3. Structural defects in a fetus following occupational HD exposure during pregnancy have been reported (Hemminki et al., 1985; Peelen et al., 1999). No studies of congenital malformations have reported data collected after 2000 (Connor et al., 2014).

4. Adverse reproductive outcomes have occurred in nurses and other healthcare workers exposed to HDs during pregnancy, including miscarriage, infertility/subfertility, preterm births, and learning disabilities in offspring (Connor et al., 2014; Fransman et al., 2007; Lawson et al., 2012; Martin, 2005; Quansah & Jaakkola, 2010).

- a) Most recently, a suggestive association between HD handling and miscarriage was found in a large sample of Nurses' Health Study 3 participants, particularly among nurses who did not

**TABLE 12-1.** Antineoplastic Agents Classified as Carcinogens

| Exposure Risk                             | Antineoplastic Drugs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Group 1: Carcinogenic to humans           | <ul style="list-style-type: none"> <li>• Arsenic trioxide<sup>a</sup></li> <li>• Azathioprine</li> <li>• Busulfan</li> <li>• Chlorambucil</li> <li>• Cyclophosphamide</li> <li>• Etoposide</li> <li>• Etoposide in combination with cisplatin and bleomycin</li> <li>• Melphalan</li> <li>• MOPP (mechlorethamine hydrochloride, vincristine, procarbazine, and prednisone)</li> <li>• Semustine</li> <li>• Tamoxifen</li> <li>• Thiotepa</li> <li>• Treosulfan</li> <li>• Other combined chemotherapy including alkylating agents</li> </ul> |
| Group 2A: Probably carcinogenic to humans | <ul style="list-style-type: none"> <li>• Azacitidine</li> <li>• Carmustine<sup>a</sup></li> <li>• Cisplatin</li> <li>• Doxorubicin<sup>a</sup></li> <li>• Nitrogen mustard</li> <li>• Procarbazine hydrochloride</li> <li>• Teniposide</li> </ul>                                                                                                                                                                                                                                                                                             |
| Group 2B: Possibly carcinogenic to humans | <ul style="list-style-type: none"> <li>• Amsacrine</li> <li>• Bleomycin</li> <li>• Dacarbazine</li> <li>• Mitomycin C</li> <li>• Mitoxantrone</li> <li>• Streptozocin</li> </ul>                                                                                                                                                                                                                                                                                                                                                              |

<sup>a</sup>Although not on International Agency for Research on Cancer list, package insert is consistent with that risk category.

Note. Based on information from International Agency for Research on Cancer, 2022.

consistently use personal protective equipment (PPE) and engineering controls (Nassan et al., 2021). Recent evidence suggests that increased adherence to using PPE and engineering controls has improved the time to conception (Nassan et al., 2019).

- b) NTP also reviewed reproductive toxicities and miscarriage. Although the program reported very low confidence that occupational exposure to antineoplastic drugs during pregnancy is associated with reproductive and developmental toxicity, it cited moderate confidence that occupational exposure to antineoplastic drugs during pregnancy is associated with miscarriage (NTP, 2019).

5. Cytogenetic effects have occurred in healthcare workers following exposure to HDs, including

chromosomal damage, chromosomal aberrations, increased frequency of micronuclei, oxidative stress and mitochondrial damage, and apoptosis (Bouraoui et al., 2011; Buschini et al., 2013; Eghbal et al., 2018; El-Ebiary et al., 2013; Ladeira et al., 2014; Liao et al., 2017; Mahmoodi et al., 2017; McDiarmid et al., 2010, 2014; Moretti et al., 2015; Ramazani et al., 2019; Roussel et al., 2019; Santovito et al., 2014; Villarini et al., 2011; Villarini et al., 2016).

6. Acute symptoms have been documented in exposed healthcare workers, such as hair loss, abdominal pain, fatigue, nausea, nasal irritation or sores, contact dermatitis, allergic reactions, skin injury, eye injury, and changes in blood work (Baykal et al., 2009; Caciari et al., 2012; Constantinidis et al., 2011; Meyer & Skov, 2010; Simons & Toland, 2017).

a) NTP cited very low confidence that occupational exposure to antineoplastic drugs is associated with acute effects because of the degree of heterogeneity in the outcomes and risk of bias concerns (NTP, 2019).

b) A recent study demonstrated that spills are common occurrences, and PPE use is suboptimal during spill cleanup (Friesen et al., 2020). Exploration of the acute symptoms experienced by those involved in spills, which pose a greater risk for acute exposure, is needed.

#### D. NIOSH List of Antineoplastic and Other Hazardous Drugs in Healthcare Settings, 2016

1. NIOSH provides a list of HDs and periodic updates at [www.cdc.gov/niosh/topics/hazdrug](http://www.cdc.gov/niosh/topics/hazdrug). At the time of this writing, the 2016 list is still in use. A 2020 revision is in draft form and can be viewed at [www.federalregister.gov](http://www.federalregister.gov).
2. The list is divided into three groups.
  - a) Group 1 includes antineoplastic drugs that meet one or more of the criteria for HDs. This group includes chemotherapy agents, targeted agents, and other biologic drugs used in cancer treatment.
  - b) Group 2 involves nonantineoplastic drugs that meet one or more of the criteria for HDs. This group includes drugs from several categories, including immunosuppressant agents, antivirals, anticonvulsants, estrogens, progestins, and androgens.
  - c) Group 3 includes nonantineoplastic drugs with primarily reproductive effects. These are drugs from different classifications that are harmful to men and women actively trying to conceive and women who are pregnant or breastfeeding.

#### E. NIOSH List of Hazardous Drugs in Healthcare Settings, 2020

1. The proposed 2020 NIOSH revisions retitled and reorganized the drug listing. Antineoplastic drugs are no longer all cytotoxic, genotoxic, and highly hazardous chemicals. NIOSH determined that grouping all antineoplastic drugs together in one table was no longer the most useful or informative for users and regrouped the tables by hazard.
2. This pending list is divided into two tables.
  - a) Table 1 includes drugs that contain a manufacturer's special handling information in the package insert or meet the NIOSH definition of an HD and are classified by NTP as "known to be a human carcinogen" or classified by the International Agency for Research on Cancer as "carcinogenic" or "probably carcinogenic" (Hazardous Drugs, 2020).
  - b) Table 2 includes drugs that meet the NIOSH definition of an HD but do not have a manufacturer's special handling information and are not classified by NTP as "known to be a human carcinogen" or classified by the International Agency for Research on Cancer as "carcinogenic" or "probably carcinogenic" (Hazardous Drugs, 2020).

#### F. Immunotherapy

1. Immunotherapy uses the patient's immune system to manage or eradicate diverse cancer types (Farkona et al., 2016). Six categories of immunotherapy approaches have been described in this book: checkpoint inhibitors, chimeric antigen receptor T cells, cytokines, immunomodulators, monoclonal antibodies (mAbs) (e.g., radioimmunotherapy), and oncolytic viral therapies.
2. Harm from occupational exposure to mAbs was believed to be minimal because of the low likelihood of internalizing the large molecules through the usual exposure routes (Halsen & Krämer, 2011); however, no direct evidence supports a particular molecular weight above which a drug cannot achieve a detectable level following repeated occupational exposure (de Lemos et al., 2018).
  - a) NIOSH does not list all mAbs as hazardous; instead, each is compared to the criteria for HDs.
  - b) Pertuzumab is hazardous because of embryo-fetal death (NIOSH, 2016).
  - c) Conjugated mAbs are hazardous because of the attached radioactive isotopes (e.g., tositumomab) or toxins (e.g., ado-trastuzumab, brentuximab vedotin, gemtuzumab ozogamicin, loncastuximab tesirine-lpyl, sacituzumab govitecan, belantamab mafodotin, polatuzumab vedotin, enfortumab vedotin, inotuzumab ozogamicin, trastuzumab deruxtecan) (NIOSH, 2016). Antibody-drug conjugates are becoming increasingly popular, with many approved in the past five years.
    - d) For mAbs conjugated with antineoplastic drugs or radioactive particles, see Chapter 10. Use safe handling precautions (e.g., PPE, closed-system drug-transfer devices [CSTDs], containment primary engineering control [C-PEC]) for immunotherapy drugs conjugated with antineoplastic drugs or radioactive particles, as these drugs are considered hazardous (NIOSH, 2016).
    - e) Based on the mechanism of action, some mAbs may cause developmental toxicity, including alemtuzumab, bevacizumab, cetuximab, panitumumab, rituximab, and trastuzumab (Halsen & Krämer, 2011); however, NIOSH (2016) does not classify these agents as HDs.
    - f) A nuclear pharmacist prepares radiolabeled mAbs for infusion. Federal and state laws require that radiation safety warning signs be placed to designate areas where radioisotopes are stored or used (McQuestion et al., 2021).
    - g) NIOSH guidelines and the package insert should be followed to determine the required PPE. Some institutions may require all PPE during the administration of mAbs because they are often given in combination or conjugated with other HDs. This makes PPE requirements simple for staff.
3. Several targeted agents meet one or more of the criteria in the NIOSH definition of HDs and should be handled as hazardous (e.g., handled with PPE and not crushed). Refer to the most recent NIOSH publication for a list of these agents (NIOSH, 2016).
4. Limited data regarding the effects of occupational exposure on these agents are available. It is unclear whether the criteria in the definition of HDs are adequate for protein-based or bioengineered drugs (Halsen & Krämer, 2011; NIOSH, 2016).
5. Novel viral-based therapies require contact isolation and PPE for infection prevention because patients may shed the viruses (Martin, 2017).
6. Most nonconjugated biologic agents do not affect DNA and thus do not cause genetic changes.
7. Antiangiogenic agents (e.g., lenalidomide, thalidomide) pose a risk to fetuses (Celgene, 2019, 2021).

#### G. Routes of occupational exposure include absorption through the skin or mucous membranes following direct drug contact or contact with surfaces or objects that are contaminated with HDs.

1. Many studies reported measurable levels of antineoplastic drugs in the urine of healthcare workers, most likely from dermal absorption (Canal-Raffin et al., 2016; Connor et al., 2010; Friese et al., 2014; Hama et al., 2012; Hon et al., 2015; Izzo et al., 2018; Miyake et al., 2013; Ndaw et al., 2010; Pieri et al., 2010; Ramphal et al., 2014, 2015; Sabatini et al., 2012; Sottani et al., 2010; Sugiura et al., 2011; Yoshida et al., 2011; Zhang et

al., 2016). Some evidence suggests that improvements in safe handling practices have led to reduced exposure for workers (Koller et al., 2018; Poupeau et al., 2017).

2. Multiple studies have documented contamination of surfaces with HDs in drug preparation, administration, and patient care areas (Berruyer et al., 2015; Bussi res et al., 2012; Chu et al., 2012; Connor et al., 2010; Guichard et al., 2019; Kopp et al., 2013; Ladeira et al., 2014; Maeda et al., 2010; Miyake et al., 2013; Moretti et al., 2015; Ramphal et al., 2014; Salch et al., 2019; Sottani et al., 2012; Sugiura et al., 2011; Villarini et al., 2011; Walton et al., 2020; Yoshida et al., 2011). These findings indicate that anyone in these areas not wearing PPE when touching surfaces contaminated with HD residue is at risk for exposure.
3. Several researchers have reported drug contamination on the outside of drug vials when delivered by the manufacturers (Connor et al., 2005; Fleury-Souverain et al., 2014; Hama et al., 2012; Kopp et al., 2013; Schierl et al., 2010). Cyclophosphamide, 5-fluorouracil, ifosfamide, and platinum have been detected on vial exteriors using various sampling techniques. These findings indicate that health-care workers may be exposed if they do not wear PPE while handling unopened drug vial.
4. Other routes of exposure
  - a) Injection from needlesticks or contaminated sharps (ASHP, 2006; NIOSH, 2004)
  - b) Inhalation of drug aerosols, dust, or droplets (Fent et al., 2014; Kiffmeyer et al., 2002)
  - c) Ingestion of contaminated foods, beverages, tobacco products, or other hand-to-mouth behaviors (NIOSH, 2004)

#### H. Hierarchy of hazard controls aimed at reducing worker exposure (NIOSH, 2015)

1. Elimination of the hazard: The highest level of protection from hazardous exposure is to eliminate the hazard, but this is not feasible with drug therapy.
2. Substitution of the hazard: The second-highest level of protection from hazardous exposure is to replace the hazard by substituting a less toxic substance, but this is also not feasible with drug therapy.
3. Engineering controls: The third highest level of protection is to use engineering controls—machines or equipment—that isolate or contain the hazard to reduce worker exposure. Examples include CSTDs and biosafety cabinets.
4. Administrative controls: The fourth level of protection includes safe handling policies, procedures, work practices, and education and training of those responsible for HD handling.
5. PPE: Despite being the lowest on the NIOSH hierarchy and placing the primary responsibility on the worker, PPE is an important aspect of multilevel

efforts for the protection of healthcare workers and consists of garments that provide barriers to protect workers from HDs.

#### I. Guidelines for PPE

##### 1. Apparel

a) Gloves: Wear two pairs of disposable gloves that are powder free and have been tested for use with HDs (U.S. Food and Drug Administration [FDA], 2020).

- (1) FDA requires permeation testing for gloves to be labeled as appropriate for use with HDs. Gloves are not tested for all known HDs because of the cost and lack of assays for many drugs; however, for gloves to be labeled for use with HDs, they must be tested with seven drugs from different classifications: carmustine, cyclophosphamide, doxorubicin, etoposide, 5-fluorouracil, paclitaxel, and thiopeta (ASTM International, 2019; Polovich & Olsen, 2018).
- (2) Gloves that prevent HD permeation for a minimum of 30 minutes should be worn.
- (3) Test results are printed on the glove box or are available from the manufacturer.
- (4) Several types of materials are used to make gloves used for HD handling (e.g., nitrile, polyurethane) (Polovich & Olsen, 2018).
- (5) Tested latex gloves provide protection but should be used with caution because of the potential for latex sensitivity.
- (6) Inspect gloves for physical defects before use.
- (7) Remove and discard gloves immediately after use; if a tear, puncture, or known drug contact occurs; or after 30 minutes of wear (ASHP, 2006; NIOSH, 2004; U.S. Pharmacopeial Convention [USP], 2019).
- (8) Wearing double gloves, with one pair under and one pair over the gown cuff or elastic band, and carefully removing them reduces the opportunity for exposure (NIOSH, 2008).
- (9) When doffing PPE, remove outer gloves, gown, shoe covers (if in use), inner gloves; wash hands with soap and water; don clean gloves to remove mask and face shield (if in use); doff gloves; and rewash hands.

b) Gowns: Wear a disposable, lint-free gown made of a low-permeability fabric, such as polyethylene-coated polypropylene or other laminate materials (Connor, 2006; Polovich & Olsen, 2018; USP, 2019).

- (1) The gown should have a solid front, long sleeves, tight cuffs, and back closure.

- (2) Discard the gown when it is knowingly contaminated, before leaving HD handling areas, and when finished with HD handling.
  - (3) Gowns are meant for single use.
  - (4) Used gowns should not be hung up or reapplied after removal. Single-use gowns minimize the transfer of drug contamination to the environment and worker clothing (NIOSH, 2008).
  - (5) All healthcare workers should wear PPE, which includes a gown tested for use with chemotherapy, when cleaning a spill or if there is a risk of spilling or splashing. If unavailable, use a lint-free gown made of a low-permeability fabric, such as polypropylene or other laminate materials, and two pair of gloves tested for use with chemotherapy. Mask and face protection should also be used.
  - c) Respirators: Wear a NIOSH-approved filtering facepiece respirator, such as a fit-tested N95, or a powered air-purifying respirator when inhalation exposure is possible (NIOSH, 2021).
    - (1) Examples include administering an aerosolized HD or cleaning an HD spill.
    - (2) If gases or vapors are present, wear a chemical cartridge-type respirator (USP, 2019).
    - (3) Consult the drug-specific safety data sheet (SDS) for the type of respirator appropriate for the situation. Surgical masks do not provide respiratory protection from HD aerosols.
  - d) Eye and face protection: Wear goggles and a face shield or a combination of goggles, mask, and face shield that provides splash protection whenever HD splashing is possible.
    - (1) Eye and face protection are necessary when administering HDs in an operating room, working at or above eye level, or cleaning up a spill (USP, 2019).
    - (2) When eye and face protection are worn, remove them last, after other PPE is removed and hands are washed with soap and water. Don clean gloves to remove eye and face protection and rewash hands with soap and water once the eye and face protection and gloves have been removed. This prevents the possible transfer of HD to the face. If administering HDs in an airborne isolation room, wash hands with soap and water after removing all PPE and then don clean gloves to remove face and eye protection (which may be contaminated with microorganisms).
  2. Situations requiring PPE: Wear PPE whenever HDs might be released into the environment. NIOSH recommends that gowns and gloves be worn for all HD handling activities and that eye, face, and respiratory protection be used when splashing or inhalation exposure is possible. The only exception is for administering an intact tablet or capsule provided in a unit-dose package, in which case a single pair of HD-tested gloves is sufficient (NIOSH, 2016). The following situations require PPE (NIOSH, 2004):
    - a) Handling HD vials, ampules, or packaging materials
    - b) Introducing or withdrawing needles or dispensing pins from HD vials
    - c) Transferring drugs from HD vials to other containers using needles or dispensing pins and syringes
    - d) Opening ampules of HDs
    - e) Administering HDs by any route
    - f) Handling HD leakage from tubing, syringe, and connection sites
    - g) Discontinuing infusions of HDs
    - h) Disposing of HDs and items contaminated by HDs
    - i) Handling the body fluids of a patient who has received HDs recently
    - j) Cleaning HD spills
    - k) Touching any surface potentially contaminated with HD residue
- J. Storage and labeling
1. Clinical areas
    - a) Store HD drug containers in a designated location that limits exposure to healthcare workers and provides appropriate storage conditions (e.g., temperature, light).
    - b) Use a distinct label on all HD containers to indicate the hazardous nature of the contents (OSHA, 2016).
    - c) Have access to instructions (e.g., SDSs) regarding what to do for accidental HD exposure.
    - d) Check HD containers before taking them from the storage area to ensure that the packaging is intact and to detect any leakage or breakage.
  2. Patient instructions for HD safety in the home (Polovich & Olsen, 2018; see Figure 12-1)
    - a) Keep HDs out of reach of children and pets.
    - b) Store HDs in containers that protect them from puncture or breakage.
    - c) Label HD containers to indicate the hazardous nature of their contents.
    - d) Provide instructions listing the procedure for handling a damaged HD container.
    - e) Store HDs in an area free of moisture and temperature extremes. Some HDs may require refrigeration.

---

**FIGURE 12-1. Safe Management of Hazardous Drugs in the Home**

---

You are getting medicine used to treat cancer. You must be careful to make sure other people do not accidentally touch the drugs or your body waste (urine, bowel movements, vomit) for a time after treatment. This form teaches you and your family how to protect others from the drugs and how to handle your body waste in your home.

**Hazardous Drugs**

Hazardous drugs are strong chemicals. Only patients who need treatment should take or touch the drugs. Items that touch the medicines (syringes, needles) are contaminated with drugs. Regardless of how you take the medicines, they remain in your body for many hours and sometimes days after your treatment. Your body will get rid of the drugs in your urine or bowel movements. Traces of the drugs also may be present in vomit, sweat, blood, semen, vaginal fluid, and saliva.

**Disposal of Hazardous Drugs**

Dispose of items contaminated with hazardous drugs separately from other trash. If required, the company supplying your medicines and equipment will give you a hard plastic container labeled with "Hazardous Drug Waste" or a similar warning. Place equipment and gloves that have touched these drugs into this container after use. If the waste is too large to fit in the plastic container, place it in a separate plastic bag and seal it tightly with rubber bands. Place sharp objects in the hard plastic container. The company will tell you who will pick up the disposal container.

*Body Waste*

You may use the toilet (septic tank or sewer) as usual. Flush with the lid closed for 48 hours after receiving these drugs. No research supports the effectiveness of double flushing; however, it may be helpful with low-volume flush toilets. Wash your hands well with soap and water afterward, and wash your skin if urine or bowel movement gets on it. Pregnant women, children, and pets should avoid touching the drugs or contaminated waste.

*Laundry*

Wash your clothing or linens normally, unless they become soiled with the drugs or body fluids, such as urine, bowel movement, or vomit. If that happens, put on disposable gloves and handle the laundry carefully to avoid getting the drugs on your skin. If you do not have a washer, place soiled items in a plastic bag until they can be washed. Wash separately from other laundry.

*Skin Care*

Hazardous drugs spilled on the skin may be irritating. If this happens, thoroughly wash the area with soap and water, then dry. Call your doctor if redness lasts for more than one hour or if a rash occurs. To prevent hazardous drugs from being absorbed through the skin, wear gloves when working with the drugs, drug-soiled equipment, or waste.

*Eye Care*

If any hazardous drug splashes into your eyes, flush them with water for 10–15 minutes and notify your doctor.

**Questions and Answers**

*Is it safe for family members to have contact with me during my treatment?*

Yes. Eating together, enjoying favorite activities, hugging, and kissing are all safe.

*Is it safe for my family to use the same toilet as I do?*

Family members should use separate toilets from the patient for 48 hours after hazardous drug administration to eliminate the risk of contact with contaminated body waste. In households with only one bathroom, patients can keep sanitizing wipes near the toilet to clean the seat and rim after use. The wiping action physically removes hazardous drug residue from surfaces. Following toileting and cleaning, patients should wash their hands with soap and water before touching other surfaces or items. At the end of 48 hours, the toilet and bathroom floor should be washed (Polovich & Olsen, 2018).

*What should I do if I do not have control of my bladder or bowels?*

Use a disposable, plastic-backed pad, diaper, or sheet to soak up urine or a bowel movement. Change immediately when soiled, and wash skin with soap and water. If you have an ostomy, your caregiver should wear gloves when emptying or changing the bags. Discard disposable ostomy supplies in the hazardous drug waste container.

*What if I use a bedpan, urinal, or commode?*

Your caregiver should wear gloves when emptying body wastes. Reusable items contaminated with body fluids during and for at least 48 hours after therapy should be handled with gloves and washed with soap and water.

*What if I vomit?*

Your caregiver should wear gloves when emptying the basin. The container should be washed with soap and water.

---

(Continued on next page)

**FIGURE 12-1.** Safe Management of Hazardous Drugs in the Home (*Continued*)*Is it safe to be sexually active during my treatment?*

Ask your doctor or your nurse this question. Traces of hazardous drugs may be present in vaginal fluid and semen for up to 48 hours after treatment. Special precautions may be necessary.

*How should I store hazardous drugs at home?*

You should store hazardous drugs and equipment in a safe place, out of reach of children and pets. Do not store hazardous drugs in the bathroom, as high humidity may damage the drugs. Check medicine labels to see if your drugs should be kept in the refrigerator or away from light. Be sure all medicines have complete labels.

*Is it safe to dispose of hazardous drugs in the trash?*

No. Hazardous drug waste is dangerous and requires separate handling. If you are receiving IV drugs at home, you should have received a special waste container for the drugs and equipment. This includes used syringes, needles, tubing, bags, cassettes, and vials. This container should be hard plastic and labeled with "Hazardous Drug Waste" or a similar warning. Follow disposal instructions from your healthcare team.

*Can I travel with my hazardous drugs?*

Yes. Usually, traveling is no problem. Some hazardous drugs require special storage (refrigeration), so you may need to make special arrangements. Check with your nurse, doctor, or medicine supplier for further instructions. Regardless of your means of travel (airplane, car), always seal your drugs in a plastic bag.

*What should I do if I spill some hazardous drugs?*

You will have a spill kit if you receive IV drugs at home. In the event of a drug spill, open the spill kit and put on two pairs of gloves, the mask, gown, and goggles before touching anything. Move others away from the spill. Absorb the spill with the disposable sponge or towels, and put them directly in the bag provided. Clean the area with dishwashing soap or detergent and water. If the spill occurs on sheets or clothing, handle them with gloves and wash them separately from other laundry. Wash clothing or bed linen soiled with body wastes in the same manner. Remove the face shield, mask, gown, and then the gloves. Place them in the plastic bag and close it. Place the first plastic bag into a second plastic bag and close it. Wash your hands with soap and water. Call the home health nurse, clinic, or doctor's office promptly to report the spill. They will let you know about plans to replace the spilled drug to complete treatment. They will also arrange to pick up the waste material or tell you where to bring it for proper disposal.

- f) Provide HD spill kits and instructions for use.
- g) Give verbal and printed or electronic instructions about handling and storing HDs, disposing of HD waste, and what to do with unused drugs.

## K. Safe handling precautions during compounding

1. USP (2019) General Chapter 800 (<800>) describes standards for the preparation of HDs. The environment in which sterile HD preparation takes place must meet all requirements for ventilation, including air exchanges per hour, particle counts, and negative pressure. See USP (2019) for the complete standards. Additionally, nonsterile drugs must be prepared following standards in Pharmaceutical Compounding—Nonsterile Preparations <795> and sterile compounding must follow standards in <797>.
2. Engineering controls
  - a) Engineering controls for compounding are divided into three categories—primary, secondary, and supplemental.
  - b) Sterile and nonsterile HDs should be prepared in a C-PEC, a ventilated device that minimizes worker and environmental HD exposure when directly handling HDs (USP, 2019).

- c) The containment secondary engineering control is the room in which the C-PEC is placed.
- d) Supplemental engineering controls, such as CSTDs, are adjunct controls to offer additional levels of protection (USP, 2019).
- e) According to NIOSH (2004), a CSTD is "a drug transfer device that mechanically prohibits the transfer of environmental contaminants into the system and the escape of hazardous drug or vapor concentrations outside the system" (p. 44). CSTDs are supplementary engineering controls and do not eliminate the need for a C-PEC or PPE (NIOSH, 2004; USP, 2019).
- f) Requirements for C-PECs
  - (1) The C-PEC must be located in a containment secondary engineering control, an area physically separate from other preparation areas and at negative pressure relative to an adjacent ante area (USP, 2019).
  - (2) It must be externally vented (preferred) or have redundant HEPA filters in series vented to the outside (USP, 2019).
  - (3) Examples include CVE (containment ventilated enclosure), class I–II biosafety cabinet, and CACI (compounding aseptic containment isolator).

- (4) The C-PEC must be used by individuals trained to employ techniques that reduce contamination.
  - (5) It must be cleaned, decontaminated, and disinfected at the end of drug preparation or immediately if a spill occurs (USP, 2019).
  - (6) The C-PEC must be serviced according to the manufacturer's recommendations.
  - (7) It must be recertified after relocation, repair, filter replacement, or every six months (Gilpin, 2018; OSHA, 2016).
  - (8) When nonsterile HDs are being prepared, such as oral drugs that require compounding or crushing, a separate C-PEC should be used (NIOSH, 2016; USP, 2019). The same C-PEC designated for sterile preparations may be occasionally used, but it must be decontaminated, cleaned, and disinfected afterward (USP, 2019). For entities that compound nonsterile and sterile HDs, the respective C-PECs must be placed in separate rooms unless those used for nonsterile compounding are sufficiently effective that the room can continuously maintain ISO7 classification throughout the nonsterile compounding activity (USP, 2019).
  - (9) A plastic-backed preparation mat should be placed on the work surface of the C-PEC (USP, 2019). The mat should be changed immediately if a spill occurs and regularly during use. It should be discarded at the end of the daily compounding activity. Disposable or clean equipment for compounding (e.g., spatulas) must be dedicated for use with HDs.
  - (10) Limit the number of items placed in the C-PEC to avoid interfering with airflow (ASHP, 2006).
  - (11) Use tubing and syringes with Luer-lock fittings. A CSTD is recommended (USP, 2019).
  - (12) Avoid filling syringes more than three-fourths full (ASHP, 2006). An overfilled syringe may separate from the plunger end. Apply a tightly fitted dead-end Luer cap or a CSTD to the end of the syringe if the dosage form allows. Syringes should not be dispensed with needles attached.
  - (13) In the pharmacy, use a CSTD to minimize leakage and exposure (Sessink et al., 2011, 2013; Siderov et al., 2010; Yoshida et al., 2013).
  - (14) Glass IV bottles should not be used for HDs because of the need for venting and the potential for breakage, which can result in exposure (Polovich & Olsen, 2018).
  - (15) Other activities that should not be performed outside of a C-PEC
    - (a) Expelling air from an HD-filled syringe
    - (b) Spiking IV bags containing HDs with IV tubing, unless a CSTD adapter is used to allow for a dry spike
    - (c) Priming IV tubing with HDs
    - (d) Crushing group 1 HD tablets
  - (16) Place a label on each HD container that says "hazardous drug" or a similar distinct warning.
  - (17) Wipe the outside of the HD container (e.g., syringe, IV bag) with a moistened wipe before placing it in a transparent, sealable bag and then inside an additional bag for transport. Wiping the final preparation will physically remove surface contamination (ASHP, 2006). Discard the wipe as contaminated waste. Avoid transferring HD contaminants to the outside of the transport bag.
  - (18) Dispose of all material that has come into contact with an HD in a waste container designated for hazardous waste.
- g) Requirements for containment secondary engineering control
- (1) Be externally vented
  - (2) Be physically separated (in a different room from other preparation areas)
  - (3) Have an appropriate air exchange
  - (4) Have a negative pressure between 0.01–0.03 inches of water column relative to all adjacent areas (USP, 2019)
- h) Requirements for CSTDs
- (1) CSTDs are a common containment supplemental engineering control, providing additional protection during compounding or administration.
  - (2) Some CSTDs have been shown to limit aerosols during compounding and administration. However, no universal performance standard exists, and CSTDs should be selected based on independent, peer-reviewed studies demonstrating containment reduction.
  - (3) CSTDs cannot substitute for a C-PEC and must be used when administering antineoplastic drugs when the dosage form allows.

- (4) If a CSTD is physically or chemically incompatible with a specific HD, use an alternate CSTD that is compatible (USP, 2019).

i) Requirements for PPE

- (1) Wash hands before donning PPE.
- (2) Wear PPE tested for use with HDs.
- (3) When doffing PPE, remove outer gloves, gown, shoe covers (if used), and inner gloves; wash hands with soap and water; don clean gloves; and remove mask and face shield (if used). Remove gloves and rewash hands.
- (4) For a spill in which a powered air-purifying respirator (PAPR) or chemical cartridge mask is used, a clean pair of gloves should be worn to remove the PAPR/cartridge mask, and it should be placed on a plastic-backed pad. Gloves should then be removed and hands washed. A final pair of gloves would be needed to clean the equipment per the manufacturer's guidelines. After, the gloves should be removed and hands washed again.

L. Transporting HDs (OSHA, 2016)

1. Transport syringes containing HDs in a sealed container with the Luer-lock end of the syringe capped. Do not transport syringes with attached needles.
2. Select a transport receptacle that can contain HD spillage if dropped (e.g., a leakproof, zipper-lock bag), and add impervious packing material as necessary to avoid damage during transport. Double bagging is considered a best practice to minimize the transfer of HD on surfaces during delivery to the administration area.
3. Label the outermost HD receptacle with a distinct label to indicate hazardous contents.
4. Do not transport parenteral antineoplastic drugs or liquid HDs in a pneumatic tube (USP, 2019).
5. Ensure that whoever transports HDs has access to a spill kit and is trained in HD spill cleanup.
6. Personnel who transport HDs must document their training according to OSHA standards and other applicable laws and regulations (USP, 2019).

M. Safe handling precautions during administration (ASHP, 2006; OSHA, 2016; Polovich & Olsen, 2018; USP, 2019; see Appendix G)

1. Don PPE tested for use with HDs before reaching into the delivery bag to remove the drug container. Do not lay the HD container on a surface unless there is a disposable, plastic-backed pad covering the surface.

2. Inspect the drug delivery bag and its contents for leakage prior to handling.
3. Work below eye level.
4. Ensure that a spill kit and HD waste container are available.
5. Wear a mask with face protection if there is a potential for HD splashing.
6. Use a CSTD when the dosage form allows.
7. When a CSTD cannot be used, place a disposable, absorbent, plastic-backed pad on the work area to absorb any drug that may spill.
