8. Use needles, syringes, and tubing with Luer-lock connectors.
9. Do not use glass bottles for HDs.
10. When administering HDs as a secondary infusion, it is recommended that back priming using a non-HD solution be used. With consistent use of CSTDs at all access points (e.g., bag spike adapters, Luer lock IV site connectors, IV tubing sets) and appropriate PPE, priming with non-HD solution via backflow/back prime method can assist with maintaining a closed system to prevent exposure. After HD administration, the back prime method can be repeated to flush the drug to ensure full medication delivery (Institute for Safe Medication Practices [ISMP], 2021). Some CSTDs only allow forward or one-way flow, which may limit the ability to back prime. If back priming is not an option, a safe strategy should be used to flush the tubing after administration to ensure the patient receives all the antineoplastic (ISMP, 2021).
11. When administering HDs as a primary infusion, the tubing can be primed with a non-HD solution. The primary tubing can also be primed with a bag of non-HD solution by the nurse, and then the tubing can be spiked into the CSTD infusion adapter spike at the point of administration. Never spike directly into an HD bag without a CSTD infusion adapter spike.
12. For drugs with a high risk of reaction (e.g., rituximab, paclitaxel), it is preferred to prime administration tubing with the drug to be more aware of when it is reaching the patient and better monitor for acute hypersensitivity reaction (see Chapter 11). In these scenarios, it is required for the pharmacy to prime the tubing with the HD drug solution within the C-PEC and deliver this with a CSTD attached to the end of the tubing. It should be clearly labeled that the line is primed with the drug to notify the receiving nurse of this setup. This procedure may also be followed for investigational drugs per sponsor requirements.
13. If using secondary tubing to administer sequential HDs, use a CSTD at the port above the pump so that the tubing can be safely disconnected and discarded with each subsequent dose. Never unspike or unhook a secondary tubing that contains an HD without a CSTD.

14. If using primary tubing to administer sequential HDs, use a CSTD at the closest port to the patient side so that tubing can be safely disconnected and discarded with each subsequent dose.
15. More research is needed on the safety of the circle priming practice. Ideally, the pharmacy should prime the tubing and apply a CSTD to the end of the tubing. If circle priming is a practice approved by individual facilities, policies must ensure strict monitoring of aseptic techniques to prevent microbial contamination and safe handling practices to control for potential exposure. Priming of tubing with HDs even partially should never be performed outside of the C-PEC.
16. After IV drug administration, remove the IV container with the tubing attached (NIOSH, 2004; Polovich & Olsen, 2018). Do not remove the spike from IV containers to reuse tubing.
17. Remove outer gloves before touching equipment.
18. Discard all HD-contaminated material and PPE in a designated hazardous waste container.
19. Wash hands with soap and water (not alcohol-based hand gels) because friction and rinsing are needed to remove HDs.
20. When doffing PPE, remove outer gloves, gown, shoe covers (if used), and inner gloves; wash hands with soap and water; don clean gloves; and remove mask and face shield (if used). Remove gloves and rewash hands.
21. In the event a PAPR or chemical cartridge mask is used, a clean pair of gloves should be worn to remove the PAPR/cartridge mask, and it should be placed on a plastic-backed pad. Gloves should then be removed and hands washed. A final pair of gloves would be needed to clean the equipment per the manufacturer's guidelines. After, the gloves should be removed and hands washed again.
22. Use detergent and water or cleansing wipes to wipe surfaces that come into contact with HDs (Polovich & Olsen, 2018).

#### N. Special precautions for radiopharmaceuticals

1. Special precautions are necessary to protect healthcare workers from exposure while caring for patients receiving radiopharmaceuticals. Radiation protection standards and regulations are determined by the U.S. Nuclear Regulatory Commission, FDA (radiopharmaceuticals), and state radiation regulatory agencies (U.S. Environmental Protection Agency, 2022). Although infusion nurses are not directly administering these drugs, patient body fluids, especially urine, serve as a source of radiation exposure.
2. Occupational radiation exposure should be kept as low as reasonably achievable. Three factors help provide protection (McQuestion et al., 2021).

- a) Time: Limit the time spent near the radioactive source. Radiation exposure is directly proportional to the time spent near the source. After a patient receives radiopharmaceuticals, the patient is considered the radioactive source. The patient's body can absorb or shield many of these particle types, limiting exposure to bystanders and healthcare workers.
- b) Distance: Maximize the space between personnel and the radioactive source. Radiation exposure decreases as the distance from the radioactive source increases.
- c) Shielding: Add a protective barrier between the radioactive source and personnel. The type of shielding used depends on the type of radiation.

3. Radiation monitoring devices are used to measure occupational exposure. An electronic personal dosimeter is the most widely used monitoring device. Healthcare workers who have the potential to receive significantly more than 10% of the annual effective dose limit during their duties (per the judgment of the radiation safety officer) and those who enter radiation areas should have an electronic personal dosimeter. The dosimeter should only be worn within the work environment, be changed according to institutional guidelines, and not be shared with anyone else. Ring dosimeters and pocket ion chamber dosimeters also exist. Monitoring the environment is also recommended (McQuestion et al., 2021).

#### O. Handling body fluids

1. After HDs
  - a) In general, safe handling precautions are recommended when handling a patient's body fluids for at least 48 hours after drug administration; however, some HDs may be present in excreta longer. If information about longer excretion time is known, use precautions for the entirety that HDs are likely to be present. Patients receiving oral HDs are expected to have HD residue in their excreta throughout therapy and at least 48 hours after the final dose.
  - b) Wear double gloves tested for use with HDs and a disposable gown when handling a patient's body fluids after receiving HDs. Wear a face shield if splashing is possible (NIOSH, 2016).
  - c) For an incontinent patient, clean the patient's skin well with each diaper change. Apply a protective barrier ointment to the skin of the diaper area to decrease the chance of irritation from contact with drug metabolites (Polovich & Olsen, 2018).
  - d) Consider external urine collection devices for male and female incontinent patients to contain

the body fluid (e.g., condom catheters, external urine management systems).

- e) Flush the toilet with the lid down after disposing of excreta from a patient who has received HDs. Cover the open toilet with a plastic-backed pad to prevent splashing or release of aerosols during flushing when a lid is not present. No research supports the effectiveness of double flushing in reducing contamination, but this may be helpful with low-volume-per-flush toilets (Polovich & Olsen, 2018).
2. After radiopharmaceuticals (McQuestion et al., 2021)
  - a) Institute standard precautions (gloves and gown) when handling body fluids (e.g., sweat, saliva, urine, bowel movements, blood, semen, vaginal fluid). The duration of precautions varies depending on the radionuclide half-life.
  - b) Consult the radiation safety officer or nuclear pharmacist for precautions based on the specific radioisotope.
  - c) Education for patients and families is also recommended (McQuestion et al., 2021).

#### P. Handling patient linens

1. After HDs (Polovich & Olsen, 2018)
  - a) To the extent possible, preclude the need for laundering linens and clothing by using disposable linens or leakproof pads to contain HD-contaminated body fluids.
  - b) Handling of HD-contaminated bed linens and clothing while wearing PPE
    - (1) In the hospital setting
      - (a) Contaminated linens should be double bagged. Ensure the outer bag is leakproof.
      - (b) In most institutions, all linens are handled as contaminated by laundry personnel before washing.
    - (2) In the home setting (Polovich & Olsen, 2018)
      - (a) Wearing gloves, place contaminated linens into a washable pillowcase, and keep them separate from other items.
      - (b) Machine wash linens and cloth diapers twice with regular detergent and separately from other household items.
      - (c) Discard disposable diapers in plastic bags to prevent leakage.
      - (d) Discard used gloves in an HD waste container or household trash based on local requirements.
2. After radiopharmaceuticals: If body fluids are present, use standard precautions (gloves and barrier

gowns) when handling the linens of a patient who has received radiopharmaceuticals (McQuestion et al., 2021).

#### Q. Disposal of HDs and materials contaminated with HDs

1. In the hospital setting (NIOSH, 2004)
  - a) Place soft contaminated materials into a sealable, leakproof bag or a rigid hazardous waste container marked with a brightly colored label indicating the content's hazardous nature.
  - b) Use puncture-proof containers for sharp or breakable items. Dispose of needles and syringes intact; do not break or recap needles or crush syringes.
  - c) Seal containers when full.
  - d) Do not dispose of drug-contaminated items in infectious waste (red) containers. Some facilities autoclave these materials, which does not deactivate HDs (NIOSH, 2004; Smith, 2002).
  - e) Follow institutional policy regarding disposal of partial doses of HDs when administration is interrupted. Some drugs must be discarded as hazardous waste in designated containers if the container is not empty (Residues of Hazardous Waste in Empty Containers, 2011).
  - f) Only environmental services personnel who have received safe handling instructions should handle hazardous waste containers. Personnel should use PPE tested for use with HDs.
2. In the home setting (Polovich & Olsen, 2018)
  - a) Some agencies that provide HDs arrange for the proper disposal of contaminated equipment.
  - b) Designate an area where filled containers are placed for pickup, preferably locked and away from children and pets.
  - c) Follow county and state regulations regarding the disposal of HD waste.

#### R. Procedures following acute HD exposure

1. Accidents, improper technique, faulty equipment, or negligence in C-PEC operation can lead to exposure.
2. Initial interventions
  - a) In the event of skin exposure, remove any contaminated garments and immediately wash contaminated skin with soap and water. Refer to the SDS for agent-specific interventions.
  - b) In case of eye exposure, immediately flush the eye with saline solution or water for at least 15 minutes (ASHP, 2006), then seek emergency treatment. Areas where HDs are handled should have a sink with an eyewash station. Two functionally equivalent and cost-effective alternatives to an eyewash station are an IV bag of 0.9% sodium chloride solution connected to IV tubing or an irrigation bag of water or normal saline attached to the tubing to flush eyes (ASHP, 2006).

- c) In the event of inhalation exposure, move away from the area as quickly as possible. Depending on the severity of symptoms, seek emergency treatment from an employee health professional or emergency department. Refer to the SDS for agent-specific interventions.
  - d) For accidental ingestion, do not induce vomiting unless indicated in the SDS. Depending on the severity of symptoms, seek emergency treatment from an employee health professional or emergency department. Refer to the SDS for agent-specific interventions.
3. Reporting (Polovich & Olsen, 2018)
- a) Employee exposure: Report HD exposure to the employee health department or as institutional policy requires.
  - b) Patient exposure: Report HD exposure as institutional policy requires. In addition, inform the patient's healthcare providers.

#### S. Spill management

1. Spills result in contamination of the environment and are a source of exposure for healthcare workers and others; therefore, HD spills must be contained and cleaned up as soon as possible (USP, 2019). Even a small-volume spill should be considered a source of exposure and handled appropriately. Spill kits must be available wherever HDs are stored, transported, prepared, or administered, including the home setting (see Figure 12-2). Train those responsible for spill management in spill cleanup. Because a qualified person must be available for spill cleanup whenever HDs are handled (USP, 2019), many organizations train all HD handlers. Some facilities may designate a hazardous materials response team to clean up large spills (Occupational Safety and Health Standards, 2004). All workplaces should have standard

operating procedures that cover the essential points of spill management.

- a) All healthcare workers should wear PPE, which includes a gown tested for use with chemotherapy, when cleaning a spill or if there is a risk of spilling or splashing. If unavailable, use a lint-free gown made of a low-permeability fabric, such as polypropylene or other laminate materials; two pair of gloves tested for use with chemotherapy; face protection; and respiratory protection based on the drug. Face protection is required to prevent droplets from contacting the eyes. Respiratory protection is intended to prevent inhalation of powders, aerosols, or vapors.
- b) Assess the exposure of any individuals involved and isolate them from the spill. If an individual's skin or clothing has contacted the HD, immediately remove the contaminated clothing and wash with soap and water. Additional personnel trained in the safe handling of HDs can assist the exposed individual while others attend to the spill.
- c) Spill kits should be located in all areas where HDs are routinely handled and if HDs are being prepared or administered in a nonroutine area. Keep others out of the area during cleanup and, if possible, have a second trained person assist with holding the spill waste disposal bag.
- d) Wear a NIOSH-approved respirator appropriate for the spilled agent (OSHA, 2016). This may include a PAPR if the capacity of the spill kit is exceeded or if airborne exposure to vapors or gases is known or suspected.
- e) Use items in the spill kit to contain the spill, such as absorbent pads, cloths, or spill control pillows.
- f) Clean up the spill according to its location and type. Access the SDS for the spilled agent to determine if a deactivator is recommended.
- g) Begin with the least-contaminated area and finish with the most-contaminated area to prevent spreading the spilled drug to noncontaminated areas.
- h) Rinse the area with water and then clean with detergent, sodium hypochlorite solution, neutralizer, or other validated decontamination solution (Power & Coyne, 2018).
- i) Rinse the area with plain water several more times. Adequate dilution of HD residue is necessary to ensure that the drug and any chemical residue have been removed and transferred to the wipes.
- j) Discard all material used in cleanup in an HD waste bag. Seal the waste bag and place it in a puncture-proof container designated for HD waste.
- k) After handling and disposal of HDs, remove the outer gloves, turning them carefully inside

**FIGURE 12-2.** Contents of an Antineoplastic Spill Kit

- 2 pairs of disposable gloves that have been tested for use with hazardous drugs
- Disposable, chemical-resistant gowns (with back closure)
- Chemical-resistant shoe covers
- Chemical splash goggles
- National Institute for Occupational Safety and Health–approved respirator masks
- Absorbent, plastic-backed sheets or spill pads
- At least 2 sealable thick plastic hazardous waste disposal bags with an appropriate warning label
- A puncture-resistant container

This may not include everything needed in the event of a spill (e.g., other items may be specific to the homecare environment/carpeting). Some contents degrade or expire over time. It may make sense to make custom kits for those on spill response teams with an appropriate, fit-tested mask.

*Note.* Based on information from American Society of Health-System Pharmacists, 2006; Polovich & Olsen, 2018.

out to avoid touching the outside. When doffing PPE, remove outer gloves, gown, shoe covers (if used), and inner gloves; wash hands with soap and water; don clean gloves; and remove mask and face shield (if used). Remove gloves and rewash hands.

- l) In the event a PAPR or chemical cartridge mask is used, a clean pair of gloves should be worn to remove the PAPR/cartridge mask, and it should be placed on a plastic-backed pad. Gloves should then be removed and hands washed. A final pair of gloves would be needed to clean the equipment per the manufacturer's guidelines. After, the gloves should be removed and hands washed again.
- m) Carpeting should be avoided in patient care settings. Several studies have documented bacterial growth and persistence in carpeting, and it is impossible to decontaminate an HD spill on carpeting (Centers for Disease Control and Prevention, 2019). If a spill occurs on carpeting (more likely in the home setting), whoever cleans the spill should don PPE and appropriate respiratory protection. An absorbent powder should be used, and the area should be vacuumed to remove the dried powder. A vacuum used in spill cleanup should be equipped with a HEPA filter to contain the HD-contaminated absorbent powder and limit further environmental contamination (Polovich & Olsen, 2018).
- n) All previous entries apply to the home setting; however, after donning PPE, dishwashing or laundry detergent and water with disposable cloths or paper towels are the recommended cleaning agents, followed by water with disposable towels. All used towels should go in a plastic bag with the used PPE. That bag should go in a second bag. Any linen or clothing that came into contact with the spill should be washed separately from other laundry. The home health nurse, clinic, or doctor's office should be called promptly to report the spill and provide guidance on using the spill kit. They will let the patient know about the need to replace the spilled drug to complete treatment. They will also arrange to pick up the waste material or tell the patient or caregiver where to bring it for proper disposal (Polovich & Olsen, 2018).
- o) Cleaning up a spill in a biosafety cabinet or compounding aseptic containment isolator (ASHP, 2006)
  - (1) Clean the spill according to the guidelines for a spill. Complete cleanup by rinsing the surface with a sterile water rinse (Polovich & Olsen, 2018).

- (2) Include the drain spillage trough in the cleaning and decontamination efforts.
- (3) If the spill contaminated the HEPA filter, seal the open front of the biosafety cabinet in plastic. Label any C-PEC as contaminated equipment. Schedule a C-PEC service technician to change the HEPA filter. Ensure that the C-PEC is not used before the filter is replaced.

- p) Cleaning up a spill in the home setting (see Figure 12-1)
- q) Report and document HD spills according to institutional policy. For any spill, complete a report about the spill and forward it to those specified by institutional policy (ASHP, 2006). Document the following:
  - (1) Name of the drug
  - (2) Approximate volume of the spill
  - (3) How the spill occurred
  - (4) The spill management procedures followed
  - (5) The names of personnel, patients, and others exposed to the spill
  - (6) A list of personnel notified of the spill

2. In the case of a spill of a radiolabeled mAb or contamination with the radioactive body fluid of a patient recently treated with radiopharmaceuticals, perform the following (McQuestion et al., 2021):
  - a) In case of contact with skin or eyes, the affected area should be flushed immediately with water.
  - b) In the event of spillage of radiopharmaceuticals, the radiation safety officer should be contacted immediately to initiate the necessary measurements and required procedures to decontaminate the area. To remove the contamination, a complexing agent, such as ethylenediaminetetraacetic acid (EDTA) solution, is recommended.
  - c) Protective shields for needles and containers must be used.
  - d) Clinicians must observe local regulations for procedures involving unsealed radioactive resources.
  - e) Use of 1 cm thick acrylic glass or lead-loaded acrylic glass shields during labeling is required.
  - f) Forceps and tongs should be used as gripping tools.
  - g) Plastic gloves, disposable waterproof gowns, and acrylic glass eye protection should be used.

#### T. Requirements for policies regarding the handling of HDs

1. Occupational Safety and Health Standards (2004) require that employers provide a safe and healthful workplace. Employers must implement policies and procedures related to the safe handling of HDs. Policies should address all aspects of handling these hazardous chemicals to protect employees, patients, families, and the environment from contamination.

2. Such policies must do the following (NIOSH, 2004; USP, 2019):
  - a) Outline procedures to ensure the safe storage, transport, administration, and disposal of hazardous agents.
  - b) Describe the procedure for identifying new HDs and updating the list of HDs used in the facility.
  - c) Require that all employees who handle HDs wear PPE.
  - d) Mandate that HDs be prepared in a biosafety or compounding aseptic containment isolator (USP, 2019).
  - e) Prohibit staff from eating, drinking, smoking, chewing gum, using tobacco, storing food, and applying cosmetics in areas where HDs are prepared or administered.
  - f) Mandate initial training for all employees who prepare, transport, or administer HDs or care for patients receiving these drugs prior to assuming these responsibilities and require documented personnel competency at least annually (USP, 2019).
  - g) Require training to include the risks of exposure and appropriate procedures for minimizing exposure; the policy should describe how training is documented (OSHA, 2012; USP, 2019).
  - h) Require that documents such as SDSs are available to healthcare workers who handle HDs.
  - i) Describe the procedures for the management of HD spills.
  - j) Set forth a plan for medical surveillance of personnel handling HDs.
  - k) Ensure that employees of reproductive capability acknowledge in writing that they have been informed of the risks of HD exposure around pregnancy (USP, 2019).
  - l) Address HD handling for workers who are actively trying to conceive or who are pregnant or breastfeeding.
    - (1) Even when all recommended precautions are used, the potential for accidental exposure cannot be eliminated.
    - (2) Developing fetuses and newborn infants may be more susceptible to harm from certain HDs. Therefore, an additional level of protection is recommended for those most vulnerable to the reproductive and developmental effects of HDs (Connor et al., 2014).
    - (3) Degree of risk to the employee is difficult to quantify and may be based on length of and type of exposure, adoption of full PPE recommendations, and use of closed-system drug-transfer devices and other engineering and administrative controls associated with safe handling.
    - (4) Institutional policy should describe the process for requesting accommodation, options available to staff members, and the ability of the institution to provide an alternative assignment. Where feasible, employees who request alternative duty for one of the noted conditions should be provided with responsibilities that do not include the handling of HDs. The ability of an employer to provide alternative duty is fluid and may vary based on census, staffing, or other factors. Whenever possible, the Oncology Nursing Society supports the provision of alternative duty to reduce risk of adverse health outcomes in individuals who are pregnant, breastfeeding, or trying to conceive and supports high level institutional strategies to operationalize fulfilling alternative assignment requests for these individuals (Oncology Nursing Society & Hematology/Oncology Pharmacy Association, 2019).
    - (5) The employee is responsible for notifying the employer of the specific situation (e.g., preconception, pregnancy, breastfeeding). The American College of Occupational and Environmental Medicine provides guidelines for reproductive hazard management (Meyer et al., 2016).
    - m) Define quality improvement programs that monitor compliance with safe handling policies and procedures.

## CHAPTER 13

# Infusion-Related Complications

A. Complications during or shortly after parenteral administration of cancer treatment (Gill et al., 2018; Gorski et al., 2021; Kreidieh et al., 2016)

1. Infiltration: passage or escape of intravenously administered drugs into the tissue
2. Vesicant extravasation: inadvertent leakage of drugs capable of causing tissue damage into the subcutaneous or subdermal tissue or other unintended sites (e.g., pleural space)
3. Irritation: a localized inflammatory reaction at the infusion or injection site
4. Flare reaction: a local allergic reaction along a vein caused by irritating drugs
5. Infusion reactions: reactions mediated by the immune system (e.g., hypersensitivity, anaphylaxis, cytokine release syndrome [CRS])

B. Extravasation of vesicants resulting in potential tissue damage

1. Pathophysiology: occurs as a result of one of two primary mechanisms
  - a) DNA-binding vesicants: The vesicant binds to nucleic acids in the DNA of healthy cells in the tissue, causing cell death. The dead cells release complexes taken up by adjacent healthy cells. The cellular uptake of extracellular substances creates a continuing cycle of tissue damage as the DNA-binding vesicant is retained and recirculated in the tissue for an extended period (Luedke et al., 1979). DNA-binding vesicants include anthracyclines (e.g., daunorubicin, doxorubicin, epirubicin, idarubicin), dactinomycin, mitomycin C, mitoxantrone, and trabectedin (Chang, 2020; Kreidieh et al., 2016; Theman et al., 2009).
  - b) Non-DNA-binding vesicants: The vesicant does not bind to cellular DNA and has an indirect effect on cells in healthy tissue (e.g., nonphysiologic pH, nonphysiologic osmolarity) (Ong & Van Gerpen, 2020). These vesicants are eventually metabolized in the tissue and are more easily neutralized than DNA-binding vesicants (Ener et al.,

2004). Examples of non-DNA-binding vesicants include plant alkaloids (e.g., vinblastine, vincristine, vindesine, vinorelbine) and taxanes, which as a group, have usually been classified as mild vesicants. Examples of taxanes include the following (Ener et al., 2004; Schrijvers, 2003; Stanford & Hardwicke, 2003):

- (1) Cabazitaxel infiltration has not caused skin or tissue impairment based on clinical trials and postmarketing reports at the time of this writing (Sanofi-Aventis U.S., 2021a).
- (2) Docetaxel extravasation may cause hyperpigmentation, erythema, and tenderness (Sanofi-Aventis U.S., 2021b).
  - (a) In a case report, erythema with significant swelling and accompanying reduction of arm range of motion was noted on the day following docetaxel extravasation from an implanted port. Despite dexamethasone and chlorpheniramine treatment, erythema progressed to  $18 \times 15$  cm in size one week later (Chang et al., 2014).
  - (b) Su et al. (2020) described bullous lesions following the venous tract after docetaxel extravasation.
  - (c) Another case study showed treatment with intralesional steroids hastened cutaneous resolution after peripheral extravasation of docetaxel (Roman et al., 2017).
  - (d) Recall dermatitis at a previous docetaxel extravasation site, occurring during subsequent docetaxel administration in another location, also has been reported (Kramer et al., 2011).
- (3) Paclitaxel injection site reactions, including reactions secondary to extravasation,

are usually mild and consist of erythema, tenderness, skin hyperpigmentation, or swelling at the injection site. These reactions have been observed more frequently with 24-hour infusions than 3-hour infusions.

- (a) Recurrence of skin reactions at a site of previous extravasation following administration of paclitaxel injection at a different site (recall reactions) has been reported.
- (b) More severe events, such as phlebitis, cellulitis, induration, skin exfoliation, necrosis, and fibrosis, have been reported. In some cases, onset occurred during a prolonged infusion or was delayed by 7–10 days (Hospira, 2021d).
- (c) Most clinical reports of paclitaxel extravasation were published in the first few years following its U.S. Food and Drug Administration approval and were reviewed by Stanford and Hardwicke (2003). They concluded that paclitaxel was a “mild vesicant” (p. 276).
- (d) Data suggest that the potential for tissue damage is dependent on paclitaxel concentration and infusion duration (Barbee et al., 2014).
- (4) Docetaxel and paclitaxel have also been classified as exfoliants, or drugs that may cause skin inflammation and peeling, without causing the underlying tissue death that typically occurs with true vesicants (Kreidieh et al., 2016).
- (5) Phlebitis, cellulitis, induration, fibrosis, and necrosis following extravasation of paclitaxel protein-bound particles for injectable suspension (Abraxane®) have been identified with postapproval use and reported to the manufacturer. In some cases, the onset of symptoms occurred during a prolonged infusion or was delayed by 7–10 days.
- (6) The available published literature supports the safety of IV administration of taxanes at recommended concentrations and durations using peripheral venous access (Barbee et al., 2014). However, some patients may require central venous access device (VAD) insertion for taxane administration (Jackson-Rose et al., 2017). In some institutions, paclitaxel may be admin-

istered for longer than 60 minutes through a peripheral line on an infusion pump. Institutions should establish monitoring procedures to minimize the risk of extravasation. Peripheral infusion of taxanes requires diligent monitoring of the site by nurses and engagement of patients to report any signs or symptoms of infiltration.

2. Factors affecting tissue damage severity following vesicant extravasation (Schulmeister, 2011)
  - a) Type of vesicant extravasated: DNA-binding vesicants cause greater tissue damage than non-DNA-binding vesicants.
  - b) Concentration and amount of vesicant in the tissue: Higher concentration or greater volume causes more damage.
  - c) Location of extravasation: Areas with little subcutaneous tissue and those overlying veins, arteries, and nerves are more likely to have more significant damage.
  - d) Patient factors: Older age, comorbidity (e.g., diabetes), and impaired immunocompetence are factors.
3. Risk factors for peripheral extravasation (Gorski et al., 2021)
  - a) Small, fragile veins
  - b) Previous multiple venipunctures
  - c) Sensory deficits in the area of the VAD or patients with communication deficits to verbalize or convey pain, tightness, or other discomforts (Gorski et al., 2021)
  - d) Application of topical skin numbing agents prior to venipuncture, which decreases sensation at and around the venipuncture site
  - e) Limited vein selection because of lymph node dissection, lymphedema, or limb removal
  - f) Impaired cognition, altered mental status (impairs ability to detect administration site sensation changes), or somnolence
  - g) Probing during IV catheter insertion
  - h) Inadequately secured IV catheter
  - i) Administration site in areas prone to movement (e.g., wrist, antecubital area)
  - j) Use of rigid IV devices (e.g., steel-winged butterfly needles)
  - k) Prior treatment with irritating or sclerosing drugs, such as chemotherapy
  - l) Administration of a vesicant peripherally when the manufacturer stipulates it should be administered via a central line, such as trabectedin (Janssen Biotech, 2020b) or daunorubicin and cytarabine liposome (Jazz Pharmaceuticals, 2021). Data suggest that trabectedin can be safely administered via a central venous

- catheter, such as a peripherally inserted central catheter (PICC), or other central VADs, such as an implanted port (Martella et al., 2015).
- m) Female sex (Gorski et al., 2021)
  - n) Current infection (Gorski et al., 2021)
4. Possible etiologies of peripheral extravasations (Sauerland et al., 2006)
    - a) Vein wall puncture, piercing, or trauma
    - b) Dislodgment of the catheter from the vein
    - c) Administration of a vesicant in a vein below a recent (less than 24 hours) venipuncture site
    - d) Administration of a vesicant in a vein below a recent or non-healed vesicant extravasation site
    - e) Inadvertent intramuscular or subcutaneous vesicant administration
    - f) Insufficient catheter length inserted into the vein, increasing the chance of extravasation with movement
  5. Risk factors for extravasation from central VADs (Sauerland et al., 2006)
    - a) Difficulty encountered during device insertion (e.g., probing during venipuncture, inability to advance guidewire or catheter)
    - b) Inadvertent slicing, piercing, or nicking of the catheter prior to or during insertion
    - c) Device misplacement with catheter tip outside of the venous system
    - d) Insufficient length of noncoring needle (implanted port)
    - e) Inadequately secured noncoring needle (implanted port)
    - f) Presence of a fibrin sheath or thrombus at the catheter tip
    - g) Catheter migration
    - h) Long dwell time of catheters inserted using a subclavian approach, in which the catheter is placed between the clavicle and first rib; increases the risk of catheter fracture secondary to compression or pinch-off
  6. Possible etiologies of extravasations from central VADs (Gibson & Bodenham, 2013; Goossens et al., 2011; Sauerland et al., 2006)
    - a) Inadvertent misplacement of catheter tip outside of the venous system (e.g., pleural space) during the insertion procedure
    - b) Vein perforation during insertion
    - c) Postinsertion vein erosion
    - d) Catheter leakage, rupture, or fracture
    - e) Separation of the catheter from a portal body (implanted port)
    - f) Incomplete insertion of a noncoring needle into an implanted port
    - g) Noncoring needle dislodgment from an implanted port
    - h) Backflow of vesicant along the catheter to the venotomy site secondary to fibrin sheath or thrombus at the catheter tip
  7. Signs and symptoms of vesicant extravasation (see Table 13-1, Appendix H)
    - a) Vein irritation and flare reactions may mimic some of the signs and symptoms of vesicant extravasation.
    - b) Vein irritation and flare reactions are unique to peripheral chemotherapy administration; they do not occur when chemotherapy is administered via central VADs because the chemotherapy is rapidly diluted in large veins (Wickham et al., 2006). However, vesicant extravasation can occur from a central VAD due to inadvertent catheter tip placement outside the venous system or erosion of the vein wall. It may cause chest pain, shortness of breath, and shock secondary to blood loss (Gibson & Bodenham, 2013). Criteria for adverse events from infusion site extravasation are found in Table 13-2.
    - c) Additional signs and symptoms of vesicant extravasation (Ener et al., 2004; Jackson-Rose et al., 2017; Pérez Fidalgo et al., 2012)
      - (1) IV flow rate that slows or stops
      - (2) Resistance during IV bolus (push) vesicant administration
      - (3) Leaking around the IV catheter or implanted port needle
      - (4) Loss of blood return
  8. Possible consequences of untreated vesicant extravasation (Goolsby & Lombardo, 2006; Pérez Fidalgo et al., 2012)
    - a) Blistering, usually beginning within three to five days
    - b) Peeling and sloughing of skin, usually beginning within two weeks after extravasation
    - c) Tissue necrosis, usually evident two to three weeks after extravasation
      - (1) DNA-binding vesicants remain in the tissue for long periods. The area of tissue necrosis becomes progressively larger and deeper over time.
      - (2) Non-DNA-binding vesicants are more easily metabolized in the tissue. Tissue necrosis is generally localized and improves over time.
    - d) Damage to tendons, nerves, and joints
    - e) Functional and sensory impairment of the affected area
    - f) Disfigurement
    - g) Loss of limb (rare)
  9. Vesicant extravasation management: A suspected vesicant extravasation is best assessed and managed using a systematic and collaborative approach that

**TABLE 13-1.** Signs and Symptoms of Infusion-Related Venous Complications

| Sign or Symptom | Vesicant Infiltration and Extravasation                                                                                                                                                                                                                                                                                   | Venous Irritation                                                                                     | Flare Reaction                                                                                                                      |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Blood return    | Immediate: Loss of blood return from IV devices usually occurs.                                                                                                                                                                                                                                                           | Blood return should be present. If loss of blood return occurs, suspect infiltration of irritant.     | Blood return is present.                                                                                                            |
| Pain            | Immediate: Pain typically occurs and is described as burning, stinging, or a sensation of coolness at and around the vesicant administration site. However, some patients do not experience pain when a vesicant extravasates.<br>Delayed: Pain usually increases in intensity over time.                                 | Aching and tightness along a peripheral vein occur as the drug infuses above the administration site. | No pain occurs; the skin overlying or above the vein may itch.                                                                      |
| Redness         | Immediate: Redness in the area of the vesicant administration site commonly occurs but is not always present or may be difficult to detect if the extravasation is occurring deeper in the tissue (e.g., as a result of needle dislodgment from the implanted port).<br>Delayed: Redness generally intensifies over time. | The vein may appear red-dened or darkened.                                                            | Immediate blotches or streaks develop along the vein, which usually subside within a few minutes. Wheals may appear along the vein. |
| Swelling        | Immediate: Swelling is commonly observed and is easier to detect when extravasation is superficial (e.g., from a peripheral vein) rather than deep in the tissue (e.g., implanted ports).<br>Delayed: Swelling typically increases over time.                                                                             | Swelling does not occur.                                                                              | Swelling does not occur.                                                                                                            |
| Ulceration      | Immediate: Skin integrity is intact.<br>Delayed: If vesicant extravasation is not treated, blistering and sloughing begin within 1–2 weeks, followed by tissue necrosis that may require surgical debridement and skin grafting or flap placement.                                                                        | Ulceration does not occur.                                                                            | Ulceration does not occur.                                                                                                          |

Note. Based on information from Goolsby & Lombardo, 2006; Gorski et al., 2021; Sauerland et al., 2006; Wickham et al., 2006.

involves the patient, the nurse administering the vesicant, and the prescribing provider.

- a) Initial management of extravasation: Assess the site and patient symptoms at the first sign of extravasation, during the time the IV device is assessed, and after initial management.
- b) Steps to take when vesicant extravasation occurs or is suspected (Goolsby & Lombardo, 2006; Schulmeister, 2011)

- (1) Immediately stop administering the vesicant and IV fluids.
- (2) Disconnect the IV tubing from the IV device. Do not remove the IV device or noncoring port needle.
- (3) Attempt to aspirate residual vesicant from the IV device or port needle using a small (1–3 ml) syringe.
- (4) Remove the peripheral IV device or port needle.

**TABLE 13-2.** Common Terminology Criteria for Adverse Events Grading for Infusion Site Extravasation

| Adverse Event               | Grade          |                                                                              |                                                                                |                                                              |       |
|-----------------------------|----------------|------------------------------------------------------------------------------|--------------------------------------------------------------------------------|--------------------------------------------------------------|-------|
|                             | 1              | 2                                                                            | 3                                                                              | 4                                                            | 5     |
| Infusion site extravasation | Painless edema | Erythema with associated symptoms (e.g., edema, pain, induration, phlebitis) | Ulceration or necrosis, severe tissue damage; operative intervention indicated | Life-threatening consequences; urgent intervention indicated | Death |

- (5) Initiate appropriate management measures found in Table 13-3 and institutional policies.
- c) Vesicant extravasation antidotes and treatments

- (1) The efficacy of extravasation antidotes and treatments is unknown. One exception is dexrazoxane for injection, which has 98.2% overall efficacy for treating anthracycline extravasation (Mouridsen et al., 2007).

**TABLE 13-3.** Vesicant Extravasation Management Guidelines

(2) In two European studies, 53 of 54 patients with biopsy-confirmed anthracycline extravasation did not require surgical intervention after receiving dexrazoxane administered via IV daily for three days. The median baseline extravasation area was 25 cm<sup>2</sup> (range 1–253 cm<sup>2</sup>), and 11 patients had extravasation areas exceeding 75 cm<sup>2</sup>. Thirteen patients had late sequelae at the extravasation site, such as pain, fibrosis, atrophy, and local sensory disturbance; all

were judged to be mild (Mouridsen et al., 2007).

- (3) A review conducted by Caballero Romero et al. (2018) noted positive outcomes in patients receiving dexrazoxane after extravasation of liposomal daunorubicin, pegylated liposomal doxorubicin, and liposomal doxorubicin.
- (4) No clinical trials have been conducted to determine the efficacy of dimethyl sulfide, sodium thiosulfate, hyaluronidase,

growth factors, early surgical intervention, saline washout or flushing, hyperbaric oxygen, or 3% solution of boric acid in treating biopsy-confirmed vesicant extravasations from peripheral IV catheters and implanted ports. Information about these antidotes and treatments is anecdotal and based on case reports.

- (5) Use of hyaluronidase for vinca alkaloid extravasation is recommended by package inserts and supported by case reports (Bertelli et al., 1994; Kreidieh et al., 2016; Maly et al., 2018; Pluschnig et al., 2015; Schrijvers, 2003). Hyaluronidase treatment is generally recommended within one hour of extravasation (Maly et al., 2018; Rubach, 2018). Topical heat is recommended to help disperse (Firat et al., 2013; Pluschnig et al., 2015; Rubach, 2018; Schrijvers, 2003).
  - (6) Limited data and conflicting case studies exist for using hyaluronidase for taxane extravasation.
    - (a) Du Bois et al. (1996) found patients with paclitaxel extravasations treated with hyaluronidase took longer to recover than those without and suggested cold therapy alone.
    - (b) Schrijvers (2003) noted a mouse study in which hyaluronidase after paclitaxel extravasation prevented ulceration.
    - (c) Pérez Fidalgo et al. (2012) recommended hyaluronidase with taxanes with limited evidence (Level V-C).
    - (d) Kimmel et al. (2018) discouraged hyaluronidase plus heat for taxanes and recommended cold alone.
  - (7) Anecdotal reports of treatment of peripheral and central VAD anthracycline extravasations with IV dexrazoxane administered as directed suggest efficacy in mitigating anthracycline-induced tissue damage (Araque Arroyo et al., 2010; Conde-Estévez et al., 2010; Fontaine et al., 2012; Langer, 2007, 2008; Uges et al., 2006). In a case report of IV dexrazoxane administration 72 hours after peripheral epirubicin extravasation (and after being initially treated with topical dimethyl sulfoxide 99%), the patient had complete recovery without any sequelae (Aigner et al., 2014).
  - (8) Anecdotal reports of treatment of intracavitary anthracycline vesicant extravasations include saline washout of the pleural space with concurrent IV dexrazoxane administration (Chang & Murray, 2016) and video-assisted thoracoscopy (to visualize tissue damage) followed by thoracoscopic-assisted pleural lavage with periprocedural IV infusion of dexrazoxane (Aguirre et al., 2017).
  - (9) A case report described liposomal doxorubicin extravasation initially treated conservatively with cold compresses on the affected arm. Three days later, when the pain worsened and skin redness increased, the patient was treated with IV dexrazoxane and completely recovered (de Vos et al., 2012).
  - (10) In a study by Onesti et al. (2017), saline washout and topical corticosteroids after extravasation in 545 patients prevented ulceration in 373 cases (Onesti et al., 2017). Taibi et al. (2020) found that five patients that underwent subcutaneous washout with saline exclusively had no necrosis and less delay in the resumption of treatment than two patients without saline washout. One case study suggested that saline washout may be helpful for oxaliplatin extravasation (Bahadori & Demiray, 2018).
10. Documentation of vesicant extravasation and treatment: Key elements for inclusion in vesicant extravasation documentation are listed in Figure 13-1. Appendix I includes an example of a vesicant drug extravasation record.
  11. Patient follow-up: Dependent on individual patient needs and institutional policies
    - a) Periodically assess patient response to extravasation treatment.
      - (1) Assess patients receiving IV dexrazoxane on each day of the three-day treatment and again four to seven days after completing dexrazoxane treatment.
      - (2) Assess patients receiving other extravasation treatments (e.g., heat/cold, hyaluronidase) the day after the suspected extravasation and four to seven days later.
      - (3) Assessments can be done in person or via phone with photographs sent electronically per institutional policy.
      - (4) Reinforce patient teaching to notify the provider of worsening signs and symptoms.
    - b) Assessment may include inspection and measurement of the extravasation area, skin integ-

**FIGURE 13-1.** Key Elements of Vesicant Extravasation Documentation

- Date and time that extravasation occurred or was suspected
- Type and size of peripheral venous access device or type of central venous access device and gauge/length of noncoring needle (implanted ports)
- Location and patency of peripheral or central venous access device
- Number and location(s) of venipuncture attempts (for peripheral vesicant administration)
- Description and quality of blood return before and during vesicant administration
- Vesicant administration technique (e.g., bolus, infusion)
- Concentration and estimated amount of extravasated vesicant
- Symptoms reported by the patient (e.g., burning, pain)
- Description of administration site appearance, including measurement of edema or redness if present
- Photographs of administration site that include date and time in the photograph field (follow institutional guidelines when obtaining photographs from patients)
- Assessment of extremity (if applicable) for range of motion and discomfort with movement
- Immediate nursing interventions (e.g., topical cooling or warming, authorized prescriber notification)
- Extravasation antidote or treatment administered
- Follow-up recommendations (e.g., return appointments, referral for wound care)
- Patient teaching (e.g., assessing skin, monitoring temperature, reporting pain) and patient's response to teaching

*Note.* Based on information from Schulmeister, 2011.

riety, presence of pain or other symptoms, arm and hand mobility (for peripheral extravasations), and sensation.

- c) Obtain follow-up photographs that include or refer to the date and time taken per institutional policy.
- d) In collaboration with the provider, refer patients for specialized care when indicated (e.g., plastic or hand surgery consultation, physical therapy, wound team, pain management, rehabilitation services).
- e) Instruct patients to protect the extravasation area from sunlight, monitor the site, and report fever, chills, blistering, skin sloughing, and worsening pain.

### C. Irritation

1. Irritants: agents that may inflame and irritate peripheral veins during or after infusion
  - a) Examples include bleomycin, carboplatin, carmustine, dacarbazine, etoposide, 5-fluorouracil, gemcitabine, ifosfamide, liposomal daunorubicin, liposomal doxorubicin, streptozocin, and topotecan (Ener et al., 2004; Pérez Fidalgo et al., 2012; Sauerland et al., 2006).
  - b) Measures to reduce irritation during infusion

- (1) Increase dilution when possible and infuse with concurrent fluid administration.
  - (2) Administer via larger rather than smaller peripheral veins for peripheral infusions.
  - (3) Apply a warm pack to the administration site during infusion. As an exception, treat irritant liposomal anthracyclines (daunorubicin and doxorubicin) with topical cold application.
  - (4) Assess the administration site and monitor for pain, redness, and swelling in patients receiving irritating agents.
2. Irritants with vesicant properties: Agents that may inflame and irritate peripheral veins and can cause skin and tissue damage (e.g., blistering, sloughing) when higher concentrations or specific amounts of the drug inadvertently enter the tissue (see Table 13-4 for irritant infiltration management guidelines)
    - a) Bendamustine hydrochloride (Bendeka®)
      - (1) Postmarketing reports of infiltration include hospitalization for erythema, marked swelling, and pain; precautions should be taken to avoid extravasation (Teva Pharmaceuticals, 2020).
      - (2) Bendeka is prepared in a 50 ml infusion bag and administered over 10 minutes. The infusion site should be monitored for redness, swelling, pain, infection, and necrosis (Teva Pharmaceuticals, 2020). Concurrent IV fluids for peripheral administration may help reduce irritation during infusion and phlebitis noted in two recent case studies (Ajewole et al., 2019; Watanabe et al., 2013).
    - b) Immunotherapy agents: Although data on the infiltration of these agents are limited, antibodies are classified as irritants most likely because of their ability to cause local allergic reactions at the infusion site rather than direct cellular toxicity. Conjugated antibodies could have vesicant potential depending on their conjugate (Sallevet et al., 2020; Shafaei et al., 2017).
    - c) Immune checkpoint inhibitors (e.g., ipilimumab, nivolumab, pembrolizumab) possess an irritant potential and may cause thrombophlebitis (Pluschnig et al., 2016). However, Rodríguez-Alarcón and Conde-Estévez (2021) noted that infiltrations of two monoclonal antibodies, nivolumab and cetuximab, had no symptoms of extravasation.
    - d) Targeted agents: Local swelling and redness have been observed with infiltration of proteasome inhibitors (e.g., carfilzomib, ixazomib) (Pluschnig et al., 2016).

**TABLE 13-4.** Irritant Infiltration Management Guidelines

| Drug                                                                                                | Immediate Topical Therapy                                                                    | Administration, Monitoring, and Follow-Up                                                                                                                                                                                                                                                                                                                                                                                 |

| Ifosfamide (Ifex®)<br>• Irritant (usually)                                              | Cold<br>Apply cold pack for 15–20 minutes at least 4 times a day for the first 24 hours.                                                   | Assess the infiltration area for pain, blister formation, and skin sloughing as needed or per institutional policy.<br>Instruct patients to monitor the infiltration site and report fever, chills, blistering, skin sloughing, and worsening pain.<br>(Baxter Healthcare, 2018)                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Irinotecan (Campostar®)<br>• Irritant<br>• Exfoliative dermatitis may occur.            | Cold<br>Flush the skin topically with sterile water and apply a cold pack for 15–20 minutes at least 4 times a day for the first 24 hours. | Assess the infiltration area for pain, blister formation, and skin sloughing as needed or per institutional policy.<br>Instruct patients to monitor the infiltration site and report fever, chills, blistering, skin sloughing, and worsening pain.<br>(Kreidieh et al., 2016; Pfizer, 2020)                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Loncastuximab tesirine-lpyl (Zynlonta®)<br>• Irritant (usually)<br>• Vesicant (rarely)  | Cold<br>Apply cold pack for 15–20 minutes at least 4 times a day for the first 24 hours.                                                   | The drug has been associated with irritation, swelling, pain, and tissue damage, which may be severe.<br>Assess the infiltration area for pain, blister formation, and skin sloughing as needed or per institutional policy.<br>Instruct patients to monitor the infiltration site and report fever, chills, blistering, skin sloughing, and worsening pain.<br>(ADC Therapeutics America, 2021)                                                                                                                                                                                                                                                                                                                                       |
| Melphalan (Alkeran®, Evomela®, Pepaxto®)<br>• Irritant (usually)<br>• Vesicant (rarely) | Cold<br>Apply cold pack for 15–20 minutes at least 4 times a day for the first 24 hours.                                                   | Assess the infiltration area for pain, blister formation, and skin sloughing as needed or per institutional policy.<br>Instruct patients to monitor the infiltration site and report fever, chills, blistering, skin sloughing, and worsening pain.<br>(Acrotech Biopharma, 2019; Ener et al., 2004; Goolsby & Lombardo, 2006; GlaxoSmithKline, 2011; Oncoceptides, 2021; Sauerland et al., 2006)                                                                                                                                                                                                                                                                                                                                      |
| Oxaliplatin (Eloxatin®)<br>• Irritant (usually)<br>• Vesicant (rarely)                  | Heat<br>Apply warm pack for 15–20 minutes at least 4 times a day for the first 24–48 hours.                                                | A warm pack may reduce local pain and inflammation. Ice packs should be avoided as they may exacerbate acute neurologic symptoms.<br>Elevate extremity (peripheral extravasations).<br>High-dose dexamethasone (8 mg twice daily for up to 14 days) has been reported to reduce oxaliplatin infiltration-related inflammation.<br>Assess the infiltration area for pain, blister formation, and skin sloughing as needed or per institutional policy.<br>Instruct patients to monitor the infiltration site and report fever, chills, blistering, skin sloughing, and worsening pain.<br>(Azaïs et al., 2015; de Lemos & Walisser, 2005; Foo et al., 2003; Kennedy et al., 2003; Kretzschmar et al., 2003; Sanofi-Aventis U.S., 2020a) |
| Streptozocin (Zanosar®)<br>• Irritant (usually)<br>• Vesicant (rarely)                  | Cold<br>Apply cold pack for 15–20 minutes at least 4 times a day for the first 24 hours.                                                   | Assess the infiltration area for pain, blister formation, and skin sloughing as needed or per institutional policy.<br>Instruct patients to monitor the infiltration site and report fever, chills, blistering, skin sloughing, and worsening pain.<br>Instruct patients with peripheral extravasations to report arm or hand swelling and stiffness.<br>(Teva Pharmaceuticals, 2021)                                                                                                                                                                                                                                                                                                                                                  |
| Topotecan (Hycamtin®)<br>• Irritant (usually)                                           | Cold<br>Apply cold pack for 15–20 minutes at least 4 times a day for the first 24 hours.                                                   | Assess the infiltration area for pain, blister formation, and skin sloughing as needed or per institutional policy.<br>Instruct patients to monitor the infiltration site and report fever, chills, blistering, skin sloughing, and worsening pain.<br>(Novartis Pharmaceuticals, 2019)                                                                                                                                                                                                                                                                                                                                                                                                                                                |

- e) Enfortumab vedotin-ejfv: In one study of 310 patients receiving enfortumab vedotin-ejfv, 1.3% experienced skin and soft tissue reactions, including delayed onset of secondary cellulitis, bullae, or exfoliation (Astellas Pharma US, 2021; Rosenberg et al., 2019).
- f) 5-Fluorouracil: The drug is administered through a central venous line using an infusion pump for continuous IV infusion regimens (Spectrum Pharmaceuticals, 2016).
- g) Irinotecan: Care should be taken to avoid the extravasation of irinotecan. If infiltration occurs, topical flushing of the skin with sterile water and application of ice is recommended (Pfizer, 2020).
- h) Loncastuximab tesirine-lpyl: Extravasation has been associated with irritation, swelling, pain, and potentially severe tissue damage. The infusion site should be monitored for possible subcutaneous infiltration during drug administration (ADC Therapeutics America, 2021).
- i) Melphalan (Alkeran®, Evomela®) and melphalan flufenamide (Pepaxto®)
  - (1) These drugs have been classified differently depending on the reference, as neither an irritant nor a vesicant (Dorr et al., 1986), as an irritant (Ener et al., 2004; Goolsby & Lombardo, 2006), and as a vesicant (Sauerland et al., 2006). Infiltration may cause local tissue damage (Acrotech Biopharma, 2019; GlaxoSmithKline, 2011; Oncopeptides, 2021).
  - (2) Care should be taken to avoid possible infiltration (e.g., monitor the IV site during a melphalan [Alkeran] infusion). With poor peripheral venous access, a central venous line is recommended. Alkeran should be administered through a fast-running IV solution into an injection port on the IV tubing; it should not be administered by direct injection into a peripheral vein (GlaxoSmithKline, 2011).
  - (3) Melphalan (Evomela) and melphalan flufenamide (prodrug of melphalan; Pepaxto) require a central line for administration (Acrotech Biopharma, 2019; Oncopeptides, 2021).
- j) Oxaliplatin
  - (1) The drug has been described as both an irritant and a vesicant (Azaïs et al., 2015; de Lemos & Walisser, 2005; Kennedy et al., 2003). Case reports describe induration, edema, red-brown skin discoloration, hyperpigmentation, and rare instances of tissue necrosis (Azaïs et al., 2015).
  - (2) Infiltration has included necrosis and injection site reactions, such as redness, swelling, and pain (Sanofi-Aventis U.S., 2020a).
  - (3) Kretzschmar et al. (2003) retrospectively reviewed 11 cases of peripheral oxaliplatin infiltration and found that even with large-volume (40 mg or greater) extravasations of oxaliplatin, tissue necrosis did not occur.
  - (4) Pericay et al. (2009) published a case report of a 165 mg dose of oxaliplatin that infiltrated when a noncoring needle dislodged from an implanted port, resulting in edema and skin discoloration. They concluded that the effect was of an irritant rather than a vesicant.
  - (5) In a case report, inadvertent intrathoracic infiltration of oxaliplatin caused pleural effusion and mediastinitis. Shortness of breath and chest pain resolved within a week of discontinuing the oxaliplatin infusion and initiating IV antibiotics (Leon-Ferre et al., 2012).
  - (6) Because cold packs cause local vasoconstriction, they may precipitate or worsen the cold neuropathy associated with oxaliplatin (Foo et al., 2003; Sanofi-Aventis U.S., 2020a).
  - (7) A warm pack applied to an oxaliplatin infiltration site is preferable and may reduce local pain and inflammation (Foo et al., 2003; Sanofi-Aventis U.S., 2020a).
  - (8) High-dose dexamethasone (8 mg twice daily for up to 14 days) has been reported to reduce oxaliplatin infiltration-related inflammation (Kretzschmar et al., 2003).
- k) Ado-trastuzumab emtansine
  - (1) Two case studies of ado-trastuzumab emtansine extravasation noted erythema, pain, blisters, and hyperpigmentation without full-thickness necrosis (Sallevelt et al., 2020; Shafae et al., 2017).
  - (2) The infusion site should be closely monitored for possible subcutaneous infiltration during drug administration (Genentech, 2020a).
- l) Vinorelbine
  - (1) This drug has been described as an irritant (de Lemos, 2005) and a vesicant (Ener et al., 2004; Goolsby & Lombardo, 2006; Hadaway, 2007; Sauerland et al., 2006). Case reports have described skin discoloration, chemical phlebitis, localized

rash, urticaria, blistering, and rarely, skin sloughing (Manganoni et al., 2012).

- (2) Extravasation can result in severe tissue injury, local tissue necrosis, and thrombophlebitis. Immediately stop the drug and institute recommended management procedures. Extravasation may cause local tissue necrosis or thrombophlebitis (Pierre Fabre Pharmaceuticals, 2020).
  - (3) A case report of vinorelbine infiltration from an implanted port described erythema and blister formation followed by ulceration, which was treated with heat, antibiotics, and subcutaneous hyaluronidase (Das & Gogia, 2016).
  - (4) Rapid IV infusion over 6–10 minutes followed by a flush of more than 75–125 ml of IV fluid may reduce vinorelbine-induced venous irritation (de Lemos, 2005).
3. Risk factors for irritation
    - a) Small veins
    - b) Prior treatment with irritating or sclerosing drugs, such as chemotherapy
  4. Possible etiologies of venous irritation (Gorski et al., 2021)
    - a) Low or high pH (less than 5 or greater than 9) of infused drugs
    - b) Solutions with high osmolality
    - c) Concentrated drugs or infusion solutions
  5. Signs and symptoms of venous irritation (see Table 13-1)
  6. Management of venous irritation
    - a) Application of a warm pack may reduce local discomfort.
    - b) Restarting the peripheral IV in a larger vein in another location may be indicated.
    - c) Consult a pharmacist to explore further dilution of irritating medications.
    - d) Instruct patients to report the development of a hard cord along the vein, pain, erythema, and temperature elevation.

#### D. Flare reaction

1. Flare reaction is characterized by transient erythema along the vein above the peripheral IV site and may be accompanied by pruritus and urticaria; blood return is present (Kreidieh et al., 2016; Wickham et al., 2006; see Appendix I).
2. Reaction may be observed during peripheral administration of anthracyclines (Kreidieh et al., 2016; Wickham et al., 2006).
3. It may occur during peripheral administration of doxorubicin and is thought to be caused by the local

release of histamine from mast cells or basophils (Curran et al., 1990).

4. Management of flare reaction (Gill et al., 2018)
  - a) Verify the presence of blood return. If absent, assess for signs and symptoms of extravasation.
  - b) Flush the vein slowly with saline and observe for resolution of flare, usually within 45 minutes.
  - c) An antihistamine may be used to treat a flare reaction and for premedication with subsequent cycles (Wilkes & Barton-Burke, 2020).
  - d) If resolution does not occur, contact the provider.
  - e) Do not resume the infusion through the IV site until the flare reaction resolves completely and a brisk blood return has been confirmed. Consider restarting the IV in another site.
  - f) Document the flare reaction, including treatment and the patient response.

#### E. Acute infusion-related reactions

1. Many systemic infusional cancer treatments, including chemotherapy and monoclonal antibodies, pose a risk for mild, moderate, and severe reactions, which can interrupt an optimal treatment plan in the short or long term. Optimal cancer treatment depends on patients receiving a full course of first-line therapy to achieve the best response (Castells et al., 2022). Oncology nurses need to be well informed and competent about the risk for reactions, short- and long-term management of reactions, ability to perform critical assessments, documentation, and collaboration with the treatment team to facilitate patient-centered care planning that leads to optimal outcomes.
  - a) Understanding the pathophysiology of acute infusion-related reactions using a precision medicine framework is helpful to clinicians when planning interventions (Jimenez-Rodriguez et al., 2018).
  - b) Using the precision medicine framework, acute infusion-related reactions are broadly described by their phenotype as standard infusion reactions (SIRs) attributed to an irritant effect, a type 1 hypersensitivity reaction (HSR) immunoglobulin E (IgE) or non-IgE mediated, a cytokine release reaction/syndrome (CRR/CRS), or a mixed HSR/CRR/CRS reaction (see Figure 13-2). This framework links the clinical presentation (phenotype) to the cellular and molecular mechanisms (endotypes) of the reaction. The phenotype and endotype are then linked to the symptoms and diagnostic biomarkers (e.g., skin testing, tryptase, IgE, interleukin-6) to better diagnose, treat, and ultimately prevent these acute

**FIGURE 13-2.** Pathways of Anaphylaxis

IgE—immunoglobulin E; IgG—immunoglobulin G; IL—interleukin; TNF- $\alpha$ —tumor necrosis factor alpha

Note. From "Diagnosis and Management of Anaphylaxis in Medicine," by M. Castells, 2017, *Journal of Allergy and Clinical Immunology*, 140(2), p. 323 (<https://doi.org/10.1016/j.jaci.2017.06.012>). Copyright 2017 by American Academy of Allergy, Asthma, and Immunology. Reprinted with permission.

infusion-related reactions. Using this precision medicine framework, clinicians can better contribute to establishing a collaborative and standardized plan of care for patients at risk of and experiencing an acute infusion-related reaction (Jakubovic et al., 2020; Jimenez-Rodriguez et al., 2018; Tsao et al., 2021).

c) A SIR phenotype can occur with any medication administered intravenously.

- (1) In general, allergists describe SIRs as mild, reversible, and may represent an irritant effect of the causative agent. Some may be severe, making it prudent to differentiate between SIR, type 1 HSR, CRR/CRS, or mixed HSR/CRR/CRS reaction, as the latter three are often characterized by an allergic component that could lead to anaphylaxis (Castells et al., 2022).
- (2) SIRs involving monoclonal antibodies may result from the antibody–antigen interactions that release cytokines; however, the exact mechanism is unclear.

Reactions with monoclonal antibodies may be mild and usually occur with the first dose.

- (3) Although SIRs can affect any organ system in the body, the most common signs and symptoms are fever and shaking chills, flushing and itching, alterations in heart rate and blood pressure, dyspnea or chest discomfort, back or abdominal pain, nausea, vomiting and diarrhea, and various types of skin rashes (LaCasce et al. 2021).
  - (4) Reactions with immunotherapy agents, such as rituximab, trastuzumab, and cetuximab, are mostly SIRs in nature and may also potentially induce anaphylaxis (LaCasce et al., 2021; see Table 13-5).
- d) A type 1 HSR phenotype is unexpected, mediated by the immune system (IgE), and is usually allergic.
- (1) It can be mild or moderate or can lead to a severe anaphylactic reaction.

**TABLE 13-5.** Immunotherapy Drugs and Associated Acute Infusion-Related Reactions

| Drug                                              | Reaction Symptoms                                                                                                                                          | Frequency                                                                                                                                                                      | Management                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Prevention                                                                                                                                                                                                                                                                                                                                 |

| <sup>90</sup> Y Ibritumomab tiuxetan (Zevalin <sup>®</sup> ) | Potentially fatal infusion reactions with features of anaphylaxis (e.g., angioedema, urticaria, bronchospasm, hypotension, hypoxia, myocardial infarction, acute respiratory distress syndrome, pulmonary infiltrates) | Uncommon<br>See rituximab package insert. Rituximab alone or as a component of the Zevalin regimen can cause severe infusion-related reactions.<br>Most reactions occur during or within 30–120 minutes after the first infusion. | Infusion-related reaction <ul style="list-style-type: none"> <li>• Stop drug.</li> <li>• Treat symptoms with supportive care medications.</li> <li>• After resolution of symptoms, consider restarting.</li> </ul> Anaphylaxis <ul style="list-style-type: none"> <li>• Stop drug.</li> <li>• Treat for anaphylaxis.</li> <li>• Do not rechallenge.</li> <li>• Permanently discontinue use unless referred to an allergist.</li> </ul>                                                                                                                | Premedications: antipyretic, H <sub>1</sub> blocker before the first and second infusions. Consider an H <sub>2</sub> blocker.<br>Known hypersensitivity or anaphylactic reactions to yttrium chloride, murine proteins, or rituximab are contraindications to treatment.<br>(Cáceres et al., 2019; LaCasce et al., 2021; Spectrum Pharmaceuticals, 2009; Wilkes & Barton-Burke, 2020) |
| Inotuzumab ozogamicin (Besponsa <sup>®</sup> )               | Dyspnea, fever, chills, cough, hypotension, hypertension, hot flashes, nausea                                                                                                                                          | Uncommon: 2%<br>Majority are grade 1–2 and occur during the first infusion.                                                                                                                                                       | Infusion-related reaction <ul style="list-style-type: none"> <li>• Stop drug.</li> <li>• Treat symptoms with supportive care medications.</li> <li>• After resolution of symptoms, consider restarting.</li> <li>• Monitor for 1 hour after infusion-related reaction.</li> </ul> Anaphylaxis <ul style="list-style-type: none"> <li>• Stop drug.</li> <li>• Treat for anaphylaxis.</li> <li>• Do not rechallenge.</li> <li>• Permanently discontinue use unless referred to an allergist.</li> </ul>                                                 | Premedications: antipyretic, glucocorticoid, H <sub>1</sub> blocker<br>(Cáceres et al., 2019; LaCasce et al., 2021; Wilkes & Barton-Burke, 2020; Wyeth Pharmaceuticals, 2017a)                                                                                                                                                                                                         |
| Isatuximab (Sarclisa <sup>®</sup> )                          | Dyspnea, cough, chills, nausea, nasal congestion, hypertension<br>Anaphylaxis has occurred.                                                                                                                            | Common: 38%<br>Majority are grade 1–2 and occur during the first infusion.<br>Grade 3 frequency is < 1%.                                                                                                                          | Infusion-related reaction <ul style="list-style-type: none"> <li>• Stop drug.</li> <li>• Treat symptoms with supportive care medications.</li> <li>• After resolution of symptoms, restart at half the rate.</li> <li>• After 30 minutes without recurrence, the initial infusion rate can be increased incrementally.</li> </ul> Anaphylaxis <ul style="list-style-type: none"> <li>• Stop drug.</li> <li>• Treat for anaphylaxis.</li> <li>• Do not rechallenge.</li> <li>• Permanently discontinue use unless referred to an allergist.</li> </ul> | Premedications: antipyretic, glucocorticoid, H <sub>1</sub> and H <sub>2</sub> blocker<br>Dose escalations are recommended.<br>(Cáceres et al., 2019; LaCasce et al., 2021; Sanofi-Aventis U.S., 2020b; Wilkes & Barton-Burke, 2020)                                                                                                                                                   |

| Tafasitamab<br>(Monjuvi®)<br>( <i>Cont.</i> ) |                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                            | Anaphylaxis <ul style="list-style-type: none"> <li>• Stop drug.</li> <li>• Treat for anaphylaxis.</li> <li>• Do not rechallenge.</li> <li>• Permanently discontinue use unless referred to an allergist.</li> </ul>                                                                                                                                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                             |
| Trastuzumab<br>(Herceptin®)                   | Fever, chills, headache, dyspnea, abdominal pain, hypotension, wheezing, dizziness, rhinitis, tachycardia, decreased oxygen saturation, respiratory distress, rash, nausea, vomiting, headache<br>Severe reactions: bronchospasm, angioedema, hypoxia, severe hypotension<br>Fever and chills generally do not recur with subsequent infusions. | Common<br>Grade 1–2 frequency is 40% with the first infusion and begins shortly after the start of infusion.<br>Grade 3 frequency is 0.3%. | Infusion-related reaction<br>Stop drug.<br>Treat symptoms with supportive care medications.<br>After resolution of symptoms, consider restarting.<br>Anaphylaxis <ul style="list-style-type: none"> <li>• Stop drug.</li> <li>• Treat for anaphylaxis.</li> <li>• Do not rechallenge.</li> <li>• Permanently discontinue use unless referred to an allergist.</li> <li>• Desensitization protocols are available.</li> </ul> | Premedications: routine premedication not indicated<br>Premedications if prior reaction: antipyretic, H <sub>1</sub> and H <sub>2</sub> blocker<br>The first dose is generally administered over 90–120 minutes, with subsequent infusions shortened to 30–45 minutes if no reactions occur.<br>(Cáceres et al., 2019; Genentech, 2010a; LaCasce et al., 2021; Wilkes & Barton-Burke, 2020) |

IV—intravenous; SC—subcutaneous

- (2) A type 1 HSR can also be non-IgE mediated (nonimmune pathway); however, it may resemble an immune allergic reaction. The endotype for IgE-mediated and non-IgE-mediated reactions is mast cell and basophil activation, causing symptoms such as flushing, pruritus, hives, angioedema, shortness of breath, wheezing, nausea, vomiting, diarrhea, hypotension, oxygen desaturation, and cardiovascular collapse (Castells & Solensky, 2020; Jimenez-Rodriguez et al., 2018).
  - (3) Type 1 HSRs can occur within minutes after the start of an infusion to as late as six hours after its completion (Castells & Solensky, 2020; LaCasce et al., 2021). See Table 13-6 for examples of chemotherapy agents associated with acute infusion-related reactions.
- e) Anaphylaxis is a systemic response that can be life threatening.
- (1) Although uncommon with most antineoplastic agents, anaphylaxis is well established with platinum drugs, taxanes, pegylated liposomal doxorubicin, asparaginase, procarbazine, etoposide, bleomycin, cytarabine, and ixabepilone (Castells et al., 2022).
  - (2) Anaphylaxis with monoclonal antibodies has been reported with rituximab (< 5%), trastuzumab (0.3%), and cetuximab (3%–4%) (LaCasce et al., 2021). Reactions with platinum agents do not usually occur until the patient has received several doses (generally after six to seven cycles) (Castells et al., 2022).
  - (3) Common signs and symptoms of anaphylaxis caused by IV medications can vary from patient to patient.
  - (4) Because anaphylaxis is potentially life threatening, it needs to be identified immediately and treated with epinephrine, the only medication that can reverse life-threatening symptoms (see Tables 13-7 and 13-8).
  - (5) Glucocorticoids and antihistamines do not play a role in the immediate treatment of anaphylaxis (Shaker et al., 2020).

**TABLE 13-6.** Chemotherapy Drugs and Associated Acute Infusion-Related Reactions

| Drug                      | Reaction Symptoms                                                                                                                                                                                                              | Frequency                                                                                                                                                                                                                                                                                             | Management                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Prevention                                                                                                                                                                                                                                                                                                                                                           |

**TABLE 13-6.** Chemotherapy Drugs and Associated Acute Infusion-Related Reactions (*Continued*)

| Drug                     | Reaction Symptoms                                                                 | Frequency                                                                                                                                                                                                                                                                                                                                                                                     | Management                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Prevention                                                                                                                                                                                                                                                                                            |
|--------------------------|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pegaspargase (Oncaspar®) | Urticaria, pruritus, angioedema, dyspnea, bronchospasm, laryngospasm, hypotension | 5%–8%, but increases to 33% after the fourth dose<br><br>Reactions may occur within minutes of administration; however delayed reactions are more common due to the slow release of the primary antigen.<br><br>Two preparations are available, <i>Escheri coli</i> and <i>Erwinia carotovora</i> , which are non-crossresistant. Other preparation can be substituted if the patient reacts. | Infusion-related reaction<br>• Stop drug.<br>• Treat symptoms with supportive care medications.<br>• After resolution of symptoms, consider restarting.<br><br>Anaphylaxis<br>• Stop drug.<br>• Treat for anaphylaxis.<br>• Do not rechallenge.<br>• Permanently discontinue use unless referred to an allergist.<br><br>The skin test is not validated. Some experts state the skin test is unreliable because of the high rate of false positives and false negatives. Desensitization protocols are available. | Premedications: antipyretic (optional), glucocorticoid (optional), H <sub>1</sub> and H <sub>2</sub> blocker<br><br>Premedications if prior reaction: glucocorticoid, H <sub>1</sub> and H <sub>2</sub> blocker (Castells et al., 2022; Sigma-Tau Pharmaceuticals, 2011; Wilkes & Barton-Burke, 2020) |

- (6) The European Society for Medical Oncology has published clinical criteria for diagnosing anaphylaxis. Familiarity with these criteria helps clinicians in the moment, when the patient requires epinephrine for anaphylaxis or impending anaphylaxis (Roselló et al., 2017; see Figure 13-3).

- (7) Anaphylactic reactions occur abruptly and can progress very quickly. This challenges the healthcare team to rapidly identify the nature of the reaction and the necessary treatment. Team familiarity with the criteria of anaphylaxis can facilitate clinical assessments and timely life-saving treatment.

*f) CRR and CRS*

- (1) CRR and CRS phenotypes are caused by the release of proinflammatory mediators, including tumor necrosis factor- $\alpha$ , interleukin-1- $\beta$ , and interleukin-6. Their endotypes include monocytes, macrophages, mast cells, and other immune cells with Fc- $\gamma$  receptors (Jimenez-Rodriguez et al., 2018).
- (2) CRR and CRS develop after cells are damaged and complement pathways are activated, resulting in a drastic increase in systemic inflammatory cytokines and interleukins (Cobb & Lee, 2021).
- (3) CRR describes an acute infusion-related reaction, which usually presents as mild or moderate and resolves with immedi-

ate treatment. CRS describes an acute and possible longer-term infusion-related reaction that generally presents as a severe, even life-threatening, systemic inflammatory reaction after the infusion of agents targeting the immune system, such as that seen in patients receiving chimeric antigen receptor (CAR) T-cell therapy. CRS typically requires more intensive interventions to resolve and may persist from hours to as late as seven days after completion of the infusion (Cobb & Lee, 2021; National Comprehensive Cancer Network, 2020). CRS may potentially result in organ failure or death (Cobb & Lee, 2021; LaCasce et al., 2021; Wilkes & Barton-Burke, 2020).

- (4) In most patients, the symptoms of CRR and CRS are less severe (National Comprehensive Cancer Network, 2020). Symptoms include mild fevers (days to weeks), tachycardia, chills, nausea, anorexia, myalgia, headache, rigors, and pain. If severe, symptoms can be life-threatening due to capillary leak, resulting in a third space fluid shift into the lungs and interstitial tissue and leading to intravascular depletion. Severe coagulopathy, with prolonged prothrombin time, partial thromboplastin time, and low fibrinogen levels, can occur with CRS, resulting in thrombocytopenia and an increased risk of thrombosis. Acute kidney injury can also occur due to hemo-

**TABLE 13-7.** Emergency Drugs for Use With Hypersensitivity or Anaphylactic Reactions

| Indication                                                                                    | Drug             | Dose                                                                                                                                                                                                                                                                                                                              | Comments                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------------------------------------------------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bronchial constriction (e.g., dyspnea, wheezing, stridor)                                     | Epinephrine      | 0.1–0.5 mg IM into thigh (0.1–0.5 ml of 1:1,000 solution or EpiPen® 0.3 mg automatic device)<br>IV administration is indicated for patients with profound hypotension or signs or symptoms of impending shock who have not responded to IM dose.                                                                                  | IM administration is preferred over IV to minimize adverse cardiac effects.<br>Anterolateral upper thigh is preferable to deltoid (may also be administered by inhalation or subcutaneously).<br>Repeat every 5–10 minutes if needed.                                                                                                                         |
| Patients who do not respond after at least 2 doses of epinephrine and take a beta-blocker     | Glucagon         | 1 mg/50 ml IV over at least 5 minutes<br>Dose may be repeated up to 5 times for a total of 5 mg.<br>A continuous infusion may be indicated.<br>Consider a higher level of care if not responding.                                                                                                                                 | The drug is given preferably via IV pump at a controlled rate to minimize adverse effects of severe nausea and vomiting. If nausea and vomiting continue or occur even with a pump-controlled rate of administration, stop the drug.<br>Glucagon counteracts the systemic effects of anaphylaxis, as glucagon acts independently of alpha and beta receptors. |
| Shortness of breath, tachypnea (rate > 20 breaths per minute), or decreased oxygen saturation | Oxygen           | 2–6 L/min via a nasal cannula; 15 L via non-rebreather, if needed                                                                                                                                                                                                                                                                 | Patients who are hemodynamically unstable may also benefit from oxygen.                                                                                                                                                                                                                                                                                       |
|                                                                                               | Albuterol        | 2.5 mg/3 ml of 0.083% inhalation solution by nebulizer or 180 mcg (2 puffs) by metered-dose inhaler                                                                                                                                                                                                                               | Hold if heart rate is > 110 beats per minute.                                                                                                                                                                                                                                                                                                                 |
| Hypotension (> 30% decrease in systolic blood pressure from baseline)                         | Epinephrine      | Recommended dose is 0.01 mg/kg (maximum dose: 0.5 mg) IM into the antero-lateral thigh.<br>The dose should be drawn up using a 1 ml syringe using the 1 mg/ml formulation of epinephrine.<br>A single-dose vial is preferred.<br>The use of an autoinjector EpiPen (0.3 mg) is preferred for speed, reliability, and ease of use. | IM administration is preferred over IV to minimize adverse cardiac effects, except in the presence of cardiovascular collapse. Cardiac monitoring is recommended.                                                                                                                                                                                             |
|                                                                                               | Normal saline IV | 500 ml fluid bolus                                                                                                                                                                                                                                                                                                                | Administer over 10 minutes once and then as ordered.<br>Multiple fluid boluses may be required if the patient remains hypotensive despite epinephrine.<br>Massive fluid shifts can occur.                                                                                                                                                                     |
| Hives, itching, flushing, swollen lips or tongue                                              | Diphenhydramine  | 25–50 mg IVP                                                                                                                                                                                                                                                                                                                      | To counteract the multiple effects of histamine release, both H <sub>1</sub> and H <sub>2</sub> antagonists should be administered.                                                                                                                                                                                                                           |
|                                                                                               | Famotidine       | 20 mg IVP                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                               |
|                                                                                               | Ranitidine       | 50 mg IVP                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                               |
| Wheezing, cough, hives, or flushing                                                           | Montelukast      | 10 mg PO                                                                                                                                                                                                                                                                                                                          | The drug has an off-label use for infusion-related reactions.<br>It may be given as premedication.                                                                                                                                                                                                                                                            |
| Pain                                                                                          | Ketorolac        | 15 mg IVP                                                                                                                                                                                                                                                                                                                         | The drug is for the short-term management of moderately severe acute pain.                                                                                                                                                                                                                                                                                    |

**TABLE 13-7.** Emergency Drugs for Use With Hypersensitivity or Anaphylactic Reactions (*Continued*)

| Indication                                                                                                 | Drug               | Dose                          | Comments                                                                                                                           |
|------------------------------------------------------------------------------------------------------------|--------------------|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| To prevent biphasic (delayed) reaction or for use with cytokine release reaction/cytokine release syndrome | Methylprednisolone | 40 mg IV (80 mg for > 120 kg) | A systematic review failed to find significant benefit in the initial prevention of anaphylaxis or as a delayed/biphasic reaction. |
|                                                                                                            | Hydrocortisone     | 100–500 mg IV                 |                                                                                                                                    |
|                                                                                                            | Dexamethasone      | 10–20 mg IV                   |                                                                                                                                    |

Additional emergency medications for advanced cardiovascular life support and emergency supplies (e.g., oxygen, suction machine with catheters, bag valve mask) should be available in a medical emergency.

IM—intramuscular; IV—intravenous; IVP—intravenous push

Note. Based on information from Campbell & Kelso, 2021; Castells et al., 2022; Commins, 2017; Galvão et al., 2017; Wilkes & Barton-Burke, 2020.

dynamic changes caused by a decrease in renal blood flow and glomerular filtration rate (Cobb & Lee, 2021).

- (5) Cancer treatments causing CRR usually include chimeric, humanized, and human monoclonal antibodies, such as rituximab and blinatumomab, and chemotherapy, such as oxaliplatin (Jimenez-Rodriguez et al., 2018). CRS is more often associated with CAR T-cell therapies (Cobb & Lee, 2021).

- g) Clinicians may find it challenging to determine what type of reaction a patient is having.

Using the precision medicine framework, acute infusion-related reactions may also be a mixture of type 1 HSR and CRR/CRS reactions. In this scenario, it is recommended to treat the reaction as a type 1 HSR.

- h) Using standardized scales to define reactions by grade helps to reduce the high variability in how reactions are reported. Clinical teams must be clear about which scale is used to ensure accurate assessment, communication, and documentation. Allergists have used the Brown grading system for generalized hypersensitivity reactions due to its clinical utility during the reac-

**TABLE 13-8.** Benefits of Epinephrine

| Benefit                                                                                     | Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Epinephrine is the most effective approach to preventing death from anaphylaxis.            | Epinephrine decreases the release of mediators of inflammation from mast cells and basophils.<br>Epinephrine prevents or reverses airflow obstruction in the upper and lower respiratory tracts and cardiovascular collapse.<br>Epinephrine increases vasoconstriction and peripheral vascular resistance.<br>Epinephrine decreases mucosal edema in the upper airway.<br>Epinephrine increases inotropy, chronotropy, and bronchodilation.<br>Antihistamines and glucocorticoids do not effectively treat anaphylaxis or prevent biphasic reactions. |
| No contraindications exist for giving epinephrine for anaphylaxis.                          | Recommended doses are effective with minor risks, as there is no other medication that can reliably reverse the lethal effects of anaphylaxis.                                                                                                                                                                                                                                                                                                                                                                                                        |
| Epinephrine given via the intramuscular route is more readily accessible than the IV route. | Giving epinephrine via the anterolateral upper thigh provides a rapid increase in plasma and tissue concentrations over the IV route. A lower risk exists for cardiovascular complications than with the IV route.                                                                                                                                                                                                                                                                                                                                    |
| Intramuscular dosing via autoinjector provides safer and more reliable dosing.              | Unfamiliarity with various epinephrine dilutions can lead to the wrong dosage. Autoinjectors have proved to eliminate dose variation when used following manufacturer instructions. If an autoinjector is not available, an institution must make a reliable plan for rapid and accurate administration of epinephrine.                                                                                                                                                                                                                               |
| Epinephrine is appropriate for anaphylaxis during pregnancy.                                | Some clinicians are reluctant to use epinephrine for anaphylaxis during pregnancy; however, it is the most effective treatment for anaphylaxis. Epinephrine may cause premature labor.                                                                                                                                                                                                                                                                                                                                                                |

Delayed administration of epinephrine is associated with fatalities.

Note. Based on information from Campbell & Kelso, 2021; Shaker et al., 2020.

**FIGURE 13-3.** European Society for Medical Oncology Clinical Criteria for Diagnosing Anaphylaxis

Anaphylaxis is highly likely when any one of the following three sets of criteria is fulfilled:

1. Acute onset of an illness (minutes to hours) with involvement of skin/mucous membranes (e.g., hives, generalized itch/flush, swollen lips/tongue/uvula) and at least one of the following:
  - a. Respiratory compromise (e.g., dyspnea, wheeze/bronchospasm, stridor, reduced peak expiratory flow, hypoxemia)
  - b. Reduced blood pressure or associated symptoms of end-organ dysfunction (e.g., hypotonia [collapse], syncope, incontinence)
2. Two or more of the following that occur rapidly after exposure to a likely allergen for that patient (minutes to several hours):
  - a. Involvement of skin/mucous membranes (e.g., generalized hives, itch/flush, swollen lips/tongue/uvula)
  - b. Respiratory compromise (e.g., dyspnea, wheeze/bronchospasm, stridor, reduced peak expiratory flow, hypoxemia).
  - c. Reduced blood pressure or associated symptoms of end-organ dysfunction (e.g., hypotonia [collapse], syncope, incontinence)
  - d. Persistent gastrointestinal symptoms (e.g., crampy abdominal pain, vomiting)
3. Reduced blood pressure after exposure to a known allergen for that patient (minutes to several hours); adult systolic blood pressure of < 90 mm Hg or > 30% decrease from that baseline

Note. Based on information from Roselló et al., 2017.

tion (Broyles et al., 2020; Fouda & Bavbek, 2020; Tsao et al., 2021). See Table 13-9 for the Brown grading system for generalized hypersensitivity reactions (Brown, 2004). See Table 13-10 for the National Cancer Institute Cancer Therapy Evaluation Program's *Common Terminology Criteria for Adverse Events* (CTCAE) for allergic reactions, anaphylaxis, and CRS. CTCAE criteria focus on the duration, severity, and interventions for the reaction. Although the Brown

grading system is not specific to the oncology population, it is focused on the specific symptoms commonly seen in HSRs (Tsao et al., 2021).

2. Risk factors for acute infusion-related reactions
  - a) Administration of a chemotherapy or immunotherapy agent known to cause HSRs
  - b) Drug versus vehicle: The vehicle in which the antineoplastic is dissolved (e.g., polysorbate 80, Cremophor) can be responsible for acute infusion-related reactions.
  - c) Access to health care, age, geography, industrialization, and preexisting allergies, such as food for young children, drugs for adolescents and adults, environmental allergens, and Hymenoptera venom (e.g., bees, yellow jackets, wasps, hornets) (Castells, 2017; Regateiro et al., 2020)
  - d) Premedication with fosaprepitant: Serious reactions, including anaphylaxis, have been reported with fosaprepitant and are thought to be related to the vehicle polysorbate 80. Do not resume use if symptoms occur with first-time administration (Hayes et al., 2021; Merck, 2019). Formulation substitutes do not contain polysorbate 80, and some institutions have substituted with IV aprepitant due to its favorable safety profile (Calcanes & Vacirca, 2019).
  - e) Previous exposure to the agent with mild symptoms of an allergic response
  - f) Failure to administer known effective prophylactic premedications
  - g) The first 5–15 minutes from the start of the infusion
  - h) The first infusion of rituximab (greater than 50% incidence) (LaCasce et al., 2021): “Priming the IV line with rituximab allows for a slow, incremental exposure, resulting in decreased hypersensitivity reaction incidence” (Laudati et al., 2018, p. 408).

**TABLE 13-9.** Brown Grading System for Generalized Hypersensitivity Reactions

| Grade      | Broad Clinical Features or Systems involved                                      | Defining Signs and Symptoms                                                                                                                                                         |
|------------|----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1–Mild     | Skin and subcutaneous tissues only                                               | Generalized erythema, urticaria, periorbital edema, angioedema                                                                                                                      |
| 2–Moderate | Features suggesting respiratory, cardiovascular, or gastrointestinal involvement | Dyspnea, stridor, wheeze, nausea, vomiting, dizziness (presyncope), diaphoresis, chest or throat tightness, abdominal pain                                                          |
| 3–Severe   | Hypoxia, hypotension, neurologic compromise                                      | Cyanosis, or blood oxygen saturation $\leq$ 92% at any stage of hypotension; systolic blood pressure < 90 mm Hg in adults; confusion; collapse; loss of consciousness; incontinence |

Mild reactions can be further subclassified into those with and without angioedema.

Note. Based on information from Brown, 2004.

**TABLE 13-10.** Common Terminology Criteria for Adverse Events Grading for Allergic Reaction, Anaphylaxis, and Cytokine Release Syndrome

| Adverse Event             | Grade                                         |                                                                              |                                                                                                                                       |                                                              |       |
|---------------------------|-----------------------------------------------|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|-------|
|                           | 1                                             | 2                                                                            | 3                                                                                                                                     | 4                                                            | 5     |
| Allergic reaction         | Systemic intervention not indicated           | Oral intervention indicated                                                  | Bronchospasm; hospitalization indicated for clinical sequelae; IV intervention indicated                                              | Life-threatening consequences; urgent intervention indicated | Death |
| Anaphylaxis               | —                                             | —                                                                            | Symptomatic bronchospasm, with or without urticaria; parenteral intervention indicated; allergy-related edema/angioedema; hypotension | Life-threatening consequences; urgent intervention indicated | Death |
| Cytokine release syndrome | Fever with or without constitutional symptoms | Hypotension responding to fluids; hypoxia responding to < 40% O <sub>2</sub> | Hypotension managed with one pressor; hypoxia requiring ≥ 40% O <sub>2</sub>                                                          | Life-threatening consequences; urgent intervention indicated | Death |

IV—intravenous; O<sub>2</sub>—oxygen

Note. From *Common Terminology Criteria for Adverse Events* [v.5.0], by National Cancer Institute Cancer Therapy Evaluation Program, 2017 ([https://ctep.cancer.gov/protocolDevelopment/electronic\\_applications/docs/CTCAE\\_v5\\_Quick\\_Reference\\_5x7.pdf](https://ctep.cancer.gov/protocolDevelopment/electronic_applications/docs/CTCAE_v5_Quick_Reference_5x7.pdf)). In the public domain.

- i) Patients with leukemia or lymphoma, especially those with high tumor/lymphocyte counts (greater than 25,000/mm<sup>3</sup>) (Wilkes & Barton-Burke, 2020)
  - j) Nurses in infusion units should confirm allergy history prior to drug administration and observe patients closely for acute infusion-related reactions. Patients need education to self-report symptoms of a reaction immediately. Failure of staff to identify early symptoms of a reaction and a lack of patient self-report may contribute to a delay in identifying a reaction and interventions for treatment (Hayes et al., 2021; Rombouts et al., 2020).
3. Risk factors for CRR/CRS
- a) Monoclonal antibodies
  - b) CAR T-cell therapy is a form of immunotherapy using genetically modified T cells to produce CARs. The T cells are isolated and modified using a retroviral or lentiviral vector. Depending on the indication, CAR T cells target a specific antigen expressed on malignant cells (e.g., cluster of differentiation 19) to cause apoptosis.
    - (1) CRR/CRS is the main complication experienced after the cell infusion and is caused by the release of interleukin-6, leading to systemic inflammation. It is seen as early as day 0 and should be anticipated with CAR-T cell therapy (Wei et al., 2020).
    - (2) Nurses caring for patients during CAR T-cell therapy need to have specific education and competency validation, given the severity of CRR/CRS, the intensity of the treatments, and the evolving approaches for identifying and managing CAR T-cell–related CRR/CRS.
    - (3) As of this writing, agents approved for CAR T-cell therapy with a black box warning for reactions and CRR/CRS, among other complications, include the following:
      - (a) Abecma® (idecabtagene vicleucel) (Celgene, 2021)
      - (b) Breyanzi® (lisocabtagene maraleucel) (Juno Therapeutics & Bristol Myers Squibb, 2021)
      - (c) Kymriah® (tisagenlecleucel) (Novartis Pharmaceuticals, 2022)
      - (d) Tecartus® (brexucabtagene autoleucel) (Kite Pharma, 2022a)
      - (e) Yescarta® (axicabtagene ciloleucel) (Kite Pharma, 2022b)
    - (4) For treatment of CRR/CRS, it is recommended to administer tocilizumab or combination tocilizumab and a cortico-

- steroid. Tocilizumab targets interleukin-6 and resolves symptoms within 24–48 hours (Genentech, 2021). The early administration of tocilizumab can prevent CRR/CRS without compromising the efficacy of CAR T-cell therapy (Kadauke et al., 2019).
4. Implement the following steps to identify, prevent, and manage acute infusion-related reactions following evidence-based medical, pharmacologic, and nursing references and institutional standards of practice.
    - a) Obtain and record baseline vital signs, height and weight, and patient assessment findings.
    - b) Perform a thorough pretreatment patient assessment to verify recovery from past treatment, consent to treatment, and the need to reinforce key education about the treatment. A chart review includes but is not limited to diagnosis, regimen/treatment plan, previous doses administered (e.g., premedications), dose modifications/delays, tolerance and reactions to past treatments, current cycle/day, cycle length, IV access, history of any category of acute infusion-related reaction, allergy history (e.g., food, medication, environment), and criteria to treat (including laboratory tests).
    - c) Review the medication list to identify a beta-blocker.
      - (1) Beta-blockers can inhibit the response to epinephrine in anaphylaxis. If patients do not respond after two doses of epinephrine and are taking a beta-blocker, 1 mg IV glucagon over at least five minutes (see Table 13-8) can exert inotropic and chronotropic effects. This counteracts the systemic effects of anaphylaxis, as glucagon acts independently of alpha and beta receptors (Campbell & Kelso, 2021).
      - (2) See Table 13-7 for more information on administration considerations. Failure to respond to two doses of epinephrine is also a possible indicator of the need for a higher level of care.
    - d) Administer premedications as ordered per institutional standards and as recommended per package insert.
      - (1) Common premedications include histamine antagonists (e.g., H<sub>1</sub> antagonist [diphenhydramine], H<sub>2</sub> antagonist [ranitidine or famotidine]), acetaminophen, and glucocorticoids (LaCasce et al., 2021).
      - (2) Peak action of oral versus IV routes can vary, and appropriate timing of premedications prior to treatment should be considered.
  - (3) Premedications do not fully protect patients from anaphylaxis (Shaker et al., 2020).
  - e) Ensure clinicians, including nurses, physicians, and advanced practice providers, are present in the infusion setting and that emergency equipment and medications are readily available. These clinicians must be competent in managing acute infusion-related reactions and providing basic life support (Neuss et al., 2017).
  - f) Obtain provider orders for emergency treatment before drug administration. Given that medications used in the oncology setting may lead to acute infusion-related reactions, written standing orders for managing acute infusion reactions are recommended, along with specific role delineation and interventions for each clinician to ensure an immediate, organized, and competent response (Commings, 2017).
  - g) With each infusion, instruct patients to report symptoms of hypersensitivity and infusion reaction immediately while concurrently visualizing and eliciting self-report of symptoms.
  - h) Monitoring for reactions in unique situations
    - (1) Acute infusion-related reactions can occur with repeated exposure to a drug and at any time during the infusion or the treatment cycle. Most reactions occur during the first or second exposure (LaCasce et al., 2021; Rombouts et al., 2020).
    - (2) Approximately 10%–30% of reactions will occur after the second exposure.
      - (a) For example, the incidence of an acute infusion-related reaction with a platinum-containing agent increases with multiple doses and can occur after the infusion has been completed (Castells et al., 2022; LaCasce et al., 2021).
      - (b) No data exist to support routine premedications prior to all cycles of platinum agents in the absence of prior reaction.
      - (c) Although it is reasonable to consider premedications or the administration of incremental doses of an IV drug from low to the maximum rate, known as titration, for patients receiving cycle 5 or beyond of a platinum-containing agent, the determination is made on a case-by-case basis (Castells et al., 2022).
    - (3) Patients with a *BRCA1/2* variant experience more immediate acute infusion reac-

- tions than those without a *BRCA1/2* variant and require close monitoring for reaction (Galvão et al., 2017).
- (4) Acute laryngopharyngeal dysesthesia, a rapid onset of cold-related sensations of dyspnea, difficulty swallowing or talking, jaw contraction, and odd sensations in the tongue and pharynx, may occur during or after an oxaliplatin infusion. It may be clinically indistinguishable from an acute infusion-related reaction (Pachman et al., 2015).
  - (5) Irinotecan-induced cholinergic syndrome is well known and may present during and within the first 24 hours of administration. It is characterized by diarrhea, abdominal cramping, emesis, diaphoresis, and, less commonly, hyperlacrimation and rhinorrhea. This syndrome may be clinically indistinguishable from an acute infusion-related reaction (Roselló et al., 2017).
  - (6) Complement activation-related pseudo-allergy (CARPA) is a non-IgE reaction that often presents with the first or second dose.
    - (a) It can range in severity, including anaphylaxis, and is managed as a type 1 HSR.
    - (b) CARPA has been associated with the vehicles Cremophor or polysorbate 80 found in taxanes, fosaprepitant, cyclosporine, diazepam, propofol, and vitamin K (Castells et al., 2022; Eisenberg, 2018).
    - (c) The first reaction is often worse and diminishes with subsequent exposures. Grade 3 reactions would indicate discontinuation before any additional doses are given, and referral to an allergist may be indicated to continue (Cáceres et al., 2019; D'Errico et al., 2020).
  - (7) Paclitaxel standard premedications, including glucocorticoid,  $H_1$  and  $H_2$  blockers, help decrease the severity of the reaction when given 30–60 minutes prior to therapy administration.
    - (a) In the absence of a reaction, dose reduction or discontinuation of all premedications after two infusions is safe and effective in preventing paclitaxel-related reactions (Yenilmez et al., 2017).
    - (b) Little evidence supports titration of paclitaxel to minimize HSR risk.
    - (c) Nymberg et al. (2021) noted titration to be associated with an increased rate of subsequent emergency medicine use compared to maintaining a set infusion rate after experiencing a reaction. More evidence surrounding paclitaxel titration is needed to guide safe practice recommendations.
    - (d) Titration can be considered a form of desensitization and needs to be planned and performed within a well-defined setting using an inter-professional approach to ensure safety.
    - (e) To reduce the incidence of infusing a Cremophor bolus, double invert the bag gently prior to administration to ensure even distribution (Castells et al., 2022).
  - (8) For patients who have successfully received and tolerated the first full dose of rituximab without a grade 3–4 acute infusion-related reaction (among other exclusion criteria), subsequent rituximab infusions may be administered at an initial rate of 20% of the total dose over 30 minutes. This is followed by the remaining 80% over 60 minutes, known as a rapid infusion. In the event of a grade 3–4 reaction, patients are not eligible for rapid infusion until they have received standard infusion rituximab without any reaction (Genentech, 2010b).
5. Clinical management of acute infusion-related reactions: Assess and treat symptoms as quickly as possible. Respiratory or cardiac arrest and death can occur within several minutes; therefore, a rapid, competent, standardized team response is required for optimal management and outcomes. Figure 13-4 provides a guide for treating acute infusion-related reactions based on grade.
- a) Stop drug infusion immediately and disconnect the allergen, noting the reaction start time.
  - b) Maintain an IV line with normal saline infusing wide open.
  - c) Call for help.
  - d) Stay with the patient and verify allergies. Request another team member to notify the provider and emergency team with pertinent details (i.e., name, location, problem, and status, including vital signs and concerns). Local emergency medical services should be called and provided with the same pertinent details if outside the hospital setting.

**FIGURE 13-4.** Infusion-Related Toxicity Algorithm

(Continued on next page)

**FIGURE 13-4.** Infusion-Related Toxicity Algorithm (*Continued*)

CV—cardiovascular; ED—emergency department; GI—gastrointestinal; HSR—hypersensitivity reaction; IV—intravenous; MD—medical doctor; N/V—nausea/vomiting; NP—nurse practitioner; PA—physician assistant; PO—by mouth; PRN—as needed; SBP—systolic blood pressure; SOB—shortness of breath; SpO<sub>2</sub>—oxygen saturation

Note. Based on information from Brown, 2004; Campbell & Kelso, 2020, 2021; Castells et al., 2022; Commins, 2017; Galvão et al., 2017; Roselló et al., 2017; Shaker et al., 2020; Wilkes & Barton-Burke, 2020.

Figure courtesy of Dana-Farber Cancer Institute. Adapted with permission.

- e) Maintain the patient upright if short of breath or vomiting. Place the patient in a supine position, if able, and elevate the legs if hypotensive (systolic blood pressure less than 60 mm Hg).
- f) Monitor vital signs (i.e., temperature, pulse, respiration, blood pressure, and oxygen saturation) as clinically appropriate until resolution (60–90 minutes postreaction). Consider an electrocardiogram if appropriate for the level of care and staff competency. Consider transfer to a higher level of care to monitor for significant cardiac changes.
- g) Maintain airway, assessing the patient for increasing respiratory tract edema, shortness of breath, and dyspnea. Administer oxygen if needed. Anticipate the need for CPR. Initiate basic life support as indicated.
- h) Observe for and evaluate symptoms.
  - (1) For grade 1–2 reactions, administer an  $H_1$  and  $H_2$  blocker.
    - (a) Treat symptoms with additional supportive care medications as indicated.
    - (b) Observe the patient until symptoms resolve, usually within 30 minutes. After the resolution of symptoms, review manufacturer instructions for additional recommendations, such as rate titrations.
    - (c) Continue ongoing assessment for signs and symptoms of acute infusion-related reaction or advancement to anaphylaxis.
    - (d) If symptoms are not resolving or worsening, prepare to administer epinephrine and activate the emergency team or local emergency services.
  - (2) For grade 3 reactions or when symptoms are worsening or not resolving, administer emergency medications based on symptoms, starting with epinephrine, and activate the emergency team or local emergency services (Campbell & Kelso, 2021; Commins, 2017).
    - (a) Because anaphylaxis is potentially life threatening, it needs to be identified immediately and treated with epinephrine, the only medication that can reverse life-threatening symptoms of anaphylaxis (see Table 13-8).
    - (b) Do not restart the causative agent with grade 3 reactions. Observe the patient until stabilized. Disposition is determined based on the severity of the reaction, patient recovery after treatment, and comorbidities. Consider referral to an allergist for desensitization.
- i) Provide emotional support to the patient and family.
- j) Document all treatments, the grade of reaction using an institution-approved hypersensitivity grading scale, and the patient's response to interventions in the medical record. Note the time the reaction started and the time tryptase levels are to be drawn (as ordered and if available) to determine the need for desensitization and assist the allergist in assessing and determining the reaction etiology at a future time.
- k) Document causative agent as an allergy in the medical record regardless of the grade of reaction.
- l) Consider allergist consult or referral to desensitization clinic.
- m) Debriefing should occur as soon as possible after an acute infusion-related reaction to review provided care, clinical decisions, team performance, and opportunities for improvement (Patient Safety Network, 2021).
- n) Known as a biphasic reaction, symptoms of anaphylaxis may recur hours after the initial intervention. Although etiology and incidence are not fully understood, consider administering a glucocorticoid (methylprednisolone 40 mg IV push [80 mg for greater than 120 kg]) for patients experiencing a grade 2 or higher reaction. A recent systematic review failed to find significant benefit to steroid use in the initial prevention of anaphylaxis or as a delayed/biphasic reaction (Campbell & Kelso, 2021; Shaker et al., 2020).
- o) Monitor the patient until symptoms of anaphylaxis have fully resolved.
  - (1) No consensus exists on the required observation time.
  - (2) Patients with severe anaphylaxis and those who require more than one dose of epinephrine are at an increased risk for a biphasic reaction; therefore, emergency department monitoring or hospital admission should be considered (Campbell & Kelso, 2021).
- p) For patients who experience a suspected anaphylactic reaction, a tryptase blood level should be drawn (as ordered and if available) no sooner than 30 minutes from the start of the reaction and again 60 minutes after the first tryptase level is drawn. If an urgent transfer is required, attempt to draw one tryptase prior to transfer to ensure sensitivity and specificity as levels peak

30–90 minutes after the onset of anaphylaxis (Schwartz, 2020).

- (1) Any elevation in serum total tryptase is consistent with anaphylaxis; however, a normal value does not exclude anaphylaxis because it may be a false negative based on the timing of the draw or may need to be compared to a baseline level.

- (a) The sample should not be drawn at the onset of the symptoms to reduce the risk of a false-positive result (Schwartz, 2020).

- (b) Results of tryptase levels drawn during the acute phase are only useful when viewed with additional postreaction values and other clinical data to capture the patient's trending and complete clinical picture.

- (c) Tryptase levels are intended only to augment postreaction assessment and interventions by the allergist for the possible benefit of a desensitization plan (Campbell & Kelso, 2020).

- (d) Elevation of serum tryptase levels is consistent with anaphylaxis, but one normal tryptase level cannot exclude anaphylaxis (Castells et al., 2022).

- (2) Avoid administering subsequent doses of the causative agent if the patient is to be desensitized to the drug.

- (a) Drug desensitization is a controlled reexposure to the causative agent to produce a temporary tolerance, allowing the patient to safely receive an uninterrupted course (Castells & Solensky, 2020).

- (b) If the drug is critical to the treatment plan, refer the patient to an allergist qualified in drug desensitization (Castells et al., 2022).

- (c) Drug desensitization is recommended after showing that the benefits outweigh the risks. It should be used with caution by competent nurses and providers under the guidance of an allergist when available (Castells et al., 2022).

## 6. Skin testing

- a) Skin testing using the prick/puncture and intradermal methods may be performed in collaboration with a qualified allergist on patients four to six weeks after they experienced an infusion-related reaction with any symptom suggestive of possible anaphylaxis (Castells et al., 2022; Jimenez-Rodriguez et al., 2018).

- b) It has limited value with most chemotherapy except for platinum-containing drugs and taxanes (Fouda & Bavek, 2020; Tsao et al., 2021).

- c) This practice is valuable because it evaluates whether patients are truly allergic to the drug or class.

- d) Skin testing for other drugs is considered investigational and not widely performed. Skin testing with vesicants is not to be performed. Testing with irritants must be performed carefully with dilution and a qualified allergist (Castells et al., 2022).

- e) Only allergists with special training in technique, interpretation, and management of rare allergic reactions should perform these tests in highly sensitive patients because of the risk of dermatologic or other toxicities associated with chemotherapy skin testing (Castells et al., 2022).

- f) Minimal data are available for skin testing with immunotherapy agents. Few allergy centers associated with oncology practices have experience with skin testing (Khan, 2016; LaCasce et al., 2021).

## F. Patient and caregiver education

1. Before therapy, inform patients and families that chemotherapy and immunotherapy agents have the potential for acute infusion-related reactions. Instruct them to report signs and symptoms immediately.
2. After infusion, instruct patients and families about the importance of immediately reporting symptoms of any delayed reaction. If a reaction is experienced, include the drug on their allergy list in the medical record to prevent future inadvertent administration.
3. Document all patient teaching and interventions.

- Chapter 21. Cutaneous Toxicities and Alopecia
- Chapter 22. Endocrine Toxicities
- Chapter 23. Fatigue
- Chapter 24. Neurologic Toxicities
- Chapter 25. Ocular Toxicities

## CHAPTER 14

# Myelosuppression

### A. Overview

1. Myelosuppression is a condition manifested by a significant decrease in the neutrophils, megakaryocytes, and erythrocytes within the bone marrow (National Cancer Institute [NCI], n.d.). It is a dose-limiting toxicity of systemic chemotherapy (Camp-Sorrell, 2018).

#### a) Neutropenia

- (1) Neutropenia is defined as a significant reduction in the absolute number of circulating neutrophils in the blood.
- (2) The absolute neutrophil count (ANC) is the basis for neutropenia classification and is generally defined as an ANC less than  $1,500/\text{mm}^3$  (Territo, 2021).
- (3) The National Comprehensive Cancer Network (NCCN, 2021c) defines febrile neutropenia as an ANC less than  $500/\text{mm}^3$  or the expectation that the neutrophil count will decline to less than  $500/\text{mm}^3$  within 48 hours.
- (4) The *Common Terminology Criteria for Adverse Events* stratifies grades of febrile neutropenia (NCI Cancer Therapy Evaluation Program, 2017; see Table 14-1).
- (5) Stratifying the severity of neutropenia related to relative infection risk helps identify those at risk following myelosuppressive therapy (NCCN, 2021c; NCI, 2017; Territo, 2021).
  - (a) Mild: ANC  $1000\text{--}1,500/\text{mm}^3$
  - (b) Moderate: ANC less than  $500\text{--}1,000/\text{mm}^3$
  - (c) Severe: ANC less than  $500/\text{mm}^3$

#### b) Anemia

- (1) In adults with cancer, hemoglobin (Hgb) of 10 g/dl or lower or 2 g/dl or greater below baseline warrants evaluation for anemia (NCCN, 2021).
- (2) Other references for adults in industrialized nations identify 14 g/dl for men and

12 g/dl for women as lower limits for normal Hgb (Braunstein, 2020).

- (3) A decrease in the hematocrit or number of red blood cells (RBCs) can be used to define anemia. Still, Hgb is used most often because it reflects the physiologic consequences of anemia (Braunstein, 2020).

c) Thrombocytopenia is a platelet count below the lower limit of normal  $140,000\text{--}400,000/\text{mm}^3$  (Kuter, 2020).

d) Cytopenia is a condition marked by lower-than-normal blood cell counts (NCI, n.d.).

e) Pancytopenia is a lower than normal number of RBCs, white blood cells (WBCs), and platelets (NCI, n.d.).

f) The nadir is the time or level at which the lowest blood cell count is reached following cytotoxic therapy. It varies with individual agents but usually occurs 7–10 days after treatment (Cancer.Net Editorial Board, 2019).

#### g) Hematopoiesis

- (1) Hematopoiesis is the production of all blood cells from hematopoietic stem cells (HSCs) (NCI, n.d.). Most hematopoiesis occurs in the bone marrow in myeloid tissues of adults (see Figure 14-1).

- (2) The process begins with HSCs (also known as pluripotent stem cells) (NCI, n.d.).

(a) These are the most primitive type of blood cells and the source of all HSCs.

(b) HSCs can self-renew and maintain their numbers because they can proliferate, differentiate, and mature into all cell lines.

(c) With each stem cell division, one daughter cell stays in the stem cell pool, whereas the other daughter cell leaves the stem cell pool and becomes committed to a distinct cell line.

**TABLE 14-1.** Common Terminology Criteria for Adverse Events Grading for Anemia, Neutropenia, and Thrombocytopenia

| Adverse Event               | Grade                                                           |                                                                   |                                                                                                                                                          |                                                                       |       |
|-----------------------------|-----------------------------------------------------------------|-------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------|-------|

(d) These committed progenitor cells differentiate and mature in the bone marrow.

(e) Whether HSCs proliferate or differentiate is determined by the body's needs in response to exogenous (e.g., high altitude) or endogenous (e.g., stress, infection, hemorrhage, drug therapy) influences. Once released into the bloodstream, mature cells have a varied life span (see Table 14-2).

2. Most chemotherapy agents cause some degree of myelosuppression (Zack, 2018). The degree and duration of chemotherapy-related myelosuppression are related to the agent's mechanism of action (e.g., cell cycle-specific drugs are associated with rapid cytopenias) and dose intensity (NCCN, 2021).

## B. Types of cytopenias

### 1. Neutropenia in patients with cancer

a) Chemotherapy-induced neutropenia is the primary dose-limiting toxicity associated with systemic chemotherapy (Zack, 2018). It has significant negative clinical consequences for patients with cancer, including life-threatening infections, prolonged hospital stays, dose reductions, and dose delays (NCCN, 2021).

b) Healthy physiology of neutrophils

- (1) Neutrophils differentiate from pluripotent stem cells and continue a maturation process in the bone marrow. After differentia-

tion, these cells progress from myeloblast to promyelocyte, myelocyte, and then metamyelocyte. Ultimately, they transform into nearly mature bands and segmented neutrophils.

- (2) This process takes approximately two weeks.

- (3) The segmented neutrophils and bands (when required) are released from the bone marrow into the bloodstream, where they live for approximately 12 hours (Mahdi, 2018; Wilson, 2018).

c) Locations of neutrophils (Rosales, 2018)

- (1) The bone marrow of a healthy adult contains mature segmented neutrophils and immature neutrophils in various stages of development. Neutrophils leave the bone marrow for the blood through pores that form between the marrow parenchyma and venous blood vessels.

- (2) Once in the bloodstream, these cells join the functional pool by circulating or lining blood vessel walls as marginated cells, meaning they adhere to endothelial cells lining the blood vessel.

- (3) Neutrophils exist in the bloodstream as mature and immature cells. These cells perform a critical role in the body's defense.

- (4) The result is the activation of neutrophil defense and movement of neutrophils to the site of infection (Rosales, 2018).

**FIGURE 14-1.** Hematopoiesis and Cytokine Delineation

**TABLE 14-2.** Life Spans of Blood Components

| Blood Component     | Typical Life Span                          |
|---------------------|--------------------------------------------|
| Red blood cell      | 90–120 days                                |
| Platelet            | 8–10 days                                  |
| Neutrophil          | < 48 hours                                 |
| Monocyte            | 5 days, but depends on many factors        |
| Macrophage          | Depends on many factors                    |
| Eosinophil          | 8–18 hours in blood and 2–5 days in tissue |
| Basophil            | 1–2 days                                   |
| Tissue mast cell    | Cutaneous: 1 year; mucosal: 1–2 weeks      |
| B lymphocyte        | Depends on type and subtype                |
| T lymphocyte        | Depends on type and subtype                |
| Natural killer cell | Approximately 10 days                      |

Note. Based on information from Kitamura, 1989; Milot & Filep, 2011; Min et al., 2012; Nayak et al., 2013; Park & Bochner, 2010; Pillay et al., 2010; Whitelaw, 1966; Zhang et al., 2007.

- (5) Neutrophils leave the blood for tissue by migrating through endothelial cells. After functioning in the tissue, neutrophils succumb to apoptosis and are phagocytized by macrophages (Rosales, 2018).

d) Pathophysiology

- (1) The bone marrow must constantly produce neutrophils because their life span is estimated to be less than 48 hours.
  - (a) Chemotherapy agents suppress bone marrow activity and damage stem cells, preventing them from continuing the maturation process.
  - (b) Therefore, chemotherapy decreases the neutrophil count as mature neutrophils die and are not replaced (Camp-Sorrell, 2018).
- (2) WBC nadir depends on the specific drugs and dosages used.
  - (a) Chemotherapy regimens that also include monoclonal antibodies (mAbs) have the potential to increase the risk of febrile neutropenia (NCCN, 2022c).
  - (b) The mAb conjugates (e.g., sacituzumab govitecan-hziy) can also put patients at risk for severe neutropenia (Immunomedics, 2021; see Chapter 9).

- i. Cell cycle-specific agents (e.g., antimetabolites) are generally less damaging because they primarily affect cells in a specific phase of the cell cycle. Severe neutropenia can develop when cell cycle-specific drugs are used in dose-intensification and combination chemotherapy regimens (Tortorice, 2018).
- ii. Cell cycle-nonspecific agents (e.g., alkylating agents, nitrosoureas) damage cells in all phases of the cell cycle, thereby causing more damage to stem cells. The extent of neutropenia with these agents is dependent on dose, schedule, and agent. For example, oxaliplatin as a single agent is expected to cause mild neutropenia, but toxicity can be much higher in regimens with 5-fluorouracil and leucovorin (Tortorice, 2018).
- iii. Some cell cycle-nonspecific agents (e.g., carmustine) produce delayed and prolonged neutropenia. Nadir occurs at three to five weeks in adults, with recovery as long as five to six weeks (Ben Venue Laboratories, 2007).

- e) Fever and febrile neutropenia: Fever is defined as a one-time oral temperature greater than 101°F (38.3°C) or oral temperature of 100.4°F (38°C) lasting one hour. Febrile neutropenia occurs when ANC is less than 500/mm<sup>3</sup> or less than 1,000/mm<sup>3</sup> with an anticipated decline to 500/mm<sup>3</sup> or less over the next 48 hours with fever (NCCN, 2021, 2022c).

f) Risk assessment

- (1) Febrile neutropenia risk should be assessed prior to the first and each subsequent treatment cycle (NCCN, 2021; Wilson et al., 2019). Increased infection risk is present in patients with fever (Taplitz et al., 2018).
- (2) Risk factors for developing febrile neutropenia in adults being treated for solid tumors (NCCN, 2022c; see Figure 14-2)
  - (a) Age 65 years or older receiving chemotherapy dose intensity
  - (b) Persistent neutropenia

**FIGURE 14-2.** Risk Factors for Developing Febrile Neutropenia**Patient Related**

- Age > 65 years
- Assigned gender female
- Poor performance status
- Poor nutritional status
- Low neutrophil count at the beginning of a treatment cycle
- Renal dysfunction
- Liver dysfunction, especially elevated bilirubin
- Cardiovascular disease
- Recent surgery
- Preexisting infection
- Open wounds

**Disease Related**

- Advanced disease stage
- Tumor involvement of the bone marrow
- Type of malignancy: hematologic (e.g., leukemia, myelodysplastic syndromes), breast, lung, colorectal, ovarian, and lymphoma
- Preexisting, prolonged, or previous episode of neutropenia

**Treatment Related**

- Previous myelosuppressive chemotherapy or radiation
- Treatment intent (curative intent rather than palliative)
- Planned relative dose intensity ( $\geq 85\%$ )
- Use of specific medications (e.g., immunosuppressive drugs)
- Chemotherapy intensity (i.e., dose dense, high dose, myeloablative)

Note. Based on information from Freifeld et al., 2011; National Comprehensive Cancer Network, 2021, 2022c.

- (c) Tumor involvement of bone marrow
- (d) Poor performance status
- (e) Renal dysfunction (creatinine clearance less than 50 ml/min)
- (f) Liver dysfunction (bilirubin greater than 2 mg/dl)
- (g) Previous chemotherapy or radiation
- (h) Open wounds or recent surgery
- (i) Chemotherapy regimen with febrile neutropenia incidence greater than 20%
- (j) Use of specific medications (e.g., phenothiazines, diuretics, immunosuppressive drugs)
- (3) Risk for developing febrile neutropenia with hematologic malignancy (NCCN, 2022c)
  - (a) Diagnosis of acute lymphoblastic leukemia, acute myelocytic leukemia, chronic lymphocytic leukemia treated with alemtuzumab, and non-Hodgkin lymphoma, especially the T-cell subtype
  - (b) Allogeneic hematopoietic stem cell transplantation (HSCT) recipients and those with graft-versus-host disease following allogeneic HSCT
- g) Clinical manifestations of infection in patients with neutropenia (NCCN, 2022c; Taplitz et al., 2018; Territo, 2021)
  - (1) A fever greater than 100.4°F (38°C) is the most reliable indicator and often the only sign of infection in patients with neutropenia. Usually, WBCs cause the classic signs of infection (e.g., redness, edema, pus). However, extremely neutropenic patients may not be able to manifest the usual signs of infection (NCCN, 2022c; Taplitz et al., 2018; Territo, 2021).
  - (2) Common sites of infection and corresponding signs and symptoms in neutropenic patients (Camp-Sorrell, 2018; NCCN, 2022c; Territo, 2021)
    - (a) Gastrointestinal tract: fever, abdominal pain, alimentary mucositis (mucositis at any level of the digestive tract), diarrhea
    - (b) Respiratory tract: fever, cough, dyspnea on exertion, adventitious breath sounds, chest discomfort, asymmetric chest wall movement, nasal flaring
    - (c) Genitourinary tract: fever, dysuria, frequency, urgency, hematuria, cloudy urine, flank pain, perineal itching, vaginal discharge
    - (d) Head and neck: swelling, itching, eye redness or drainage, ear pain or discharge, nasal congestion or drainage, oral ulcerations, difficulty swallowing, fever
    - (e) Indwelling devices (e.g., venous access devices, ventricular peritoneal shunts): fever, erythema, pain or tenderness, edema, drainage, induration at the site
    - (f) Dermatologic and mucous membranes: erythema, tenderness, warm skin, edema (especially in axilla, mouth, sinuses, perineal, or rectal areas), rashes, itching, skin lesions, fever, draining open wounds
    - (g) Central nervous system: change in mental status, headache, seizure, vision changes, photosensitivity, fever, nausea, lethargy
    - (h) Hematologic/immunologic: decrease in diastolic blood pressure, headache, oliguria, fever, flushed appearance
  - (3) Septic shock associated with neutropenia has a high mortality rate (O'Leary, 2018). For hospitalized patients, it may be as high as 50%.

## h) ANC calculation

- (1) Use laboratory data to assess neutropenia by calculating ANC. Note that neutropenia can occur when the total WBC count is within the normal range of 4,000–10,000/mm<sup>3</sup> (Camp-Sorrell, 2018; Territo, 2021).
- (2) Calculating ANC is essential to achieving a correct assessment of neutrophil status.
- (3) To calculate ANC,  $ANC = \% \text{ neutrophils (polys + bands)} \times WBCs$ .
  - (a) Obtain complete WBC count, including differential. The differential will include mature neutrophils, referred to as segs for segmented neutrophils or PMNs/polys for polymorphonuclear neutrophils. In addition, immature neutrophils will be present; these are known as bands.
  - (b) Add the total number of mature polys and less mature neutrophil bands.
  - (c) Convert the sum from (b) to a percentage.
  - (d) Multiply total WBC count by total neutrophil percentage (polys + bands). ANC calculation example: WBCs = 1,500, polys = 30, bands = 5.
    - i. Add polys and bands:  $30 + 5 = 35$ .
    - ii. Convert sum to percentage:  $35 \div 100 = 0.35$ .
    - iii. Multiply WBC count by percentage to find ANC:  $1,500 \times 0.35 = 525/\text{mm}^3$ .

## i) Collaborative management

- (1) Nurses play an essential role in preventing infection in patients with neutropenia and cancer through evidence-based nursing practice, research, and patient education (Wilson et al., 2019).
  - (a) Hand hygiene: Proper hand hygiene is the most effective measure to prevent infection. It reduces the risk of healthcare-associated infections by decreasing the person-to-person transmission of pathogens (Camp-Sorrell, 2018; Centers for Disease Control and Prevention, 2021b; Wilson et al., 2019).
  - (b) Diet
    - i. No recent studies have linked neutropenic diets (restricting fresh fruits and vegetables) with a lower risk of infection

for neutropenic patients with cancer.

- ii. Dietary precautions regarding the omission of fresh fruits and vegetables remain unsupported (Gardner et al., 2008).
  - iii. Uncooked fruits and vegetables should be thoroughly washed (Wilson et al., 2019).
  - iv. Basic safe food handling practices should be employed, such as avoiding uncooked and undercooked meats, seafood, eggs, and unwashed fruits and vegetables (Camp-Sorrell, 2018).
- (c) Environment: Protective or strict isolation studies reveal no significant differences in documented infections, febrile episodes, or antibiotic use for patients with chemotherapy-induced neutropenia. Protective isolation has no effect on the host's endogenous flora and no impact on organisms transmitted by water or food (Camp-Sorrell, 2018).
- i. In general, patients with chemotherapy-induced neutropenia do not require specific room ventilation.
  - ii. Allogeneic HSCT recipients should reside in rooms with HEPA filtration with more than 12 air exchanges per hour. Air pressure in these rooms should be positive compared to surrounding areas, such as hallways, toilets, and anterooms (Anderson-Reitz, 2018; NCCN, 2022c; Zack, 2018).
- (d) Plants and flowers
- i. No studies are available that evaluate the potential harm of plants and flowers to patients with chemotherapy-induced neutropenia (Wilson et al., 2019).
  - ii. Because fresh or dried flowers could expose patients with cancer to *Aspergillus* and *Fusarium*, these flowers should be kept out of patient rooms (Freifeld et al., 2011).
- (e) Treatment with colony-stimulating factors (see Table 14-3)

- i. Granulocyte macrophage–colony-stimulating factor treatments include sargramostim (Genzyme, 2018).
  - ii. Granulocyte–colony-stimulating factor (G-CSF) treatments include filgrastim and pegfilgrastim (Amgen, 2021a, 2021b; Coherus BioSciences, 2021; Mylan GmbH, 2018; Pfizer, 2021a, 2021b; Sandoz, 2017, 2019; Teva Pharmaceuticals, 2019).
  - iii. NCCN (2022a) recommends using these drugs when the risk of febrile neutropenia is higher than 20%.
  - iv. The manufacturer recommends initiation of G-CSF no earlier than 24 hours following chemotherapy (Amgen, 2021a, 2021b; Coherus BioSciences, 2021; Mylan GmbH, 2018; Pfizer, 2021a, 2021b; Sandoz, 2017, 2019; Teva Pharmaceuticals, 2019).
  - v. The manufacturer of G-CSF warns that the safety of administration simultaneously with chemotherapy has not been established. The rationale is the potential sensitivity of rapidly dividing myeloid cells to cytotoxic agents (Amgen, 2021a, 2021b; Coherus BioSciences, 2021; Mylan GmbH, 2018; Pfizer, 2021a, 2021b; Sandoz, 2017, 2019; Teva Pharmaceuticals, 2019).
- (f) For patients diagnosed with small cell lung cancer and receiving platinum/etoposide or topotecan-containing regimens, administering trilaciclib prior to therapy is indicated to decrease the incidence of myelosuppression. Trilaciclib works by inhibiting CDK4/6 (cyclin-dependent kinase), which is required for HSC and progenitor cell function and to produce neutrophils, RBCs, and platelets. This transient inhibition results in the myeloprotection of HSCs and progenitor cells during the G<sub>1</sub> phase of the cell cycle.
- (g) Prevention of trauma to the patient's skin and mucous membranes is prudent based on the clinical presentation of cancer-related infections (NCCN, 2022c).
- i. Provide meticulous care for all indwelling devices.
  - ii. Prevent pressure sores and constipation (NCCN, 2022).
  - iii. Change water in pitchers, denture cups, and nebulizers daily.
  - iv. Consider the risk–benefit ratio for invasive procedures (e.g., thoracentesis, paracentesis, central vascular access device placement).
  - v. Use only an electric razor to shave unwanted hair.
  - vi. Protect skin from cuts and burns. Immediately cleanse and treat any wound that breaks the skin.
  - vii. Use a soft toothbrush for frequent oral care (minimum three to four times daily). Allow toothbrush to dry before storing.
- (h) Patient education on protective measures for neutropenic patients (Centers for Disease Control and Prevention, n.d.)
- i. Report fever, chills, and other signs and symptoms of infection at onset.
  - ii. Wash hands frequently with soap and water or an antiseptic hand rub. Hands may remain colonized with microorganisms if they are not dried properly after washing.
  - iii. Bathe daily.
  - iv. Avoid activities that may compromise skin integrity.
  - v. Wear gloves when working in the garden.
  - vi. Perform frequent oral assessment and care with a soft toothbrush.
  - vii. Cleanse the perineal area from front to back after toileting.
  - viii. Avoid exposure to pathogens or people experiencing signs and symptoms of contagious conditions.
- (i) Protective measures
- i. Do not share food utensils.

**TABLE 14-3.** Growth Factors

| Classification            | Mechanism of Action                                                           | Drug                                                            | Route | Indications                                                                                                                                                                                                   | Side Effects                                                                                                                                                                                                           | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Kinase inhibitor       | Transient inhibitor of cyclin-dependent kinase 4/6; hematopoietic stimulation for neutrophils, red blood cells, and platelets is dependent on cyclin-dependent kinase 4/6 activity. | Trilaciclib (Cosela™)                | IV    | To decrease the incidence of myelosuppression in adult patients with extensive-stage small cell lung cancer when administered prior to a platinum/etoposide or topotecan regimen<br>May be used before platinum/etoposide regimen with or without immune checkpoint inhibitor to decrease the incidence of anemia and red blood cell transfusions for patients with extensive-stage small cell lung cancer | Fatigue, hypocalcemia, hypokalemia, hypophosphatemia, increased aspartate aminotransferase, headache, pneumonia<br>Infusion site reactions, including phlebitis and thrombophlebitis, during infusion                     | Administer as a 30-minute infusion to be completed within 4 hours prior to the start of chemotherapy on each day chemotherapy is administered.<br>If dose is missed, discontinue chemotherapy on the day it was missed.<br>Consider resuming the drug and chemotherapy on the next scheduled chemotherapy date.<br>If the drug is discontinued, wait 96 hours from the final dose before resuming chemotherapy.                                                                                                                                                                                                                          |
| Cytokine growth factor | Binds to the human keratinocyte growth factor receptor to promote proliferation, differentiation, and migration of epithelial cells                                                 | Palifermin (human G-CSF; Kepivance®) | IV    | To decrease the incidence and duration of severe oral mucositis in patients with hematologic malignancies requiring hematopoietic stem cell support for myelotoxic therapy                                                                                                                                                                                                                                 | Common: skin toxicities (rash, edema, erythema, pruritus), fever, gastrointestinal events, respiratory complications, pain, arthralgias, dysesthesias, hypertension<br>Serious: potential for stimulation of tumor growth | Dosage is 60 mcg/kg IV bolus daily for 3 consecutive days before myelotoxic therapy (the third dose should be given 24–48 hours prior to starting myelotoxic therapy) and 3 consecutive days after myelotoxic therapy (first of these doses should be administered after, but on the same day of, hematopoietic stem cell infusion and at least 4 days after most recent dose of palifermin); a total of 6 doses is given.<br>Reconstitute with sterile water.<br>Do not shake vigorously or agitate the vial.<br>Protect from light.<br>Do not filter.<br>Discard after 1 hour at room temperature.<br>(Swedish Orphan Biovitrum, 2013) |

*Note.* Review package inserts for dosing and prescribing information.

G-CSF—granulocyte-colony-stimulating factor; HSCT—hematopoietic stem cell transplantation; IV—intravenous; SC—subcutaneous

- ii. Do not eat any food that has not been cooked or washed.
- iii. Adhere to safe food handling practices, and avoid consuming food when the safety of preparation, storage, or serving is not guaranteed.
- iv. Do not provide direct care for pets or farm animals; avoid contact with animal excreta.
- v. Refrain from direct or indirect contact with reptiles, fish, and birds.
- vi. Avoid exposure to fresh or dried plants and flowers because of the risk of *Aspergillus* infection.
- vii. Do not enter, travel through, or stay in an area of construction or renovation, where construction material or debris has been placed, or where fields have recently been plowed.
- viii. Consider vaccination for influenza and pneumonia (Centers for Disease Control and Prevention, 2021a).
- ix. Avoid contact with people who have been vaccinated with a live vaccine within the past 30 days.

(2) Management of neutropenic fever

(a) Risk factor evaluation is recommended for patients with febrile neutropenia who have not received prophylactic G-CSF.

- i. The intent is to negate poor clinical outcomes associated with febrile neutropenia and age older than 65 years, ANC less than 100 neutrophils/mm<sup>3</sup>, neutropenia expected for longer than 10 days, infection including pneumonia, or hospitalization at the time of fever.
- ii. Filgrastim, tbo-filgrastim, filgrastim-sndz, or filgrastim-aafi may be administered based on the risk for poor outcome.
- iii. Pegfilgrastim and pegfilgrastim biosimilars are not recommended for therapeutic use (NCCN, 2021, 2022b).

(b) Obtain cultures (NCCN, 2022c).

- i. Urine: Cultures are warranted when patients are symptomatic, have an indwelling urinary catheter, or if their urinalysis is abnormal.
- ii. Blood: Two blood samples should be cultured. Three options exist (NCCN, 2022).
  - One set can be obtained peripherally, and one can be obtained from a central venous catheter (preferred).
  - Both sets can be obtained peripherally.
  - Both sets can be obtained through a central venous catheter.
  - The positive predictive value of a catheter culture is less than a peripheral culture.
  - Obtaining blood cultures from the catheter and peripherally may help determine whether the catheter is the source of the bloodstream infection based on the differential time to positivity.

iii. Stool: For diarrhea, follow institutional guidelines for *Clostridium difficile* assay and enteric pathogen screen.

iv. Skin: Aspirate or biopsy skin lesions. Vesicular or ulcerated skin lesions require viral cultures.

v. Venous access device cutaneous site: Consider routine fungal/*Mycobacterium* culture if inflammation is present.

vi. Throat and nasopharynx: Sources of infection should be investigated when viral respiratory symptoms are present, especially during seasonal outbreaks.

(c) Conduct a site-specific history and physical examination to identify the source of infection (NCCN, 2022c; Taplitz et al., 2018).

- i. Assess venous access devices, skin, lungs, sinuses, mouth, pharynx, esophagus, bowel, rectum, and perivaginal and

- perirectal areas for signs and symptoms of infection.
    - ii. Obtain historical data, including comorbidities, date, last chemotherapy regimen, previous infections, recent antibiotic therapy or prophylaxis, medications, and HIV status. Explore exposure risks, including those at home with similar symptoms, pets, travel, recent blood product transfusion, or exposure to tuberculosis.
  - (d) Obtain a chest x-ray if respiratory symptoms are present.
  - (e) Once initial cultures have been obtained, administer empiric broad-spectrum antibiotics as ordered until the organism source is identified.
  - (f) Monitor blood culture reports daily and anticipate antibiotic therapy based on findings.
2. Anemia in patients with cancer
- a) Erythropoiesis: This process involves erythrocyte (RBC) production in the bone marrow (Wilson, 2018).
    - (1) The kidneys are the primary producers of erythropoietin (EPO), the growth factor that stimulates HSCs to produce RBCs.
    - (2) RBC production is regulated by oxygen levels. When oxygen levels are low, the kidney releases EPO to stimulate HSCs to produce more RBCs.
  - b) Physiology of erythrocytes (Mahdi, 2018; Turgeon, 2018)
    - (1) In the bone marrow, HSCs become erythrocytes via a series of maturation phases over approximately two days, where RBCs become smaller and more condensed.
    - (2) Beginning as a proerythroblast, the cell has a nucleus and is not condensed.
    - (3) The nucleus decreases in size as it evolves to the stages of basophilic erythroblast and then polychromatophilic erythroblast.
    - (4) In the next stage as a reticulocyte, the nucleus has been expelled from the cell, but polyribosomes remain present. Eventually, the mature erythrocyte has no nucleus or polyribosome.
  - c) RBC mass and volume: Homeostasis of erythropoiesis is a continuous process driven by oxygen levels and EPO response. The average number of circulating RBCs in adults is five million RBCs per microliter.
  - d) RBC life span
    - (1) A typical RBC has a life span of approximately 120 days in the peripheral circulation (Mahdi, 2018).
    - (2) The RBC life span, time for maturation in the bone marrow, and low turnover explain why anemia occurs later than neutropenia and thrombocytopenia following myelosuppressive therapy (Camp-Sorrell, 2018).
  - e) Pathophysiology
    - (1) Many causes for anemia exist in patients with cancer, including myelosuppressive therapy, bone marrow involvement, inadequate EPO levels due to renal insufficiency, nutritional deficits, blood loss at tumor sites, and RBC destruction (Camp-Sorrell, 2018; NCCN, 2021).
    - (2) Classification of anemia based on RBC size: Mean corpuscular volume, which reflects the size of RBCs, is used in the differential diagnosis of microcytic, normocytic, or macrocytic anemia (Braunstein, 2020).
  - f) Incidence
    - (1) Many patients (30%–90%) experience some degree of anemia associated with the diagnosis and treatment of cancer (NCCN, 2021).
      - (a) Severity may increase with comorbidities, concurrent radiation therapy, cumulative doses of cytotoxic agents, and insufficient nutritional intake.
      - (b) The incidence of anemia in patients with hematologic malignancies has been reported as three times higher than in those with solid tumors (Camp-Sorrell, 2018).
    - (2) The average time to Hgb nadir is two weeks. The cancer diagnosis, frequency of treatments, regimen, and dosing schedule contribute to the onset, severity, and duration of anemia (NCCN, 2021).
  - g) Risk factors
    - (1) Medications that suppress bone marrow function, interfere with erythrocyte development and function, or suppress EPO production
      - (a) Platinum drugs due to combined renal and bone marrow toxicity (NCCN, 2021)
      - (b) Immunotherapies (e.g., alemtuzumab) (Genzyme, 2020a)
      - (c) Pharmacologic agents (e.g., chloramphenicol, quinacrine, hydantoins) (Braunstein, 2020)

- (d) High-dose chemotherapy for HSCT
- (2) Malignancies that originate or metastasize to the bone marrow and suppress RBC precursors
- (3) Radiation therapy to areas of the skeleton involved with hematopoiesis (Camp-Sorrell, 2018; NCCN, 2021)
- (4) Acute or chronic blood loss directly related to tumor invasion
- (5) Advanced age, which places patients at risk for anemia of malignancy (NCCN, 2021, 2022b)
- (6) Poor nutrition
  - (a) Anorexia, nausea, vomiting, stomatitis, early satiety, and diarrhea may contribute to decreased oral intake and absorption of nutrients.
  - (b) Lack of calorie, protein, vitamin, and mineral intake, reflected in weight loss or weakness, compromises cellular functions, including erythrocyte production (NCCN, 2021a).
- (7) Comorbidities
  - (a) Renal insufficiency: Chemotherapy agents known to have nephrotoxic properties (e.g., cisplatin) place patients at risk because kidney function is essential for EPO production. When EPO levels are low, more hypoxia is required to stimulate EPO response (Camp-Sorrell, 2018; NCCN, 2021).
  - (b) Alcohol abuse and liver dysfunction (Braunstein, 2020)
  - (c) Cardiopulmonary disease (Braunstein, 2020; NCCN, 2021)
- (8) Female sex (Braunstein, 2020)
- h) Clinical manifestations (Braunstein, 2020)
  - (1) Cardiopulmonary
    - (a) Dyspnea and hypoxia
    - (b) Tachycardia and heart murmurs
    - (c) Orthostatic hypotension
  - (2) Integumentary
    - (a) Pallor of oral mucous membranes, conjunctivae, lips, nail beds, and palms of hands or soles of feet
    - (b) Hair loss, thinning, and early graying
    - (c) Brittle fingernails and toenails
    - (d) Cyanosis
    - (e) Hypothermia
  - (3) Neuromuscular
    - (a) Headache, dizziness
    - (b) Drowsiness, restlessness, and inability to concentrate
    - (c) Paresthesias
  - (d) Fatigue and weakness
  - (4) Decreased urine output
- i) Adverse outcomes (Gosselin, 2018)
  - (1) Because low tissue oxygenation is related to reduced sensitivity of tumors to radiation therapy and some chemotherapy, hypoxia may adversely affect treatment outcomes.
  - (2) Low oxygen levels are directly associated with fatigue and weakness and may adversely affect quality of life.
  - (3) Hypoxic tissue promotes angiogenic factors that may contribute to tumor growth.
  - (4) Postoperative mortality is increased in the presence of anemia.
  - (5) Survival times of anemic patients are shorter than those without anemia for most tumor types.
- j) Management (NCCN, 2022a)
  - (1) Fatigue is an early and frequent symptom of anemia with a significant negative impact on quality of life. Interventions should be aimed at identifying and managing fatigue.
    - (a) Encourage frequent rest periods to conserve energy.
    - (b) Use exercise when benefits outweigh risks.
    - (c) Explore complementary therapies (e.g., relaxation, massage, yoga) with the potential to minimize fatigue (NCCN, 2022a).
    - (d) Assess nutritional intake for adequate content and quantity.
    - (e) Teach patients and their family members or caregivers the importance of hydration.
  - (2) Monitor laboratory results related to anemia (see Table 14-4) and take appropriate action when abnormal (e.g., vitamin B<sub>12</sub> deficiencies, iron deficiencies).
  - (3) Interventions for hypoxia
    - (a) Provide supplemental oxygen.
    - (b) Teach energy conservation.
    - (c) Consider measures to increase Hgb (Camp-Sorrell, 2018; NCCN, 2022a).
      - i. Blood transfusions
      - ii. Erythropoiesis-stimulating agents
      - iii. Manufacturer (Amgen, 2018, 2019; Janssen Biotech, 2018; Pfizer, 2020) black box warnings are supported by eight randomized studies that each demonstrated decreased over-

**TABLE 14-4.** Laboratory Assessment of Anemia: Normal Values (Adults)

| Laboratory Test                   | Normal Value                                                                        |
|-----------------------------------|-------------------------------------------------------------------------------------|
| Coombs test (direct and indirect) | Negative                                                                            |
| Ferritin                          | Male: 20–300 ng/ml; female: 15–120 ng/ml                                            |
| Hemoglobin                        | Male: 13.5–18 g/dl; female: 12–16 g/dl                                              |
| Hematocrit                        | Male: 42%–52%; female: 37%–47%                                                      |
| Mean corpuscular volume           | 78–100 fl                                                                           |
| Mean corpuscular hemoglobin       | 27–31 pg/cell                                                                       |
| Red blood cell count              | Male: 4.7–6 million/mm <sup>3</sup> ; female: 4.2–5.4 million cells/mm <sup>3</sup> |
| Red cell distribution width       | 11.5%–14%                                                                           |
| Reticulocyte count                | 0.5%–1.85% of erythrocytes                                                          |
| Serum B <sub>12</sub>             | 190–900 pg/ml                                                                       |
| Serum erythropoietin level        | Male: 17.2 mU/ml; female: 18.8 mU/ml                                                |
| Serum folate                      | > 3.5 mcg/L                                                                         |
| Serum iron                        | Male: 75–175 mcg/dl; female: 65–165 mcg/dl                                          |
| Total iron-binding capacity       | 250–450 mcg/dl                                                                      |

all survival and locoregional control when erythropoiesis-stimulating agents were used in patients diagnosed with advanced breast, cervical, head and neck, lymphoid, and non-small cell lung cancers.

### 3. Thrombocytopenia in patients with cancer

#### a) Healthy physiology of platelets (Kuter, 2020)

- (1) The thrombocyte (platelet) precursor megakaryocyte is the largest hematopoietic cell descending from the HSC. The goal of thrombopoiesis is to produce and release mature platelets so that a healthy

amount (150,000–400,000/mm<sup>3</sup>) is circulating at any given time.

- (2) The major steps in thrombopoiesis (Machlus & Italiano, 2013)

#### (a) Two phases of megakaryocyte development

- i. The first phase takes several days marked by pronounced nuclear proliferation and an increase in cytoplasm.
- ii. During the second phase, the megakaryocytes remodel their cytoplasm into proplatelets and then into platelets.
- iii. The individual platelets are formed through fragmentation of the plasma membranes.
- iv. When the megakaryocyte completes maturation, its membrane ruptures, and the cytoplasm separates into platelets.
- v. One megakaryocyte can release thousands of platelets. The time for megakaryocytes to complete polyploidization, mature, and release platelets is approximately five days. The life span of circulating platelets is seven to eight days. There is no reserve in the bone marrow.

#### (b) Pathophysiology (Rodriguez, 2018)

- i. Thrombocytopenia after chemotherapy is evident in approximately 8–14 days and is directly related to bone marrow suppression.
- ii. Severity varies with drug, dose, and schedule.
- iii. For some agents (e.g., carmustine, carboplatin, dactinomycin, daunorubicin, lomustine, mitomycin C), it is a dose-limiting toxicity (Rodriguez, 2018).

#### b) Risk factors

- (1) Myelosuppressive chemotherapy or radiation therapy to marrow-producing skeletal sites
- (2) Immunotherapy (e.g., interferon)
- (3) Comorbidities (e.g., liver disease)
- (4) Destruction of platelets in the presence of autoimmune disease (e.g., immune thrombocytopenic purpura) or disseminated intravascular coagulation

- (5) Bone marrow infiltration of primary or metastatic malignancies
- (6) Drug therapy affecting platelet function (Camp-Sorrell, 2018; Kuter, 2020)
  - (a) Aspirin
  - (b) Nonsteroidal anti-inflammatory drugs
  - (c) Quinine and quinidine
  - (d) Thiazide diuretics (e.g., furosemide)
  - (e) Benzene and benzene derivatives
  - (f) Tricyclic antidepressants
  - (g) Antimicrobials (e.g., chloramphenicol, zidovudine)
  - (h) Heparin
- (7) Herbal agents (e.g., ginkgo, garlic, ginger, turmeric)
- c) Clinical manifestations (Rodriguez, 2018)
  - (1) Cardiopulmonary
    - (a) Adverse changes in peripheral pulses, tachycardia, hypotension, and orthopnea
    - (b) Dyspnea, tachypnea, adventitious breath sounds, and hemoptysis
  - (2) Head and neck
    - (a) Petechiae of oral or nasal membranes
    - (b) Epistaxis
    - (c) Periorbital edema, subconjunctival hemorrhage, eye pain, and blurred or double vision
  - (3) Integumentary system
    - (a) Petechiae, bruising, pallor, or acrocyanosis anywhere on the skin or mucous membranes
    - (b) Bleeding from surgery, devices, or wound sites
  - (4) Neurologic
    - (a) Change in mental status, confusion, restlessness, or lethargy
    - (b) Widening pulse pressure, an abnormal change in pupil size, diminished reflexes, or loss of motor strength or coordination
    - (c) Headache and seizures
  - (5) Gastrointestinal
    - (a) Abdominal pain or distension
    - (b) Rectal bleeding, tarry stools, and hematemesis
    - (c) Enlarged and palpable spleen
  - (6) Genitourinary
    - (a) Menorrhagia
    - (b) Hematuria, dysuria, and low urine output
- d) Management
  - (1) Monitor laboratory findings and take appropriate action.
    - (a) Obtain platelet count, prothrombin time, partial thromboplastin time, Hgb, hematocrit, D-dimer, fibrinogen, and fibrin.
    - (b) Test stool, urine, and emesis for occult blood.
  - (2) Maintain a safe environment.
    - (a) Instruct patients to avoid activities that may cause injury.
    - (b) Assess the home environment and use nonskid rugs, nightlights, and ambulatory assistive devices to prevent falls.
  - (3) Educate patients and families on ways to maintain skin integrity through the following (Rodriguez, 2018).
    - (a) Using a soft toothbrush
    - (b) Blowing nose gently
    - (c) Using an electric razor versus a straight razor
    - (d) Using an emery board versus a metal nail file
    - (e) Using water-soluble lubricants for sexual intercourse
    - (f) Avoiding any sexual activity that may compromise skin or mucous membrane integrity
    - (g) Avoiding the use of tampons
    - (h) Using laxatives or stool softeners to avoid constipation
    - (i) Refraining from using mechanical, oral irrigation, or aggressive dental flossing
    - (j) Avoiding dental and other invasive procedures
  - (4) Medications and treatments (Rodriguez, 2018)
    - (a) Administer platelet transfusions.
    - (b) Consider administering interleukin-11 (Wyeth Pharmaceuticals, 2015).

## CHAPTER 15

# Gastrointestinal and Mucosal Toxicities

### A. Nausea and vomiting

1. Overview: Up to 80% of patients with cancer may experience nausea and vomiting, and these symptoms can be the most distressing and feared side effects of cancer treatment (Lee et al., 2019; National Cancer Institute [NCI], 2021b).

- a) Adherence to antiemetic guidelines has been shown to decrease the incidence of chemotherapy-induced nausea and vomiting (CINV) in patients receiving highly or moderately emetogenic chemotherapy (Abunahlah et al., 2016; Gilmore et al., 2014; Patil et al., 2017).

- b) Continued advances in the scientific understanding of the pathophysiology of CINV have produced increasingly effective antiemetic agents and combination regimens. Prevention of acute emesis associated with highly emetogenic chemotherapy can be achieved in 50%–75% of patients. In those receiving moderately emetogenic chemotherapy, successful prevention of acute emesis improves to 75%–90% of patients (Escobar et al., 2015; Navari et al., 2016; Wickham, 2012).

- c) Despite these advances in acute emesis control, higher percentages of patients continue to experience suboptimal control of delayed CINV symptoms, most notably nausea, which is significantly underestimated by clinicians (Naito et al., 2020; Vidall et al., 2015).

- d) Given the prominent negative impact of CINV on patient quality of life, oncology nurses must be vigilant and proactive when assessing for and managing CINV (Sommariva et al., 2016).

2. Definitions

- a) Nausea is an unpleasant subjective awareness of the need to vomit; the experience is described as a wavelike feeling occurring in the stomach or back of the throat; it typically precedes vomiting (Camp-Sorrell, 2018; NCI, 2021b).

- b) Retching is a rhythmic contraction involving the esophagus, diaphragm, and abdominal muscles to

eject stomach contents; this is commonly referred to as “dry heaves” (NCI, 2021b).

- c) Vomiting is the forceful expulsion of gastric contents through the mouth (NCI, 2021b).

3. Pathophysiology

- a) Nausea, retching, and vomiting are independent phenomena that can occur sequentially or as separate entities. Progress continues in understanding the complex neurophysiologic structures in the central and peripheral nervous systems and the gastrointestinal (GI) tract that underly CINV (NCI, 2021b).

- b) Nausea is mediated through the autonomic nervous system; however, its subjective nature results in less-precise insight into its mechanisms (NCI, 2021b).

- c) Vomiting results from the stimulation of a complex process that involves the activation of various peripheral and central pathways and neurotransmitter receptors (see Figures 15-1 and 15-2).

- d) The emetic reflex is thought to be influenced by three separate areas of the brain stem: the central pattern generator (commonly referred to as the vomiting center [VC]) and two areas in the dorsal brain stem called the nucleus tractus solitarius and area postrema, which are commonly referred to as the chemotherapy trigger zone (CTZ) (Hesketh, 2022a).

- e) The VC is a cluster of neurons located in the medulla. Stimulation of the VC results in efferent impulses from the central nervous system to the salivation center, cranial nerves, respiratory center, and abdominal muscles. This leads to the initiation of emesis (National Comprehensive Cancer Network [NCCN], 2022b; Navari & Aapro, 2016). In other words, the VC is the final common pathway for emesis; it serves as the control and integration center for the numerous inputs and stimuli from various sources and sends signals to different organs and tissues, resulting in vomiting (Tipton, 2014).

**FIGURE 15-1.** Mechanisms of Emesis

**FIGURE 15-2.** Neuroreceptors

Note. Based on information from National Comprehensive Cancer Network, 2022b.

f) The VC may be stimulated through peripheral or central pathways.

(1) Vagal afferents: GI and pharyngeal

(a) The GI vagal afferent is thought to be the primary cause of acute chemotherapy-induced vomiting (Hesketh, 2008).

(b) Chemotherapy stimulates enterochromaffin cells in the GI tract, causing them to release serotonin (5-hydroxytryptamine-3 [5-HT<sub>3</sub>]) (Hesketh, 2008).

(c) Serotonin release causes the activation of the vagus nerve, which stimulates vomiting through the VC (Hesketh, 2008; Navari & Aapro, 2016).

(d) 5-HT<sub>3</sub> receptors along the vagus nerve may also be involved in acute nausea and vomiting related to abdominal distension, radiation to the abdomen or chest, and pharyngeal irritation (Tipton, 2014).

(e) Additional receptors involved in this process may include neurokinin-1 (NK<sub>1</sub>) and cholecystokinin-1 (Hesketh, 2008).

(f) This peripheral nervous system pathway is primarily associated with acute emesis occurring within 24

hours of chemotherapy (Hesketh, 2022a).

(2) CTZ

(a) The CTZ, formed by the nucleus tractus solitarius and area postrema, is located at the caudal end of the fourth ventricle of the brain (Hesketh, 2008, 2022a; Navari & Aapro, 2016).

(b) The CTZ lies outside of the blood-brain barrier. As a result, the CTZ may be stimulated by emetogens in the blood or cerebrospinal fluid (Hesketh, 2022a).

(c) The CTZ appears to be a prominent source of afferent input to the VC and is an important site for neurotransmitter receptors involved in the vomiting response, including 5-HT<sub>3</sub>, NK<sub>1</sub>, muscarinic (M<sub>1</sub>), dopamine (D<sub>2</sub>), and histamine (H<sub>1</sub>) receptors (Hesketh, 2022a).

(d) Opioids, dopaminergic agonists, chemotherapy, and toxins may stimulate the CTZ and result in vomiting (Hesketh, 2008).

(e) This central nervous system pathway is primarily associated with delayed CINV, occurring more than 24 hours after chemotherapy (Hesketh, 2022a).

(3) Higher cortical centers: Nausea and vomiting may result from anxiety, memory, fear, pain, or a conditioned response to sights or smells; this is predominantly displayed as anticipatory nausea and vomiting (Hesketh, 2022a).

(4) Vestibular apparatus

(a) Labyrinthitis and motion sickness may result in nausea and vomiting (Tipton, 2014).

(b) Surgery can also induce vomiting through stimulation of the vestibular system.

(5) Other potential causes of nausea and vomiting (NCCN, 2022b)

(a) Brain metastases

(b) Side effects of other medications

(c) Excessive secretions

(d) Gastroparesis

(e) Electrolyte imbalance

(f) Uremia

(g) Anxiety

(h) Vestibular dysfunction

(i) Malignant ascites

- (j) Partial or complete bowel obstruction
  - (k) Cannabinoid hyperemesis syndrome
  - (l) Rapid opioid withdrawal
  - (m) Pancreatitis
4. Risk factors and classification of CINV
- a) Most patients are at some degree of risk for experiencing CINV. However, patient-specific factors related to the disease site, chemotherapy agents, and personal history can influence the onset, severity, and duration of symptoms (Hesketh, 2022a; NCI, 2021b).
  - b) Patient-related risk factors (Camp-Sorrell, 2018; Molassiotis et al., 2016; NCCN, 2022b; NCI, 2021b)
    - (1) Anxiety prior to the chemotherapy cycle
    - (2) History of poorly controlled CINV with previous encounters
    - (3) Expectancy of experiencing CINV after treatment
    - (4) Young or middle-aged patients (e.g., younger than age 50 years)
    - (5) Female sex
    - (6) Alcohol use: Patients who have a history of low or no alcohol consumption have more nausea and vomiting than patients with a history of high alcohol consumption.
    - (7) Susceptibility to motion sickness
    - (8) History of pregnancy-induced nausea and vomiting (e.g., morning sickness)
  - c) Acute-onset CINV may occur within a few minutes of chemotherapy administration. It typically peaks after five to six hours and resolves within 24 hours (NCCN, 2022b).
    - (1) Incidence: Acute CINV is predominantly related to the drug class, dose level, frequency of administration, and emetogenic potential of the antineoplastic agent or combination regimen (NCI, 2021b).
      - (a) Hesketh et al. (1997) originally developed the classification of chemotherapy agents based on the risk of acute emetogenicity without antiemetic prophylaxis; this work also produced an algorithm to define the emetogenic risk of multiagent regimens and served as the framework for future guideline development.
      - (b) Grunberg et al. (2005) further refined the classification into four categories for the emetogenic potential of IV chemotherapy. Current treatment guidelines published by NCCN, the American Society of Clinical Oncology (ASCO), and the Multinational Association of Supportive Care in Cancer/European Society for Medical Oncology (MASCC/ESMO) are based on these categories (Hesketh et al., 2020; NCCN, 2022b; Roila et al., 2016).
        - i. High: Emesis occurs in greater than 90% of patients.
        - ii. Moderate: Emesis occurs in 30%–90% of patients.
        - iii. Low: Emesis occurs in 10%–30% of patients.
        - iv. Minimal: Emesis occurs in fewer than 10% of patients.
      - (c) The routine use of antiemetic prophylaxis also affects the observed incidence of acute CINV (Gilmore et al., 2014).
  - (2) Prevention of acute CINV (NCCN, 2022b)
    - (a) Prophylactic medications should be administered before chemotherapy.
    - (b) If the patient is receiving chemotherapy from multiple emetogenic risk categories, prophylactic antiemetic therapy should be based on the highest emetogenic risk medication (Hesketh et al., 2020; NCCN, 2022b).
  - d) Delayed-onset CINV occurs more than 24 hours after chemotherapy administration and may last for several days (NCCN, 2022b; NCI, 2021b).
    - (1) Incidence: Delayed-onset CINV occurs commonly with highly emetogenic chemotherapy, single-agent administration, and regimens that include carboplatin, cisplatin, cyclophosphamide, or anthracyclines.
    - (2) It is more common in patients who have experienced acute emesis.
    - (3) For multiday treatments, the time frame of delayed emesis may depend on the chemotherapy agents included in the regimen and the emetogenic potential of agents administered on the final day of treatment.
  - e) Anticipatory CINV occurs in the days or hours leading up to chemotherapy administration. It is likely a conditioned response, and therefore, occurs after a previous experience with CINV (NCCN, 2022b).
    - (1) Incidence: Anticipatory CINV occurs in 18%–57% of patients, with nausea being more common than vomiting (NCCN, 2022b).

- (2) It may be triggered by a particular smell, taste, sight, or sound experienced in the treatment environment (NCI, 2021b).
  - (3) To minimize the risk of anticipatory CINV, effective and proactive antiemetic control and prevention of acute and delayed CINV are essential.
  - f) Breakthrough CINV occurs following chemotherapy administration, despite guideline-driven prophylactic antiemetic treatment, and may require rescue antiemetics (Navari, 2015).
  - g) Refractory CINV occurs when guideline-driven antiemetic prophylaxis has not been effective in the previous cycle and continues to be ineffective in a subsequent cycle (Navari, 2015).
5. Assessment: Identify the potential patient-related risks and physiologic causes of nausea and vomiting, classify the type of nausea and vomiting, and determine the level of emetogenicity of the chemotherapy agents prescribed (see Figures 15-3 and 15-4). See Table 15-1 for NCI's toxicity criteria and grading scale for nausea and vomiting.

a) Chemotherapy (NCCN, 2022b)

- (1) Evaluate the emetogenic potential of all prescribed chemotherapy agents, including oral and IV formulations, and verify that the patient has appropriate antiemetics premedications ordered as part of their treatment regimen.
- (2) Confirm that the patient has been prescribed and has successfully obtained antiemetic prescriptions through their retail pharmacy for delayed and breakthrough CINV at home. Evaluate the need for financial assistance related to prescription coverage and refer to appropriate resources.

b) Immunotherapy

- (1) Patients receiving immunotherapy agents may experience nausea and vomiting as part of a flu-like syndrome.
- (2) Monoclonal antibodies may be associated with acute nausea and vomiting during the infusion or hypersensitivity reaction.

**FIGURE 15-3.** Emetogenic Potential of Intravenous Antineoplastic Drugs

| Medications With High Incidence (90%–100%)                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                       |

<sup>a</sup> Any regimen that includes an anthracycline and cyclophosphamide (e.g., regimen consisting of cyclophosphamide, doxorubicin, vincristine, and prednisone)

<sup>b</sup> Discrepancies in categorization noted in the references

AC—anthracycline plus cyclophosphamide; AUC—area under the plasma concentration versus-time curve; MIU—million international units

Note. Based on information from Grunberg et al., 2011; National Comprehensive Cancer Network, 2022b; Roila et al., 2016.

- (3) Cytokine release syndrome, a possible toxicity related to chimeric antigen receptor (CAR) T cells, monoclonal antibodies, and other immunotherapies, may result in nausea and vomiting (Bonifant et al., 2016; Kroschinsky et al., 2017).
- (4) Biosimilars are expected to have the same emetic risk as to the originator product unless expressly noted otherwise (NCCN, 2022b).
- c) Targeted therapy (Navari & Aapro, 2016; Roila et al., 2016)
  - (1) New targeted therapies have varying doses and combinations and extended schedules that may include daily oral use.
  - (2) Because of the lack of prospective trials regarding nausea and vomiting related to targeted therapies given in the absence of antiemetic therapy, evidence regarding emetogenicity and appropriate antiemetic therapy for these medications is limited.
  - (3) The incidence and severity of nausea and vomiting with targeted therapies are not well studied.
  - (4) As increasing numbers of oral targeted therapies are approved, it is important to review antiemetic guidelines for appropriate management recommendations.
- d) Radiation therapy can produce or compound nausea and vomiting when administered locally near the upper abdomen, as total body irradiation (TBI), or when combined with chemotherapy as sensitization (NCCN, 2022b).
- e) Physical causes (NCCN, 2022b)
  - (1) Tumor obstruction
  - (2) Gastroparesis
  - (3) Constipation
  - (4) Increased intracranial pressure
  - (5) Brain metastasis
  - (6) Vestibular dysfunction
  - (7) Uncontrolled pain
  - (8) Fluid volume status
  - (9) Pancreatitis
- f) Metabolic causes
  - (1) Hypercalcemia
  - (2) Hyponatremia
  - (3) Hyperglycemia
  - (4) Uremia
  - (5) Increased creatinine
- g) Other medications or agents (e.g., opioids, antibiotics, cannabis)
  - (1) Rapid opioid withdrawal
  - (2) Cannabinoid hyperemesis syndrome
- h) Psychological causes
  - (1) Anxiety
  - (2) Fear
  - (3) Emotional distress
6. Potential complications of nausea and vomiting (Camp-Sorrell, 2018; NCI, 2022b; Tipton, 2014)
  - a) Discomfort
  - b) Treatment delay or withdrawal from treatment
  - c) Diminished quality of life (e.g., impaired mobility, fatigue)
  - d) Dehydration
  - e) Metabolic disturbances
  - f) Anorexia, weight loss, and nutritional depletion

- g) Physical and mental deterioration
  - h) Increased intracranial pressure
  - i) Aspiration
  - j) Esophageal tears
  - k) Wound dehiscence
  - l) Decreased ability to perform self-care
  - m) Costs associated with treatment
  - n) Family and caregiver strain
  - o) Lost productivity and missed work
7. Collaborative management: pharmacologic interventions
- a) Antiemetic therapy aims to prevent nausea and vomiting (NCCN, 2022b).
    - (1) Consider the level of emetogenicity based on the medication, route of administration, and dose administered. Choose the prophylactic antiemetic regimen based on the drug with the highest emetogenicity. Consider patient-specific risk factors (Hesketh et al., 2020; Roila et al., 2016).
    - (2) Patients receiving multiday regimens must be assessed for acute and delayed

CINV based on the emetogenicity of the individual drugs on each given day and the timing of administration in the drug sequence. Overlap of acute and delayed CINV can occur (NCCN, 2022b).

- (3) Patient response to pharmacologic interventions for nausea and vomiting requires frequent assessment, with treatment modification as appropriate (NCCN, 2022b).
- (4) Corticosteroids are not recommended as antiemetic prophylaxis or treatment with cellular therapies, such as CAR T-cell therapy, due to the risk of decreased persistence of the population postinfusion. They should be avoided three to five days prior to and 90 days after CAR T-cell infusion (NCCN, 2022b).
- (5) It is recommended that checkpoint inhibitors, including programmed cell death protein 1 (PD-1), programmed cell death-ligand 1 (PD-L1), and cytotoxic

**FIGURE 15-4.** Emetogenic Potential of Oral Antineoplastic Drugs

| Medications With Moderate to High Incidence (≥ 30%)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

In the public domain.

T-lymphocyte antigen 4 (CTLA-4), not be administered with concurrent, prolonged therapeutic steroids due to concerns of potential adverse effects on drug efficacy through dampening of the immune response (Hesketh et al., 2020).

(a) When checkpoint inhibitors are administered as single-agent or combination therapy, the emetogenic risk is minimal, and no CINV prophylaxis is required (NCCN, 2022b).

(b) Checkpoint inhibitors are increasingly combined with chemotherapy agents of various emetogenic risk categories. Insufficient evidence exists to recommend omitting dexamethasone from antiemetic prophylaxis following current antiemesis guidelines for combination regimens that include checkpoint inhibitors, given the short duration of steroid administration relative to treatment cycle length (Hesketh, 2022b; Hesketh et al., 2020).

(6) Dexamethasone-sparing antiemetic prophylaxis regimens using alternate, less frequent, or individualized dosing of dexamethasone may be appropriate for patients receiving moderately emetogenic chemotherapy, non-cisplatin highly emetogenic chemotherapy, or combination anthracycline and cyclophosphamide regimens who are intolerant of corticosteroid adverse effects (i.e., insomnia, GI upset, agitation, increased appetite, or weight gain) or have complicating comorbidities (e.g., diabetes mellitus) (Lee et al., 2019; NCCN, 2022b; Okada et al., 2019).

b) Prevention and management of anticipatory CINV

(1) With anticipatory CINV being a learned behavioral response, the best means of prevention is to provide the most effective control of acute and delayed CINV in the initial treatment cycles (Roila et al., 2016).

(2) Benzodiazepines may reduce the occurrence of anticipatory CINV. They should be administered beginning the night before treatment and may be repeated one to two hours before chemotherapy (NCCN, 2022b; Roila et al., 2016).

c) Prevention and management of acute and delayed CINV related to IV antineoplastic administration

(1) ASCO, MASCC/ESMO, and NCCN have published antiemetic guidelines (Aapro et al., 2019; Hesketh et al., 2020; NCCN, 2022b; Roila et al., 2016). Guidelines from ASCO and MASCC/ESMO are consistent; NCCN guidelines share similarities, with a few notable variations.

(2) For patients receiving IV highly emetogenic chemotherapy agents

(a) NCCN recommends using a four-drug combination of olanzapine, an NK<sub>1</sub> receptor antagonist, a 5-HT<sub>3</sub> receptor antagonist, and dexamethasone prior to chemotherapy administration on day 1 (NCCN, 2022b).

i. Two additional treatment regimens are proposed as alternatives to the preferred four-drug combination regimen and include the following:

- A three-drug regimen consisting of olanzapine, palonosetron, and dexamethasone
  - A three-drug regimen consisting of an NK<sub>1</sub> receptor antagonist, 5-HT<sub>3</sub> receptor antagonist, and dexamethasone
- ii. Lorazepam may be combined with the aforementioned antiemetics to improve control in high-risk regimens (NCCN, 2022b).
  - iii. An H<sub>2</sub> antagonist or proton pump inhibitor can be added to minimize dyspepsia that can contribute to nausea (NCCN, 2022b).
  - iv. Antiemesis prophylaxis with combination olanzapine, aprepitant, and dexamethasone; olanzapine alone; or aprepitant and dexamethasone should be given on days 2–4. This varies depending on the prophylaxis treatment option given on day 1 (NCCN, 2022b).
- (b) ASCO also recommends using a four-drug combination consisting of a 5-HT<sub>3</sub> receptor antagonist, an NK<sub>1</sub> receptor antagonist, dexamethasone, and olanzapine prior to chemotherapy (Hesketh et al., 2020).
- i. Dexamethasone and olanzapine should be administered on days 2–4. Patients receiving an anthracycline and cyclophosphamide should only receive olanzapine on days 2–4.
  - ii. If aprepitant was administered on day 1, it should also be administered on days 2–3 (Hesketh et al., 2020).
- (c) MASCC/ESMO recommends a three-drug combination consisting of a 5-HT<sub>3</sub> receptor antagonist, an NK<sub>1</sub> receptor antagonist, and dexamethasone; the addition of olanzapine may be considered if nausea is of particular concern (Aapro et al., 2019; Roila et al., 2016).
- (d) Anthracycline plus cyclophosphamide regimens are classified as highly emetogenic chemotherapy (Aapro et al., 2019; Hesketh et al., 2020; NCCN, 2022b; Roila et al., 2016).
- (3) For patients receiving IV moderately emetogenic chemotherapy agents
- (a) NCCN recommends using a two-drug combination of a 5-HT<sub>3</sub> receptor antagonist and dexamethasone prior to chemotherapy on day 1 (NCCN, 2022b).
    - i. Two additional three-drug regimens are proposed as alternatives to the two-drug combination for certain patient-related risk factors or previous ineffective control of CINV with the 5-HT<sub>3</sub> and dexamethasone regimen.
      - Olanzapine, palonosetron, and dexamethasone (NCCN, 2022b)
      - An NK<sub>1</sub> receptor antagonist, a 5-HT<sub>3</sub> receptor antagonist, and dexamethasone (NCCN, 2022b)
    - ii. Lorazepam may be combined with the aforementioned antiemetics to improve control (NCCN, 2022b).
    - iii. The addition of an H<sub>2</sub> antagonist or proton pump inhibitor may be considered (NCCN, 2022b).
    - iv. Antiemesis prophylaxis consisting of dexamethasone, a 5-HT<sub>3</sub> receptor antagonist, olanzapine, or aprepitant with or without dexamethasone may be given on days 2 and 3. This will depend on the prophylaxis given on day 1 (NCCN, 2022b).
  - (b) ASCO and MASCC/ESMO recommend using a two-drug combination of a 5-HT<sub>3</sub> receptor antagonist and dexamethasone prior to chemotherapy on day 1 (Hesketh et al., 2020; Roila et al., 2016).
    - i. ASCO recommends an NK<sub>1</sub> receptor antagonist should be added to the two-drug regimen for patients receiving carboplatin dosed at an area under the curve greater than or equal to 4 mg/ml/min (Hesketh et al.,

- 2020). MASCC/ESMO guidelines agree with this approach but do not specify a dosing cutoff for carboplatin (Aapro et al., 2019; Roila et al., 2016).
- ii. Dexamethasone should be administered on days 2 and 3 if the patient is receiving chemotherapy associated with delayed nausea and vomiting, such as cyclophosphamide, doxorubicin, and oxaliplatin (Hesketh et al., 2020; Roila et al., 2016).
- (4) For patients receiving IV agents categorized as low emetogenic risk
    - (a) NCCN recommends a single dose of dexamethasone, metoclopramide, prochlorperazine, or a 5-HT<sub>3</sub> receptor antagonist prior to chemotherapy on day 1 (NCCN, 2022b).
      - i. Lorazepam may be combined with the aforementioned antiemetics to improve control (NCCN, 2022b).
      - ii. The addition of an H<sub>2</sub> antagonist or proton pump inhibitor may be considered (NCCN, 2022b).
    - (b) ASCO recommends a single dose of dexamethasone or a 5-HT<sub>3</sub> receptor antagonist prior to chemotherapy on day 1 (Hesketh et al., 2020).
  - (5) For patients receiving IV agents categorized as minimal emetogenic risk, no routine prophylaxis is recommended (Hesketh et al., 2020; NCCN, 2022b; Roila et al., 2016).
- d) Prevention and management of acute and delayed CINV related to oral antineoplastic administration (NCCN, 2022b)
- (1) For patients receiving oral agents categorized as high to moderate emetogenic risk
    - (a) Administer a 5-HT<sub>3</sub> receptor antagonist prior to taking oral chemotherapy and continue daily (NCCN, 2022b).
    - (b) Lorazepam may be combined with the aforementioned antiemetics to improve control (NCCN, 2022b).
    - (c) The addition of an H<sub>2</sub> antagonist or proton pump inhibitor may be considered (NCCN, 2022b).
  - (2) For patients receiving oral agents categorized as low to minimal emetogenic risk
    - (a) No routine prophylaxis is recommended, but antiemetics may be prescribed as needed. If the patient experiences nausea and vomiting, consider metoclopramide, prochlorperazine, or a 5-HT<sub>3</sub> receptor antagonist (NCCN, 2022b).
    - (b) Lorazepam may be combined with the aforementioned antiemetics to improve control (NCCN, 2022b).
    - (c) The addition of an H<sub>2</sub> antagonist or proton pump inhibitor may be considered (NCCN, 2022b).
- e) Treatment of delayed CINV
- (1) Delayed nausea is often more common and severe than acute nausea and is more difficult to treat (NCCN, 2022b).
  - (2) 5-HT<sub>3</sub> receptor antagonists, although effective for preventing acute vomiting, are not as effective for delayed vomiting.
  - (3) For patients receiving highly emetogenic chemotherapy or moderately emetogenic chemotherapy agents
    - (a) NCCN recommends dexamethasone be administered daily during chemotherapy and for two to three days after chemotherapy administration to help prevent delayed CINV (NCCN, 2022b).
    - (b) ASCO recommends dexamethasone and olanzapine on days 2–4 for patients receiving highly emetogenic chemotherapy agents unless they receive anthracycline and cyclophosphamide. In this case, ASCO recommends olanzapine only for days 2–4 (Hesketh et al., 2020).
    - (c) MASCC/ESMO recommends olanzapine specifically for concerns related to delayed nausea (Aapro et al., 2019).
  - (4) To prevent delayed CINV in patients receiving carboplatin, an NK<sub>1</sub> receptor antagonist should be given in combination with a 5-HT<sub>3</sub> receptor antagonist and dexamethasone (Aapro et al., 2019; Roila et al., 2016).
- f) Management of breakthrough CINV
- (1) Consider adding other antiemetic agents from different drug classifications, using caution to avoid overlapping side effects (Hesketh et al., 2020). Alternative agents not previously mentioned that can be used in breakthrough CINV management include dronabinol, nabilone, haloperi-

- dol, metoclopramide, scopolamine, prochlorperazine, and promethazine (NCCN, 2022b; see Table 15-2).
- (2) 5-HT<sub>3</sub> receptor antagonists are of limited effectiveness in managing breakthrough CINV when used following administration of long-acting or extended-release formulations of the same drug class, such as palonosetron, granisetron transdermal patch, or extended-release granisetron injection (NCCN, 2022b).
  - (3) Around-the-clock antiemetic dosing should be strongly considered for patients with breakthrough CINV (NCCN, 2022b).
  - (4) Persistent or intractable vomiting may preclude oral intake of medication; consider alternate administration routes (e.g., IV, rectal, transdermal) or formulations (e.g., orally dissolving films or tablets) of antiemetic agents. Oral granisetron is superior to transdermal granisetron for complete control of CINV and should be considered when feasible (Chua et al., 2020).
  - (5) Consider an H<sub>2</sub> antagonist or proton pump inhibitor for patients with dyspepsia (NCCN, 2022b).
  - (6) Monitor patient hydration status and electrolytes and correct as needed (NCCN, 2022b).
  - (7) Olanzapine may be an effective option for breakthrough CINV (Aapro et al., 2019; Chiu et al., 2016; Roila et al., 2016) and should be included in the prophylactic antiemesis regimen for patients with breakthrough nausea and vomiting (Hesketh et al., 2020).
  - (8) Due to limited evidence establishing superior efficacy as compared to newer antiemetic agents, as well as medical and legal concerns, medical cannabis and cannabidiol (CBD) oil are not recommended by NCCN, ASCO, or MASCC/ESMO in their most recent respective guidelines for prophylaxis or management of CINV. The quality of evidence supporting the use of U.S. Food and Drug Administration–approved cannabinoids for the treatment of CINV remains low (Garcia & Shamliyan, 2018; Hesketh, 2022b).
  - (9) Consider using nonpharmacologic interventions in conjunction with antiemetics.
8. Collaborative management: nonpharmacologic interventions
    - a) Behavioral interventions, including hypnosis, progressive muscle relaxation, biofeedback, yoga, systematic desensitization, music therapy, and acupuncture or acupressure, may be used as adjunct therapies to manage anticipatory CINV (NCCN, 2022b; Roila et al., 2016).
    - b) Management of patient expectations may help prevent chemotherapy-induced nausea (Lee et al., 2019).
    - c) Several nonpharmacologic interventions have been studied to prevent and manage CINV; however, effectiveness has not been established. These interventions may be considered for use in conjunction with antiemetics and include acupuncture, acupressure, aromatherapy, exercise, ginger, massage, therapeutic touch, and yoga (Lee et al., 2019; Marx et al., 2017).
  9. Dietary interventions (American Cancer Society, 2020; NCCN, 2022b)
    - a) Encourage patients to eat small, frequent meals and avoid skipping meals, as an empty stomach can worsen nausea.
    - b) Encourage patients to eat bland food or cold or room temperature food to minimize smells or tastes that may be unappealing.
    - c) Encourage patients to drink clear liquids (e.g., fruit juice, broth) and sip small amounts slowly throughout the day.
    - d) Encourage patients to avoid fried, spicy, fatty, or very sweet food and avoid food with strong odors.
    - e) Ensure that patients are eating enough protein and calories. A calorie-dense liquid replacement meal (e.g., protein shake) may be used.
    - f) Encourage patients to avoid overeating to minimize indigestion.
    - g) Encourage patients to use plastic forks and spoons if metal silverware causes a bitter taste.
    - h) Consider referral to an outpatient dietitian who specializes in cancer nutrition.
  10. Patient and family education
    - a) Instruct patients to take antiemetics as prescribed and notify the provider if they cannot do so for any reason.
    - b) Remind patients to take antiemetics before arriving for treatment. Ensure that antiemetics have been taken prior to administration of chemotherapy.
    - c) Encourage patients to notify the provider's office before antiemetic prescriptions have run out to ensure a refill can be dispensed without disrupting the medication supply.
    - d) Instruct patients to notify providers if nausea and vomiting persist for longer than 24 hours or if they cannot maintain fluid intake.

**TABLE 15-2.** Commonly Used Agents for Prevention and Treatment of Chemotherapy-Induced Nausea and Vomiting

| Classification         | Mechanism of Action                                                                                                                                           | Drug       | Route, Dose, and Schedule for Adult Patients                                                                                                                                                                    | Indications                                                                                                                                                                                                                                 | Side Effects                                                                                                                                                             | Nursing Considerations                                                                                                                                                                                                                          |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Atypical antipsychotic | Acts on multiple receptor sites, including dopamine, histamine, serotonin, and acetylcholine-muscarine                                                        | Olanzapine | 2.5–10 mg PO daily<br>Consider a lower dose if previous dose caused excessive sedation.<br>Bedtime administration is recommended due to sedation effect, unless being used as premedication prior to treatment. | Prevention of acute and delayed nausea and vomiting                                                                                                                                                                                         | Dizziness, sedation, weight gain, altered cardiac conduction (prolonged QTc), anticholinergic effects (e.g., constipation, dry mouth, blurred vision, urinary retention) | The drug is contraindicated in patients with dementia. The risk of extrapyramidal symptoms is increased in patients receiving metoclopramide or haloperidol. (Alkermes, 2021; Camp-Sorrell, 2018; National Comprehensive Cancer Network, 2022b) |
| Benzodiazepine         | Acts as a central nervous system depressant; interferes with afferent nerves from the cerebral cortex by gamma-aminobutyric acid inhibition, causing sedation | Alprazolam | 0.5–1 mg PO given the night before treatment and repeated 1–2 hours before chemotherapy administration                                                                                                          | Prevention of anticipatory nausea and vomiting<br>Treatment for breakthrough chemotherapy-induced nausea and vomiting with anxiety component                                                                                                | Sedation, confusion, hyperactivity, agitation, dizziness, light-headedness, hallucinations                                                                               | Use a starting dose of 0.5 mg PO in older adult patients, patients with advanced liver disease, or other pertinent comorbidities. (Camp-Sorrell, 2018; National Comprehensive Cancer Network, 2022b; Pfizer, 2011)                              |
|                        |                                                                                                                                                               | Lorazepam  | 0.5–2 mg PO, sublingual, or IV every 6 hours<br>For anticipatory nausea and vomiting: 0.5–2 mg PO beginning the night before treatment and repeated 1–2 hours before chemotherapy administration                | In combination with other antiemetics as needed for acute or delayed nausea and vomiting<br>Prevention of anticipatory nausea and vomiting<br>Treatment for breakthrough chemotherapy-induced nausea and vomiting with an anxiety component | Sedation, confusion, hyperactivity, agitation, dizziness, light-headedness, hallucinations                                                                               | Use with caution in older adult patients and those with hepatic or renal dysfunction. (Camp-Sorrell, 2018; National Comprehensive Cancer Network, 2022b; West-Ward A Hikma Company, 2017)                                                       |
| Cannabinoid            | Activates cannabinoid receptors                                                                                                                               | Dronabinol | 5–10 mg capsules PO every 4–6 hours or 2.1–4.2 mg/m <sup>2</sup> oral solution, PO three to four times daily                                                                                                    | Treatment of breakthrough or refractory nausea and vomiting                                                                                                                                                                                 | Sedation, vertigo, euphoria, dysphoria, dry mouth, tachycardia, orthostasis, appetite stimulation                                                                        | The incidence of paranoid reactions or abnormal thinking increases with maximum doses. (Camp-Sorrell, 2018; National Comprehensive Cancer Network, 2022b)                                                                                       |

**TABLE 15-2.** Commonly Used Agents for Prevention and Treatment of Chemotherapy-Induced Nausea and Vomiting (*Continued*)

| Classification          | Mechanism of Action                   | Drug          | Route, Dose, and Schedule for Adult Patients                                                                           | Indications                                         | Side Effects                                                                                                                 | Nursing Considerations                                                                                                                                                                                                                                                                                                                                         |
|-------------------------|---------------------------------------|---------------|------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Neurokinin-1 antagonist | Neurokinin-1 receptor antagonist      | Aprepitant    | 125 mg PO on day 1 of chemotherapy, then 80 mg PO on days 2 and 3<br>Also available as a 130 mg IV injectable emulsion | Prevention of acute and delayed nausea and vomiting | Fatigue, headache, dyspepsia, decreased appetite, hiccups                                                                    | When administered with dexamethasone, aprepitant causes an increase in dexamethasone serum levels. Consider decreasing dose of dexamethasone by 50%. Aprepitant injectable emulsion is not interchangeable with the IV formulation of fosaprepitant. (Camp-Sorrell, 2018; Heron Therapeutics, 2022; Merck, 2010; National Comprehensive Cancer Network, 2022b) |
|                         |                                       | Fosaprepitant | 150 mg IV once on day 1                                                                                                | Prevention of acute and delayed nausea and vomiting | Fatigue, infusion site reactions, infusion-related hypersensitivity reactions, diarrhea, hiccups, lack of appetite, headache | When administered with dexamethasone, fosaprepitant causes an increase in dexamethasone serum levels. Consider decreasing dose of dexamethasone by 50%. (Camp-Sorrell, 2018; Merck, 2018; National Comprehensive Cancer Network, 2022b)                                                                                                                        |
|                         |                                       | Rolapitant    | 180 mg PO once on day 1                                                                                                | Prevention of acute and delayed nausea and vomiting | Neutropenia, anemia, hiccups, abdominal pain, decreased appetite, dizziness, dyspepsia, urinary tract infection, stomatitis  | Dexamethasone dose does not need to be adjusted. It can be given with or without meals. (Camp-Sorrell, 2018; National Comprehensive Cancer Network, 2022b; Tesaro, 2017)                                                                                                                                                                                       |
| Serotonin inhibitors    | 5-HT <sub>3</sub> receptor antagonist | Dolasetron    | 100 mg PO once on days chemotherapy is administered                                                                    | Prevention of acute and delayed nausea and vomiting | Headache, diarrhea, dizziness, fatigue, prolonged QT interval, cardiac arrhythmia                                            | IV dolasetron is not recommended because it is associated with an increased risk of cardiac arrhythmias. (Camp-Sorrell, 2018; National Comprehensive Cancer Network, 2022b; Sanofi-Aventis U.S., 2013)                                                                                                                                                         |

**TABLE 15-2.** Commonly Used Agents for Prevention and Treatment of Chemotherapy-Induced Nausea and Vomiting (*Continued*)

| Classification                           | Mechanism of Action                                                    | Drug                       | Route, Dose, and Schedule for Adult Patients                                                                                        | Indications                                         | Side Effects                                                                    | Nursing Considerations                                                                                                                                                                                                                                                                          |
|------------------------------------------|------------------------------------------------------------------------|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|---------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Serotonin inhibitors<br>( <i>Cont.</i> ) |                                                                        | Ondansetron                | 16–24 mg PO or 8–16 mg IV once on day of chemotherapy<br>Orally disintegrating tablet formulation: 8 mg<br>Oral soluble film: 24 mg | Prevention of acute and delayed nausea and vomiting | Headache, fatigue, malaise, constipation, drowsiness, sedation, QT prolongation | PO ondansetron has a lower risk of cardiac arrhythmia than IV ondansetron. A single dose larger than 16 mg of ondansetron is not recommended because of the increased risk of prolonged QT interval. (Camp-Sorrell, 2018; Glaxo SmithKline, 2016; National Comprehensive Cancer Network, 2022b) |
|                                          |                                                                        | Palonosetron               | 0.25 mg IV 30 minutes prior to chemotherapy on day 1                                                                                | Prevention of acute and delayed nausea and vomiting | Headache, constipation                                                          | The mean terminal elimination half-life is approximately 40 hours. IV palonosetron is more effective for preventing delayed nausea than other 5-HT <sub>3</sub> receptor antagonists. (Camp-Sorrell, 2018; MGI Pharma, 2006; National Comprehensive Cancer Network, 2022b)                      |
| Combination                              | Neurokinin-1 receptor antagonist/5-HT <sub>3</sub> receptor antagonist | Netupitant/palonosetron    | Netupitant 300 mg and palonosetron 0.5 mg (as a fixed combination product) PO given once on day 1                                   | Prevention of acute and delayed nausea and vomiting | Headache, fatigue, weakness                                                     | Monitor patients for hypersensitivity reactions. Avoid use in patients with severe hepatic impairment or end-stage renal disease. (Camp-Sorrell, 2018; Helsinn Therapeutics, 2021a, 2021b; National Comprehensive Cancer Network, 2022b)                                                        |
|                                          |                                                                        | Fosnetupitant/palonosetron | Fosnetupitant 235 mg and palonosetron 0.25 mg (as a fixed combination product) IV given once on day 1                               | Prevention of acute and delayed nausea and vomiting | Headache, fatigue, weakness                                                     | Monitor patients for hypersensitivity reactions. Avoid use in patients with severe hepatic impairment or end-stage renal disease. (Camp-Sorrell, 2018; Helsinn Therapeutics, 2021a, 2021b; National Comprehensive Cancer Network, 2022b)                                                        |

5-HT<sub>3</sub>—5-hydroxytryptamine-3; IV—intravenous; PO—by mouth; QTc—QT interval corrected; SC—subcutaneous

- e) Refer patients to educational materials, such as NCI's (2018) *Eating Hints: Before, During and After Cancer Treatment*.

## B. Anorexia and cachexia

### 1. Overview

- a) Anorexia is the loss of a desire to eat (NCI, 2022c).
- b) Cachexia derives from the Greek words *kakos* and *hexis*, meaning "bad condition" (Peixoto da Silva et al., 2020). Cancer cachexia is "a multifactorial syndrome characterised by an ongoing loss of skeletal muscle mass (with or without loss of fat mass) that cannot be fully reversed by conventional nutritional support and leads to progressive functional impairment" (Fearon et al., 2011, p. 490; see Figure 15-5).

### 2. Pathophysiology: Anorexia and cachexia result from a complicated process involving numerous physiologic and psychological factors.

#### a) Tumor effects

- (1) Ascites and obstructions of the bowel and GI tract can lead to nutrient malabsorption, nausea, vomiting, and pain (e.g., tumors causing dysphagia or affecting GI function) (Archid et al., 2019).
- (2) Substances released by the tumor can lead to inflammation and satiety, contributing to anorexia and cachexia (Mattox, 2017; Peixoto da Silva et al., 2020).
  - (a) Proinflammatory cytokines such as interleukin-1 (IL-1), IL-6, IL-8, tumor necrosis factor-alpha, and interferon gamma (Peixoto da Silva et al., 2020)
  - (b) Lactate (Peixoto da Silva et al., 2020)
  - (c) Parathyroid hormone-related peptide (Peixoto da Silva et al., 2020)

- (3) Hypercalcemia secondary to bony involvement or paraneoplastic syndrome may lead to nausea, vomiting, and anorexia (Feldenzer & Sarno, 2018).

- (4) Decreased hypothalamic response signals from functional damage can reduce appetite (Peixoto da Silva et al., 2020).

- (5) Low protein and albumin levels lead to more extracellular water, and less intracellular water causes low oncotic pressure and increases weight loss (Schwarz et al., 2017).

#### b) Treatment effects

- (1) Surgery may result in gastroparesis, dumping syndrome, malabsorption, obstruction, and fluid and electrolyte abnormalities (Granda-Cameron & Lynch, 2018).
- (2) Chemotherapy and radiation therapy side effects can occur, including nausea, vomiting, mucositis, taste changes, xerostomia, constipation, and diarrhea (Peixoto da Silva et al., 2020).
- (3) Combination therapy may result in a higher number of adverse effects.

#### c) Psychosocial effects

- (1) Cancer-related depression often coexists with anorexia and cachexia, especially in patients with late-stage disease or multiple symptoms. The prevalence of depression among patients with cancer is estimated to be 15%–25% (Weber & O'Brien, 2017).
- (2) Anxiety, fear, grief, fatigue, pain, and reaction to body image changes may contribute to anorexia (Weber & O'Brien, 2017).
- (3) Cachexia results in decreased survival and poor response to treatment (NCI, 2022c).

### 3. Types of anorexia and cachexia

- a) Anorexia (Laviano, Koverech, & Seelaender, 2017)

**FIGURE 15-5. Cancer Cachexia**

#### Diagnostic Criteria

- Weight loss > 5% over the past 6 months; or
- Body mass index < 20 kg/m<sup>2</sup> and any degree of weight loss > 2%; or
- Appendicular skeletal muscle index consistent with sarcopenia (another wasting syndrome) and weight loss of > 2%

#### Stages of Cancer Cachexia

- Precachexia: weight loss of ≤ 5%, along with other symptoms such as impaired glucose tolerance or anorexia
- Cachexia: weight loss > 5% or other symptoms and conditions consistent with the diagnostic criteria for cachexia
- Refractory cachexia: patients experiencing cachexia who are no longer responsive to cancer treatment, have a low performance score, and have a life expectancy of < 3 months

Note. Based on information from Fearon et al., 2011.

- (1) Primary anorexia results from an altered body image perception, resulting in a refusal to eat.
  - (2) Secondary anorexia results from acute and chronic diseases creating an inflammatory response.
- b) Cachexia (Granda-Cameron & Lynch, 2018)
  - (1) Primary cachexia results from the tumor causing an inflammatory response and multiple metabolic alterations originating from tumor cells and activated immune cells.
  - (2) Secondary cachexia results from treatment affecting a patient with cancer's nutritional intake.
4. Incidence
  - a) Anorexia
    - (1) Anorexia is present in 15%–25% of patients with cancer at diagnosis and 26% of those receiving chemotherapy (NCI, 2022c).
    - (2) It is the fourth most common symptom in advanced cancer and only surpassed by pain, fatigue, and weakness (Peixoto da Silva et al., 2020).
  - b) Cachexia
    - (1) Prevalence in patients with cancer is widely variable (12%–85%) (Granda-Cameron & Lynch, 2018).
    - (2) Incidence varies based on the cancer type (Ni & Zhang, 2020; Peixoto da Silva et al., 2020).
      - (a) Gastric or pancreatic cancer: more than 80%
      - (b) Colon, lung, and prostate cancers and non-Hodgkin lymphoma: 50%–61%
      - (c) Breast cancer, advanced head and neck cancers, some leukemias, Hodgkin lymphoma, and sarcoma: 40%
    - (3) Approximately 20%–30% of cancer-related deaths are attributed to cachexia, a sign of poor prognosis (Ni & Zhang, 2020; Son et al., 2020).
5. Risk factors
  - a) Solid tumors, especially gastric and pancreatic cancers (Ni & Zhang, 2020; Peixoto da Silva et al., 2020)
  - b) Comorbidities with other chronic or end-stage diseases associated with cachexia, such as AIDS, congestive heart failure, chronic obstructive pulmonary disease, rheumatoid arthritis, and tuberculosis (Peixoto da Silva et al., 2020)
  - c) Very young and older adults
  - d) Depression
  - e) Cancer treatments
    - (1) Chemotherapy, immunotherapy, and targeted therapy
      - (a) Platinum-based treatments contribute to weight loss and muscle wasting (Moreira-Pais et al., 2018).
      - (b) Tyrosine kinase inhibitors (TKIs), such as sorafenib or lenvatinib, may contribute to loss of skeletal muscle (Uchikawa et al., 2020).
    - (2) Surgical procedures, such as esophagectomy and gastrectomy, can cause early satiety (NCI, 2022c).
    - (3) Radiation (Arends et al., 2017)
      - (a) Head and neck or esophagus radiation can cause mucositis and decreased food intake.
      - (b) Pelvic area radiation can cause GI symptoms.
  - f) Cancer and its treatment side effects, such as emesis, dysphagia, mucositis, reduced or altered taste, and pain (Peixoto da Silva et al., 2020)
6. Clinical manifestations
  - a) Anorexia is an involuntary weight loss of greater than 5% of usual weight (Biswas & Acharyya, 2020).
  - b) It is clinically diagnosed when patients report a negative appetite change (Laviano, Koverech, & Seelaender, 2017).
    - (1) Changes in taste and smell
    - (2) Early satiety
  - c) Changes in GI tract function (Peixoto da Silva et al., 2020)
    - (1) Dysmotility
    - (2) Inactivation of bile salts or pancreatic enzymes
    - (3) Partial or complete obstruction
  - d) Loss of muscle mass and adipose tissue
  - e) Fatigue and weakness
  - f) Immune system impairment
  - g) Metabolic dysfunction
  - h) Hypoalbuminemia
7. Assessment: Subjective reporting of anorexia in patients with cancer makes assessment difficult; no consensus exists on specific methods for assessment (Abraham et al., 2019).
  - a) Dietary intake and nutrition
    - (1) Perform a nutritional assessment, including a dietary intake evaluation.
    - (2) Patients may keep a food and fluid diary or recall nutritional intake (Arends et al., 2017).
    - (3) Use a validated nutrition screening tool (Arends et al., 2017; Dijksterhuis et al., 2021).

- (a) Nutrition Risk Screening 2002 (NRS-2002) detects the early benefit of nutritional intervention and is performed within 48 hours of hospitalization (Rabito et al., 2017).
  - (b) Malnutrition Universal Screening Tool (MUST) identifies malnutrition in community settings and hospitals by reviewing nutritional status and disease-related factors (Rabito et al., 2017).
  - (c) Malnutrition Screening Tool (MST) is a quick and straightforward three-question tool that can be completed upon admission by staff, caregivers, or patients (Rabito et al., 2017).
  - b) Measuring body composition (Arends et al., 2017; Ni & Zhang, 2020)
    - (1) Computed tomography (CT) measurement at the level of the third lumbar vertebrae has a high level of accuracy and specificity and is the gold standard.
    - (2) Magnetic resonance imaging is the equivalent of a CT scan without radiation exposure, but it can be costly.
    - (3) Dual x-ray absorptiometry scans appendicular muscles with low radiation exposure and cost, but it can overestimate lean body mass.
    - (4) Anthropometric methods are not as accurate, and it is difficult to differentiate between lean body mass and fat tissue (Casadei & Kiel, 2021).
      - (a) Weight: Consider correcting weight when excess fluid may be present (i.e., pleural effusions, ascites, edema).
      - (b) Height with a stadiometer
      - (c) Body circumference of waist, hip, and limbs
      - (d) Body mass index
      - (e) Skinfold thickness
        - i. Triceps skinfold thickness estimates body fat.
        - ii. Mid-arm muscle circumference estimates muscle mass.
    - (5) Bioelectrical impedance analysis
  - c) Assess physical performance with the Eastern Cooperative Oncology Group Performance Status Scale or Karnofsky Performance Status Scale (Arends et al., 2017).
  - d) Assess functional status (Meregaglia et al., 2019).
    - (1) Functional Assessment of Anorexia-Cachexia Therapy is a 39-item, question-validated tool to assess patient status.
      - (2) Functional status tools include symptom distress and quality-of-life questions.
    - e) Grading: See Table 15-3 for NCI's anorexia grading scale.
    - f) Assess laboratory results (Ni & Zhang, 2020).
      - (1) Evaluate inflammatory markers and cytokines.
        - (a) Examples include hemoglobin, albumin, C-reactive protein, ghrelin, adiponectin, leptin, insulin-like growth factor 1, IL-1, IL-6, and tumor necrosis factor- $\alpha$ .
        - (b) The best indicators of cancer cachexia are albumin and C-reactive protein levels.
      - (2) Evaluate for endocrine abnormalities, such as thyroid dysfunction, metabolic abnormalities, and hypogonadism (NCCN, 2022c).
    - g) Assess for social or financial factors that may inhibit adequate nutritional intake (NCCN, 2022c).
    - h) Reconcile medications to assess for any that may interfere with intake (NCCN, 2022c).
8. Collaborative management and effect on clinical outcomes: Treatment of anorexia should focus on treating any reversible causes (NCCN, 2022c). Although no standard of care treatment exists for cancer cachexia, treatment is the primary objective (Son et al., 2020). Identifying and treating cancer cachexia aims to improve treatment tolerability, improve survival, and optimize quality of life (Roeland et al., 2020).
- a) Symptom management: Management of symptoms, such as nausea and vomiting, mucositis, oral candidiasis, diarrhea, constipation, taste changes, dysphagia, xerostomia, fatigue, pain, and depression, may improve anorexia.
  - b) Pharmacologic interventions (NCCN, 2022c)
    - (1) Reduced or lack of appetite
      - (a) Megestrol acetate: 200–600 mg PO daily, increasing to 400–800 mg daily at the end of life
      - (b) Olanzapine: 5 mg PO daily
      - (c) Dexamethasone: 3–4 mg PO daily
      - (d) Cannabinoids may be considered.
    - (2) Early satiety: metoclopramide 5–10 mg PO four times daily 30 minutes before meals and at bedtime
    - (3) Depression: mirtazapine 7.5–30 mg oral PO every night at bedtime
  - c) Nonpharmacologic interventions (Dev et al., 2017; NCCN, 2022c)
    - (1) Nutritional counseling and nutrition (Arends et al., 2017; Roeland et al., 2020)

**TABLE 15-3.** Common Terminology Criteria for Adverse Events Grading for Anorexia

| Adverse Event | Grade                                                |                                                                                                             |                                                                                                                                            |                                                              |       |
|---------------|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|-------|
|               | 1                                                    | 2                                                                                                           | 3                                                                                                                                          | 4                                                            | 5     |
| Anorexia      | Loss of appetite without alteration in eating habits | Oral intake altered without significant weight loss or malnutrition; oral nutritional supplements indicated | Associated with significant weight loss or malnutrition (e.g., inadequate oral caloric and/or fluid intake); tube feeding or TPN indicated | Life-threatening consequences; urgent intervention indicated | Death |

TPN—total parenteral nutrition

Note. From *Common Terminology Criteria for Adverse Events* [v.5.0], by National Cancer Institute Cancer Therapy Evaluation Program, 2017 ([https://ctep.cancer.gov/protocolDevelopment/electronic\\_applications/docs/CTCAE\\_v5\\_Quick\\_Reference\\_5x7.pdf](https://ctep.cancer.gov/protocolDevelopment/electronic_applications/docs/CTCAE_v5_Quick_Reference_5x7.pdf)). In the public domain.

- (a) Refer to a registered dietitian for early and regular assessment and counseling.
  - (b) Provide high-calorie and high-protein oral supplements as needed and tolerated.
  - (c) Enteral or parenteral nutrition should not be routinely offered to treat cachexia in patients with advanced cancer. A short-term trial may be considered in a select group of patients with malabsorptive disorders, reversible bowel obstruction, or undergoing curative treatment.
    - i. Enteral: A nasogastric tube or percutaneous endoscopic gastrostomy can be used for patients with a functioning bowel. Complications include aspiration pneumonia, electrolyte abnormalities, diarrhea, and infection.
    - ii. Parenteral: Total parenteral nutrition (requiring central venous access) and peripheral parenteral nutrition can be used. Complications include an increased infection rate.
  - (d) Consider swallowing evaluation (NCCN, 2022c).
- (2) Physical activity
- (a) Physical activity can preserve muscle mass and function, reduce systemic inflammation, and decrease systemic catabolism (Ni & Zhang, 2020).
  - (b) Exercise programs should include resistance and aerobic exercises that are realistic and achievable (Laviano, Di Lazzaro Giraldo, & Koverech, 2017).
- (3) Psychosocial support
- (a) Monitor for depression, fatigue, living alone, low income, and access to food, which may affect nutritional intake, and refer to appropriate resources (Williams, 2020).
  - (b) Physical changes associated with weight loss can cause patient and family distress (Buonaccorso et al., 2021). Refer to psychosocial and emotional support as needed.
  - (c) Early consultation of a palliative care team has shown to improve outcomes (Dev et al., 2017; Schwarz et al., 2017).
  - (4) Integrative medicine: Complementary and alternative medicine may be helpful, including acupuncture, aromatherapy, mind-body therapies, music therapy, prayer, and spiritual uplifting (NCI, 2021a; Zhang et al., 2018).
9. Patient and family education
- a) Provide education on the overall condition and the risk and benefits of all treatment options (NCCN, 2022c).
  - b) Instruct patients to take medications as prescribed for symptom management and notify providers of symptoms that may be affecting dietary intake.
  - c) Provide examples of high-protein, high-calorie, and nutrient-dense foods (Roeland et al., 2020) and refer to additional educational print resources, such as NCI's (2018) *Eating Hints: Before, During and After Cancer Treatment*.
  - d) Encourage small, frequent meals and snacks in an attractive setting.
  - e) Monitor and record weight weekly, using the same scale at the same time of the day, and notify providers of any weight decreases.

- f) Advise patients that a lack of interest in food is normal at the end of life and that nutritional support is insufficient to reverse weight loss as cancer progresses (NCCN, 2022c). Encourage involvement in family meals, even if patients have no appetite, and offer support to patients, families, and caregivers to cope with decreased intake (Buonaccorso et al., 2021).
- g) Encourage patients to engage in physical activity, including aerobic and resistance exercise (Buonaccorso et al., 2021).

## C. Diarrhea

### 1. Overview

- a) Definition: Diarrhea is defined as loose or watery stools three or more times daily that may be acute, chronic, or persistent (National Institute of Diabetes and Digestive and Kidney Diseases, 2016). Diagnostic criteria include greater than 75% water content, increase in daily stool weight, and frequency (Pessi et al., 2014).
  - (1) Classification based on duration (National Institute of Diabetes and Digestive and Kidney Diseases, 2016)
    - (a) Acute: Diarrhea lasts one to two days and typically resolves independently.
    - (b) Persistent: Diarrhea lasts two to four weeks.
    - (c) Chronic: Diarrhea lasts at least four weeks and has potentially transient symptoms.
  - (2) Classification based on grade (NCI Cancer Therapy Evaluation Program [CTEP], 2017; see Table 15-4)
- b) Antineoplastic treatment-induced diarrhea
  - (1) Diarrhea in patients with cancer is associated with the disease and its treatments, including radiation therapy, chemotherapy, targeted therapy, and immunotherapy,

as well as graft-versus-host disease (Bossi et al., 2018).

- (2) Classification of chemotherapy-induced diarrhea based on intensity (Bossi et al., 2018)
  - (a) Uncomplicated: grade 1–2 toxicity without additional signs or symptoms
  - (b) Complicated: grade 3–4 diarrhea or grade 1–2 diarrhea with one or more of the following: cramping, nausea, vomiting, fever, bleeding, dehydration, sepsis, neutropenia, or decreased performance status
- (3) Chemotherapy-induced diarrhea contributes to treatment alterations (60%), interference in daily activities (30%), dose delays (28%), treatment discontinuation (15%), and death related to dehydration (5%) (McQuade et al., 2016).

- 2. Pathophysiology: The pathophysiology and etiology of diarrhea in patients with cancer can be multifaceted. All possible causes of diarrhea need to be considered to treat patients appropriately.

### a) Classifications of diarrhea

#### (1) Osmotic diarrhea

- (a) Osmotic diarrhea usually is related to injury to the gut, dietary factors, or problems with digestion.
- (b) Water is drawn into the intestinal lumen, resulting in increased stool volume and weight.
- (c) Lactose intolerance is an example of this type of diarrhea.
- (d) New-onset lactose intolerance can occur in patients undergoing cancer treatment (Andreyev et al., 2014).
- (e) Osmotic diarrhea is associated with large stool volumes and sometimes is improved with fasting or elimina-

**TABLE 15-4.** Common Terminology Criteria for Adverse Events Grading for Diarrhea

| Adverse Event | Grade                                                                                             |                                                                                                                                                         |                                                                                                                                                                              |                                                              |       |
|---------------|---------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|-------|
|               | 1                                                                                                 | 2                                                                                                                                                       | 3                                                                                                                                                                            | 4                                                            | 5     |
| Diarrhea      | Increase of < 4 stools per day over baseline; mild increase in ostomy output compared to baseline | Increase of 4–6 stools per day over baseline; moderate increase in ostomy output compared to baseline; limiting instrumental activities of daily living | Increase of ≥7 stools per day over baseline; hospitalization indicated; severe increase in ostomy output compared to baseline; limiting self-care activities of daily living | Life-threatening consequences; urgent intervention indicated | Death |

Note. From *Common Terminology Criteria for Adverse Events* [v5.0], by National Cancer Institute Cancer Therapy Evaluation Program, 2017 ([https://ctep.cancer.gov/protocolDevelopment/electronic\\_applications/docs/CTCAE\\_v5\\_Quick\\_Reference\\_5x7.pdf](https://ctep.cancer.gov/protocolDevelopment/electronic_applications/docs/CTCAE_v5_Quick_Reference_5x7.pdf)). In the public domain.

- tion of the causative factor (e.g., lactose, sorbitol) (Andreyev et al., 2012, 2014; Burgers et al., 2020).
- (2) Secretory diarrhea
    - (a) The small and large intestines secrete more fluids and electrolytes than can be absorbed.
    - (b) Infection and inflammation of the gut; damage to the gut caused by chemotherapy, radiation therapy, or graft-versus-host disease; and certain endocrine tumors can cause secretory diarrhea.
    - (c) The imbalance between absorption and secretion leads to the production of a large volume of fluid and electrolytes in the small bowel.
    - (d) This type of diarrhea is associated with large volumes and may require a bowel rest with parenteral nutrition followed by slow diet progression as tolerated (Muehlbauer, 2014).
  - (3) Exudative diarrhea
    - (a) This type is caused by alterations in mucosal integrity, epithelial loss, enzyme destruction, and defective absorption of the colon.
    - (b) Mucosal inflammation and ulceration caused by inflammatory diseases, cancers, and cancer treatment may result in the outpouring of plasma, proteins, mucus, and blood into the stool, which can result in exudative diarrhea (Bisanz et al., 2010).
  - (4) Inflammatory diarrhea
    - (a) Inflammatory diarrhea develops from invasive or toxin-producing bacteria causing impaired mucosal integrity that may result in tissue damage (Barr & Smith, 2014).
    - (b) It is characterized by fecal leukocytes, lactoferrin/calprotectin, or blood (Burgers et al., 2020).
  - (5) Dysentery is diarrhea characterized by blood in the stool (Schmidt-Hieber et al., 2017).
  - (6) Altered GI motility is seen in some endocrine disorders, such as hyperthyroidism and diabetes mellitus. Other causes can include small intestinal bacterial overgrowth and certain bile acids (Burgers et al., 2020; Yde et al., 2018).
- b) Pathophysiologic mechanisms by antineoplastic agent category
- (1) Chemotherapy (Andreyev et al., 2014)
    - (a) The metabolic by-products of agents can cause direct mucosal damage and toxicity (e.g., SN-38G from irinotecan), mitotic arrest of cells in the GI tract resulting in alterations to the osmotic gradient (e.g., with 5-fluorouracil), or stimulation of inflammatory cytokines, tumor necrosis factor-alpha, and prostaglandins.
    - (b) Diarrhea can also be cholinergically mediated, as with irinotecan (early onset).
    - (c) Osmotic diarrhea by way of development of lactose intolerance is seen in approximately 10% of patients treated with 5-fluorouracil and generally resolves after treatment.
  - (2) Targeted therapy (Bossi et al., 2018)
    - (a) Secretory diarrhea is associated with excessive chloride secretion related to many anti-epidermal growth factor receptor (EGFR) agents; this toxicity may also be amplified with combination radiation therapy.
    - (b) Ischemic mucosal damage may result from agents such as TKIs.
    - (c) Though the exact mechanism is unknown, drugs that target angiogenesis, such as vascular endothelial growth factor (VEGF)-targeted therapies, can lead to intestinal wall ulceration and disturbed platelet-endothelial cell homeostasis, causing inflammation leading to diarrhea.
    - (d) Mammalian target of rapamycin (mTOR) inhibitors are associated with gut microflora disequilibrium and malabsorption.
  - (3) Immunotherapy: Immune-mediated colitis, as well as resulting diarrhea, is a primary immune-related adverse event associated with immunotherapies, specifically checkpoint inhibitors, and may present as acute or delayed (often five to seven weeks after therapy) (Spain et al., 2016).
- c) Differential diagnosis for diarrhea in patients with cancer (Schmidt-Hieber et al., 2017)
- (1) Paraneoplastic diarrhea is rare and triggered by the secretion of vasoactive intestinal polypeptide, leading to watery diarrhea and electrolyte alterations.

- (2) Malabsorption
    - (a) Fat malabsorption: Steatorrhea or stools being described as oily, pale, foul-smelling, or difficult to flush may indicate fat maldigestion (Fernandes & Andreyev, 2020). This can result from small intestinal bacterial overgrowth, pancreatic exocrine insufficiency, obstruction of lymphatic vessels, bowel resection, or radiation therapy-induced intestinal lymphangiectasia (Andreyev et al., 2014).
    - (b) Bile acid malabsorption results from impaired absorption of bile acids in the terminal ileum (Fernandes & Andreyev, 2020).
  - (3) Small intestinal bacterial overgrowth can occur from alterations to function, motility, anatomy, metabolic, or immune disorders (Grace et al., 2013).
  - (4) Stool impaction (Bossi et al., 2018)
  - (5) Neutropenic enterocolitis (also called typhlitis) has a pathogenesis that is not entirely understood and is characterized by mucosal injury and neutropenia (Rodrigues et al., 2017).
  - (6) Excess use of laxatives
  - (7) Infection-related diarrhea (Brahmer et al., 2018)
    - (a) Bacterial infections: nontyphoidal *Salmonella*, *Sigella*, *Yersinia*, *Clostridium difficile*, *Escherichia coli*, *Campylobacter*
    - (b) Viral infections: norovirus, rotavirus, adenovirus, cytomegalovirus
    - (c) Parasitic infections: *Blastocystis*, *Cryptosporidium*, *Cyclospora cayetansensis*, *Entamoeba histolytica*, *Giardia lamblia*, *Cystoisospora belli*, *Sarcocystis hominis*, *Sarcocystis suihominis*, *Strongyloides stercoralis*
  - (8) Surgical resection (Bossi et al., 2018)
3. Incidence: The incidence of diarrhea varies greatly depending on the agents that are used. The specific agent, dose, schedule, and combination with other cancer therapies influence the severity of chemotherapy-induced diarrhea (McQuade et al., 2016; see Figure 15-6).
- a) Chemotherapy: Overall incidence may be as high as 80%; incidence of postchemotherapy chronic diarrhea may be as high as 49%. Regimens containing either irinotecan or 5-fluorouracil account for up to 80% of chemotherapy-induced diarrhea and one-third of patients experiencing grade 3–4 diarrhea (McQuade et al., 2016).
    - (1) 5-Fluorouracil: Diarrhea is more common with administration with leucovorin (up to 50%), and severity increases with bolus administration (Stein et al., 2010).
    - (2) Irinotecan
    - (3) Capecitabine
    - (4) Taxanes
      - (a) Cabazitaxel
      - (b) Docetaxel
      - (c) Paclitaxel
    - (5) Anthracyclines
  - b) Targeted therapy: Overall incidence is approximately 60% and is primarily associated with TKIs (Bossi et al., 2018; Pessi et al., 2014).
    - (1) Small molecule EGFR inhibitors
    - (2) Anti-EGFR monoclonal antibodies
      - (a) Cetuximab
      - (b) Panitumumab
    - (3) Phosphoinositide 3-kinase inhibitors (PI3K): Highest risk are idelalisib and duvelisib for diarrhea and colitis.
    - (4) Small molecule VEGF inhibitors
    - (5) BCR-ABL1 and KIT TKIs
    - (6) Cyclin-dependent kinase inhibitors (CDK): Highest rates are with abemaciclib, but they are typically low grade.
    - (7) Trastuzumab antibody–drug conjugates
    - (8) mTOR inhibitors
    - (9) Anaplastic lymphoma kinase (ALK) inhibitors: most commonly with ceritinib; rarely severe
    - (10) Mitogen-activated protein kinase (MAPK) inhibitors
    - (11) Bruton tyrosine kinase (BTK) inhibitors
    - (12) Poly(ADP-ribose) polymerase (PARP) inhibitors
  - c) Immunotherapy (Bossi et al., 2018; Brahmer et al., 2018; Dougan et al., 2020; Haanen et al., 2017; Puzanov et al., 2017; Thompson et al., 2019)
    - (1) Anti-CTLA-4 (up to 54% incidence): Higher incidence of diarrhea than PD-1/PD-L1 inhibitors; GI toxicity is the first immune-related adverse event leading to anti-CTLA-4 discontinuation.
    - (2) Anti-PD-1 drugs: Approximately 20% of patients on PD-L1 inhibitors will develop diarrhea of any grade, with severe toxicities much less common than anti-CTLA-4 agents.
4. Clinical manifestations
- a) Increase in frequency of bowel movements or loose consistency of stool

**FIGURE 15-6. Antineoplastics With High Risk for Diarrhea and Colitis**

| Antineoplastic Chemotherapies                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

- b) Gas or abdominal cramping
  - c) Clinical findings indicating dehydration
    - (1) Decreased skin turgor
    - (2) Dry mucous membranes
    - (3) Decreased urine output
    - (4) Laboratory findings
      - (a) Elevated serum creatinine
      - (b) Hypokalemia
      - (c) Metabolic acidosis
      - (d) Hyponatremia or hypernatremia
    - (5) Signs of infection (e.g., fever) (Andreyev et al., 2014)
  - d) Diarrhea can contribute to numerous sequelae, including dehydration, fever, malnutrition, sepsis, frank bleeding, moderate to severe cramping, renal insufficiency, cardiac dysfunction, and severe electrolyte imbalance. It can impair quality of life, cause treatment delays, force drug dose reductions and discontinuation, and even cause death (Andreyev et al., 2014; Koselke & Kraft, 2012).
    - (1) Additional sequelae may include perianal skin breakdown, discomfort, or infection; reduced absorption of oral medications; anxiety; and exhaustion.
    - (2) Immune-mediated colitis is characterized by abdominal pain, rectal or mucosal bleeding, and large bowel inflammation. It can progress to intestinal colitis and possibly death (Spain et al., 2016).
5. Risk factors
- a) Disease related (NCI, 2022b)
    - (1) Carcinoid syndrome
    - (2) Colon cancer
    - (3) Lymphoma
    - (4) Medullary carcinoma of the thyroid
    - (5) Pancreatic cancer
    - (6) Pheochromocytoma
  - b) Treatment related
    - (1) Chemotherapy: 5-fluorouracil, irinotecan, capecitabine, taxanes, anthracyclines, platinum salts (Bossi et al., 2018)
    - (2) Targeted therapy: anti-EGFR, anti-HER2, anti-BRAF, anti-MEK, anti-MEL4/ALK, anti-VEGF, TKIs, anti-mTOR, anti-CDK4/6, anti-PARP (Bossi et al., 2018)
    - (3) Immunotherapy: anti-CTLA-4, anti-PD-1/PD-L1 (Thompson et al., 2019)
    - (4) Radiation therapy: Monotherapy or combination radiation therapy, particularly to the pelvis, abdomen, or lower thoracic and lumbar spine, can lead to the destruction of the cells of the lumen of the bowel and can be acute or chronic toxicity (NCI, 2022b).
- (5) Surgery: Manipulation of the bowel during surgery may cause diarrhea or ileus. Procedures associated with higher risks of diarrhea include celiac plexus block, cholecystectomy, esophagogastrectomy, gastrectomy, pancreatic duodenectomy, intestinal resection, and vagotomy (NCI, 2022b).
  - (6) Other pharmacologic agents: antibiotics, magnesium-containing antacids, anti-hypertensives, colchicine, digoxin, iron, lactulose, laxatives, methyldopa, metoclopramide, misoprostol, potassium supplements, propranolol, theophylline (NCI, 2022b)
- c) Acute or chronic conditions (NCI, 2022b)
    - (1) Immunosuppression
    - (2) Infection related to mucositis and neutropenia (e.g., infection with rotavirus, *E. coli*, *Shigella*, *Salmonella*, *Giardia*, or *C. difficile*)
    - (3) Graft-versus-host disease
    - (4) Diabetes, hyperthyroidism, inflammatory bowel disease (e.g., Crohn disease, diverticulitis, gastroenteritis, HIV/AIDS, ulcerative colitis), obstruction (tumor related)
    - (5) Malabsorption, partial bowel obstruction, bowel edema, motility disruption
  - d) Behavioral and psychosocial (NCI, 2022b)
    - (1) Anxiety and stress
    - (2) Dietary causes (e.g., lactose intolerance; ingestion of caffeine, alcohol, or spicy or fatty foods; use of hyperosmotic dietary supplements)
6. Assessment: Timely and accurate assessment is critical to managing diarrhea and preventing severe sequelae, including death (NCI, 2022b).
- a) Assessment tools
    - (1) The *Common Terminology Criteria for Adverse Events* is the current standard for assessing and grading treatment-related toxicities, including diarrhea (Bossi et al., 2018; NCI CTEP, 2017). This does not consider volume, duration, social impact, or rectal urgency (Fernandes & Andreyev, 2020; see Figure 15-7).
    - (2) Bristol Stool Scale (Fernandes & Andreyev, 2020)
    - (3) Gastrointestinal Symptom Rating Scale (Fernandes & Andreyev, 2020)
    - (4) ALERT-B screening tool (Fernandes & Andreyev, 2020)

**FIGURE 15-7.** Evidence-Based Recommendations for the Management of Cancer Treatment–Induced Diarrhea

Assessment and Evaluation

History

- Physiologic history of gastrointestinal disturbances (e.g., baseline, treatment, and disease related)
- Current treatment type
- Duration, volume, consistency, and frequency of diarrhea
- Confounding factors (e.g., fever, orthostatic hypotension, abdominal pain or cramping, weakness)
- Symptom interference with quality of life and function

Physical assessment: abdominal assessment (e.g., visual assessment, auscultation for bowel sounds, palpitation, percussion as appropriate)

Laboratory assessment: Complete blood count, electrolytes, stool workup (e.g., presence of blood, fecal leukocytes, infectious sources), lactoferrin, and fecal calprotectin testing may be indicated at baseline and every 3 weeks during treatment with anti-programmed cell death protein 1 checkpoint inhibitors.

Common Terminology Criteria for Adverse Events Grading for Diarrhea

| Grade 1                                                                                           | Grade 2                                                                                                                                                 | Grade 3                                                                                                                                                                       | Grade 4                                                      | Grade 5 |
|---------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|---------|
| Increase of < 4 stools per day over baseline; mild increase in ostomy output compared to baseline | Increase of 4–6 stools per day over baseline; moderate increase in ostomy output compared to baseline; limiting instrumental activities of daily living | Increase of ≥ 7 stools per day over baseline; hospitalization indicated; severe increase in ostomy output compared to baseline; limiting self-care activities of daily living | Life-threatening consequences; urgent intervention indicated | Death   |

Classification

Uncomplicated

- Grade 1–2 toxicity
- No additional signs or symptoms
- May be managed with nonpharmacologic approaches, including dietary changes and increased oral hydration to 3–4 L of water daily
- May also introduce pharmacologic measures

Complicated

- Grade 3–4 toxicity
- Grade 1–2 toxicity with ≥ 1 complicating symptoms (e.g., cramping, nausea, vomiting, fever, bleeding, dehydration, sepsis, neutropenia, decreased performance status)
- Should be managed in the hospital with IV fluids, electrolyte replacement, and pharmacologic measures

Management by Treatment Type

Chemotherapy and Targeted Therapy

Uncomplicated

- Decrease or delay chemotherapy or targeted therapy.
- Initiate oral hydration and electrolyte replacement, if indicated.
- Initiate loperamide.
- Consider dietary modifications.
- Initiate IV fluids if patients are unable to tolerate oral fluids.
- Notify treating physician.

Complicated

- Discontinuation (temporarily or permanently) of causative agent may be necessary.
- Consider anticholinergic agents.
- Transition to or escalate dosing of octreotide.
- Continue or initiate antibiotic therapy if infection related.
- Consider stool evaluation.
- Evaluate labs (e.g., complete blood count, electrolytes) daily.
- Initiate or continue dietary modifications.

Assessment for Symptom Resolution

- Chemotherapy and targeted therapy: Assess diarrhea every 12–24 hours and escalate care as required in the presence of increased grading or persistent diarrhea; discontinue loperamide after 12 hours without diarrhea.
- Immunotherapy: Assess diarrhea every 12–24 hours; taper corticosteroids over 4–6 weeks before resuming. When symptoms improve to grade 1 or better, treatment may be restarted in the presence of low-dose steroids after evaluation of risks and benefits.
- Regardless of treatment, consider use of a patient journal to document stool frequency and characteristics in the ambulatory setting.

See Table 15-8 for Common Terminology Criteria for Adverse Events Grading of Colitis.

Note. Based on information from Bossi et al., 2018; Brahmer et al., 2018; National Cancer Institute, 2022b; National Cancer Institute Cancer Therapy Evaluation Program, 2017; National Comprehensive Cancer Network, 2022a; Puzanov et al., 2017; Thompson et al., 2019

## b) Assessment elements (Andreyev et al., 2014)

## (1) History

- (a) Assess patients for concerning symptoms, which include abdominal cramps or nausea not responsive to pharmacologic management, inability to eat, increased fatigue, dizziness, chest pain, vomiting, reduced urine output secondary to dehydration, fever (higher than 38.5°C), GI bleed, changes in mental status, and previous admission for diarrhea-related complications.
- (b) Include a diet history to evaluate for items that could contribute to diarrhea (e.g., irritating foods, alcohol, coffee, fiber, fruit, lactose-containing foods or fluids, sorbitol-based gum, candy, herbal teas that may contain laxatives), as well as history or new onset of food or lactose intolerance or allergies.
- (c) Assess stool quality and characteristics, including duration, continence, changes in bowel patterns, frequency, consistency, volume, odor, and visible presence of blood.
- (d) Evaluate current or recent medications, including antacids (especially those containing magnesium), antiarrhythmics, antibiotics, antihypertensives, caffeine, diuretics, laxatives or stool softeners, magnesium oxide, nonsteroidal anti-inflammatory drugs, potassium or calcium supplements, pro-motility agents (e.g., metoclopramide), proton pump inhibitors, and theophylline.
- (e) Evaluate other confounding factors, including travel history (outside the United States), use of alternative therapies (e.g., dietary supplements, herbal remedies), and opioid withdrawal.
- (f) Other etiologies of diarrhea include abdominopelvic radiation, prior intestinal surgeries, malabsorption, stool impaction.
- (g) The presence of ileostomy should be evaluated. Normal output averages 600–800 ml daily (Livia de Oliveira et al., 2018). These patients are generally on a baseline regimen of loperamide and should be assessed for

adherence to this regimen and oral intake.

## (2) Physical assessment

- (a) Vital signs
- (b) Weight (with attention to significant weight gain or loss)
- (c) Physical examination, with particular attention to the GI system (e.g., visual inspection; palpation and auscultation of the abdomen with attention to guarding and rebound tenderness; assessment for fecal impaction, including in patients with neutropenia, unless such an examination would cause severe rectal pain)
- (d) Alterations in skin integrity, mainly focused on the perianal area
- (e) Evaluation for signs and symptoms of dehydration, including hypotension, delayed capillary refill, and reduced skin turgor

## (3) Laboratory assessment (Bossi et al., 2018; NCCN, 2022a)

- (a) Stool sample for consistency, presence of blood, and infectious sources: Conduct *C. difficile*, *Salmonella*, *E. coli*, or *Campylobacter* testing. Consider testing for rotavirus and norovirus in the winter and bacterial and parasite cultures if travel would put patients at risk.
- (b) Serum chemistries for electrolyte imbalance, specifically potassium
- (c) Albumin levels, which may be decreased with diarrhea
- (d) Complete blood count to determine if neutropenia or infection is present
- (e) Acid–base balance and lactate concentrations in the presence of hypotension and tachycardia
- (f) Urinalysis
- (g) Biopsy of ulcerations to evaluate for viral infection, particularly cytomegalovirus
- (h) Blood cultures can be performed to detect bloodstream infection in patients with severe, persistent diarrhea accompanied by neutropenia, fever, or blood in the stool.

## (4) Radiographic and endoscopic assessment (Bossi et al., 2018)

- (a) CT scan of the abdomen to evaluate for enterocolitis, perforation, abscess, bowel ischemia, and pancreatitis
- (b) Endoscopy

- (c) Ultrasound to assess peristalsis and intestinal wall thickening
  - (d) Colonoscopy is generally not recommended for patients with suspected neutropenia.
7. Collaborative management
- a) Fluid resuscitation: Rapid fluid resuscitation is unnecessary in patients with mild hypovolemia. The ideal rate of fluid intake should exceed the rate of losses. Urine output should be met and sustained at a minimum of 0.5 ml/kg/hr (Bossi et al., 2018).
    - (1) Oral: Daily fluid intake of 2–4 L of water is recommended, in some cases with the addition of salt and sugar (Bossi et al., 2018; Pessi et al., 2014).
    - (2) IV: Fluid bolus, preferably using normal saline (never hypotonic solutions such as 5% dextrose in water), should be implemented to evaluate blood plasma volume increases. If hemodynamic stability is not achieved, further evaluation from an intensivist or nephrologist should be sought (Andreyev et al., 2014).
  - b) Electrolyte repletion
    - (1) Hypokalemia: potassium less than 3.5 mEq/L
    - (2) Hypomagnesemia: less than 0.4 mmol/L or, in symptomatic patients, less than 0.4–0.7 mmol/L
    - (3) Hypocalcemia: adjusted calcium concentration less than 2.2 mmol/L
    - (4) Hypophosphataemia: If severe (less than 0.3 mmol/L) or moderate (0.3–0.6 mmol/L), consider repletion; hypomagnesemia and hypocalcemia might predispose patients to hypophosphatemia.
  - c) Pharmacologic management
    - (1) Chemotherapy- and targeted therapy-induced diarrhea
      - (a) Loperamide is a nonanalgesic agonist that decreases intestinal motility through activity on the mu-opioid receptor in the mesenteric plexus (McQuade et al., 2016).
        - i. The first dose is 4 mg; each additional dose is 2 mg. Patients can take this medication every two to four hours or after each unformed stool, taken 30 minutes before food if possible (Andreyev et al., 2014; Thorpe et al., 2017).
        - ii. Maximum dosing is 16 mg daily (Bossi et al., 2018).
      - (b) Octreotide is a synthetic somatostatin analog that increases intestinal transit time by inhibiting gut hormones (McQuade et al., 2016).
        - i. Starting dose is generally 100–150 mcg three times daily but can be rapidly titrated as needed to 500 mcg three times daily.
        - ii. It may be administered via IV or subcutaneous injection.
        - iii. Octreotide may be effective in patients refractory to loperamide (Andreyev et al., 2014; Bossi et al., 2018; Thorpe et al., 2017).
      - (c) Tincture of opium decreases intestinal motility through activity on the mu-opioid receptors; it contains 10 mg/ml of morphine (McQuade et al., 2016).
        - i. Dosing is 10–15 drops per three to four hours. Evidence is limited, specifically in chemotherapy- and targeted therapy-induced diarrhea; however, it may be used as second-line therapy (Koselke & Kraft, 2012).
        - ii. Monitor for side effects, including nausea and vomiting (most common), painful urination, allergic reaction, seizure, abdominal pain, constipation, and potential for respiratory depression (McQuade et al., 2016).
      - (d) Evidence is mixed regarding using steroids alone or in combination with loperamide (Shumar et al., 2019).
      - (e) Antibiotics are only indicated for patients with suspected infectious etiology that display clinical manifestations, such as fever, hypotension, and neutropenia (Bossi et al., 2018; Koselke & Kraft, 2012).
      - (f) Prophylactic atropine
        - i. Irinotecan is a chemotherapy agent that can cause acute diarrhea (during or immediately after administration) or delayed diarrhea.
        - ii. Immediate-onset diarrhea is caused by acute cholinergic properties and often is accom-

- panied by other symptoms, including abdominal cramping, rhinitis, lacrimation, and salivation.
- iii. The mean duration of symptoms is 30 minutes, and they usually respond rapidly to atropine.
  - iv. Delayed diarrhea is defined as diarrhea occurring more than 24 hours after administration of irinotecan and is commonly treated with loperamide (NCCN, 2022a).
  - v. Prophylactic atropine may be considered (unless clinically contraindicated) for patients who experience cholinergic symptoms (Bossi et al., 2018; see Table 15-5).
- (g) Uridine triacetate is used for early-onset severe toxicity of 5-fluorouracil/capecitabine-induced diarrhea within 96 hours following agent administration. The recommended dose is 10 g orally every six hours for 20 doses (Bossi et al., 2018).
- (2) Immune-mediated diarrhea (Spain et al., 2016): Refer to section D for a full review of colitis management.
- d) Other management strategies
- (1) For severe immune-mediated colitis with resulting diarrhea, colectomy may be appropriate in select cases (Spain et al., 2016).
  - (2) Dietary modifications, including a bland diet, may be implemented (Schmidt-Hieber et al., 2017; Thorpe et al., 2017).
  - (3) Evidence suggests the potential efficacy of probiotics in reducing antibiotic-associated diarrhea; however, more studies are needed to evaluate safety (Bowen et al., 2019).
  - (4) Skin barriers should be used to help prevent skin breakdown
- e) Interventions by category
- (1) Uncomplicated
    - (a) Oral hydration and electrolyte replacement
    - (b) Antidiarrheal medication
      - i. Administer antidiarrheal medication as appropriate once an infection has been ruled out.

**TABLE 15-5.** Common Antidiarrheal Medications

| Classification      | Mechanism of Action                                                                                 | Drug                                                                      | Route, Dose, and Schedule for Adult Patients <sup>a</sup>                                                      | Side Effects <sup>a</sup>                                                         | Nursing Considerations <sup>a</sup>                                                                                                                                                                                                                                                                                                |
|---------------------|-----------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Anticholinergics    | Antagonist of acetylcholine                                                                         | Atropine                                                                  | Used for early-onset cholinergic diarrhea (e.g., irinotecan induced), 0.25–1 mg IV or SC                       | Dry mouth, blurred vision, photophobia, constipation, xerostomia, tachyarrhythmia | Antacids interfere with absorption of the drug. The drug is contraindicated in patients with closed-angle glaucoma. (Intas Pharmaceuticals, 2019)                                                                                                                                                                                  |
| Antimotility agents | Slows gastrointestinal transit time and promotes reabsorption of water from bowel; anti-peristaltic | Diphenoxylate hydrochloride with atropine sulfate (Lomotil <sup>®</sup> ) | Individualize dosage. Initial dose is 10 mg followed by 5 mg PO four times daily; maximum dose is 20 mg daily. | Dry mouth, urinary retention, confusion, sedation, restlessness                   | Bacterial diarrhea should also be managed with the appropriate antimicrobial therapy. The drug is contraindicated for the treatment of diarrhea secondary to pseudomembranous colitis. In patients with advanced liver disease, the drug may precipitate hepatic coma. Do not use in children younger than 2 years. (Pfizer, 2017) |

**TABLE 15-5.** Common Antidiarrheal Medications (*Continued*)

| Classification                       | Mechanism of Action                                                                                                     | Drug                      | Route, Dose, and Schedule for Adult Patients <sup>a</sup>                                                                                                                                         | Side Effects <sup>a</sup>                                                                                                | Nursing Considerations <sup>a</sup>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Antimotility agents ( <i>Cont.</i> ) |                                                                                                                         | Loperamide (Imodium® A-D) | Initial dose is 4 mg PO followed by 2 mg PO after each unformed stool; do not exceed 16 mg daily.<br>Exception: Doses are higher for late-onset irinotecan-induced diarrhea (2 mg every 2 hours). | Constipation, fatigue, urinary retention, drowsiness, dizziness                                                          | Bacterial diarrhea should also be managed with the appropriate antimicrobial therapy.<br>Do not use in children younger than 2 years. (Janssen Biotech, 1998)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Somatostatin analogs                 | Inhibits growth hormone, glucagon, and insulin; prolongs intestinal transit time; increases sodium and water absorption | Octreotide (Sandostatin®) | 100–150 mcg SC or IV three times daily<br>Doses may be escalated to 500 mcg SC or IV three times daily or by continuous IV infusion 25–50 mcg/hr.                                                 | Abdominal discomfort, flatulence, constipation, diarrhea, nausea, dizziness, headache, cardiac dysrhythmias, bradycardia | The drug may interact with insulin, oral hypoglycemic medications, beta-blockers, and calcium channel blockers. Insulin requirements may be decreased.<br>Monitor for hyperglycemia and hypoglycemia.<br>The drug may decrease levels of cyclosporine when given concurrently.<br>The drug may increase risk of developing gallstones.<br>The drug is recommended after failure of loperamide or in patients with complicated diarrhea. Complicated diarrhea is defined as involving abdominal cramping, nausea and vomiting, fever, sepsis, neutropenia, or bleeding.<br>Sandostatin LAR Depot is under investigation for the treatment of chemotherapy-induced diarrhea. (Novartis Pharmaceuticals, 2021d) |

<sup>a</sup> Consult product information for complete list of contraindications, drug interactions, and dosage ranges.

IV—intravenous; PO—oral; SC—subcutaneous

- ii. This will reduce stool frequency, volume, and peristalsis.
- iii. Mistakenly using an antidiarrheal to treat diarrhea caused by infection can intensify diarrhea severity and infectious complications.

- (c) Dose reduction or discontinuation of chemotherapy if diarrhea is chemotherapy induced
- (d) Diet modification
- (2) Complicated
  - (a) Inpatient hospitalization, including intensive care for grade 4

- (b) IV fluids if patients cannot tolerate oral hydration
  - (c) Initiation or continuation of loperamide
  - (d) Introduction or continuation of bland diet or clear liquids
  - (e) Consideration of somatostatin
  - (f) Consideration of antibiotic therapy if diarrhea is infection related
  - (g) Delay or discontinuation of chemotherapy if diarrhea is chemotherapy induced
  - (h) Consideration of corticosteroids, infliximab, probiotics, or dose reduction or discontinuation of immunotherapy agent for immune-related diarrhea
  - (i) Withholding of immunotherapy agent if diarrhea is immune mediated
  - (j) IV electrolyte supplementation
  - (k) For graft-versus-host disease–related diarrhea, steroids, loperamide, and consideration of IV nutrition (Lieow & Christensen, 2014)
8. Patient and family education (Muehlbauer et al., 2009)
- a) Discuss treatment-related risks and diarrhea manifestations with patients and caregivers at the outset of treatment, using visual aids, such as the Bristol Stool Scale, as appropriate (Andreyev et al., 2014).
  - b) Educate patients to be aware of their baseline bowel functioning, monitor for changes in bowel habits, and report changes to their provider.
  - c) Start antidiarrheal medications at the specified time. Antidiarrheal medications should be provided with specific chemotherapy agents so that patients can self-administer at the onset.
  - d) Instruct patients on dietary recommendations and fluid intake.
    - (1) Avoid foods high in insoluble fiber (e.g., raw fruits and vegetables), greasy or fried foods, lactose, skins, seeds, legumes, caffeine, alcohol, and hyperosmotic liquids. These may be stimulating or irritating to the GI tract.
    - (2) Include foods high in soluble fiber or pectin in their diets and low insoluble fiber foods, such as rice noodles, bananas, white toast, skinned turkey or chicken, fish, and mashed potatoes.
    - (3) Maintain fluid intake by drinking 8–10 large glasses each day of clear fluids (e.g., bouillon; weak, tepid decaffeinated tea; gelatin; sports drinks). Water alone lacks the needed electrolytes and vitamins. Carbonated and caffeinated drinks contain relatively few electrolytes and may worsen diarrhea. Fluids with glucose are useful because glucose absorption drives sodium and water back into the body.
  - (4) Limit the use of sugar-free candies or gum made with sugar alcohol (sorbitol), which can cause diarrhea (NCI, 2022b).
  - (5) Eat food at room temperature if not tolerated otherwise. Hot and cold foods may aggravate diarrhea.
  - (6) Limit or avoid milk and other dairy products.
  - (7) Avoid hyperosmotic supplements (e.g., Ensure®), which can contribute to the production of loose, high-volume stools.
  - e) Instruct patients and families on skin care.
    - (1) Clean the rectal area with mild soap and water after each bowel movement, rinsing well and patting dry with a soft towel. Cleansing decreases the risk of infection and skin irritation.
    - (2) Apply moisture-barrier ointment to protect perianal skin.
    - (3) Take warm sitz baths to relieve pain related to perianal inflammation. Anesthetic creams or sprays may help to relieve pain related to inflammation.
  - f) Educate patients and families on symptoms to report.
    - (1) Understand when diarrhea can be self-managed and when to seek help.
    - (2) Report excessive thirst, fever, dizziness or light-headedness, palpitations, rectal spasms, excessive cramping, watery or bloody stools, and continued diarrhea despite antidiarrheal treatment. These symptoms can be life threatening.
- D. Colitis
1. Overview: Colitis is a general term for a disorder characterized by the inflammation of the colon (NCI CTEP, 2017). Colitis has multiple causes and, therefore, slightly different definitions based on the causative agent.
    - a) Neutropenic enterocolitis (also called typhlitis): Though the etiology is not fully understood, neutropenic enterocolitis generally results from neutropenia and damage to the bowel mucosa from chemotherapy. Neutropenic enterocolitis can be life threatening (Nesher & Rolston, 2012; Palmore et al., 2019; Rodrigues et al., 2017).
      - (1) Severe neutropenia (absolute neutrophil count less than 500/mm<sup>3</sup>) decreases

- the immune response against local tissue invasion by intestinal microbes.
- (2) Mucosal injury predisposes the colon to distension and necrosis (Rodrigues et al., 2017).
  - (3) Mucosal motility can be altered, making the colon more vulnerable to bacterial invasion and overgrowth (Rodrigues et al., 2017).
  - (4) Multiple proinflammatory mediators inside the intestinal lumen cause increased mucosal permeability (Nesher & Rolston, 2012).
  - (5) The cause is frequently polymicrobial and includes bacterial and fungal species, such as *C. difficile* or *Candida albicans* (Nesher & Rolston, 2012; Palmore et al., 2019).
- b) *C. difficile* colitis (Neemann & Freifeld, 2017)
- (1) *C. difficile* is a gram-positive, spore-forming, anaerobic rod transmitted via the fecal-oral route.
  - (2) Pathogenesis
    - (a) Disruption of the normal microbiome flora
    - (b) Colonization with *C. difficile* toxigenic strain
    - (c) Activation of *C. difficile* genes to produce cytotoxin proteins
    - (d) Mucosal damage causing inflammation
- c) Immune-mediated colitis: Symptoms relate to diarrhea, but it has a clinically distinct diagnosis, with accompanying abdominal pain and radiographic or endoscopic findings of colonic inflammation. Inflammation in the colon is the most common GI immune-related adverse event related to immunotherapy (Dougan et al., 2020).
- (1) Anti-CTLA-4 monoclonal antibody (e.g., ipilimumab): Blockade of CTLA-4 leads to more frequent adverse events than other categories of immunotherapies (Dougan et al., 2020).
    - (a) Fully humanized monoclonal antibody (immunoglobulin G1) against CTLA-4 that promotes antitumor T-cell immunity
    - (b) Causes apoptosis of activated T cells, which negatively regulates T-cell activation
    - (c) Mechanism of action (Barina et al., 2016)
      - i. CTLA-4 monoclonal antibodies suppress CTLA-4, which causes activation of T cells.
      - ii. Subsequently, activated T cells cause tissue damage inside the
- colon, which destroys mucosal immunity and disrupts the enteric flora and antibody levels.
- iii. Ultimately, this causes inflammation in the GI mucosa and is manifested in diarrhea and immune-mediated colitis.
- (2) Anti-PD-1 drugs: Diarrhea and colitis with PD-L1 agents have a similar presentation as with PD-1 agents.
- (a) PD-1 inhibitor monoclonal antibodies (e.g., nivolumab, pembrolizumab)
    - i. Nivolumab and pembrolizumab are human immunoglobulin G4 monoclonal antibodies that bind to the PD-1 receptor and block its interaction with PD-L1 and PD-L2.
    - ii. Mechanism of action (Chen et al., 2017)
      - Signaling limits effector function on the activated T cells in the periphery.
      - Depletion of regulatory T cells causes inhibition or block of anti-inflammatory mechanisms.
      - Inhibited cytokine production and widespread immune dysregulation result.
    - iii. PD-1 inhibitors can cause colLAGENOUS colitis (Baroudjian et al., 2016).
      - It is characterized by a subepithelial collagen band (more than 10 mcm) with increased intraepithelial lymphocytes.
      - Blocking the PD-1 pathway may trigger mucosal T lymphocytes.
      - It is diagnosed from colonoscopy with pathologic interpretation.
  - (b) PD-L1 inhibitors (e.g., atezolizumab, avelumab, cemiplimab, durvalumab)
    - i. Mechanism of action: Blockade of the PD-L1 pathway causes an increase in T-cell activation, which ultimately leads to decreased tumor size.
    - ii. When the PD-L1 pathway is blocked, immune responses

are inhibited without causing antibody-dependent cellular cytotoxicity.

iii. Combining checkpoint inhibitors, such as ipilimumab and nivolumab, further increases risk and toxicity (Kroschinsky et al., 2017).

iv. Combination checkpoint inhibitors and radiation therapy to the abdomen also increase toxicity risk, most frequently diarrhea and colitis.

(3) PI3K inhibitors (e.g., idelalisib): mechanism of action

(a) Inhibits PI3K pathway to induce apoptosis of malignant B cells

(b) Causes tissue damage in the colon and mucosal lining, which manifests as diarrhea and immune-mediated colitis (Louie et al., 2015)

## 2. Incidence

a) Neutropenic enterocolitis: True incidence is unknown but is estimated to be approximately 5%–6% of hospitalized adults with hematologic malignancies undergoing chemotherapy or with aplastic anemia. It is frequently underreported (Rodrigues et al., 2017).

b) *C. difficile* colitis

(1) *C. difficile*–associated diarrhea is the most common cause of nosocomial diarrhea in the United States, occurring in upwards of 25% of patients.

(2) Patients with cancer are at a high risk of developing *C. difficile*–associated diarrhea. Of those receiving myelosuppressive cancer therapies, approximately 7% will develop *C. difficile*–associated diarrhea, and of those cases, approximately 8% will develop more severe colitis.

(3) Incidence of positive *C. difficile* blood cultures is 18%–44% (Nesher & Rolston, 2012).

(4) Relapse can occur in as many as 35% of patients (Neemann & Freifeld, 2017).

c) Immune-mediated colitis: Highest rates of GI adverse events occur in patients receiving combination ipilimumab and nivolumab, with all-grade colitis, severe colitis, and severe diarrhea reported in 13.5%, 9.4%, and 9.2%, respectively. Symptoms of diarrhea and colitis generally develop within six to eight weeks of immune checkpoint inhibitor therapy (Thompson et al., 2019).

(1) CTLA-4 monoclonal antibodies

(a) Approximately 40% of patients will experience some form of GI symptomatology, and anywhere from 8% to 22% develop colitis (Dougan et al., 2020; Gupta et al., 2015; Haanen et al., 2017).

(b) Colon perforation occurs in up to 1.5% of patients (Haanen et al., 2017).

(c) The median onset of ipilimumab-induced colitis was 34 days or following three treatments (Cramer & Bresalier, 2017).

(d) Ipilimumab 3 mg/kg: Approximately 7% of patients experienced diarrhea with up to six stools above baseline, with only 5% of patients experiencing colitis (Bristol-Myers Squibb, 2022).

i. The median onset to grade 2 colitis was 1.4 months.

ii. The median onset to grade 3–5 colitis was 1.7 months.

(2) Anti-PD-1 drugs include monoclonal antibodies directed at both PD-1 (e.g., nivolumab, pembrolizumab) and PD-L1 (e.g., avelumab, atezolizumab, cemiplimab, durvalumab) (Baxi et al., 2018).

(a) Up to 61% of patients experience immune-related adverse events, including GI, dermatologic, and hepatic toxicities (Cramer & Bresalier, 2017; Gupta et al., 2015).

(b) Approximately 19% of patients present with diarrhea (Baxi et al., 2018; Cramer & Bresalier, 2017).

(c) Incidence of colitis is much less frequent in patients receiving anti-PD-1 drugs than anti-CTLA-4 therapy. Less than 1% of patients develop colitis on anti-PD-1 therapy (Haanen et al., 2017).

(3) PI3K inhibitors

(a) Idelalisib (Esposito et al., 2019)

(b) Copanlisib (Bayer HealthCare Pharmaceuticals, 2021a; Curigliano & Shah, 2019)

## 3. Risk factors

a) Patients currently receiving an immunotherapy agent that induces colitis are at risk.

b) History of colitis, whether chemotherapy induced or from previous immunotherapy agents, is a risk factor. Patients who received anti-CTLA-4 therapy and had associated colitis had a higher inci-

- dence of colitis when exposed to other immunotherapy agents, such as PD-1 inhibitors (Chen et al., 2017).
- c) Preexisting bowel abnormalities are a risk factor, such as autoimmune diseases (e.g., Crohn disease ulcerative colitis), diverticulitis, history of bowel surgery, and extensive tumor infiltration (Donia et al., 2017).
  - d) Neutropenic enterocolitis can occur in patients receiving high-dose chemotherapy and chemotherapy given for acute leukemia treatment (Palmore et al., 2019).
  - e) Neutropenia is a risk factor, as it reduces the body's immune response and allows for overgrowth of the intestinal microbes (Nesher & Rolston, 2012).
  - f) Radiation therapy increases the risk of mucosal damage and causes injury and destruction to the normal mucosa (Nesher & Rolston, 2012).
  - g) Nonsteroidal anti-inflammatory drug use is associated with an increased risk of anti-CTLA-4-induced colitis (Haanen et al., 2017).
  - h) Antibiotic use is associated with increased risk for the development of *C. difficile*-associated diarrhea and colitis.
  - i) Prior and prolonged hospitalizations for colitis are also risk factors (Neemann & Freifeld, 2017).
4. Clinical manifestations (see Table 15-6)
- a) Neutropenic enterocolitis (Palmore et al., 2019; Rodrigues et al., 2017)
    - (1) Febrile and neutropenic (absolute neutrophil count less than 500/mm<sup>3</sup>)
    - (2) Bowel wall thickening of greater than 4 mm
    - (3) Right lower quadrant inflammatory mass and mucosal edema: Extensive involvement of the large bowel and terminal ileum may occur.
    - (4) Abdominal pain, cramping, and tenderness
    - (5) Nausea, vomiting, and abdominal distension
    - (6) Diarrhea, possibly hematochezia
  - b) Immune-mediated colitis
    - (1) Diarrhea
    - (2) Nausea/vomiting
    - (3) Abdominal pain
    - (4) Possible fever or chills
    - (5) Hematochezia
5. Assessment
- a) History
    - (1) Assess patients for concerning symptoms, including abdominal cramps, nausea/vomiting, oral intake and nutritional status, symptoms of dehydration (e.g., dizziness), fever or chills, changes in mental status, and recent admissions.
  - (2) Assess stool quality and characteristics, including duration, continence, changes in bowel patterns, frequency, consistency, volume, odor, and presence of blood (Fernandes & Andreyev, 2020).
  - (3) Evaluate current or recent medications, including the type of anticancer therapy and any other agents patients are taking or prescribed for symptom management, including herbal remedies and over-the-counter medications.
- b) Physical assessment
- (1) Vital signs
  - (2) Weight
  - (3) Physical examination, with particular attention to the GI system (e.g., visual inspection, palpation, auscultation, presence of guarding or rebound tenderness, assessment for fecal impaction)
  - (4) Signs of dehydration, including decreased skin turgor, decreased urine output, hypotension, tachycardia, and delayed capillary refill
- c) Laboratory assessment
- (1) Stool testing
    - (a) Infectious etiologies: As the oncology patient population is at increased risk for infection, it is important to rule out *C. difficile*, cytomegalovirus via DNA polymerase chain reaction (PCR), ova, and parasites (Brahmer et al., 2018).
    - (b) Inflammatory markers: Fecal calprotectin and lactoferrin are highly sensitive to colonic inflammation. Fecal calprotectin is a stool inflammatory marker that has been widely used in clinical practice for patients with inflammatory bowel disease and is used as a predictive tool for immune-related colitis (Dougan et al., 2020; Tian et al., 2018).
    - (c) Fecal occult blood test
    - (d) Fecal leukocytes
  - (2) Serum chemistries for electrolyte imbalances
  - (3) Albumin
  - (4) Acid-base balance and lactate if sepsis suspected
  - (5) Blood cultures
  - (6) Urinalysis
  - (7) Complete blood count to determine neutropenia, anemia

**TABLE 15-6.** Comparison of Chemotherapy-Induced and Immune-Mediated Colitis

| Characteristic                   | Chemotherapy Induced                                                                                                                                                                                                                                                                                                                                                                                                | Immune Mediated                                                                                                                                                                       |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Distribution                     | Superficial                                                                                                                                                                                                                                                                                                                                                                                                         | Continuous, superficial                                                                                                                                                               |
| Primary location of inflammation | Diffuse pancolitis                                                                                                                                                                                                                                                                                                                                                                                                  | Left colon<br>Distal colon and rectum<br>Diffuse pancolitis                                                                                                                           |

Note. Based on information from Anand & Glatt, 1993; Barina et al., 2016; Baroudjian et al., 2016; Bavi et al., 2017; Cramer & Bresalier, 2017; Gupta et al., 2015; Nesher & Rolston, 2012; Palmore et al., 2019; Rodrigues et al., 2017; Weidner et al., 2015; Yanai et al., 2017.

(8) Erythrocyte sedimentation rate and C-reactive protein are used to help diagnose inflammatory disease (Assasi et al., 2015).

(9) HIV, hepatitis A and B, and blood quantiferon testing for tuberculosis should be routinely performed in patients at high risk for those infections in preparation for starting infliximab (Brahmer et al., 2018).

d) Radiographic assessment

(1) CT scan can evaluate bowel perforation, obstruction, toxic megacolon, and intestinal wall thickening. CT scan is 85.2% sensitive and 75% specific for colitis (Dougan et al., 2020).

(2) Another method to detect bowel abnormalities is via a fluorodeoxyglucose positron-emission tomography (FDG-PET)/CT study.

(3) Colonoscopy with biopsies for histologic examination is not recommended if neu-

tropenic enterocolitis is suspected (Puzanov et al., 2017; Rodrigues et al., 2017).

(4) Endoscopic biopsies are the gold standard for diagnosing GI immune-related adverse events from checkpoint inhibitors. The degree of mucosal injury found on endoscopy is the most predictive factor of treatment responsiveness, as opposed to Common Terminology Criteria for Adverse Events grade or severity of symptoms (Dougan et al., 2020; Tian et al., 2018).

(5) Ultrasonography may be used to measure the thickness of the bowel wall and may help measure the clinical course of colitis (Nesher & Rolston, 2012).

e) Differential diagnoses

(1) As neutropenic enterocolitis generally involves pain in the right lower abdominal quadrant, it can mimic acute appendicitis. Other differential diagnoses include *C. difficile* colitis, graft-versus-host dis-

- ease, cytomegalovirus, norovirus, ischemic colitis, and inflammatory bowel disease (Rodrigues et al., 2017).
- (2) *C. difficile* colitis can include other infectious diarrhea, noninfectious complicated diarrhea, inflammatory bowel disease, celiac disease, and immune-mediated colitis (Polage et al., 2012).
  - (3) Neutropenic colitis can include cytomegalovirus infection, opportunistic viral infections, and fungal colitis (Dougan et al., 2020).
6. Collaborative management and prevention
- a) Preventing diarrhea includes early recognition of symptoms.
    - (1) Proper grading of diarrhea is essential for proper management.
    - (2) NCI CTEP's (2017) grading criteria are used to assess symptoms of diarrhea or colitis and implement a treatment management strategy (see Figure 15-8).
  - b) Interprofessional collaboration promotes improved patient outcomes (Mistry et al., 2017).
    - (1) Educate and inform clinicians on identifying, grading, and managing diarrhea and colitis.
    - (2) Early intervention can improve patient outcomes.
    - (3) Minimize the likelihood of permanent or severe side effects.
  - c) Rule out infectious colitis.
    - (1) Perform stool tests for enteric pathogens and *C. difficile* (by PCR) (Gupta et al., 2015).
    - (2) Rule out cytomegalovirus infection by performing immunohistochemical staining on biopsy samples from colonoscopy (Gupta et al., 2015).
    - (3) Rule out fungal causes of colitis.
  - d) Perform diagnostics.
    - (1) Colonoscopy in any patient with grade 2 or higher diarrhea (Cramer & Bresalier, 2017) with biopsies (Puzanov et al., 2017)

**FIGURE 15-8.** Common Terminology Criteria for Adverse Events Grading for Colitis

| Adverse Event | Grade                                                                              |                                         |                                         |                                                              |       |
|---------------|------------------------------------------------------------------------------------|-----------------------------------------|-----------------------------------------|--------------------------------------------------------------|-------|
|               | 1                                                                                  | 2                                       | 3                                       | 4                                                            | 5     |
| Colitis       | Asymptomatic; clinical or diagnostic observations only; intervention not indicated | Abdominal pain; mucus or blood in stool | Severe abdominal pain; peritoneal signs | Life-threatening consequences; urgent intervention indicated | Death |

| Management by Treatment Type |                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |   |   |

Note. Grading criteria from *Common Terminology Criteria for Adverse Events* [v.5.0], by National Cancer Institute Cancer Therapy Evaluation Program, 2017 ([https://ctep.cancer.gov/protocolDevelopment/electronic\\_applications/docs/CTCAE\\_v5\\_Quick\\_Reference\\_5x7.pdf](https://ctep.cancer.gov/protocolDevelopment/electronic_applications/docs/CTCAE_v5_Quick_Reference_5x7.pdf)). In the public domain.

- (2) Plain x-rays to visualize dilation of small bowel and gas
- (3) CT scan to visualize bowel wall thickening
- (4) Fecal occult blood test
- (5) Testing to rule out infectious etiologies, including stool and blood cultures and PCR assay for *C. difficile*
- e) Neutropenic enterocolitis
  - (1) Holding chemotherapy
  - (2) Bowel rest (Palmore et al., 2019)
  - (3) Aggressive IV fluid resuscitation (Palmore et al., 2019; Rodrigues et al., 2017)
  - (4) Initiation of broad-spectrum antibiotics with consideration of antifungal agents (Palmore et al., 2019; Rodrigues et al., 2017)
  - (5) Consideration of granulocyte-colony-stimulating factor until resolution or an absolute neutrophil count greater than  $1,000/\text{mm}^3$  (Nesher & Rolston, 2012)
  - (6) Testing to rule out infectious etiologies: Collect stool cultures for fungal sources or cytomegalovirus and perform a PCR assay for *C. difficile* (Rodrigues et al., 2017).
  - (7) Delay of chemotherapy until full resolution and consideration of dose modification for subsequent cycles (Nesher & Rolston, 2012)
  - (8) Surgical intervention may be necessary with perforation, uncontrolled sepsis or GI bleeding, or the development of other conditions, such as abscess (Palmore et al., 2019; Rodrigues et al., 2017).
- f) *C. difficile* colitis
  - (1) *C. difficile* colitis is managed with oral vancomycin or fidaxomicin. Metronidazole is reserved for nonsevere cases for which other treatments may not be available (Palmore et al., 2019).
  - (2) Antidiarrheals are contraindicated because they decrease motility, allowing *C. difficile* bacteria and toxins to fester and overgrow (Anand & Glatt, 1993).
- g) Immune-mediated colitis (see Figure 15-8)
  - (1) Effective colitis and diarrhea management is accomplished by early intervention regardless of the immunotherapy agent.
  - (2) Colitis-related mortality with immunotherapy agents has been associated with delayed reporting, nonadherence with the antidiarrheal regimen, and failure to hold the immunotherapy agent (Naidoo et al., 2015).
  - (3) Early identification and diagnosis with timely implementation of therapy are critical (Gondal et al., 2016).
- (4) With early intervention, colitis is reversible.
- (5) Interventions by grade
  - (a) Grade 1 bowel symptoms: Patients generally respond well to conservative management (Tian et al., 2018).
    - i. Treat symptomatically using antidiarrheals, such as loperamide or diphenoxylate-atropine (Dougan et al., 2020).
    - ii. Monitor for dehydration and institute fluid and electrolyte replacement if needed (Thompson et al., 2019).
    - iii. Consider holding immunotherapy; it may be resumed if toxicity does not worsen or improves (Brahmer et al., 2018).
    - iv. Monitor closely (Thompson et al., 2019).
    - v. Dietary modification should include bland foods; add bulking agents, such as psyllium (Dougan et al., 2020; Puzanov et al., 2017).
  - (b) Grade 2 bowel symptoms
    - i. Hold checkpoint inhibitor therapy and continue treatment with antidiarrheal. Consider permanent discontinuation of CTLA-4 agents; anti-PD-1 agents may be restarted if patients recover to grade 1 or less (Cramer & Bresalier, 2017; Puzanov et al., 2017; Thompson et al., 2019).
    - ii. High-dose corticosteroids should be initiated if suspected colitis or uncomplicated diarrhea does not improve with conservative measures for two to three days (Puzanov et al., 2017). Most patients will respond to first-line treatment with steroids and achieve remission after a four-to-six-week taper. Initiate at 1 mg/kg daily of prednisone or methylprednisolone. If there is no improvement after two to three days, increase to 2 mg/kg daily and consider adding infliximab or vedolizumab (Dougan et al., 2020;

- Puzanov et al., 2017; Thompson et al., 2019). Once symptoms decrease to grade 1 or less, resume therapy, and continue a four-to-six-week steroid taper. Rapid tapering of steroids may result in recurrent colitis (Brahmer et al., 2018; Cramer & Bresalier, 2017).
- iii. Approximately 30%–40% of patients treated with high-dose corticosteroids require secondary immune suppression with a biologic agent. In patients with corticosteroid-resistant colitis, infliximab or vedolizumab, which are monoclonal antibodies that target inflammatory cytokine tumor necrosis factor- $\alpha$ , are recommended. A response is generally seen in one to three infusions (Dogan et al., 2020; Gupta et al., 2015; Yanai et al., 2017).
    - Approximately 17% of patients with ipilimumab-related colitis are treated with infliximab after corticosteroid failure of symptom reduction (Barina et al., 2016).
    - Infliximab is contraindicated in patients with perforation or sepsis (Yang et al., 2017).
    - Early initiation is associated with faster symptom resolution, decreased hospitalization, and decreased recurrence of colitis (Abu-Sbeih et al., 2019; Dogan et al., 2020).
  - iv. Consider gastroenterology consult.
  - v. Loperamide may be continued if infectious etiology is ruled out.
- (c) Grade 3–4 bowel symptoms
- i. Consider permanently discontinuing checkpoint inhibitor therapy and initiating corticosteroids (Puzanov et al., 2017; Thompson et al., 2019).
  - ii. Initiate at 1–2 mg/kg daily of prednisone or equivalent, followed by a one-month steroid taper (Puzanov et al., 2017; Thompson et al., 2019).
  - iii. If grade 3–4 symptoms persist with corticosteroids after three to five days, initiate infliximab or vedolizumab (Puzanov et al., 2017; Thompson et al., 2019).
  - iv. Consider hospitalization with a gastroenterology consult (Brahmer et al., 2018; Dogan et al., 2020).
  - v. Perform an endoscopy to rule out other etiologies of inflammation, including infection, ischemia, new-onset celiac disease, pancreatic insufficiency, and medication-induced diarrhea; assess or reassess mucosal severity (Dogan et al., 2020).
- h) Total colectomy
- (1) Colectomy was used as a definitive treatment in 8% of patients with ipilimumab-related colitis after failure of medical therapy (Barina et al., 2016).
  - (2) Surgery is reserved for patients in whom medical therapy has failed or those with bowel perforation (Gupta et al., 2015).
- i) Management of PD-1 inhibitor-induced colitis (Baroudjian et al., 2016)
- (1) Pembrolizumab-induced collagenous colitis
    - (a) It is recommended to perform a colonoscopy with biopsies.
    - (b) If a diagnosis of collagenous colitis is made with pathology, it is recommended to continue with PD-1 inhibitor therapy while initiating corticosteroid therapy, such as budesonide 9 mg daily, along with symptomatic management.
  - (2) General early intervention includes the withdrawal of PD-1 inhibitor therapy and initiation of steroids.
7. Patient and family education
- a) Educate patients and caregivers on the definition of diarrhea and the importance of reporting bowel movements.
    - (1) Underreporting of diarrheal episodes may cause a delay in therapy.
    - (2) Patients should report to the treatment team any changes in bowel patterns, increase in stools over baseline, fever, abdominal distention, pain or cramping,

nausea, blood in stool, and increased gas (Brahmer et al., 2018).

- b) Although the median onset of colitis and diarrhea has been outlined previously, symptoms of colitis or diarrhea can occur any time after patients have received an immunotherapy or chemotherapy agent.

- (1) Drink fluids to maintain clear or pale yellow-colored urine.
- (2) Eat a well-balanced diet. Patients with mild grade 1 diarrhea or colitis can follow the diet provided by the Academy of Nutrition and Dietetics (Naidoo et al., 2015).
- (3) Work with a dietitian to determine foods that cause flares and avoid those foods.

## E. Pancreatitis

### 1. Overview

- a) Pancreatitis is inflammation of the pancreas classified as either acute or chronic.
- b) Classifications (Greenberg et al., 2016)
  - (1) Acute pancreatitis is mild acute, moderately severe, or severe.
    - (a) Mild acute: absence of organ failure or local or systemic complication
    - (b) Moderately severe: transient organ failure (resolves within 48 hours) or local or systemic complications without persistent organ failure (greater than 48 hours)
    - (c) Severe: persistent organ failure that may involve one or multiple organs
  - (2) Chronic pancreatitis is inflammation of the pancreas that does not heal, worsens over time, and leads to permanent damage (Gardner et al., 2020).

### 2. Guidelines for diagnosis

- a) Acute pancreatitis is the presence of at least two of the following three features: upper abdominal pain, serum amylase or lipase more than three times the upper limit of normal, or imaging suggestive of pancreatitis, such as CT scan, magnetic resonance imaging, or ultrasonography (Greenberg et al., 2016).
- b) Severe pancreatitis is persistent organ failure for more than 48 hours despite IV fluid resuscitation and a serum C-reactive protein level of 150 mg/dl or greater at baseline or in the first 72 hours (Greenberg et al., 2016).
- c) Chronic pancreatitis is best diagnosed using abdominal pain, steatorrhea, or a contrast-enhanced CT scan; however, a CT scan may be inconclusive in the early stages. Magnetic resonance imaging, magnetic resonance cholan-

giopancreatography, or endoscopic ultrasonography with or without biopsy may also be used for diagnosis (Barry, 2018).

### 3. Incidence and risk factors

- a) Treatment with L-asparaginase and PEG-asparaginase, older age, and higher cumulative doses of asparaginase (Lieu et al., 2016). The prevalence of asparaginase-associated pancreatitis is 7%–11%, with median onset after two doses (range 1–11 doses) (Stenger, 2019; Zhang et al., 2020).
- b) Other chemotherapy agents (e.g., carboplatin, cisplatin, cytarabine, ifosfamide, paclitaxel, vinorelbine): Onset is variable and may range from hours to one month after administration (Ngo et al., 2015).
- c) Immune checkpoint inhibitors (e.g., ipilimumab, nivolumab, pembrolizumab, atezolizumab): Patients treated with CTLA-4 inhibitors have an increased incidence of pancreatitis when compared to patients treated with PD-1 inhibitors (George et al., 2019).
- d) Targeted therapies (e.g., axitinib, bosutinib, dasatinib, sorafenib, sunitinib, nilotinib, ponatinib, vemurafenib) (Clamon et al., 2017): Pancreatic effects can range from asymptomatic pancreatic enzyme elevation to acute pancreatitis.
  - (1) Frequency of acute pancreatitis in clinical trials is 0%–4.3% (Clamon et al., 2017).
  - (2) Amylase and lipase elevation frequently are reported with TKIs (Clamon et al., 2017).
  - (3) A meta-analysis evaluating pancreatitis with VEGF receptor TKIs (e.g., sunitinib, sorafenib, pazopanib, axitinib, vandetanib, cabozantinib, ponatinib, regorafenib) observed a 1.95-fold increased risk of all-grade pancreatitis; however, the risk of severe (grade 3 or higher) was not significant (Ghatalia et al., 2015).
- e) Obstructions of the duct system (e.g., periampullary neoplasms), cholelithiasis, and congenital alterations in the ductal system (e.g., pancreas divisum)
- f) Hypertriglyceridemia, hypercalcemia
- g) Diabetes
- h) Tumor lysis syndrome
- i) Post-endoscopic retrograde cholangiopancreatography: Pancreatitis is the most common post-procedure complication. The risk is increased with chronic pancreatitis and after inadvertent cannulation of the pancreatic duct (Phillip et al., 2017).
- j) Alcohol abuse
- k) Illicit drug use

- l) Pediatrics: hematopoietic stem cell transplantation (HSCT)
- m) Infection
- 4. Clinical manifestations (Banks et al., 2013)
  - a) Three main manifestations
    - (1) Acute onset of persistent, severe epigastric abdominal pain, which may be right upper quadrant or, rarely, confined to the left side: Approximately 50% radiates to the back. Pain may be partially relieved by sitting up or bending forward.
    - (2) Pancreatic enzyme elevations
      - (a) Serum amylase: Rises within 6–12 hours. The elevation is greater than three times the upper limit of normal and has a sensitivity for diagnosing acute pancreatitis; if uncomplicated, amylase returns to normal after three to five days.
      - (b) Serum lipase: Rises 4–8 hours after onset of symptoms, peaks at 24 hours, and returns to normal within 8–14 days. These elevations occur earlier, last longer than amylase elevations, and are more sensitive in patients with pancreatitis second to alcohol abuse.
      - (c) Trypsinogen activation peptide: Is elevated early and may help detect early acute pancreatitis and predict severity (Dixit et al., 2016)
    - (3) CT scan positive for signs of pancreatic inflammation
  - b) Other clinical findings (Tang, 2021)
    - (1) Fever
    - (2) Tachycardia and hypovolemia
    - (3) Hypoxemia
    - (4) Dyspnea due to diaphragmatic inflammation
    - (5) Nausea and vomiting: incidence of approximately 90%
    - (6) Jaundice, elevated liver function tests
    - (7) Hypoactive bowel sounds, ileus
    - (8) Leukocytosis, elevated hematocrit from hemoconcentration due to extravasation of intravascular fluid into third space
    - (9) Elevated blood urea nitrogen, hypocalcemia, hyperglycemia, hypoglycemia
    - (10) Hemorrhagic pancreatitis: manifested by ecchymotic discoloration around the umbilicus (Cullen sign) or along the flank (Grey Turner sign); suggests possible retroperitoneal bleeding in the setting of pancreatic necrosis
    - (11) Later complications: hemorrhage, sepsis, multisystem organ failure
- 5. Assessment
  - a) Perform a physical examination to find and document the preceding clinical manifestations.
  - b) The epigastrium may be minimally tender to palpation. With severe pancreatitis, patients may have significant tenderness to palpation, abdominal distention, and hypoactive bowel sounds due to ileus from inflammation (Tang, 2021).
- 6. Collaborative management: Treatment and follow-up will depend on the etiology of pancreatitis and its severity (Bade et al., 2019; Working Group IAP/APA Acute Pancreatitis Guidelines, 2013). The primary treatment is holding or discontinuing any agent that may cause the condition.
  - a) Pancreatitis associated with checkpoint inhibitors may require immunosuppression with corticosteroids (Davies, 2016).
  - b) Pancreatitis associated with L-asparaginase tends to respond after the drug is discontinued and aggressive treatment is initiated. It will most likely recur if the drug is used again (Bade et al., 2019; Lieu et al., 2016). Because reduced L-asparaginase exposure is related to a decreased cure rate in acute lymphoblastic leukemia, the drug should not be discontinued unless pancreatitis is diagnosed. L-asparaginase is contraindicated in patients with a history of severe pancreatitis (Bade et al., 2019).
  - c) Insert a nasogastric tube if patients have nausea and vomiting or ileus to rest the gut and pancreas during the acute phase (Bade et al., 2019; Working Group IAP/APA Acute Pancreatitis Guidelines, 2013).
  - d) Use Ringer's lactate for initial fluid resuscitation (Working Group IAP/APA Acute Pancreatitis Guidelines, 2013).
  - e) Implement nutritional support (Working Group IAP/APA Acute Pancreatitis Guidelines, 2013).
    - (1) Restart oral feeding if pancreatitis is mild, abdominal pain decreases, and inflammatory markers improve.
    - (2) Provide enteral tube feeding if pancreatitis is predicted to be severe. Either the nasojejunal or nasogastric route can be used.
    - (3) Parenteral nutrition is a second-line therapy if tube feeding is not tolerated and nutritional support is required.
  - f) Monitor serum lipase, amylase, glucose, electrolytes, and liver function tests. Amylase and lipase are monitored at baseline, two to three days after administration of PEG-asparaginase, and then weekly for at least four weeks after each dose (Bade et al., 2019).
  - g) Treat hyperglycemia as indicated.

- h) Provide effective pain control and monitor for increasing pain, which may indicate progression of pancreatitis.
  - i) Prevention of infectious complications
    - (1) IV antibiotic therapy is not recommended to prevent infectious complications in acute pancreatitis (Crockett et al., 2018; Working Group IAP/APA Acute Pancreatitis Guidelines, 2013). IV antibiotics should be given with suspected infection with necrotizing pancreatitis (Working Group IAP/APA Acute Pancreatitis Guidelines, 2013).
    - (2) Probiotic prophylaxis is not recommended (Working Group IAP/APA Acute Pancreatitis Guidelines, 2013).
    - (3) Selective gut decontamination has shown some benefits, but further studies are needed (Working Group IAP/APA Acute Pancreatitis Guidelines, 2013).
  - j) Monitor vital signs, urine output, blood urea nitrogen concentrations and hematocrit, oxygen saturation, and condition carefully for signs of hypovolemic shock. It is important to use physiologic metrics and goals to guide initial fluid resuscitation to ensure adequate organ perfusion (James & Crockett, 2018).
7. Patient and family education
- a) Instruct patients to use analgesics for pain control.
  - b) Implement oral and nasal care while patients are NPO (nothing by mouth) with a nasogastric tube.
  - c) Ensure that patients understand the importance of adherence to dietary, pharmacologic, and lifestyle recommendations.
  - d) Ensure that patients and significant others can recognize the early symptoms of pancreatitis, such as abdominal pain, especially associated with vomiting, and instruct them to seek medical intervention when these occur.

## F. Mucositis

1. Overview: Mucositis is a potential complication of systemic cytotoxic therapy, EGFR inhibitors, TKIs, and radiation therapy (Harris et al., 2014). Severe mucositis can contribute to hospitalization, the need for narcotic analgesia or total parenteral nutrition, suboptimal delivery of antineoplastic treatment, and morbidity and mortality (Mercadante et al., 2015). Mucositis and stomatitis are often used interchangeably, but they do not reflect identical processes (Peterson et al., 2015).
  - a) Mucositis refers to inflammatory or ulcerative lesions of the oral mucosa or GI tract resulting

from chemotherapy agents or ionizing radiation (Pulito et al., 2020).

- b) Stomatitis refers to an array of symptoms in the oral cavity, including mucosal inflammation, ulcers, chelates or dry lips, and oral pain (Hartl et al., 2017).
  - c) Alimentary tract mucositis refers to mucosal injury across the oral and GI mucosa continuum from the mouth to the anus (Peterson et al., 2015).
2. Pathophysiology
- a) Historically, oral mucositis was attributed to the direct effects of cytotoxic drugs or radiation therapy on the epithelial stem cells. It is now known to be a result of a complex, sequential series of biologic events that culminate in the destruction of epithelial stem cells and interruption of epithelial renewal, which results in erythema and atrophy of the epithelial tissue (Lalla et al., 2014).
  - b) The current biologic model for oral mucositis includes five phases: initiation, upregulation/activation, signaling and amplification, ulceration, and healing (Lalla et al., 2014).
    - (1) Initiation: Radiation and chemotherapy negatively affect the cells and strands of DNA in the basal epithelium and submucosa. Free radicals (reactive oxygen species) also are generated and play an interfering role in the biologic events of the later stages (Lalla et al., 2014).
    - (2) Upregulation/activation: The negative effect on the cells and DNA and the reactive oxygen species activates a cascade of reactions that produce proinflammatory cytokines. These compounds stimulate several pathways, leading to lesions or the death of basal cells by apoptosis (Lalla et al., 2014). Nuclear factor kappa B results in the upregulation of many genes and the release of proinflammatory cytokines, such as tumor necrosis-alpha, IL-1 beta, and IL-6.
    - (3) Signaling and amplification: In addition to causing direct tissue damage, proinflammatory cytokines activate the production of tissue-damaging tumor necrosis factor-alpha, IL-1 beta, IL-6, and other cytokines that alter mucosal tissues. The release of proinflammatory cytokines damages the cells and provides a positive feedback that amplifies the lesions caused directly by the radiation or chemotherapy (Sonis, 2011).
    - (4) Ulceration: Tissue injury in the GI mucosa appears as ulcers that penetrate through

- the epithelium to the submucosa. Bacteria penetrate the submucosa and stimulate macrophage activity, which increases the release of proinflammatory cytokines. Angiogenesis also is stimulated (Sonis, 2011).
- (5) Healing: Signals from extracellular tissues stimulate epithelial proliferation until the mucosa returns to its normal thickness. Neutropenia may prolong the healing process (Sonis, 2011).
3. Incidence of oral mucositis
- a) Prevalence and incidence are inconsistent because of the lack of standardized scoring criteria, tumor location, different treatment regimens, and underreporting (Villa & Sonis, 2015). Incidence varies depending on cancer treatment, dose, and frequency (Fulton, 2018).
- b) Incidence in HSCT recipients is approximately 80% (Eilers et al., 2019). The intensity of the conditioning regimen, transplant type, and TBI can influence incidence and severity (Chaudhry et al., 2016).
- c) Incidence in patients undergoing head and neck radiation therapy is 65%–90% (Sonis, 2011).
- (1) It occurs in almost all patients treated for cancers of the mouth, oropharynx, and nasopharynx, and approximately two-thirds of patients treated for cancers of the hypopharynx or larynx (Moslemi et al., 2016).
- (2) Concomitant chemotherapy and targeted therapy agents increase risk (Villa & Sonis, 2015).
- d) Stomatitis and diarrhea have been reported with targeted therapies.
- (1) The term *stomatitis* has been used for oral lesions secondary to targeted therapy agents to distinguish from mucositis due to conventional chemotherapy and radiation therapy (Shankar et al., 2017).
- (2) Certain mTOR inhibitors have reported rates of 66% (Shankar et al., 2017).
- (3) Lesions secondary to targeted therapy agents are often accompanied by a skin rash (Al-Dasooqi et al., 2013).
4. Risk factors
- a) Development of mucositis depends on treatment- and patient-related factors (Villa & Sonis, 2016).
- b) Treatment-related factors
- (1) Chemotherapy agents (Chaveli-López & Bagán-Sebastián, 2016)
- (a) Antimetabolites
- i. Increased risk with bolus 5-fluorouracil
- ii. Methotrexate for prophylaxis of graft-versus-host disease following HSCT (Solodokin et al., 2020)
- (b) Antitumor antibiotics
- (c) Alkylating agents, including high-dose melphalan
- (d) Plant alkaloids
- (2) Targeted therapies
- (a) mTOR inhibitors (Shankar et al., 2017)
- (b) TKIs (Califano et al., 2015)
- (3) Immunotherapy agents: PD-1/PD-L1 inhibitor therapy may induce or accelerate oral complications by aberrant cell activation, such as what has been seen in graft-versus-host disease or autoimmune conditions (Jackson et al., 2015).
- (4) Patients receiving myeloablative and reduced-intensity conditioning regimens prior to HSCT have a high incidence and severity of oral mucositis (Chaudhry et al., 2016).
- (5) Radiation therapy
- (a) Radiation therapy following surgical resection in patients with head and neck cancer
- (b) Combined chemotherapy and radiation (Eilers et al., 2019)
- (c) TBI or concomitant radiation therapy to the head or neck (Villa & Sonis, 2015)
- (d) Greater incidence when EGFR inhibitor treatment is added to radiation therapy (De Sanctis et al., 2016)
- (6) Drugs or therapies that alter mucous membranes (Wujcik, 2014)
- (a) Oxygen therapy dries out the mucosal lining.
- (b) Anticholinergics decrease salivary flow (Wujcik, 2014).
- (c) Phenytoin causes gingival hyperplasia.
- (d) Steroids can result in fungal overgrowth.
- c) Patient-related risk factors
- (1) Ill-fitting dentures, as they can irritate the mucosa and break integrity (NCI, 2019)
- (2) Poor oral hygiene, periodontal disease: Periodontitis-associated bacteria have been related to the onset and worsening of ulcerative mucositis (NCI, 2019).
- (3) Persistent alcohol or tobacco use
- (a) Alcohol and tobacco irritate the mucosa and disrupt salivary gland function, affecting microcirculation

and possibly delaying healing (Khairnar et al., 2017).

- (b) Chronic alcohol use is associated with mucosal atrophy and hyper-regeneration of the basal layer cells, increasing susceptibility of the mucosa and predisposing patients to malnutrition (De Sanctis et al., 2016).
  - (4) Xerostomia or hyposalivation
  - (5) Dehydration, as it alters mucosal integrity
  - (6) Poor nutritional status
    - (a) Poor nutrition can lead to delayed healing and an increased risk of breakdown (Maria et al., 2017).
    - (b) Unintentional weight loss before therapy can occur (i.e., more than 5% weight loss over one month or more than 10% in the last six months) (De Sanctis et al., 2016).
    - (c) Low body mass index (less than 18.5 kg/m<sup>2</sup>) can lead to delayed healing and increased risk of breakdown in undernourished patients (Maria et al., 2017).
    - (d) Irritating foods (e.g., acidic, spicy) may inflame and traumatize mucosa (Oral Cancer Foundation, n.d.; Wujcik, 2014).
  - (7) Immunosuppression due to comorbidities
  - (8) Neutropenia
  - (9) Hepatic or renal impairment: inadequate metabolism or excretion of drugs
  - (10) Age (Fulton, 2018)
    - (a) Older patients are at higher risk for severe oral mucositis because of age-related decline in kidney function and decreased creatinine clearance rates, which can affect the excretion of chemotherapy and lead to drugs remaining longer in the circulation, causing more damage.
    - (b) Younger patients (20 years and younger) are also at risk for more severe oral mucositis because of increased epithelial mitotic rates and increased EGFR in epithelial tissue (Treister, 2022).
  - (11) Genetic factors may play a significant role. Animal studies have shown that various gene expression-related changes occur after chemotherapy or radiation therapy (Villa & Sonis, 2016).
5. Clinical manifestations
- a) Presentation of oral mucositis depends on the modality (e.g., chemotherapy, targeted therapy,

immunotherapy, radiation therapy, combined therapy), type of drugs administered, dosage or intensity, and schedule of administration (Villa & Sonis, 2016).

- (1) First signs of mucositis usually begin approximately three to four days after the chemotherapy infusion and when patients complain of mucosal irritation (Shankar et al., 2017). Ulcer formation develops, peaks on days 7–14, and resolves about a week after peaking (Villa & Sonis, 2016).
  - (2) HSCT recipients experience mucositis two to five days following the conditioning regimen (McCullough, 2016).
  - (3) Patients receiving radiation to the head and neck complain of oral soreness and develop erythema at the end of the first week of treatment when cumulative doses reach 10 Gray (Gy). By 12–14 days, when cumulative doses reach 30 Gy, multiple ulcerations develop, and as radiation accumulates, ulcerative lesions become more diffuse and painful. These lesions are then present throughout therapy (usually 60–70 Gy). Ulcerations remain at their peak for at least two weeks following completion of treatment. They usually begin to resolve over two to four weeks but can persist for up to eight weeks (Moslemi et al., 2016; Villa & Sonis, 2015).
  - b) Intensity increases with higher doses of cytotoxic drugs. Drugs that are not usually stomatotoxic at standard doses (e.g., cyclophosphamide) can cause cellular damage to the mucosa at high doses (Keefe et al., 2007).
  - c) Signs and symptoms
    - (1) Oral mucosal changes (e.g., erythema, pallor, white patches, discolored lesion, ulcers), edematous oral mucosa, tongue
    - (2) Mucosal ulcerations: irregularly shaped lesions that typically lack peripheral erythema (Shankar et al., 2017)
    - (3) Mouth lesions with mTOR inhibitors: clinically mimic aphthous stomatitis (commonly called canker sores) (Shankar et al., 2017)
    - (4) Difficulty talking, changes in voice strength, pain when talking
    - (5) Pain on swallowing, inability to swallow
    - (6) Saliva: changes in amount or consistency, watery or thick and ropy
6. Assessment
- a) Use a standardized assessment tool or scale when performing a physical examination. Scales designed for clinical use consider the symp-

toms, signs, and functional disturbances associated with oral mucositis and assign an overall score.

- (1) Oral Assessment Guide: This tool contains eight categories that reflect oral health and function: voice, swallowing, lips, tongue, saliva, mucous membrane, gingiva, and teeth/dentures (Aoki et al., 2019). It has been identified as the only validated tool consistently judged to be user-friendly and appropriate for children and adults (Whithorn, 2021).
- (2) The World Health Organization (1979) Oral Toxicity Scale combines mucosal changes, pain, and functionality into a single composite score (Epstein et al., 2012).
  - (a) Grade 0: no changes
  - (b) Grade 1: soreness, erythema
  - (c) Grade 2: soreness, erythema, ulceration, and can eat solid food
  - (d) Grade 3: soreness, erythema, ulceration, and can consume a liquid diet only
  - (e) Grade 4: soreness, erythema, ulceration, and oral alimentation is not possible
- (3) The World Health Organization tool grades the severity of mucositis, whereas the Oral Assessment Guide addresses overall changes in the oral cavity (Whithorn, 2021).
- (4) NCI CTEP's (2017) *Common Terminology Criteria for Adverse Events* consists of a 1–5 grading scale associated with descriptions of oral mucosal changes.
  - (a) Grade 1: asymptomatic or mild symptoms; intervention not indicated
  - (b) Grade 2: moderate pain or ulcer that does not interfere with oral intake; modified diet indicated
  - (c) Grade 3: severe pain; interfering with oral intake
  - (d) Grade 4: life-threatening consequences; urgent intervention indicated
  - (e) Grade 5: death
- (5) Patient-reported outcome measures are questionnaires completed by patients to assess symptom burden and functionality (Kingsley & Patel, 2017). They allow for clinical interventions to be measured from the patient's perspective of the level of impairment and quality of life (Kingsley & Patel, 2017).

(a) Patient-Reported Oral Mucositis Symptom scale (Kushner et al., 2008; see Figure 15-9).

(b) Oral Mucositis Weekly Questionnaire (Epstein et al., 2007)

(c) Oropharyngeal Mucositis-specific Quality of Life Instrument

b) Whichever tool is used, it should be standard practice for all relevant patients in the health service (Whithorn, 2021).

## 7. Collaborative management and prevention

a) Several different agents and interventions have been studied to prevent and treat mucositis (Shankar et al., 2017). The Multinational Association of Supportive Care in Cancer and International Society of Oral Oncology provide evidence-based guidelines endorsed by the American Society of Clinical Oncology, European Society for Medical Oncology, and Oncology Nursing Society. The Oncology Nursing Society Putting Evidence Into Practice resources provide evidence-based interventions for patient care (Eilers et al., 2019).

b) Good oral hygiene practices and oral care protocols are beneficial and may reduce the risk, duration, and severity of oral mucositis (Shankar et al., 2017).

(1) The most important aspect of any oral care protocol is the consistency of use; oral care positively affects mucositis prevention and management (Eilers et al., 2019).

(2) The protocol should include brushing with a soft toothbrush and flossing at least twice daily (Eilers et al., 2019).

(3) Microorganism colonization of oral ulcerations may prolong healing, so it is important to reduce the oral bacterial load with routine oral hygiene (Shankar et al., 2017).

c) Orthodontic appliances or poorly fitting dentures may traumatize the oral mucosa and should be removed or adjusted (Villa & Sonis, 2016). Braces may need to be removed if patients undergo transplantation or if prolonged periods of neutropenia are anticipated.

d) Patient education may improve adherence with oral care, frequency, and ability to cope with mucositis (Shankar et al., 2017).

e) Conduct a pretreatment dental evaluation with attention to potentially irritating teeth surfaces, underlying gingivitis, periodontal infection, and ill-fitting dentures. Crucial dental work should be done before chemotherapy begins.

f) Emphasize intake of high-protein foods and increased fluid intake (greater than 1,500 ml daily).

**FIGURE 15-9.** Patient-Reported Oral Mucositis Symptom (PROMS) Scale

This questionnaire asks you to evaluate some situations you may have experienced in the past week. All of the situations refer to the condition of your mouth. You can indicate the severity of the situation by placing a vertical mark along the lines below.

**Mouth pain**

No pain \_\_\_\_\_ worst possible pain

**Difficulty speaking because of mouth sores**

No trouble speaking \_\_\_\_\_ impossible to speak

**Restriction of speech because of mouth sores**

No restriction of speech \_\_\_\_\_ complete restriction of speech

**Difficulty eating hard foods (hard bread, potato chips, etc.) because of mouth sores**

No trouble eating hard foods \_\_\_\_\_ impossible to eat hard foods

**Difficulty eating soft foods (Jello, pudding, etc.) because of mouth sores**

No trouble eating soft foods \_\_\_\_\_ impossible to eat soft foods

**Restriction of eating because of mouth sores**

No restriction of eating \_\_\_\_\_ complete restriction of eating

**Difficulty drinking because of mouth sores**

No trouble drinking \_\_\_\_\_ impossible to drink

**Restriction of drinking because of mouth sores**

No restriction of drinking \_\_\_\_\_ complete restriction of drinking

**Difficulty swallowing because of mouth sores**

Not difficult to swallow \_\_\_\_\_ impossible to swallow

**Change in taste**

No change in taste \_\_\_\_\_ complete change in taste

## g) Prevention of oral mucositis

- (1) Oral cryotherapy is recommended for patients receiving bolus 5-fluorouracil or high-dose melphalan with or without TBI, a conditioning regimen for HSCT (Correa et al., 2020). It is important to note that although not for oral mucositis, oral cryotherapy during oxaliplatin infusion has been shown to prevent oral thermal hyperalgesia (oral temperature sensitivity) (Bauman et al., 2019).
- (2) Recombinant human keratinocyte growth factor-1 (palifermin) at a dose of 60 mcg/

kg daily for three days prior to a conditioning treatment and for three days after treatment is recommended in patients receiving high-dose chemotherapy and TBI, followed by autologous HSCT for a hematologic malignancy (Lalla et al., 2014).

- (3) Low-level laser therapy is recommended for patients receiving HSCT conditioned with high-dose chemotherapy with or without TBI and patients receiving radiation therapy without concomitant chemotherapy for head and neck cancer (Lalla et al., 2014).

- (4) Benzydamine mouthwash is recommended for patients with head and neck cancer receiving moderate-dose radiation therapy (up to 50 Gy) without concomitant chemotherapy (Elad et al., 2020).
- (5) Zinc supplements may not help prevent mucositis in patients with oral cancer receiving radiation or chemoradiation (Shuai et al., 2019).
- (6) *Lactobacillus* lozenges have been proven effective in patients with head and neck cancer undergoing chemoradiation (Shankar et al., 2017; Sharma et al., 2012).

#### h) Prevention of GI mucositis

- (1) Amifostine greater than 340 mg/m<sup>2</sup> IV is recommended to prevent proctitis in patients receiving radiation therapy (King et al., 2020).
- (2) If loperamide is ineffective for treating diarrhea induced by standard or high-dose chemotherapy associated with HSCT, octreotide at a dose greater than 100 mcg given subcutaneously twice daily is recommended (Krishnamurthi & Macaron, 2021).
- (3) The following recommendations have been suggested; however, the evidence is weaker:
  - (a) Amifostine IV can prevent esophagitis induced by chemoradiation in patients with non-small cell lung cancer (Elad et al., 2020; King et al., 2020; Lalla et al., 2014). Evidence is available that amifostine lessens the degree and duration of acute mucositis. Still, there are issues to consider, including the frequency of side effects such as nausea and vomiting, difficulty with IV administration, the timing of dose delivery, and the cost of the drug. Any potential benefit should be weighed with the toxicity associated with amifostine (King et al., 2020).
  - (b) Sucralfate enemas can treat chronic radiation-induced proctitis in patients with rectal bleeding who are not neutropenic or thrombocytopenic (Bansal et al., 2016).
  - (c) Sulfasalazine 500 mg twice daily can be used to prevent radiation-induced enteropathy in patients receiving radiation therapy to the pelvis (Pal, 2021).
  - (d) Probiotics containing *Lactobacillus* species are used to prevent diar-

rhea in patients receiving chemotherapy or radiation therapy for a pelvic malignancy (Ciorba et al., 2015).

- (e) Hyperbaric oxygen is used to treat radiation-induced proctitis in patients receiving radiation therapy for a solid tumor (Cooper & Hanley, 2022).

#### i) Symptom control: pain reduction

- (1) Oral agents to promote cleansing, moisture, and comfort (see Table 15-7)
- (2) Patient-controlled analgesia for patients undergoing HSCT
- (3) Use of 2% morphine mouthwash for patients receiving chemoradiation for head and neck cancer (Sarvzadeh et al., 2015)
- (4) Use of 0.5% doxepin mouthwash for all patients with oral mucositis-induced pain (Sio et al., 2019)
- (5) Transdermal fentanyl for patients receiving conventional or high-dose chemotherapy with or without TBI (Shankar et al., 2017)

#### j) Colonization of damaged mucosa by bacteria, fungi, and viruses is thought to occur during the ulceration phase (Vanhoecke et al., 2015). Culture mucosal lesions so that an appropriate antimicrobial agent can be prescribed. *Candida* lesions are white or cream-colored plaques on the mucosa and often are treated while cultures are pending.

#### 8. Patient and family education: Teach oral cavity self-management techniques.

- a) Perform a daily oral self-examination, and report signs and symptoms of mucositis.
- b) Comply with an oral hygiene program. Oral hygiene should be performed after every meal and at bedtime. If mild to moderate dysfunction is present, the frequency of oral hygiene should be increased to every two to four hours. If the condition progresses to more severe dysfunction, hourly care may be indicated. The program should include the following:
  - (1) Floss teeth with dental tape at least once daily or as the clinician advises (Harris et al., 2014).
  - (2) Brush all tooth surfaces with a soft toothbrush for at least 90 seconds at least twice daily. Allow toothbrushes to air dry before storing, and replace toothbrushes frequently (Harris et al., 2014). Sponge swabs are not as effective as toothbrushes and should be avoided when cleaning the teeth, except in patients who cannot tolerate a toothbrush because of severe pain with mucositis. However, sponge swabs may be beneficial for cleaning the mucous

**TABLE 15-7. Mucositis Management**

| Agent                                                                                                        | Efficacy                                                                                                                                                                                                                                                                                                                          | Comments                                                                                                                                                                                                                                                                             |
|--------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Amifostine                                                                                                   | Strong evidence supports the use of amifostine for the prevention of radiation-induced proctitis. Weaker evidence supports use to prevent esophagitis induced by chemoradiation in patients with non-small cell lung cancer.                                                                                                      | Dose of 340 mg/m <sup>2</sup> IV                                                                                                                                                                                                                                                     |
| Benzydamine mouthwash                                                                                        | Strong evidence supports effectiveness in patients with head and neck cancer receiving moderate-dose radiation therapy (up to 50 Gy).                                                                                                                                                                                             | Nonsteroidal anti-inflammatory analgesic<br>Inhibits production of proinflammatory cytokines                                                                                                                                                                                         |
| Chlorhexidine                                                                                                | Chlorhexidine is not recommended for prevention but may have other indications, such as treatment of gingivitis.                                                                                                                                                                                                                  | Contains alcohol<br>Reports of rinse-induced discomfort and taste alteration<br>Can turn teeth brown                                                                                                                                                                                 |
| Cryotherapy (ice chips)                                                                                      | Cryotherapy consistently reduces the incidence and severity of oral mucositis among patients receiving bolus 5-fluorouracil. Weaker evidence supports use for patients receiving high-dose melphalan with or without total body irradiation followed by autologous hematopoietic stem cell transplantation.                       | 30 minutes of cryotherapy suggested prior to 5-fluorouracil therapy<br>Not recommended in patients receiving capecitabine or oxaliplatin because of potential discomfort with exposure to coldness                                                                                   |
| Dexamethasone mouthwash (0.1 mg/ml)                                                                          | Dexamethasone mouthwash is recommended for patients receiving mTOR (mechanistic target of rapamycin) inhibitors.                                                                                                                                                                                                                  | Relieves aphthous-like ulcers, which differ from chemotherapy-induced ulcers, which are irregularly shaped and typically lack peripheral erythema                                                                                                                                    |
| 0.5% doxepin mouthwash                                                                                       | Evidence is weaker but supports the benefit of treating pain.                                                                                                                                                                                                                                                                     | Tricyclic antidepressant with anxiolytic properties                                                                                                                                                                                                                                  |
| Glutamine                                                                                                    | Evidence suggests caution for patients undergoing hematopoietic stem cell transplantation. Oral glutamine is suggested for patients with head and neck cancer receiving chemoradiation.                                                                                                                                           | Essential amino acid                                                                                                                                                                                                                                                                 |
| Honey                                                                                                        | Evidence suggests honey is useful in preventing oral mucositis in patients with head and neck cancer receiving radiation therapy or chemoradiation.                                                                                                                                                                               | Carbohydrate compound                                                                                                                                                                                                                                                                |
| Keratinocyte growth factor-1: palifermin                                                                     | Palifermin is approved to prevent oral mucositis in patients undergoing autologous hematopoietic stem cell transplantation receiving high-dose chemotherapy or total body irradiation.                                                                                                                                            | 60 mcg/kg/day IV for 3 days prior to the preparatory regimen and for 3 days post-transplant<br>Can cause tongue discoloration and an unpleasant aftertaste                                                                                                                           |
| Low-level laser therapy                                                                                      | Low-level laser therapy to reduce incidence of oral mucositis is recommended in patients receiving high-dose chemotherapy with or without total body irradiation before hematopoietic stem cell transplantation and suggested in patients with head and neck cancer receiving radiation therapy without concomitant chemotherapy. | Requires expensive equipment and specialized operator training; limited to centers capable of supporting this technology                                                                                                                                                             |
| Mixed rinses, which may include lidocaine, diphenhydramine, magnesium hydroxide (milk of magnesia), Mylanta® | Data demonstrating efficacy are lacking for the prevention and treatment of mucositis.                                                                                                                                                                                                                                            | Agents potentially useful for pain or discomfort only<br>Alcohol-based elixirs to be avoided<br>May adhere to mucous membranes and build up residue, making oral care difficult or uncomfortable<br>Potential of some preparations to contribute to tooth decay due to sugar content |

**TABLE 15-7. Mucositis Management (Continued)**

| Agent                                    | Efficacy                                                                                                                                         | Comments                                                                                                                                                                                                |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2% morphine mouthwash                    | Evidence is weaker but supports effectiveness.                                                                                                   | For patients receiving chemoradiation for head and neck cancer<br>Limited utility with topical morphine<br>Potential for burning with oral alcohol-based formulations                                   |
| Mucosal coating agents                   | Evidence from randomized trials is lacking to support benefit.                                                                                   | Variety of agents: Gelclair®, Orabase®, sucralfate suspension                                                                                                                                           |
| Nonalcohol-based bland rinses            | Evidence may be insufficient or lacking; however, bland rinses are harmless and can be helpful for oral hygiene maintenance and patient comfort. | 0.9% saline, sodium bicarbonate, or 0.9% saline plus sodium bicarbonate<br>Sodium bicarbonate recommended by Oncology Nursing Society Putting Evidence Into Practice                                    |
| Octreotide                               | Strong evidence supports effectiveness.                                                                                                          | Dose of $\geq 100$ mcg subcutaneously twice daily to treat diarrhea induced by standard- or high-dose chemotherapy associated with hematopoietic stem cell transplantation if loperamide is ineffective |
| Oral zinc supplements                    | Evidence is weaker but supports effectiveness in patients receiving radiation therapy or chemoradiation for head and neck cancer.                | Essential trace element needed for tissue repair; has an antioxidant effect                                                                                                                             |
| Patient-controlled analgesia             | Strong evidence supports its effectiveness in treating pain.                                                                                     | Recommended for patients undergoing hematopoietic stem cell transplantation                                                                                                                             |
| Probiotics: <i>Lactobacillus</i> species | Evidence is weaker but supports effectiveness.                                                                                                   | To prevent diarrhea in patients receiving chemotherapy or radiation therapy for a solid tumor                                                                                                           |
| Sucralfate enemas                        | Weaker evidence supports effectiveness.                                                                                                          | For chronic radiation-induced proctitis in patients with rectal bleeding                                                                                                                                |
| Topical lidocaine                        | Limited data exist; use may provide significant relief of limited duration.                                                                      | Requires frequent application; may lead to decreased sensitivity and additional trauma and impair taste perception<br>Prophylaxis not recommended                                                       |

Note. Based on information from Eilers et al., 2019; Elad et al., 2020; Harris et al., 2014; Lalla et al., 2014; Maria et al., 2017; McGuire et al., 2013; Peterson et al., 2015; Pilotte et al., 2011; Van Seville et al., 2015; Wardill et al., 2014.

membranes of the oral cavity (Harris et al., 2014).

- (3) Cleanse the oral cavity after meals, at bedtime, and at other times by vigorously swishing the mouth with a nonalcohol bland rinse. Oral rinsing should be done to remove excess debris, hydrate the oral mucosa, and aid in removing organisms (Treister, 2022).
- (4) Apply water-based moisturizers to lips.
- (5) Maintain hydration.
- (6) Consider using oral moisturizers to promote comfort if xerostomia exists.
- (7) Avoid irritating agents, including commercial mouthwashes containing phenol, astringents, or alcohol; highly abrasive types of toothpaste; acidic, hot, or spicy

foods and beverages; rough foods; alcohol; tobacco; poorly fitting dentures; braces; and lemon-glycerin swabs and solutions (Harris et al., 2014).

- (8) Recommendations for patients with dentures (NCI, 2019)
  - (a) Remove dentures and other oral devices when cleaning the mouth. If mouth sores are present, or if the mouth is inflamed or painful, avoid using removable oral devices to prevent further irritation.
  - (b) Brush and rinse dentures daily.
  - (c) Clean dentures twice daily with a denture cleaner, and rinse well.
  - (d) Report pain associated with mucositis.

## G. Perirectal cellulitis

1. Overview: Perirectal cellulitis is inflammation and edema of the perineal and rectal area.
2. Pathophysiology
  - a) Tears of the anorectal mucosa allow infection. The most common anaerobic organisms include *Bacteroides fragilis*, *Peptostreptococcus*, *Prevotella*, *Fusobacterium*, *Porphyromonas*, and *Clostridium*. The most common aerobic bacteria include *Staphylococcus aureus*, *Streptococcus*, and *Escherichia coli*. Community-acquired methicillin-resistant *Staphylococcus aureus* (MRSA) has been implicated in rectal abscess infections (Hebra, 2020).
  - b) A perianal abscess is a simple anorectal abscess.
  - c) Perirectal abscesses are more complex and involve different planes in the anorectum (Choe et al., 2018).
  - d) Infection starting as a local abscess can lead to systemic sepsis.
3. Incidence: Overall incidence has decreased in the past decade, presumably because of the early use of empiric antibiotics in patients with febrile neutropenia. Perirectal abscesses are more common in patients with anorectal cancer or hematologic malignancies and may be present at the initial diagnosis (Hebra, 2020).
4. Risk factors (Hebra, 2020)
  - a) Chronic neutropenia or thrombocytopenia
  - b) Constipation: The passage of hard stool causes trauma to the rectal mucosa.
  - c) Diarrhea: Caustic fluid irritates and breaks down perirectal tissue.
  - d) Perirectal mucositis caused by chemotherapy or radiation therapy
  - e) Any rectal trauma, such as rectal stimulation or the use of rectal thermometers, enemas, or suppositories
  - f) Hemorrhoids or anal fissures/abscesses
5. Assessment
  - a) Ask patients if they are experiencing perineal or rectal discomfort.
    - (1) Patients with an anorectal abscess often present with severe pain in the anal or rectal area. Pain is constant and not necessarily associated with a bowel movement (Rizzo et al., 2010). Pain may be described as dull, aching, or throbbing, which may worsen when sitting or before defecation.
    - (2) Fear of defecation related to pain may not be reported and may increase the risk of constipation.
  - b) Monitor for the presence of fever.
  - c) Perform a physical examination of the perineal area. The entrance site for the infective agent

may be a small tear that shows minimal irritation.

- (1) An area of fluctuance or patch of erythematous indurated skin overlying perianal skin may be seen with a superficial perianal abscess (Vogel et al., 2016).
  - (2) Localized tenderness, gross swelling, fluctuance, erythema, and drainage may be observed if an abscess is present. An abscess of the perirectal area may produce bloody, purulent, or mucoid drainage.
  - (3) Deeper abscesses may not have findings on physical examination and may only be discovered via digital rectal examination or by imaging (Vogel et al., 2016).
  - (4) If possible, obtain a culture to identify infectious organisms (Hebra, 2020).
- d) Consider an abdominal or pelvic CT scan if an abscess is suspected. Magnetic resonance imaging and transperitoneal or endorectal ultrasound can confirm a diagnosis when a deep abscess is suspected (Vogel et al., 2016).
6. Collaborative management
  - a) Ensure that antibiotic coverage includes a specific anaerobic agent and broad-spectrum aerobic coverage. Consider *Enterococcus* or *Candida* coverage if appropriate (NCCN, 2022b).
  - b) The primary treatment for an anorectal abscess is surgical drainage. Any undrained abscess can expand and progress to systemic infection (Abcarian, 2011).
  - c) Administer antipyretic medications to relieve fever.
  - d) Teach and encourage patients to take sitz baths or use gentle external perineal irrigation (Hebra, 2020).
  - e) Administer stool softeners and encourage patients to eat a low-bulk diet. Consult a dietitian as needed (Hebra, 2020).
  - f) Inspect the perirectal mucosa frequently for any signs of irritation or skin breakdown.
7. Patient and family education
  - a) Instructions for patients and significant others
    - (1) Maintain meticulous perineal hygiene, especially in the presence of neutropenia.
    - (2) Apply appropriate barrier creams.
    - (3) Monitor carefully for any signs of infection or worsening of tissue integrity.
  - b) Ensure that patients and significant others can perform the following:
    - (1) Identify the risk factors for perirectal cellulitis.
    - (2) Implement measures that minimize the risk of developing perirectal cellulitis.

- (3) Identify situations that require prompt, professional intervention.
  - (a) Pain, redness, or swelling in the affected area
  - (b) Body temperature greater than 100.4°F (38°C)

## H. Constipation

1. Overview: Constipation is the slow movement of stool through the intestines characterized by infrequent bowel movements, hard stool, the sensation of abdominal bloating or cramping, straining with bowel movements, and feeling of incomplete evacuation (Davies et al., 2020; Larkin et al., 2018; Rogers et al., 2020).
  - a) It is commonly associated with decreased frequency in defecation of less than three bowel movements in a week and is often accompanied by abdominal discomfort or distention, excessive flatulence, or rectal pressure (Camp-Sorrell, 2018; Larkin et al., 2018).
  - b) If left untreated, constipation can lead to morbidity, including malnutrition, fatigue, hemorrhoids, anal fissures, and in severe cases, GI perforation (Davies et al., 2020; McQuade et al., 2016; Wickham, 2020).
  - c) Constipation may be a presenting symptom of the cancer diagnosis, a side effect of therapy, the result of tumor progression, or unrelated to cancer or its treatment.
  - d) The cause is usually multifactorial; the most common are decreased bowel motility due to decreased fiber intake, dehydration, immobility, and narcotic pain medications (Larkin et al., 2018).
2. Pathophysiology: A decrease in intestinal motility results from one of the following mechanisms (Davies et al., 2020; Larkin et al., 2018).
  - a) Primary or functional: intrinsic factors that slow peristalsis, such as decreased physical activity, lack of time or privacy for defecation, and decreased fiber in the diet
  - b) Secondary: pathologic processes, such as autonomic nervous system dysfunction, preexisting bowel disorders, obstruction, spinal cord compression from tumor, hypercalcemia, hypokalemia, and hypothyroidism
  - c) Iatrogenic: use of pharmacologic agents, such as opioids, chemotherapy, anticonvulsants, and psychotropic medications (Larkin et al., 2018; NCCN, 2022c)
3. Incidence
  - a) Constipation is reported as one of the most common problems for patients with cancer; however, its incidence is not well defined.
  - b) In patients with cancer, the constipation rate is 43%–58%, whereas, in patients with advanced cancer, constipation is reported at 40%–90% (Davies et al., 2020; Larkin et al., 2018; NCCN, 2022c; Rogers et al., 2020).
  - c) Opioid-induced constipation impacts up to 97% of patients with cancer (Davies et al., 2020).
  - d) In 85%–95% of cases, constipation decreases quality of life, even though two-thirds may be mild to moderate (Dzierżanowski & Ciałkowska-Rysz, 2015).
4. Clinical manifestations (Larkin et al., 2018; McQuade et al., 2016; NCI, 2022b)
  - a) Abdominal distention, discomfort, or rectal discomfort or pain
  - b) Nausea and vomiting
  - c) Anorexia
  - d) Impaction and obstruction
  - e) Ileus
  - f) Anal fissures
  - g) Hemorrhoids
  - h) Urinary retention
  - i) Ruptured bowel and life-threatening sepsis
5. Risk factors (Davies et al., 2020; Larkin et al., 2018; NCI, 2022b; Wickham, 2020)
  - a) Disease related: mesenteric and omental masses or malignant adhesions, internal or external obstruction of the bowel by tumor
  - b) Mechanical pressure on the bowel: bowel obstruction second to the tumor in the GI tract, pressure from ascites
  - c) Spinal cord injury or compression
  - d) Bowel disorders: irritable bowel syndrome, Crohn disease
  - e) Neurologic disorders: stroke, Parkinson disease, multiple sclerosis
  - f) Systemic disorders: lupus, amyloidosis, scleroderma
  - g) Decreased mobility
  - h) Anorexia causing poor nutritional intake
  - i) Metabolic and endocrine disorders: hypothyroidism, hyperthyroidism, diabetes mellitus
  - j) Electrolyte disturbances: hypokalemia, hypercalcemia
  - k) Treatment related (see Table 15-8)
    - (1) Neurotoxic effects: cancer chemotherapy, targeted therapy, or immunotherapy agents
    - (2) Surgical: manipulation of intestines, surgical trauma to neurogenic pathways of intestines or rectum
    - (3) Radiation therapy: radiation fibrosis (NCI, 2022b; Wickham, 2020)
    - (4) Nutritional deficiencies: decreased intake of fiber, roughage, and fluids

**TABLE 15-8.** Common Cancer Treatments With High Risk for Constipation

| Causative Agent | Agents                                                                                                    | Mechanism of Action                                                                                                                                                                                                    |
|-----------------|-----------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Antiemetics     | 5-HT <sub>3</sub> receptor antagonists: ondansetron, granisetron, palonosetron, netupitant, palonosetron, | Increases colonic transit time                                                                                                                                                                                         |
| Opioids         | Opioid analgesics: fentanyl, hydrocodone, codeine, hydromorphone, morphine, oxycodone, methadone          | Affects the ability of the small bowel and colon to maintain motility and peristalsis<br>Affects electrolyte and water secretion and absorption in the bowel<br>Primary agents causing medication-induced constipation |
| Radiation       | Radiation to the bowel or abdominal field                                                                 | Fibrosis                                                                                                                                                                                                               |

Based on information from Davies et al., 2020; Larkin et al., 2018; National Comprehensive Cancer Network, 2022b, 2022c; Wickham, 2020.

- (5) Side effects of pharmacologic agents (NCI, 2022b; Wickham, 2020; see Figure 15-10)

- (a) Antineoplastics
- (b) Anticholinergics
- (c) Diuretics
- (d) Opioids
- (e) Aluminum- and calcium-based antacids
- (f) Calcium and iron supplements
- (g) Tricyclic antidepressants
- (h) Antihypertensives
- (i) Antispasmodics
- (j) 5-HT<sub>3</sub> antagonists
- (k) Nonsteroidal anti-inflammatory drugs
- (l) Barbiturates

- (6) Personal factors (Davies et al., 2020; Dzierżanowski & Ciałkowska-Rysz, 2015; NCI, 2022b; Wickham, 2020)

- (a) Interference with usual bowel movement routine
- (b) Lack of privacy
- (c) Lack of response to the defecation reflex: pain, fatigue, social circumstances

- (d) Depression, anxiety
- (e) Decreased physical activity/exercise
- (f) Overuse of laxatives

6. Assessment: Assessment is a key component in preventing and managing opioid-induced and nonopioid-induced constipation. All patients with cancer should be evaluated for constipation and routinely reassessed if constipation is present (Davies et al., 2020; Larkin et al., 2018; Mesía et al., 2019; NCI, 2022b; Wickham, 2020).

- a) Assess the presence of risk factors.
- b) Determine facts about the patient's last bowel movement (e.g., when it occurred, amount, consistency, color, presence of blood). Structured self-rating tools can be useful for a more accurate assessment of constipation. Available tools are the Bristol Stool Form Scale, Constipation Assessment Scale, Common Terminology Criteria for Adverse Events, Patient Assessment of Constipation–Symptoms, bowel function diary, and bowel function index (Larkin et al., 2018; Mesía et al., 2019; NCI CTEP, 2017; Ueberall et al., 2011; Wickham, 2020).
- c) Using the Rome IV Diagnostic Criteria for Opioid-Induced Constipation, assess for new or worsening symptoms when starting and changing opioid therapy. Assess for straining, lumpy or hard stools, a sensation of incomplete evacuation, a sensation of anorectal blockage or obstruction, the need to manually disimpact stool (more than 25% of the time), patient perception of distress related to bowel movement, and less than three bowel movements a week (Gaertner et al., 2015; Rome Foundation, 2016).
- d) Assess usual dietary patterns, focusing on fluid and fiber intake.
- e) Assess mobility, activity level, and functional status.
- f) Assess for abdominal pain, distension, and presence or absence of bowel sounds.
- g) Assess for the presence of straining, rectal pressure, excessive flatulence, or cramping.
- h) Determine current medication usage.
- i) Use laboratory results to assist in the metabolic evaluation.
- j) Perform abdominal palpation and rectal examination if appropriate. A rectal examination is not routinely performed in pediatric patients. Rectal or stoma manipulation for examinations, enemas, or suppositories should be avoided in patients who are myelosuppressed because of the risk of bleeding, fissures, or abscesses (NCI, 2022b; Wickham, 2020).

**FIGURE 15-10.** Oncolytic Agents With Increased Risk of Constipation

| Chemotherapy agents                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

- k) Use radiographic imaging to differentiate between mechanical obstruction and decreased motility from an ileus.
7. Collaborative management: The cause of constipation is often multifactorial and should be considered prior to initiating treatment. Management of constipation should be individualized to the patient and based on opioid use and care goals. It should also balance lifestyle modifications and nonpharmacologic approaches with pharmacologic approaches as appropriate (Larkin et al., 2018; Rogers et al., 2020). Although many treatment options exist for constipation, optimal pharmacologic management of constipation in patients with cancer requires further investigation (Davies et al., 2020; Ginex et al., 2020; Larkin et al., 2018; Rogers et al., 2020). The Oncology Nursing Society, Multinational Association of Supportive Care in Cancer, European Society for Medical, and NCCN (2022c) palliative care guidelines offer guidance for treating opioid-induced and nonopioid-induced constipation. Nurses must know the GI side effects of medications and anticipate which patients are at increased risk for constipation. Prevention of constipation is a priority in patients with cancer. Patients on opioids should be considered for a prophylactic bowel regimen with stimulant and osmotic laxatives prior to initiation of opioid therapy (NCCN, 2022c; Rogers et al., 2020).
- a) Pharmacologic interventions (see Table 15-9)
- (1) Peripherally acting mu-opioid receptor antagonists (PAMORAs) are used to treat constipation caused by opioid pain medication. Current PAMORAs include subcutaneous methylnaltrexone, oral methylnaltrexone, and oral naldemedine (Davies et al., 2020).
    - (a) PAMORAs work by protecting the bowel from the effects of the opioid at the receptor sites in the bowel.
    - (b) In patients with laxative-resistant opioid-induced constipation, PAMORAs combined with a bowel regimen should be considered (Davies et al., 2020; Larkin et al., 2018; Rogers et al., 2020).
    - (c) The decision to use PAMORAs should be balanced with the benefit of opioid-constipation relief with potentially undesirable side effects (Rogers et al., 2020).
  - (2) Osmotic laxatives increase the bulk of stools by attracting and retaining water in the bowel, resulting in a softer stool (NCI, 2022b).
    - (a) Lactulose
    - (b) Sorbitol
    - (c) Polyethylene glycol (Miralax®)
  - (3) Stimulant laxatives chemically stimulate the smooth muscles of the bowel to increase contractions (NCI, 2022b).
    - (a) Bisacodyl (Dulcolax®)
    - (b) Senna (Senokot®)
  - (4) Emollient and lubricant laxatives soften hardened feces and facilitate the passage through the lower intestine (NCI, 2022b; Wickham, 2017, 2020).
    - (a) Docusate
    - (b) Mineral oil
    - (c) Glycerin suppository
    - (d) Enema: phosphate (Fleet®), microenema, mineral oil
  - (5) Bulk-forming laxatives increase bowel water absorption, leading to softer stools (NCI, 2022b; Wickham, 2017). They have limited use in cancer-related constipation. These agents are not recommended for patients with advanced cancer or opioid-induced constipation (Larkin et al., 2018; McQuade et al., 2016; Wickham, 2017).
- b) Nonpharmacologic management to prevent constipation
- (1) Include increased physical activity or passive exercise as appropriate (Larkin et al., 2018; NCI, 2022b). This promotes the urge to defecate by helping to move feces into the rectum.
  - (2) Help patients to maintain usual bowel habits during hospitalization. Baseline bowel habits are important to determine adequate bowel function. The change from baseline is more important than the number of bowel movements (Rangwala et al., 2012).
  - (3) Provide privacy and comfort. Inadequate privacy conditions and dependence on a caregiver are directly correlated to risk for constipation (Davies et al., 2020; Larkin et al., 2018.). Avoid using a bedpan when constipation exists (NCI, 2022b).
  - (4) Increase fluid intake to 2,000 ml daily unless contraindicated (NCI, 2022b).
  - (5) Modify diet, as tolerated, to include high-fiber foods, as fiber adds bulk to the stool and assists food in passing more quickly through the stomach and intestines.
    - (a) Insoluble fiber includes wheat bran, fruit and root vegetable skins, whole

**TABLE 15-9.** Pharmacologic Management of Constipation in Adult Patients

| Classification                                             | Mechanism of Action                                                                                                                                                                                              | Drug                                                                                                                                       | Route, Dose, and Schedule                                                                                                                                                                                                                                                                                                                                                                   | Side Effects                                                                                                        | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**TABLE 15-9.** Pharmacologic Management of Constipation in Adult Patients (*Continued*)

| Classification                                  | Mechanism of Action                                                                                                                           | Drug                                                       | Route, Dose, and Schedule                                                                                                                        | Side Effects                                                       | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Stimulant laxatives                             | Acts directly on the colon to stimulate motility and peristalsis                                                                              | Senna                                                      | Oral 8.6 mg tablets: 1–2 tablets once or twice daily for opioid-induced constipation                                                             | Electrolyte or fluid imbalance with excess catharsis or excess use | Stimulant laxatives are often used as first-line laxatives, particularly for opioid-induced constipation. No evidence shows that adding docusate with senna has any added benefit. Stimulant laxatives are contraindicated in patients with suspected intestinal obstruction or severe dehydration. Overuse of stimulant laxatives can lead to bowel dependence. (McQuade et al., 2016; National Cancer Institute, 2022b; Wickham, 2017) |
|                                                 |                                                                                                                                               | Bisacodyl (Dulcolax®)                                      | Oral: 5–15 mg daily, up to 30 mg daily                                                                                                           | Abdominal cramps or discomfort, diarrhea, proctitis                | The drug should be taken within 2 hours of any other medications. The drug should be avoided for known or suspected ulcerative lesions in the colon. Stimulant laxatives are contraindicated in patients with suspected intestinal obstruction or severe dehydration. Overuse of stimulant laxatives can lead to bowel dependence. (McQuade et al., 2016; National Cancer Institute, 2022b; Wickham, 2017)                               |
| Detergent laxatives and surfactants (softeners) | Direct action on the intestine facilitating water and fats to penetrate into dry stool, which softens the stool and allows for easier passage | Docusate sodium<br>Docusate calcium                        | Docusate sodium (oral): 50–400 mg daily<br>Docusate calcium (oral): 240 mg daily                                                                 | Abnormal and bitter taste in mouth, cramps, diarrhea, nausea       | Increase fluid intake and take with a full glass of fluid with each dose. These agents are often used prophylactically in combination with an oral laxative for individuals at high risk for constipation. (McQuade et al., 2016; National Cancer Institute, 2022b)                                                                                                                                                                      |
| Lubricants                                      | Increases water retention, lubricates the bowel, and softens stool                                                                            | Glycerol suppositories<br>Mineral oil<br>Mineral oil enema | Glycerol suppositories (rectal): 2–3 g suppository for 15 minutes once daily<br>Mineral oil (oral): 10–30 ml daily<br>Mineral oil enema: 1 daily | Perianal irritation                                                | Excessive doses may lead to malabsorption of fat-soluble vitamins. Oral mineral oil should be avoided in individuals with aspiration risk as this can lead to lipid pneumonitis. Avoid giving with additional stool softeners, as this can increase toxicity. (National Cancer Institute, 2022b; Wickham, 2020)                                                                                                                          |

(Continued on next page)

**TABLE 15-9.** Pharmacologic Management of Constipation in Adult Patients (*Continued*)

| Classification         | Mechanism of Action                                                                                                                 | Drug                                                                                  | Route, Dose, and Schedule                                                   | Side Effects                                                                              | Nursing Considerations                                                                                                                                                                                                                                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bulk-forming laxatives | Causes water to be retained in the bowel, thus increasing the bulk of the stool                                                     | Psyllium<br>Methylcellulose                                                           | Psyllium (oral): 1–3 times daily<br>Methylcellulose (oral): 1–3 times daily | Flatulence, abdominal distension, bloating, mechanical obstruction, anaphylactic reaction | The drug should not be used for patients with established constipation. The drug should not be used for patients with opioid-induced constipation. Bulk-forming laxatives must be taken with 200–300 ml of water to avoid intestinal obstruction and are not an option for patients with poor tolerance of fluids. (Larkin et al., 2018; Wickham, 2017)        |
| Rectal preparations    | Creates an osmotic effect on the intestine, pulling water into the intestines to penetrate dry stool, and also promotes peristalsis | Glycerin suppository<br>Phosphate enema (Fleets®)<br>Sodium citrate enema (Microlax®) | Once daily for suppositories and enemas                                     | Electrolyte imbalances<br>Anal irritation                                                 | Avoid rectal manipulation in patients who are neutropenic. Rectal laxatives and suppositories should be reserved for constipation management when not responding to other interventions and avoided in patients with neutropenia and thrombocytopenia. (Davies et al., 2020; Larkin et al., 2018; National Comprehensive Cancer Network, 2022a; Wickham, 2017) |

SC—subcutaneous

- wheat and whole grains, beans, berries, seeds, and nuts.
- (b) Soluble fiber absorbs liquid to form a gel that eases stool movement and includes fruits, vegetables, beans, barley, and oat bran.
  - (c) Studies have not established specific fiber recommendations for constipation in patients with cancer (NCI, 2022b).
  - (d) A diet high in fiber is not recommended for patients with a current or history of bowel obstruction or who have undergone a colostomy (NCI, 2022b). Obtain a nutrition consult to individualize diet modifications.
- c) Complementary and alternative medicine: Limited evidence exists for using acupuncture to manage constipation in patients with cancer (Rogers et al., 2020). A small body of literature demonstrated that short-term acupressure might be beneficial in treating constipation in patients with advanced cancer (Wang et al., 2019).
8. Patient and family education
- a) Encourage patients to exercise regularly. Regular exercise stimulates GI motility.
  - b) Instruct patients to report constipation and be aware of constipation-associated complications, such as fecal impaction.
  - c) Stress that patients call a physician to initiate a bowel program if three days pass without a bowel movement.
  - d) Ensure that patients prescribed opioids are started on pharmacologic and nonpharmacologic interventions to prevent constipation and maintain the bowel program until opioids are discontinued (Davies et al., 2020; Larkin et al., 2018; NCI, 2022b; NCCN, 2022a, 2022c; Rogers et al., 2020).

## CHAPTER 16

# Cardiovascular Toxicities

### A. Overview

1. Cardiovascular toxicity is a potential complication of cancer therapy that may result from the direct effects of cancer treatment on heart function and structure or may be due to accelerated development of cardiovascular disease, especially in the presence of traditional cardiovascular risk factors (Chang, Moudgil, et al., 2017; see Table 16-1).
2. Cardiovascular risk factors should be evaluated in all patients starting cardiotoxic cancer therapies.
  - a) Cardiovascular risk factors include cardiovascular disease history, medical risk factors (e.g., diabetes, hypertension, chronic kidney disease), lifestyle risk factors (e.g., smoking, obesity), prior cardiotoxic cancer therapies, and the presence of abnormal cardiac biomarkers (e.g., troponin, brain natriuretic peptide).
  - b) Patients can be stratified for risk of cardiovascular complications based on these factors in conjunction with the specific class of cardiotoxic cancer therapy being initiated (Lyon et al., 2020).
3. Classes of cardiotoxic cancer therapies include chemotherapy agents (e.g., anthracyclines), targeted therapies (e.g., HER2 therapies, vascular endothelial growth factor [VEGF] inhibitors, multitargeted kinase inhibitors, combination rapidly accelerated fibrosarcoma B-type [BRAF] and mitogen-activated protein kinase enzyme [MEK] inhibitors, proteasome inhibitors), and endocrine therapies (e.g., androgen deprivation therapies) and immunotherapies (e.g., immune checkpoint inhibitors, immunomodulatory agents) (Lyon et al., 2020).
4. Novel targeted therapies
  - a) Although novel targeted therapies are considered less toxic and better tolerated by patients than classic chemotherapy agents, rare but serious cardiovascular complications have been described.
  - b) For cancer survivors, the risk of death from cardiovascular causes exceeds that of tumor recurrence for many forms of cancer (Herrmann, 2020; Okwuosa et al., 2017).

5. Side effects: Cardiovascular toxicity encompasses a broad range of cardiovascular side effects related to cancer therapy, including alterations in conduction pathways (e.g., dysrhythmias), vasculature (e.g., hypertension), coronary arteries (e.g., myocardial ischemia), cardiac myocytes (e.g., left ventricular dysfunction, heart failure, myocarditis), pericardial fluid accumulation (e.g., pericardial effusion), and valvular disease (Chang, Okwuosa, et al., 2017; Jain et al., 2017).

### B. Conduction pathway disorders

1. Conduction pathway disorders are disturbances in the regular excitation of the heart (Herrmann, 2020).
2. Conduction disturbances are classified according to origin (e.g., atrial, ventricular) or degree of life-threatening symptoms.
  - a) Sinus dysrhythmias associated with antineoplastic agents usually are transient dysrhythmias, are of short duration, and often are asymptomatic and do not necessitate alteration of the chemotherapy regimen.
  - b) The most commonly observed dysrhythmias associated with cancer treatment include atrial fibrillation and cardiac repolarization abnormalities manifested as QT prolongation and ventricular arrhythmias (e.g., torsades de pointes) (Abu Rmilah et al., 2020; Ganatra et al., 2018; Porta-Sanchez et al., 2017).
3. Atrial fibrillation
  - a) Definition: Atrial fibrillation is the most common of the atrial dysrhythmias and is characterized by an absence of discrete P waves and an “irregularly irregular” ventricular rate that may be caused by factors such as heart disease, hypertension, thyroid problems, and viral infection.
  - b) Pathophysiology: The exact mechanism leading to increased rates of atrial fibrillation in patients with cancer remains unclear; however, it has been suggested that atrial fibrillation may represent an inflammatory complication of cancer (Chu et al., 2019; Ganatra et al., 2018; Herrmann, 2020).

**TABLE 16-1.** Cardiotoxicity of Cancer Therapy

| Classification      | Drug                                     | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Alkylating agents<br>( <i>Cont.</i> ) | Cyclophosphamide (high dose)<br>( <i>Cont.</i> ) | CHF<br>Heart failure (7%–28%)<br>Left ventricular systolic dysfunction<br>MI<br>Myocardial hemorrhage<br>Myocardial necrosis<br>Myocarditis<br>Acute myopericarditis<br>Pericardial effusion (33%)<br>Pericarditis<br>Prolonged QT interval<br>Supraventricular arrhythmia<br>Ventricular fibrillation<br>Ventricular tachycardia | Monitor for cardiotoxicity, including myocarditis, myopericarditis, pericardial effusion, cardiac tamponade, and CHF, which have been reported and may be fatal. The risk for cardiotoxicity increases with high doses, older patients, history of radiation to the chest wall, and previous or current treatment with cardiotoxic agents.<br>Monitor for supraventricular (atrial fibrillation and flutter) and ventricular (tachyarrhythmia associated with severe QT prolongation) arrhythmias.<br>Monitor patients with risk factors and preexisting cardiac disease for cardiotoxicities.<br>Diuretics, angiotensin-converting enzyme inhibitors, and beta-blockers can be initiated if clinically indicated and if no contraindications exist.<br>The spectrum of clinical manifestations from cyclophosphamide-induced cardiotoxicity is variable in presentation and severity. Common manifestations include tachyarrhythmias, hypotension, heart failure, myocarditis, and pericardial disease. These typically present within the first 48 hours of drug administration but may be seen up to 10 days after initiation. Hemorrhagic myocarditis is a rare complication that is uniformly and rapidly fatal.<br>Mild to moderate heart failure and small pericardial effusions generally resolve within a few days to weeks after discontinuation of cyclophosphamide.<br>The risk of cardiotoxicity appears to be dose related (150 mg/kg and 1.5 g/m <sup>2</sup> daily) and occurs 1–10 days after administering the first dose of cyclophosphamide. Higher doses of this drug may produce significant cardiotoxicity, including fatal hemorrhagic myocarditis.<br>Myocardial necrosis may result in rare circumstances.<br>(Truven Health Analytics, 2021; Wolters Kluwer Health, 2021) |

| Anthracyclines<br>( <i>Cont.</i> ) | Doxorubicin<br>(Adriamycin®)<br>( <i>Cont.</i> ) |                                                         | <p>Cardiotoxicity risk factors include prior or concomitant radiation therapy to the chest wall, previous therapy with other anthracyclines or anthracenediones, and concomitant use of other cardiotoxic drugs. Cardiotoxicity risk is dose dependent.</p> <p>Cumulative doses &gt; 550 mg/m<sup>2</sup> are associated with an increased risk of cardiomyopathy. The maximum recommended cumulative doxorubicin dose in combination with paclitaxel is 340–380 mg/m<sup>2</sup>.</p> <p>Fatal cases of cardiotoxicity have occurred at doses &lt; 400 mg/m<sup>2</sup> (all in combination with concurrent administration of cardiotoxic or hepatotoxic agents); therefore, cardiac monitoring is imperative regardless of dosing.</p> <p>Continuous infusion administration may allow for higher cumulative dosing of &gt; 450 mg/m<sup>2</sup> and have been administered with no observed cardiac abnormalities.</p> <p>Administration using a weekly schedule of 20 mg/m<sup>2</sup> was associated with less cardiac damage than an every-3-week schedule of 60 mg/m<sup>2</sup>.</p> <p>Prior doses of other anthracyclines or anthracenediones should be included when calculating total cumulative doses of doxorubicin.</p> <p>Delayed-onset, dose-related cardiomyopathy is the most common and well-known cardiotoxicity and is likely to be irreversible and unresponsive to treatment.<br/>(Truven Health Analytics, 2021; Wolters Kluwer Health, 2021)</p> |
|                                    | Doxorubicin liposomal<br>(Doxil®)                | Cardiomyopathy (Kaposi sarcoma: < 1%)<br>CHF (up to 2%) | <p>Assess for a history of cardiovascular disease, which increases the risk for cardiac complications.</p> <p>Assess left ventricular cardiac function via MUGA or ECG at baseline, during therapy, and after discontinuation to assess for acute and delayed toxicities.</p> <p>Cardiotoxicity risk has been observed with cumulative anthracycline doses of 450–550 mg/m<sup>2</sup>.</p> <p>Cardiotoxicity at lower doses may occur in patients who received mediastinal irradiation or patients with preexisting heart disease.</p> <p>Chronic effects seen with cumulative doses approaching 550 mg/m<sup>2</sup> may result in CHF.<br/>(Truven Health Analytics, 2021; Wolters Kluwer Health, 2021)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Chemotherapy Agents (Cont.)</b> |                           |                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Anthracyclines<br>(Cont.)          | Mitoxantrone              | Bradyarrhythmia<br>Cardiovascular abnormalities<br>(4%–15%)<br>CHF (2.6%)<br>Edema (10%–30%)                                                                                                                            | Monitor patients for bradyarrhythmia, which has been reported as low as 38 bpm on day 2 of therapy.<br>Establish baseline cardiac function.<br>Monitor cardiac status with ECG. Monitor for cardiac arrhythmias, including decreased LVEF, CHF, tachycardia, ECG changes, and MI (rare).<br>Assess cardiac function and LVEF by physical examination, history, and ECG prior to therapy in all patients and consistently after treatment initiation in patients at elevated risk (e.g., history of anthracycline therapy or mediastinal irradiation, preexisting cardiovascular disease).<br>Cardiotoxicity is observed with prolonged administration and at doses > 80–100 mg/m <sup>2</sup> . Previous treatment with doxorubicin, radiation therapy, or a history of cardiac disease increases risk.<br>Monitor for cardiotoxicity beyond doses of 100 mg/m <sup>2</sup> .<br>The maximum dose is considered 160 mg/m <sup>2</sup> ; cardiotoxicity risk increases with cumulative dose. (Truven Health Analytics, 2021; Wolters Kluwer Health, 2021)                                                           |
| Antimetabolites                    | Azacitidine               | Atrial fibrillation (< 5%)<br>Cardiorespiratory arrest (< 5%)<br>Chest pain (16.4%)<br>CHF (< 5%)<br>Dilated cardiomyopathy (< 5%)<br>Heart failure (< 5%)<br>Hypertension (8.6%)<br>Hypotension (6.8%)<br>Pericarditis | Monitor coadministration with other cardiotoxic medications.<br>Toxicity usually is self-limiting and responds to a drug holiday. (Truven Health Analytics, 2021; Wolters Kluwer Health, 2021)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                                    | Capecitabine<br>(Xeloda®) | Cardiotoxicity<br>Chest pain<br>Edema (33%)<br>Takotsubo cardiomyopathy<br>Vasospasm                                                                                                                                    | Monitor for MI, ischemia, angina, dysrhythmias, cardiac arrest, cardiac failure, sudden death, ECG changes, and cardiomyopathy, all of which have been observed using this agent.<br>Assess for chest pain, even in patients with no prior history, as it has been observed within the first few doses of capecitabine in combination with other chemotherapy, radiation therapy, or both. Patients may have elevated ST intervals but show no signs of ischemia on ECG or stress echocardiogram.<br>These adverse events may be more common in patients with a prior history of coronary artery disease. Assess for edema, particularly in patients undergoing combination therapy with docetaxel, for whom rates were highest.<br>Interrupt drug if grade 2–3 adverse reactions occur; discontinue drug for grade 4 toxicity.<br>Takotsubo cardiomyopathy is a reversible condition characterized by transient apical and midventricular wall motion; patients may present with radiating chest pain, nausea and vomiting, and shortness of breath. **TABLE 16-1.** Cardiotoxicity of Cancer Therapy (*Continued*)

| Classification                                | Drug                                  | Side Effects                                                                                                                                                                     | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------------|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Targeted Therapy Agents (Cont.)</b>        |                                       |                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Small molecule inhibitors<br>( <i>Cont.</i> ) | Alectinib<br>(Alecensa <sup>®</sup> ) | Bradyarrhythmia (8.6%–11%)<br>Edema (30%)<br>Fatal cardiac arrest reported in 1 patient in clinical trials<br>Fatal endocarditis (0.4%)                                          | Monitor patients for signs and symptoms of cardiac dysfunction, particularly bradycardia, which may require dose reduction, pause in therapy, or discontinuation.<br>Monitor heart rate and blood pressure regularly. Advise patients to report any changes in heart or blood pressure medication.<br>Dosing may be reinstated with recovery to asymptomatic bradycardia or a heart rate of at least 60 bpm. Discontinue drug in the presence of recurrent bradycardia.<br>(Truven Health Analytics, 2021; Wolters Kluwer Health, 2021)                                                                                                                                                                                                                               |
|                                               | Axitinib<br>(Inlyta <sup>®</sup> )    | Heart failure (2%; grade 3–4: 1%)<br>Hypertension (40%; grade 3–4: 16%)<br>Hypertensive crisis (< 1%)                                                                            | Monitor patients for signs and symptoms of cardiac dysfunction, particularly heart failure and hypertension, including hypertensive crisis, which may require dose reduction, pause in therapy, or discontinuation.<br>Monitor for hypertension (> 150 mm Hg systolic; > 100 mm Hg diastolic), which has been reported, particularly in patients with renal cell carcinoma. The onset of hypertension occurred at a median of 1 month after treatment initiation, although blood pressure increases have occurred as early as 4 days after initiation.<br>Blood pressure should be well controlled before starting this drug; regularly monitor blood pressure during therapy.<br>(Truven Health Analytics, 2021; Wolters Kluwer Health, 2021)                        |
|                                               | Bortezomib<br>(Velcade <sup>®</sup> ) | Heart disease (15%)<br>Heart failure (5%)<br>Hypertension (6%)<br>Hypotension (12%–15%)<br>Peripheral edema (7%)                                                                 | Closely monitor patients with existing heart disease or risk factors for heart disease during therapy. Assess for cardiac dysfunction, including development or exacerbation of CHF and new-onset decreased LVEF, which have been observed, even in patients with no prior history of cardiac abnormalities.<br>Hypotension, including orthostatic and postural hypotension, has been reported; risk increases with concurrent use of medications that can cause hypotension, a history of syncope, and dehydration. Management may include adjusting antihypertensive medications, hydration, and administering mineralocorticoids (e.g., fludrocortisone) or adrenergic agents (e.g., epinephrine).<br>(Truven Health Analytics, 2021; Wolters Kluwer Health, 2021) |
|                                               | Bosutinib<br>(Bosulif <sup>®</sup> )  | Chest pain (7%–12%)<br>Edema (17%–20%)<br>Hypertension (1% to < 10%)<br>Pericardial effusion (1% to < 10%)<br>Pericarditis (0.1% to < 1%)<br>Prolonged QT interval (1% to < 10%) | Monitor for signs of fluid retention, which may present as pericardial effusion, pleural effusion, pulmonary edema, or peripheral edema.<br>Consider dose reductions or pause in therapy for symptomatic pericardial effusions.<br>(Truven Health Analytics, 2021; Wolters Kluwer Health, 2021)                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Small molecule inhibitors<br>( <i>Cont.</i> ) | Ponatinib<br>(Iclusig®) | Arterial ischemia (11%–42%)<br>Atrial fibrillation (7%)<br>Bradyarrhythmia (1%)<br>Cardiac dysrhythmia (19%)<br>Heart failure (6%–15%)<br>Hypertension (53%–71%)<br>Myocardial ischemia (21%)<br>Peripheral artery occlusive disease (12%)<br>Peripheral edema (13%–22%)<br>Venous thromboembolism (4%–10%) | <p>Monitor for signs and symptoms of cardiac dysfunction, particularly cardiac ischemia, infarction, or hypertension, which may require dose reduction, pause in therapy, or discontinuation.</p> <p>Assess patients with hypertension for confusion, headache, chest pain, or shortness of breath, which may require urgent clinical intervention.</p> <p>Frequently assess and manage blood pressure prior to and during treatment.</p> <p>Hold therapy to evaluate patients with signs and symptoms of abnormal heart rate, including rapid heart rate in the presence of atrial fibrillation and slow heart rate in the presence of bradyarrhythmia.</p> <p>Interrupt treatment and consider evaluating for renal artery stenosis if significant worsening, labile, or treatment-resistant hypertension occurs.</p> <p>Cardiac vascular occlusions requiring revascularization procedures have occurred, including life-threatening and fatal MI and coronary artery occlusion.</p> <p>Interrupt or discontinue treatment immediately if arterial occlusion is suspected.</p> <p>Consider risks versus benefits before restarting therapy.</p> <p>The drug has a black box warning for arterial occlusion (i.e., MI, stroke, stenosis of large arteries of the brain, severe peripheral vascular disease), venous occlusive events, and life-threatening or fatal heart failure and left ventricular dysfunction.</p> <p>Arterial ischemia includes cardiovascular, cerebrovascular, and peripheral vascular ischemia.</p> <p>Atrial fibrillation was the most common arrhythmia reported during clinical trials, and approximately 50% of cases were grade 3–4.</p> <p>Additional grade 3–4 arrhythmia events included syncope, tachycardia, bradycardia, QT prolongation, atrial flutter, supraventricular tachycardia, ventricular tachycardia, atrial tachycardia, complete atrio-ventricular block, cardiorespiratory arrest, loss of consciousness, and sinus node dysfunction, with some patients requiring hospitalization.</p> <p>Fatal and life-threatening arterial occlusions may occur within 2 weeks of initiation and at dosages as low as 15 mg daily; median time to first onset is 193 days, so monitoring should be long term for these patients.</p> <p>Risk factors include hypertension, hyperlipidemia, and preexisting cardiac disease. Event frequency increased with age. Occlusions also occurred in patients without cardiovascular risk factors and in patients aged ≤ 50 years.</p> <p>Peripheral arterial occlusive events requiring revascularization procedures have occurred, including fatal mesenteric artery occlusion and life-threatening peripheral arterial disease. Digital or distal extremity necrosis requiring amputation has also occurred.</p> <p>The median time to onset of the first peripheral vascular arterial occlusive event was 478 days. **TABLE 16-1. Cardiotoxicity of Cancer Therapy (Continued)**

| Classification                         | Drug                       | Side Effects                                                                                                                                                                                                                                  | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Targeted Therapy Agents (Cont.)</b> |                            |                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Small molecule inhibitors<br>(Cont.)   | Regorafenib<br>(Stivarga®) | Hypertension (30%–59%; grade 3–4: 8%–28%)<br>Hypertensive crisis (0.25%)<br>MI (1.2%)<br>Myocardial ischemia (1.2%)                                                                                                                           | Patients should be monitored for signs and symptoms of cardiac dysfunction, particularly cardiac ischemia, infarction, or hypertension, which may require dose reduction, pause in therapy, or discontinuation. Blood pressure should be adequately controlled prior to initiation of the drug and monitored weekly for the first 6 weeks during therapy, then at least every cycle. The drug should be temporarily withheld or permanently discontinued in patients with severe or uncontrolled hypertension.<br>(Truven Health Analytics, 2021; Wolters Kluwer Health, 2021)                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                                        | Ribociclib<br>(Kisqali®)   | Peripheral edema (12%)<br>Prolonged QT interval (3%)<br>Sudden cardiac death (0.3%)<br>Syncope (2.7%)                                                                                                                                         | Monitor for signs and symptoms of cardiac dysfunction, particularly prolongation of QT interval, electrolyte imbalances, and syncope, which may require dose reduction, pause in therapy, or discontinuation. Assess ECG prior to initiation, during therapy, and as clinically indicated, as ECG changes have been observed within the first 4 weeks of treatment and were reversible with dose interruption. Monitor serum potassium, calcium, phosphorus, and magnesium prior to initiation, during therapy, and as clinically indicated. Prolongation of the QT interval, which is drug concentration–dependent, can result in sudden death. Avoid use of ribociclib in patients with preexisting QT prolongation or those at risk (e.g., long QT syndrome, recent MI, CHF, unstable angina, bradyarrhythmias). Avoid concomitant use of drugs known to prolong the QT interval. Correct any electrolyte abnormalities prior to starting therapy to avoid QT prolongation.<br>(Truven Health Analytics, 2021; Wolters Kluwer Health, 2021) |
|                                        | Romidepsin<br>(Istodax®)   | ECG changes (QT prolongation)<br>ECG ST-segment changes (2%–63%)<br>Hypotension (7%–23%)<br>QTc prolongation (at least 2%)<br>Supraventricular arrhythmia (6%)<br>Ventricular arrhythmia (4%)                                                 | Monitor international normalized ratio more frequently in patients receiving concurrent warfarin therapy. ECG changes, including T-wave and ST-segment changes, have been reported; prior to administration, confirm that potassium and magnesium levels are within normal limits. Monitor for ECG changes in patients with congenital long QT syndrome, a history of significant cardiovascular disease, or concomitant use of antiarrhythmic or QT-prolonging agents, for whom these risks are elevated. Obtain baseline and periodic ECGs. Monitor for and correct electrolyte abnormalities.<br>(Truven Health Analytics, 2021; Wolters Kluwer Health, 2021)                                                                                                                                                                                                                                                                                                                                                                               |
|                                        | Sorafenib<br>(Nexavar®)    | Cardiac dysrhythmia (< 1%)<br>CHF (1.9%)<br>Edema<br>Heart failure exacerbation<br>Hypertension (19.1%; grade 3–4: 4.3%)<br>Hypertensive crisis (< 1%)<br>MI (1.9%–2.9%)<br>Myocardial ischemia (1.9%–2.9%)<br>Prolonged QT interval (< 0.1%) | Monitor for signs and symptoms of cardiac dysfunction, particularly cardiac ischemia, hypertension, and MI, which may require dose reduction, pause in therapy, or discontinuation. Monitor for QT interval prolongation in patients with CHF, bradyarrhythmias, electrolyte abnormalities, and concomitant use of other drugs known to prolong the QT interval. Monitor blood pressure weekly for the first 6 weeks of treatment, then every 2–3 weeks for the duration of treatment. Avoid use in patients with congenital long QT syndrome. Hypertension can be severe and potentially persistent. Treat preexisting hypertension with standard hypertensive agents before treatment initiation. In the presence of prolonged QT interval, monitor ECGs and electrolytes (i.e., magnesium, calcium, potassium) in at-risk patients, and interrupt treatment with QTc interval > 500 ms or increases from baseline ≥ 60 ms.<br>(Truven Health Analytics, 2021; Wolters Kluwer Health, 2021)                                                  |

bpm—beats per minute; CHF—congestive heart failure; CYP—cytochrome P450; ECG—electrocardiogram; echo—echocardiography; HER2—human epidermal growth factor receptor 2; IV—intravenous; LLN—lower limit of normal; LVEF—left ventricular ejection fraction; MI—myocardial infarction; ms—milliseconds; MUGA—multigated acquisition; QTc—corrected QT interval; QTcF—corrected QT interval using Fridericia's calculation

## c) Incidence

- (1) Atrial fibrillation is the most common supraventricular dysrhythmia in patients with cancer and may occur acutely, during or after chemotherapy and radiation therapy, or following surgical intervention.
- (2) Atrial fibrillation most notably occurs in the postoperative setting, with 13%–20% following lung resection and 20%–25% following esophageal surgery (Chu et al., 2019; Ganatra et al., 2018; Tang, 2019).

## d) Risk factors (Chu et al., 2019; Ganatra et al., 2018)

- (1) Older age
- (2) Preexisting cardiovascular disease
- (3) Hypertension
- (4) Heart failure
- (5) Sleep apnea
- (6) Pericardial disease
- (7) Pulmonary embolism
- (8) Valvular disease
- (9) Chronic obstructive pulmonary disease
- (10) Electrolyte abnormalities
- (11) Thyroid disorders
- (12) Chronic kidney disease

## e) Clinical manifestations (Chu et al., 2019)

- (1) Palpitations
- (2) Chest discomfort
- (3) Dyspnea and fatigue may result from decreased cardiac output due to loss of atrial kick (approximately one-third of cardiac output), which worsens all other cardiac disease symptoms.
- (4) Dizziness

## f) Assessment

- (1) Assess patient history for known medical conditions or medications that may precipitate dysrhythmias. Elimination of preventable risks may reduce incidence or severity (López-Fernández et al., 2019).
- (2) Obtain a baseline electrocardiogram (ECG).
- (3) Maintain ongoing monitoring (continuous or intermittent) of ECG rhythm.
- (4) Compare apical and peripheral heart rates (Asnani et al., 2017).
- (5) Perform follow-up assessments of vital signs and for symptoms of dyspnea, hypoxemia (shown as low oxygen saturation), hypotension, or chest discomfort (Asnani et al., 2017).
- (6) Replace electrolytes and maintain within normal ranges.

## g) Collaborative management

- (1) Correct contributing factors, such as hypoxemia, anemia, fluid imbalance, and electrolyte abnormalities.
- (2) Administer electrolyte replacement to a goal potassium value greater than 4 mEq/L and magnesium value greater than 2 mEq/L (Abu Rmilah et al., 2020).
- (3) Optimal calcium levels are not established, but the usual goal is ionized calcium levels greater than 1.1 mEq/L.

## h) Patient and family education

- (1) Patients with truly lone atrial fibrillation need to be aware that their risk of stroke is extremely low, approximately 1.3% over a 15-year period (Lane et al., 2015). However, regular clinical reassessment of their stroke risk using the CHA2DS2-VASc score is essential, particularly as age increases and the prospect of developing comorbidities becomes more likely (Lane et al., 2015).
- (2) All patients with atrial fibrillation should be aware of the risk factors that can increase their risk of stroke.
- (3) Patients need to be aware of the potential harms of medications used to treat atrial fibrillation (e.g., beta-blockers, antidysrhythmics), which can include life-threatening ventricular arrhythmias (and lead to death in rare cases), deterioration of left ventricular systolic function, and organ toxicity (particularly with long-term use).
- (4) Patients need to be aware that late recurrences of atrial fibrillation after cardioversion or catheter ablation are a possibility and that more than one procedure may be required.
- (5) Patients need to know what has caused their atrial fibrillation, how it will affect their lives (consequences), and the therapeutic options.
- (6) To enable realistic treatment expectations, patients need to know what they have been prescribed and, why they are taking it, how to take it (e.g., dose; frequency; timings; with, before, or after food; with other tablets), what will happen if they fail to adhere as prescribed, any factors that may modify drug efficacy, any possible side effects, and the likelihood of treatment success or failure (Lane et al., 2015).

## 4. QT prolongation

## a) Definition

- (1) QT prolongation is an abnormality in the conduction system of the heart that

can put patients at risk for ventricular arrhythmias (i.e., torsades de pointes, syncope, and sudden death) (Vandael et al., 2017).

- (2) The QT interval represents the duration of electrical depolarization and repolarization of the ventricles, beginning at the initiation of the QRS complex and ending where the T wave returns to the isoelectric baseline (Abu Rmilah et al., 2020).
- (3) The approximate duration of a regular QT interval is 350–460 ms.
- (4) The QT interval is inversely correlated with heart rate; therefore, it is shorter with more rapid heart rates and longer with slower rates.
- (5) Because of this inverse relationship, the QT interval is routinely transformed (normalized) using various formulas into a heart rate–dependent corrected value known as the QTc interval.
- (6) The QTc interval represents the QT interval at a standardized heart rate of 60 beats per minute.
  - (a) Several correction formulas have been developed to improve the accuracy of QT measurement with QTc values (Fridericia, 2003; Kim, Masha, et al., 2021).
  - (b) QTc intervals at the upper limit of normal have been proposed for males (greater than 450 ms) and females (greater than 460 ms).
  - (c) A QTc greater than 500 ms or a QT change from a baseline of greater than 60 ms should be of particular concern because it can predispose patients to torsades de pointes (Herrmann, 2020). This polymorphic ventricular tachyarrhythmia appears on ECG as a continuous twisting of the vector of the QRS complex around the isoelectric baseline.
  - (d) Torsades de pointes may degenerate into ventricular fibrillation, leading to sudden cardiac death (Abu Rmilah et al., 2020).
  - (e) A feature of torsades de pointes is the pronounced prolongation of the QT interval in the supraventricular beat preceding the arrhythmia.

#### b) Pathophysiology

- (1) The arrhythmogenic mechanisms underlying QT prolongation in patients with cancer are not well established.

- (2) Prolonged QT interval may be caused by the tumor, cancer treatment, metabolic abnormalities (e.g., abnormal electrolytes), or underlying cardiac disease (e.g., myocardial ischemia, heart failure), which create an arrhythmogenic substrate (Tamargo et al., 2015).
- (3) The most commonly identified antineoplastic agents that affect cardiac repolarization include histone deacetylase inhibitors, tyrosine kinase inhibitors (TKIs), the BRAF inhibitor vemurafenib, and arsenic trioxide (Moslehi & Deininger, 2015; Nair et al., 2017).

#### c) Incidence

- (1) Variability exists in the incidence of QTc prolongation in various cancer drugs, ranging from 0% to 22.7%. Severe prolongation (QTc greater than 500 ms) has been reported in 0%–5.2% (Porta-Sanchez et al., 2017; Wolters Kluwer Health, 2021).
- (2) However, the reported incidence of QTc prolongation is higher with specific TKIs, such as nilotinib (38.7%) and dasatinib (41.7%) (Abu Rmilah et al., 2020).

#### d) Risk factors

- (1) Medications known to prolong QTc, including arsenic trioxide, dasatinib, 5-fluorouracil, lapatinib, nilotinib, pazopanib, sunitinib, tamoxifen, temsirolimus, and vorinostat (Kim, Masha, et al., 2021)
- (2) Presence of multiple comorbidities (e.g., preexisting cardiac disease)
- (3) Polypharmacy with concomitant QT-prolonging agents (e.g., antiemetics, antidepressants, antibiotics)
- (4) Electrolyte disturbances (particularly hypokalemia and hypomagnesemia) and other metabolic abnormalities
- (5) Diurnal effects
- (6) Autonomic tone

#### e) Clinical manifestations (Kim, Irizarry-Caro, et al., 2021)

- (1) Palpitations
- (2) Syncope
- (3) Presyncope

#### f) Assessment

- (1) Identify the etiology of the QT prolongation, such as toxic substances, other metabolic abnormalities, or primary or structural abnormalities of the heart itself.
- (2) Replace electrolytes (potassium and magnesium), and maintain within normal ranges.

#### g) Collaborative management

- (1) Correct contributing factors, such as hypoxemia, anemia, fluid imbalance, and electrolyte abnormalities.
- (2) Administer electrolyte replacement to a goal potassium value greater than 4 mEq/L and magnesium value greater than 2 mEq/L (Kim, Irizarry-Caro, et al., 2021).
  - (a) Optimal calcium levels are not established, but ionized calcium levels below 2.8 mg/dl are a reasonable threshold to begin calcium replacement therapy.
  - (b) Patients with hypotension or low cardiac output may require calcium replacement when ionized calcium falls below 3.2–3.6 mg/dl.
  - (c) Replacement therapy should be monitored with ionized calcium levels (Kim, Irizarry-Caro, et al., 2021; Kim, Masha, et al., 2021).
- (3) Prior to starting medications with the potential for QT prolongation, obtain a baseline ECG with QT measurement, with subsequent ECG monitoring for QT intervals as indicated by prescribing information.
- (4) In patients with excessive corrected QT interval prolongation (greater than 500 ms), QT-prolonging cancer drugs should not be initiated, and potential causes or contributing factors should be evaluated and corrected.
- (5) Concomitant treatment with QT-prolonging drugs (e.g., antiarrhythmics, antibiotics, antifungals) should be avoided.

#### h) Patient and family education

- (1) Teach patients and families the symptoms of QT prolongation and the potential urgency of treatment.
- (2) Once QT prolongation has been identified, teach preventive strategies, such as hydration or electrolyte replacement. Emphasize that vomiting or diarrhea may disrupt fluid or electrolyte balance.
- (3) Patients need to be aware of the medications that can cause QT prolongation.

### C. Vascular abnormalities: hypertension

1. Definition: Hypertension is a systolic blood pressure of 140 mm Hg or greater or a diastolic blood pressure of 90 mm Hg or greater (Unger et al., 2020).
  - a) Hypertension is the most frequent comorbid condition reported in patients with cancer and is associated with an increased risk of cardiovas-

cular complications, including stroke, myocardial infarction, and heart failure (de Souza et al., 2015; Unger et al., 2020).

- b) It is particularly increased in patients treated with angiogenesis inhibitors, commonly known as vascular signaling pathway (VSP) inhibitors, including the VEGF inhibitors and other small molecule TKIs (Lankhorst et al., 2015; Nair et al., 2017; Tini et al., 2019). Drug-related hypertension can occur from initiation until one year after treatment onset (Zamorano et al., 2016).
- ### 2. Pathophysiology
- a) The exact mechanism underlying the development of hypertension related to cancer therapy is unknown. Proposed mechanisms include abnormalities in endothelial function and angiogenesis, nitric oxide pathway inhibition, decrease in vascular wall compliance and flexibility, oxidative stress, and glomerular injury developing from loss of VEGF effect, as well as renal thrombotic microangiopathy (Katsi et al., 2019; Priori et al., 2015; Zamorano et al., 2016).
  - b) Multikinase inhibition results in antiangiogenesis by blocking the BCR-ABL receptor and the actions of VEGF, which decreases cellular nitric oxide (Jiang et al., 2021). Hypertension is related to the loss of the VEGF effect on the vascular endothelial wall leading to diminished nitric oxide synthase and loss of the vasodilatory effects of nitric oxide (de Souza et al., 2015; Plummer et al., 2019).
  - c) Lower nitric oxide levels are associated with sodium and water retention (Rust & Ekmekcioglu, 2017).
  - d) Vasoconstriction results from the interference with nitric oxide production in the arteriolar walls by the VSP inhibitors (Agarwal et al., 2018).
- ### 3. Incidence
- a) Hypertension incidence has increased to 80% in patients with cancer treated with VEGF inhibitors (Lankhorst et al., 2015; Tini et al., 2019).
  - b) Hypertension associated with antiangiogenic therapies and multikinase inhibitors occurs with high frequency (4%–80%) and is dose dependent (Agarwal et al., 2018). Approximately 11%–16% of patients receiving bevacizumab have significant hypertension that requires adding or adjusting antihypertensive medications (Tini et al., 2019).
- ### 4. Risk factors
- a) Advancing age
  - b) Preexisting hypertension or cardiovascular disease (Katsi et al., 2019)
  - c) Treatment with bevacizumab, pazopanib, sorafenib, sunitinib, or vandetanib (Katsi et al., 2019)

- d) Proteinuria usually precedes hypertension with bevacizumab therapy (Dempsey et al., 2021).
  - e) Renal insufficiency, hyperthyroidism, Cushing syndrome, increased intracranial pressure, and hypomagnesemia independent of chemotherapy toxicity (Dempsey et al., 2021)
  - f) Medications such as antidepressants, including tricyclic antidepressants and selective serotonin reuptake inhibitors
  - g) Race: Hypertension tends to be more common, more severe, occurs earlier in life, and is associated with more significant target-organ damage in Black people.
5. Clinical manifestations
- a) Most patients with high blood pressure have no signs or symptoms, even if blood pressure readings reach dangerously high levels.
  - b) A few people with high blood pressure may have headaches, shortness of breath, or nosebleeds, but these signs and symptoms are not specific and usually do not occur until blood pressure has reached a severe or life-threatening stage.
  - c) Increases in blood pressure with multikinase inhibitors and antiangiogenic agents may be asymptomatic or accompanied by headache, visual disturbances, fatigue, tachycardia, or heart failure.
6. Assessment (Unger et al., 2020)
- a) Obtain a comprehensive patient history to establish a baseline. Assess for medications (e.g., sinus or cold remedies) or clinical conditions that may contribute to altered blood pressure.
  - b) Evaluate laboratory values to determine specific cardiovascular risk factors prior to starting VSP inhibitors.
  - c) Blood pressure assessment should have a minimum of two standardized measurements and set a goal of less than 140/90 mm Hg for most patients, following recommendations for all adults.
  - d) Higher-risk patients, including those with diabetes or chronic kidney disease, should achieve a lower goal (e.g., 130/80 mm Hg).
  - e) Evaluate pain control, as pain may contribute to hypertension.
  - f) Assess for stress management and other medications used in these patients (e.g., steroids, nonsteroidal anti-inflammatory drugs, erythropoietin) that can cause hypertension to estimate blood pressure adequately.
7. Collaborative management of hypertension (Plummer et al., 2019; Unger et al., 2020)
- a) Early diagnosis and control of blood pressure to the recommended guideline parameters allow for effective antiangiogenic therapy for optimal cancer treatment (Agarwal et al., 2018).
  - b) A baseline blood pressure measurement and regular monitoring are recommended while patients are receiving VEGF inhibitors, especially during the first cycle of chemotherapy, when most patients experience an elevation in blood pressure.
  - c) Blood pressure should be actively monitored weekly during the first cycle of VSP inhibitor therapy and then at least every two to three weeks for the duration of treatment.
  - d) Patients with preexisting hypertension and on multiple antihypertensive agents should be evaluated for renal function and proteinuria.
  - e) Antihypertensive therapy must be individualized to patients according to medical history and the specific properties of different antihypertensive agents (Whelton et al., 2018; Williams et al., 2018).
  - f) Antihypertensive agent classes that have been specifically prescribed to control hypertension associated with VSP inhibitor therapy include thiazide diuretics, beta-blockers, dihydropyridine calcium channel blockers, angiotensin-converting enzyme inhibitors, and angiotensin receptor blockers (Agarwal et al., 2018; Whelton et al., 2018). Some agents may be preferable (e.g., renin-angiotensin or sympathetic system inhibitors) over others (e.g., thiazide diuretics) to minimize the risk of electrolyte depletion.
  - g) Hypertension associated with TKIs is typically manageable with appropriate therapy. Early intervention is key to minimizing additional cardiovascular adverse effects such as heart failure (Agarwal et al., 2018).
  - h) Patients should keep a blood pressure measurement log, especially during the first week of treatment, because the magnitude of elevation is unpredictable.
  - i) Target blood pressure should be based on the *2020 International Society of Hypertension Global Hypertension Practice Guidelines* (Unger et al., 2020).
  - j) Antihypertensive therapy should be adjusted accordingly based on associated comorbidities (e.g., less than 140/90 mm Hg) in patients with diabetes or chronic kidney disease.
8. Patient and family education
- a) Hypertension can be life threatening and cause stroke. Patients should be prepared to recognize signs of a hypertensive crisis or stroke.
    - (1) Memory lapses
    - (2) Blackouts or near syncope
    - (3) Visual abnormalities
    - (4) Persistent headache

- (5) Slurred words
- (6) Numbness or tingling of an extremity
- (7) Facial droop
- b) Patients may require guidance with self-administration of antihypertensive agents.
- c) Many antihypertensive agents can cause immediate orthostasis, dizziness, nausea, and risk of falling.
- d) Patients should be instructed to use a validated, automated oscillometric device that measures blood pressure in the brachial artery (upper arm) and perform measurements in a quiet room after five minutes of rest in the seated position with the back and arm supported.
- e) Blood pressure generally should be checked in both arms to determine if a difference exists. It is important to use an appropriately sized arm cuff.
- f) Adherence to taking medications as prescribed should be emphasized to patients.
- g) Patients should be aware of the potential side effects of medications and when to report them to their healthcare provider.
- h) Before starting TKIs, patients need to have a baseline blood pressure measurement and be aware of the target blood pressure.

#### D. Venous thromboembolism (VTE)

1. Definition: VTE is a serious, life-threatening disorder and the second leading cause of death in hospitalized patients with cancer (Grover et al., 2021). VTE consists of deep vein thrombosis (DVT), which typically involves the deep veins of the legs or pelvis, and its complication, pulmonary embolism (PE).
2. Pathophysiology: Endothelial wall damage is thought to relate to atherosclerotic events such as VTE. This is supported by the fact that VTE occurs with a higher incidence in patients treated with VEGF inhibitors (Wang et al., 2018).
3. Incidence
  - a) The risk of VTE in patients with cancer ranges widely and is based on various factors, such as type of cancer, stage of cancer, medical comorbidities, and type of treatment (Grilz et al., 2018; Horowitz & Brenner, 2020).
  - b) For example, patients with pancreatic cancer can have rates of VTE as high as 20% (Grover et al., 2021).
  - c) The treatment regimen can also play a factor in VTE risk. In patients with multiple myeloma, the incidence of VTE associated with thalidomide alone is relatively low (approximately 3%) (Wang et al., 2018).
  - d) However, the addition of thalidomide to a multiagent chemotherapy regimen, including dexamethasone, can increase that risk to 20%–28% (Grover et al., 2021).

#### 4. Risk factors

- a) A variety of anticancer agents have been shown to increase the risk of thrombotic events in patients with cancer (Canale et al., 2019; Oppelt et al., 2015; Wang et al., 2018).
- b) Treatment with platinum-based agents (e.g., cisplatin, carboplatin, oxaliplatin), immunomodulatory agents (e.g., thalidomide, lenalidomide, pomalidomide), anti-epidermal growth factor receptor antibodies (e.g., cetuximab, panitumumab, necitumumab), VEGF-targeted molecules (e.g., bevacizumab, aflibercept), and TKIs (e.g., sunitinib, sorafenib, axitinib) are associated with a significantly increased risk of VTE (Grover et al., 2021).
- c) Patients with pancreatic, lung, or gastric cancers and those with metastatic cancers have the highest incidence of VTE (Wang et al., 2018). Other risk factors are edema, immobility, dehydration, congestive heart failure, and erythropoiesis-stimulating agents (Grover et al., 2021).

5. Clinical manifestations: Unilateral pain, redness, and swelling of the affected extremity are manifestations of DVT. PE symptoms include shortness of breath, cough, and chest pain.

6. Assessment: Obtain a health history at every clinic or hospital visit. Assess patients for signs and symptoms of VTE, such as pain, redness, and swelling of extremities, especially unilaterally, as well as shortness of breath, cough, and chest pain.

#### 7. Collaborative management

- a) Refer patients for diagnostic testing (e.g., venous Doppler study, computed tomography angiography). Initiate anticoagulant therapy when indicated and monitor therapeutic levels when necessary.
- b) Discontinue medications thought to contribute to VTE.

#### 8. Patient and family education (Wang et al., 2018)

- a) Teach patients the signs and symptoms of vascular complications.
- b) Teach lifestyle changes that may reduce the incidence and severity of vascular complications, such as smoking cessation, low-fat diet, moderate exercise, and stress management.
- c) Advise patients to report symptoms to healthcare providers so that assessment and preventive strategies can be implemented early.

#### E. Coronary artery disease

##### 1. Myocardial ischemia

- a) Several cancer treatments, including cytotoxic drugs, targeted therapies, and radiation therapy, are associated with an increased risk of coronary artery disease with or without acute coronary syndromes.
- b) The most common cancer therapies associated with myocardial infarction and myocardial isch-

emia are angiogenesis inhibitors (e.g., lenalidomide, thalidomide), antimetabolites (e.g., capecitabine; 5-fluorouracil), antimicrotubule agents (e.g., docetaxel, ixabepilone, paclitaxel), monoclonal antibody TKIs (e.g., bevacizumab), proteasome inhibitors (e.g., carfilzomib), and small molecule TKIs (e.g., erlotinib, imatinib, nilotinib, pazopanib, ponatinib, ramucirumab, regorafenib, sorafenib, ziv-aflibercept).

## 2. Pathophysiology

- a) The exact mechanism of cardiotoxicity resulting in myocardial ischemia associated with these agents is not entirely understood. Potential mechanisms include coronary artery thrombosis, coronary arteritis, coronary vasospasm, direct toxic effects, interaction with the coagulation system, autoimmune responses, and apoptosis of the myocardial cells and endothelium, mimicking toxic myocarditis (Caforio et al., 2017).
- b) Myocarditis-induced edema of myocytes creates increased automaticity and impaired perfusion. Increased workload and myocardial stress are thought to be the mechanism for myocardial ischemia and infarction. Thromboses resulting from an increased propensity for clotting may involve coronary arteries (Palaskas et al., 2020).

## 3. Incidence

- a) 5-Fluorouracil: Incidence of myocardial ischemia is 1%–68%.
  - (1) It occurs within two to five days after initiating treatment and presents as angina-like chest pains; however, myocardial infarction, arrhythmias, heart failure, cardiogenic shock, and sudden death have been reported (Chang, Moudgil, et al., 2017; Okwuosa et al., 2017).
  - (2) Cardiac mortality rate with 5-fluorouracil is 2.2%–13%.
- b) Capecitabine: Incidence of cardiotoxicity is 3%–9%. The onset of anginal symptoms ranges from three hours to four days after therapy (Chang, Moudgil, et al., 2017).
- c) Antimicrotubule agents: Incidence of myocardial ischemia is 0.5%–5% with paclitaxel and 1.7% with docetaxel (Chang, Moudgil, et al., 2017).
- d) Monoclonal antibody TKIs (e.g., bevacizumab): Incidence of high-grade ischemia is 0.6%–1.5% (Moslehi & Deininger, 2015).
- e) Small molecule TKIs (e.g., erlotinib, sorafenib): Incidence of myocardial infarction and ischemia is 2.3% when erlotinib is combined with gemcitabine (Mudd et al., 2021). Sorafenib is associated with myocardial infarction in 2.7%–3% of patients (Moslehi & Deininger, 2015).

## 4. Risk factors

- a) Cancer therapies associated with myocardial ischemia, including bevacizumab, bortezomib, capecitabine, docetaxel, doxorubicin, erlotinib, 5-fluorouracil, hydroxyurea, paclitaxel, pazopanib, rituximab, and sorafenib (Okwuosa et al., 2017)
- b) Androgen deprivation (Hu et al., 2020)
- c) Cetuximab used for locally advanced squamous cell head and neck cancer: Similar events were not observed with cetuximab when treating metastatic colorectal cancer (ImClone, 2016).
- d) Interleukin-2 resulting in capillary permeability with myocarditis (Muehlbauer et al., 2018)
- e) Taxane therapy: Few patients suffer coronary artery disease with now-established drug monitoring and dose attenuation plans (Han et al., 2019).
- f) Agents enhancing hypercoagulability: No relationship to any specific chemotherapy or immunotherapy agent has been demonstrated (Grover et al., 2021).
- g) High-dose chemotherapy: Patients may present with rare unexplained chest pain with ischemic ECG changes that spontaneously resolve without medical intervention (Caforio et al., 2017).
- h) Aromatase inhibitors (Okwuosa et al., 2017)
- i) Transarterial chemoembolization with unclear etiology (Wang et al., 2018)

## 5. Clinical manifestations

- a) General signs and symptoms: anxiety, generalized fatigue and weakness, restlessness, agitation
- b) Cardiovascular: retrosternal chest discomfort, tachycardia, new murmur or S<sub>2</sub> or S<sub>3</sub>, congestive heart failure symptoms, hypertension or hypotension
- c) Gastrointestinal: nausea, abdominal pain, indigestion, vomiting
- d) Neurologic: light-headedness, near syncope, syncope
- e) Pulmonary: dyspnea, wheezing, tachypnea, pulmonary rales
- f) Integumentary: diaphoresis; cool, clammy skin; pallor
- g) Elevated cardiac enzymes indicative of myocardial infarction (Caforio et al., 2017)
- h) Ischemic ECG changes in up to 68% of patients (Caforio et al., 2017)

## 6. Assessment

- a) Dysrhythmias are common in patients with cancer; life-threatening ventricular tachycardia or ventricular fibrillation is most common in the first two hours.
- b) Cardiac enzymes (e.g., creatine phosphokinase-MB, troponin I, troponin T) measured in the serum are elevated when a myocardial injury occurs (Han et al., 2019).

- c) Echocardiogram or multigated acquisition scan to assess for left ventricular ejection fraction (LVEF)
  - d) Diagnostic right heart catheterization to measure cardiac output and pulmonary capillary wedge pressure.
7. Collaborative management (Han et al., 2019)
- a) Initiate medical treatment as appropriate (e.g., supplemental oxygen; morphine 2–4 mg IV as needed for analgesia; nitroglycerin sublingually as needed for chest pains).
  - b) Administer oxygen at a rate sufficient to maintain oxygen saturation above 90%, unless otherwise contraindicated.
  - c) Observe for dysrhythmias and ischemic changes, low oxygen saturation, or extremes in blood pressure.
  - d) Obtain an order for aspirin 325 mg to be chewed as soon as a 12-lead ECG is performed and ST changes are present. Administer with caution in patients with low platelet counts and brain metastases.
  - e) Consider patient candidacy for reperfusion strategies, such as cardiac catheterization with angioplasty, stent placement, or intracoronary/IV thrombolysis (Iannaccone et al., 2018).
  - f) Consider ischemia-reducing or myocardial preservation strategies, such as the administration of nitrates, beta-blockers, or statins (Okwuosa et al., 2017; Wang et al., 2017).
  - g) Maintain potassium greater than 4 mEq/L, magnesium greater than 2 mEq/L, and ionized calcium greater than 1 mEq/L (Iannaccone et al., 2018).
  - h) Consider discontinuation of antineoplastic agents thought to cause cardiac ischemia or infarction, such as fluoropyrimidines, oxaliplatin, sorafenib, or tamoxifen.
  - i) Determine the need for follow-up assessment of coronary arteries and myocardial function with exercise stress testing, cardiac catheterization, echocardiogram, or multigated acquisition scan (Han et al., 2019).
  - j) Aggressively manage cardiac risk factors (e.g., hypertension, hyperlipidemia).
  - k) Management of coronary artery disease in patients with cancer needs interprofessional cooperation to formulate a reasonable and individualized plan with special consideration for anticancer therapy (Han et al., 2019).
8. Patient and family education
- a) Explain the disease process, diagnostic tests, and medications to patients and families.
  - b) Provide emotional support to patients and families to lower their level of anxiety, which can reduce heart rate and myocardial oxygen demand.
  - c) Provide instruction regarding risk factor modification (Anderson et al., 2017).
  - d) Educate patients and families regarding reportable symptoms, such as chest discomfort, left arm or neck pain, and dyspnea.
  - e) Educate patients and families regarding managing risks for cardiac ischemia specific to oncology (e.g., anemia, cardiac demands of infection, electrolyte disturbances).
  - f) Include patient teaching on cardiac medications and unique considerations in oncology care (e.g., the risk for low blood pressure increased when febrile; electrolyte disturbances with nausea and vomiting may contribute to cardiac dysrhythmias).
  - g) Provide referrals and education regarding cardiac rehabilitation programs (Anderson et al., 2016).
- F. Left ventricular dysfunction and heart failure
1. Definition
- a) Heart failure is defined as an inadequate contractile force to eject the required amount of blood for perfusion of the body (Hunt et al., 2009; Lindenfeld et al., 2010).
  - b) It is classified as primary or secondary based on the primary etiology and has three types: acute, early-onset progressive, or chronic late progressive (Metra & Teerlink, 2017).
  - c) A consensus definition for cardiotoxicity-induced cardiomyopathy and heart failure is lacking. Multiple definitions include the following:
    - (1) The National Cancer Institute (n.d.) broadly defines cardiotoxicity as “toxicity that affects the heart.”
    - (2) The *Common Terminology Criteria for Adverse Events* defines left ventricular dysfunction and heart failure based on severity (grades 1–5), with a decrease in LVEF of 10% or greater from baseline or LVEF less than 50% (National Cancer Institute Cancer Therapy Evaluation Program, 2017).
      - (a) Grade 1: asymptomatic with laboratory values (e.g., brain natriuretic peptide) or cardiac imaging abnormalities
      - (b) Grade 2: symptoms with moderate activity or exertion
      - (c) Grade 3: symptoms at rest or with minimal activity or exertion
      - (d) Grade 4: life-threatening consequences, urgent intervention indicated
      - (e) Grade 5: death

- (3) The Cardiac Review and Evaluation Committee supervising trastuzumab clinical trials defined drug-related cardiotoxicity as one or more of the following (Bloom et al., 2016):

- (a) Cardiomyopathy characterized by a decrease in LVEF, either global or more severe in the septum
- (b) Symptoms associated with congestive heart failure
- (c) Signs associated with congestive heart failure (e.g., S<sub>3</sub> gallop, tachycardia, both)
- (d) Reduction in LVEF from baseline of at least 5% to less than 55%, with accompanying signs or symptoms of congestive heart failure, or a reduction in LVEF of at least 10% to less than 55% without accompanying signs or symptoms

- (4) The U.S. Food and Drug Administration defined anthracycline-induced cardiotoxicity as a greater than 20% decrease in LVEF when the baseline is normal or a greater than 10% decrease when the baseline is not normal (Bloom et al., 2016).

- (5) The American Society of Echocardiography and European Association of Cardiovascular Imaging defined cancer therapeutics-related cardiac dysfunction as a decrease in LVEF of more than 10% to a value less than 53% confirmed by repeat imaging (Bloom et al., 2016; Plana et al., 2014).

## 2. Pathophysiology

### a) Anthracycline-induced cardiotoxicity

- (1) The exact mechanism is not fully understood, although multiple pathways have been implicated (McGowan et al., 2017).
- (2) The most commonly accepted pathophysiologic mechanism is the oxidative stress hypothesis, which suggests that the generation of reactive oxygen species and lipid peroxidation of the cell membrane damage cardiomyocytes.
- (3) Other proposed mechanisms include intercalation into nuclear DNA to impair protein synthesis and inhibition of topoisomerase II to inhibit DNA repair (Franco & Lipshultz, 2015; Sawicki et al., 2021).
- (4) Several agents have been identified as potentially effective prophylaxis for anthracycline-induced cardiotoxicity, including beta-blockers, statins, angioten-

sin antagonists, and dexrazoxane (Sawicki et al., 2021).

- (a) Dexrazoxane is a topoisomerase II beta inhibitor that converts an active ion-binding form to prevent toxic radical injury. The recommended dosing ratio of dexrazoxane to doxorubicin is 10:1 (Wolters Kluwer Health, 2021).

- (b) Dexrazoxane is reconstituted with sterile water and may be further diluted with lactated Ringer's solution for rapid IV infusion; it should not be administered via IV push (Wolters Kluwer Health, 2021).

### b) Targeted therapy-associated toxicity

- (1) The mechanisms of action proposed for targeted therapy-associated toxicity (e.g., trastuzumab) are typically related to either on- or off-target adverse reactions, such as left ventricular dysfunction or heart failure.

- (2) On-target toxicity occurs when the specific kinase targeted by the therapy provides an important physiologic function in addition to the target tumor tissue (Chaar et al., 2018). An example of on-target toxicity is cardiotoxicity that may occur with trastuzumab. It is believed that trastuzumab interferes with HER2 functioning in cardiac tissue, which manifests as left ventricular systolic dysfunction (Herrmann, 2020).

- (3) Off-target toxicity is observed when a nonselective TKI modulates the function of a kinase involved in normal vascular physiology and is not the target in cancer cells (Herrmann, 2020). A typical example is the unintended inhibition of the AMP-activated protein kinase (known as AMPK) by sunitinib, a mechanism that may be partially responsible for cardiomyopathy.

3. Incidence (Cardinale et al., 2020; McGowan et al., 2017; Zamorano et al., 2016)

- a) Cardiotoxicities resulting in left ventricular dysfunction or cardiomyopathy and heart failure are relatively common and serious side effects of cancer treatment. Heart failure due to cancer therapy has been linked to a 3.5-fold increased mortality risk compared with idiopathic cardiomyopathy (Bloom et al., 2016).

- b) Anthracyclines produce some degree of cardiac dysfunction in 50% of patients over a 10–20-year period after exposure. Approximately 3%–5%

develop overt heart failure (McGowan et al., 2017). Anthracycline-induced left ventricular dysfunction or heart failure may be classified as the following:

- (1) Acute-onset anthracycline-induced toxicity, which develops in 1% of patients, presents immediately after infusion and manifests as supraventricular arrhythmia, ECG changes, and transient decline in myocardial contractility, which is usually present and reversible.
  - (2) Early-onset, chronic progressive, anthracycline-induced cardiotoxicity occurs during therapy or within the first year after treatment in 1.6%–2.1% of patients (Cardinale et al., 2020).
  - (3) Late-onset, chronic progressive, anthracycline-induced cardiotoxicity occurs one year or later after completion of therapy in 1.6%–5% of patients. Late-occurring cardiotoxicity may not be clinically evident until 10–20 years after the first dose of treatment (Bloom et al., 2016; Cardinale et al., 2020), with a median of 7 years after treatment (Zamorano et al., 2016).
- c) Trastuzumab-induced cardiotoxicity does not appear to be cumulative dose dependent and is associated with reversible cardiomyocyte dysfunction, which typically recovers after treatment discontinuation of the targeted agent and initiation of heart failure therapy (Nemeth et al., 2017).
- (1) Patients who received the combination therapy of trastuzumab with anthracyclines have a higher chance of developing left ventricular dysfunction or heart failure (Nemeth et al., 2017).
  - (2) Adjuvant trastuzumab after anthracyclines and paclitaxel is associated with a 4%–18.6% incidence of left ventricular dysfunction and 1.6%–3.3% incidence of heart failure (Nemeth et al., 2017).
- d) Bevacizumab, a humanized monoclonal antibody against VEGF, has an adverse complication of heart failure (14% incidence) (Wolters Kluwer Health, 2021).
4. Risk factors
- a) Anthracycline-induced cardiotoxicity (Cardinale et al., 2020)
    - (1) Lifetime cumulative dose (Camp-Sorrell, 2018)
    - (2) Infusion regimen
    - (3) Preexisting cardiac disease
    - (4) Preexisting hypertension
    - (5) Concomitant use of other chemotherapy agents known to cause cardiotoxicity (e.g., cyclophosphamide, trastuzumab, paclitaxel)
    - (6) History of prior mediastinal radiation therapy
    - (7) Female sex
    - (8) Age younger than 5 years or older than 65 years
    - (9) Increased length of time since completion of chemotherapy
    - (10) Increase in biomarkers (e.g., troponins, natriuretic peptides) during and after administration (Zamorano et al., 2016)
  - b) Trastuzumab-induced cardiotoxicity (Dempsey et al., 2021)
    - (1) Age older than 50 years
    - (2) Borderline LVEF before treatment
    - (3) History of cardiovascular disease
    - (4) Presence of cardiovascular risk factors (e.g., diabetes, dyslipidemia, elevated body mass index greater than 30 kg/m<sup>2</sup>)
    - (5) Prior treatment with anthracyclines
    - (6) Genetic predisposition and immune status
5. Clinical manifestation (Metra & Teerlink, 2017)
- a) Signs
    - (1) Edema: lower-extremity swelling, abdominal ascites
    - (2) Jugular venous distension
    - (3) Hepatomegaly: enlarged liver
    - (4) Abnormal heart sounds: S<sub>3</sub> gallop, murmurs
    - (5) Tachycardia
    - (6) Hypotension
    - (7) Tachypnea
    - (8) Abnormal lung sounds: crackles
  - b) Symptoms
    - (1) Fatigue, weakness, exercise intolerance
    - (2) Dyspnea
    - (3) Orthopnea
    - (4) Paroxysmal nocturnal dyspnea
    - (5) Increased abdominal girth
    - (6) Frequent coughing, especially at night when lying flat
    - (7) Sudden weight gain
6. Assessment
- a) Perform a comprehensive history and physical assessment.
  - b) Obtain a history of treatments received for cancer therapy.
  - c) Determine the etiology of heart failure (e.g., ischemic vs. nonischemic).
  - d) Classify the presenting syndrome (e.g., acute vs. chronic; systolic vs. diastolic).
  - e) Identify concomitant disease relevant to heart failure (e.g., amyloidosis, hemochromatosis).

- f) Evaluate for the presence of coronary artery disease and valvular problems.
  - g) Assess the severity of symptoms.
  - h) Perform diagnostic and interventional procedures as needed (e.g., cardiac catheterization).
7. Collaborative management and prevention (Metra & Teerlink, 2017)
- a) Identify precipitating factors for acute decompensated heart failure.
    - (1) Patient-related factors
      - (a) Nonadherence to medications
      - (b) Excessive salt intake
      - (c) Physical and environmental stressors
    - (2) Cardiac-related factors
      - (a) Cardiac arrhythmias (e.g., atrial fibrillation, ventricular fibrillation, bradyarrhythmias)
      - (b) Uncontrolled hypertension
      - (c) Acute myocardial infarction
      - (d) Valvular disease, worsening mitral regurgitation
    - (3) Caution with concomitant medications
      - (a) Steroids
      - (b) Chemotherapy (e.g., doxorubicin, cyclophosphamide)
      - (c) Nonsteroidal anti-inflammatory drugs
      - (d) Thiazolidinediones
  - b) Establish the diagnosis of left ventricular dysfunction or heart failure.
    - (1) Echocardiography to assess left ventricular function
    - (2) Chest x-ray to evaluate for pulmonary edema, pleural effusion, and cardiomegaly
    - (3) Nuclear imaging to detect the location and severity of coronary artery disease
    - (4) Coronary angiography to evaluate coronary artery disease
    - (5) Endomyocardial biopsy to diagnose anthracycline-induced cardiomyopathy
    - (6) Thyroid profile to evaluate for hypothyroidism or hyperthyroidism as heart failure etiology
    - (7) Viral titers to evaluate causes of myocarditis, endocarditis, and pericarditis
    - (8) Iron studies to evaluate for hemochromatosis resulting in heart failure
  - c) Commonly recommended pharmacologic therapies for heart failure include the following:
    - (1) Angiotensin-converting enzyme inhibitors
    - (2) Angiotensin receptor blocker
    - (3) Aldosterone antagonists
    - (4) Cardiac glycosides
    - (5) Direct-acting vasodilator
8. Patient and family education
- a) Dietary modifications: Instruct patients on sodium restriction to 2,000 mg daily to prevent volume overload.
  - b) Physical activity: Encourage physical activity, except during periods of acute exacerbation when physical rest is recommended.
  - c) Weight monitoring: Patients should be advised to perform daily weight monitoring and notify their healthcare provider in case of sudden and unexpected weight gain (more than 2 pounds per day for two consecutive days or more than 5 pounds per week) for possible adjustment of diuretic dose.
  - d) Alcohol intake: Moderate intake (one drink per day for women and two drinks per day for men) is permitted except in cases of alcoholic cardiomyopathy.
  - e) Encourage smoking cessation.
- G. Myocarditis
1. Definition: Myocarditis is an infrequent but often lethal cardiac complication characterized by inflammation of the myocardium, resulting from anticancer therapeutics commonly referred to as immune checkpoint inhibitors or blockers (Ribas & Wolchok, 2018).
  2. Pathophysiology
    - a) The precise mechanisms by which immune checkpoint inhibitors cause cardiotoxicity remain undefined (Moslehi et al., 2021).
    - b) Suggested mechanisms include a shared antigen between the tumor and myocardium, T-cell receptor targeting a different but homologous muscle antigen as the tumor antigen, or certain T-cell receptors targeting dissimilar antigens (Johnson et al., 2016).
  3. Incidence
    - a) The true incidence of myocarditis associated with immune checkpoint inhibitors is likely underestimated due to a combination of factors, including the lack of specificity in the clinical presentation, the potential of overlap with other cardiovascular and general medical illnesses, the challenges in the diagnosis, and a general lack of awareness of this condition (Ganatra & Neilan, 2018; Moslehi et al., 2021).
    - b) Reports suggest that the incidence of immune checkpoint inhibitor-associated myocarditis is 0.27%–1.14% (Johnson et al., 2016; Mahmood et al., 2018). However, the true incidence may be higher, as initial reports identified only severe cases (Norwood et al., 2017).
    - c) The prevalence of immune checkpoint inhibitor-associated myocarditis is higher with

combination immunotherapies. Pharmacovigilance data suggest that a combination of ipilimumab and nivolumab is accompanied by a 4.74-fold risk of myocarditis compared with nivolumab alone (Johnson et al., 2016).

#### 4. Risk factors

- a) Combination therapy of anti-cytotoxic T-lymphocyte antigen 4 and anti-programmed cell death protein 1 agents appears to be the strongest risk factor.
- b) Cardiac-related, immune-related, and cancer-related risk factors impact the risk for immune checkpoint inhibitor-associated myocarditis (Wang et al., 2017).
- c) Genetic variation, including germline or somatic (i.e., in the tumor), may contribute to the development of immune checkpoint inhibitor-associated myocarditis (Moslehi et al., 2021).

#### 5. Clinical manifestations

- a) The clinical presentation of immune checkpoint inhibitor-associated myocarditis is variable. Myocarditis typically occurs early, with elevated troponin, may present with a normal LVEF, and may have a fulminant course.
- b) Fulminant cases are characterized by early onset following treatment, arrhythmias and conduction disturbances, concomitant skeletal myositis and myasthenia gravis, and sudden death (Escudier et al., 2017; Mahmood et al., 2018; Moslehi et al., 2018; Salem et al., 2018).
- c) Diagnosing myocarditis in patients treated with immune checkpoint inhibitors can be challenging. A multipronged approach has been proposed to rule out other causes for symptomatology, such as acute coronary syndromes.
- d) Diagnostic tests can include a combination of cardiac biomarkers, cardiac imaging, and endomyocardial biopsy (Bonaca et al., 2019).
- e) Endomyocardial biopsy is considered the gold standard for diagnosing myocarditis (Caforio et al., 2017; Moslehi et al., 2019). The histopathologic features of immune checkpoint inhibitor-associated myocarditis involve myocardial infiltration of T lymphocytes (cluster of differentiation [CD]4+ and CD8+) and macrophages, and myocyte death (Johnson et al., 2016).

#### 6. Assessment

- a) Assess for symptoms of myocarditis, which include chest pain, fatigue, fast or abnormal heartbeat, shortness of breath, and lower extremity edema.
- b) Currently, no consensus exists regarding screening, surveillance, prevention, or treatment strate-

gies for immune checkpoint inhibitor-associated myocarditis (Moslehi et al., 2021).

- c) Baseline ECG and troponin levels are recommended in all patients (Ganatra & Neilan, 2018; Hu et al., 2019; Neilan et al., 2018; Wang et al., 2017).
- d) High-risk patients should undergo surveillance with serum troponin measurements after the initiation of treatment (Shafi et al., 2017).

#### 7. Collaborative management and prevention

- a) Treatments for myocarditis have been largely extrapolated from therapies for noncardiac immune checkpoint inhibitor-associated toxicities, including cessation of immune checkpoint inhibitors, supportive management, and glucocorticoids (Brahmer et al., 2018).
- b) Administer high steroid doses (e.g., methylprednisolone 1 g/kg), followed by a four- to six-week taper upon symptom improvement (Zhang et al., 2020).
- c) Consider initiating other immune modulators if patients are not responding clinically to steroids (Arangalage et al., 2017; Esfahani et al., 2019; Mahmood et al., 2018; Palaskas et al., 2020; Salem et al., 2018; Tay et al., 2017).
  - (1) Infliximab
  - (2) IV immunoglobulin
  - (3) Plasmapheresis
  - (4) Abatacept
  - (5) Alemtuzumab
  - (6) Antithymocyte globulin
  - (7) Mycophenolate

#### 8. Patient and family education

- a) Instruct patients that it is important to stay in close contact with their treatment center during immune checkpoint inhibitor therapy.
- b) Instruct patients that they will be monitored closely to detect potential immune-related adverse effects and to see how well immunotherapy is working against their cancer.
- c) Instruct patients that immune-related adverse events can range from mild to life threatening, can occur during or after treatment, and may affect one or more organ systems.
- d) Instruct patients regarding the side effects of steroid therapy, which include increased appetite, weight gain, mood changes, water retention, and high blood pressure.
- e) Corticosteroid therapy should not be discontinued suddenly. The healthcare team will instruct patients on lowering the dose slowly over several weeks.
- f) Oral corticosteroids can weaken the immune system's ability to fight fungal and *Pneumocystis jirovecii* pneumonia infections. The provider may prescribe an antifungal medica-

tion, such as fluconazole, and prophylaxis with trimethoprim-sulfamethoxazole.

- g) Patients treated with immune checkpoint inhibitors may be provided a wallet card that states the type of immunotherapy received, potential side effects, and contact numbers for the cancer care team.
- h) Instruct patients to notify all healthcare providers involved in their care that they are receiving or have received immunotherapy.

## CHAPTER 17

# Pulmonary Toxicities

### A. Overview

1. Pulmonary toxicity ranges from reversible short-term reactive airway disease to diffuse permanent fibrosis and structural destruction.
  - a) Cytotoxic drugs are a leading cause of pulmonary toxicity and account for 23%–51% of cases of drug-induced interstitial lung disease (ILD) (Conte et al., 2022; Skeoch et al., 2018). On rare occasions, these toxicities are fatal (Abdel-Rahman & Elhalawani, 2015; Kaku et al., 2022; Osawa et al., 2015).
  - b) The onset of pulmonary toxicities is variable and may occur acutely, within hours to days, or may be more long term, after many months to years (Skeoch et al., 2018; Thalambedu & El-Habr, 2020).
  - c) Pulmonary toxicities can occur as a consequence of chemotherapy, targeted therapy, or immunotherapy, with increasing risk and severity with combination therapies (Iwashita et al., 2021; National Comprehensive Cancer Network [NCCN], 2022a).
  - d) Drug-induced ILD is the most prevalent of the drug-induced pulmonary toxicities.
  - e) Additional pulmonary toxicities are emerging as multitargeted therapies become more common.
2. Determining the etiology of pulmonary signs and symptoms in patients with cancer can be challenging because drug-induced toxicity can mimic a broad spectrum of pathogenic causes, including infection and neoplasm (Leger et al., 2017). Consequently, it is imperative to understand the potential for toxicity and to detect pulmonary toxicity as early as possible.
  - a) Common symptoms of pulmonary toxicities are dyspnea, cough, chest pain, low-grade fever, and fatigue (Conte et al., 2022; Johkoh et al., 2021; NCCN, 2022a; Rapoport et al., 2021).
  - b) A computed tomography (CT) scan is the primary diagnostic test used to differentiate specific pulmonary conditions. However, histologic sampling may be necessary to determine the precise

pathology (Conte et al., 2022; Johkoh et al., 2021; Rapoport et al., 2021).

### B. ILD

1. ILD is a heterogeneous group of lung disorders involving damage to the alveoli and surrounding interstitium that culminates in inflammation and fibrosis. ILD includes acute chemotherapy-induced pneumonitis, pulmonary capillary permeability syndrome, chemotherapy-related acute respiratory distress syndrome, hypersensitivity/eosinophilic pneumonitis, cryptogenic (of unknown cause) organizing pneumonia, pulmonary fibrosis, and pulmonary alveolar proteinosis (Jouneau et al., 2020; Samarelli et al., 2021).
2. Pathophysiology
  - a) Postulated pathologic changes (Cottin, 2016; Jouneau et al., 2020; Podolanczuk et al., 2021; Samarelli et al., 2021)
    - (1) Injury to the lung parenchyma
    - (2) Inflammation of alveoli, alveolar cell walls, interstitial spaces, and terminal bronchioles
    - (3) Release of interleukins and transforming growth factors
    - (4) Destruction of the alveolar-capillary endothelium, leading to changes in interstitial fibroblasts
    - (5) Activation of fibroblasts and myofibroblasts, causing collagen deposition in the alveolar interstitium
    - (6) Pulmonary alveolar proteinosis–like changes, which may occur with long-term interstitial pneumonitis and may be linked to the severity of the disease
  - b) The disease results predominantly from inflammatory features (Samarelli et al., 2021).
    - (1) Fluid or bloody exudates in alveoli
    - (2) Fluid between alveoli (interstitial spaces) from the degradation of the alveolar wall
    - (3) Fibrosis and stiffening of vascular, airway, and alveolar walls

- c) Immune checkpoint inhibitors create a T-cell hyperexpansion with immune hyperactivity (Possick, 2017; Rapoport et al., 2021; Shannon et al., 2020).
    - (1) Direct interaction of T cells with healthy tissues
    - (2) High levels of cluster of differentiation (CD) 4 helper T cytokines and increased migration of cytolytic CD8 T cells and organ damage
    - (3) Programmed cell death-ligand 2 localized to antigen-presenting cells (e.g., macrophages) with toxic lung effects
    - (4) Direct lung injury caused by cytokines
  - d) Resolution results in scarring and fibrosis of tissue, beginning in the interstitium and later involving the alveolar sacs. Pulmonary fibrosis is the chronic continuation of some acute pneumonitis syndromes.
  - e) Stiff, noncompliant lungs have poor elasticity, which increases the work of breathing.
  - f) Chronic exposure to chemotherapy agents may result in changes in lung connective tissue, obliteration of alveoli, and dilation of air spaces, leading to a honeycomb appearance on x-rays and scans (Diederich, 2016).
  - g) Increased pulmonary pressure from connective tissue and fibrotic banding leads to pulmonary hypertension, cor pulmonale, and heart failure (Mathai & Danoff, 2016).
  - h) Cellular mechanisms of injury
    - (1) Direct damage: Some chemotherapy agents (e.g., high-dose cytarabine, bleomycin, mitomycin C) cause direct damage to the alveoli and capillary endothelium (Madabhavi et al., 2017; Saijo, 2018).
    - (2) Metabolic damage: Cyclophosphamide metabolism in the lung leads to the formation of alkylating metabolites and acrolein, which may cause toxicity (Patel, 1990).
    - (3) Multikinase inhibitors (e.g., sorafenib), including tyrosine kinase inhibitors (e.g., imatinib, dasatinib), and epidermal growth factor receptor inhibitors (e.g., cetuximab, panitumumab) impede alveolar repair mechanisms that can enhance the effect of previous lung injury (Vahid & Marik, 2008).
    - (4) Immune checkpoint inhibitors may produce a unique physiologic autoimmune response that results in interstitial pneumonitis, but exact mechanisms of pathology remain unclear. Incidence may increase when immune checkpoint inhibitors are given in combination with chemotherapy agents (Possick, 2017; Shannon et al., 2020; Teuwen et al., 2015).
  - (5) Acute onset of pulmonary edema (noncardiogenic) is related to cytokine-induced capillary leak syndrome (Siddall et al., 2017).
  - (6) Hemorrhagic pneumonitis is a parenchymal injury with microvascular bleeding similar to alveolar hemorrhage that occurs in alveolar and interstitial spaces (J.A. Park, 2021).
  - (7) Hypersensitivity pneumonitis is characterized by an acute, rapid-onset immunologic alveolar reaction that leads to capillary permeability, fluid extravasation, and lymphocytic or eosinophilic infiltration of the alveoli and interstitium, impeding gas exchange (Raghu et al., 2020).
  - (8) Cryptogenic organizing pneumonia, previously called bronchiolitis obliterans organizing pneumonia, is characterized by the development of fibrous connective tissue between and involving alveolar and bronchiolar spaces, inflammatory activation of autoimmune collagen deposition, and obstruction of the ventilating airways (Bellanger et al., 2015). It has been reported in patients with breast and lung cancer receiving chemoradiation (Epler & Kelly, 2020; Falcinelli et al., 2015).
  - (9) Pulmonary alveolar proteinosis (PAP) is a syndrome in which alveolar macrophages are dysfunctional, causing surfactant proteins and lipids to accumulate in the pulmonary alveoli and impeding gas exchange. Although the triggering mechanisms are not well understood, autoimmune activation is suspected. It is characterized by granulocyte macrophage-colony-stimulating factor deficiency. In hematologic malignancies, it is classified as secondary PAP, particularly myelodysplastic syndromes. It is unclear if it is triggered by medication exposure or immune deficits (Jouneau et al., 2020).
3. Incidence: ILD incidence varies based on the individual patient and medication-related factors. Pneumonitis syndromes are infrequent.
    - a) Incidence increases when pulmonary-toxic agents are administered concomitantly with thoracic irradiation (Arroyo-Hernández et al., 2021).
    - b) Incidence is influenced by cumulative dose with some agents (Leger et al., 2017).

- c) Combining agents with similar pulmonary toxicities may enhance the risk for adverse effects (Leger et al., 2017; Teuwen et al., 2015).
  - d) The incidence of pneumonitis is higher in specific populations, even when equivalent drug exposure has been experienced. Immune checkpoint inhibitor-induced pneumonitis is more common among patients with lung cancer and renal cell cancer than those with melanoma (Possick, 2017; Shannon et al., 2020) and when combination immune checkpoint inhibitor therapy is administered (Gutierrez et al., 2020).
4. Risk factors
- a) General patient-specific risk factors (Ariad Pharmaceuticals, 2022; Handa et al., 2018; Podolanczuk & Putman, 2021)
    - (1) Advancing age causes an imbalance of cell types that can cause architectural distortion and the inability to cope with cumulative environmental insults (Schneider et al., 2021). This can lead to a susceptibility to pulmonary toxicity from certain cytotoxic drugs (Handa et al., 2018; Koshikawa et al., 2020).
    - (2) Tobacco smoking is associated with inflammation in the lung parenchyma (Dawod et al., 2020; Handa et al., 2018; Podolanczuk & Putman, 2021).
    - (3) Deteriorating creatinine clearance that affects drug clearance can increase the risk of developing ILD (Handa et al., 2018; Koshikawa et al., 2020).
    - (4) Previous treatment with bleomycin had been known to increase the risk of pulmonary complications in the postoperative setting. It is generally accepted that oxygen administration can increase the risk of bleomycin toxicity, and the standard practice is to limit oxygen administration. However, it remains unclear whether the threshold and duration of oxygen therapy can increase toxicity in patients treated with bleomycin (Aakre et al., 2014).
    - (5) Prior lung disease (e.g., chronic obstructive pulmonary disease) or reduced lung reserve can increase the risk of ILD development (Handa et al., 2018; Willemsen et al., 2016).
    - (6) Autoimmune disease enhances the release of inflammatory mediators that increase drug-related pulmonary toxicity (Tewwen et al., 2015).
    - (7) Graft-versus-host disease is a risk factor due to acute and subacute patterns of lung injury (Abugideiri et al., 2016).
  - b) Treatment-related factors (see Table 17-1)
    - (1) The physiologic effects of specific antineoplastic agents on tissues, metabolism, immune activity, and epithelial and endothelial cells can cause the following (Conte et al., 2022; Iwashita et al., 2021; Long & Suresh, 2020).
      - (a) Bronchospasm
      - (b) Noncardiogenic pulmonary edema
      - (c) Hypersensitivity pneumonitis
      - (d) Cryptogenic organizing pneumonia
      - (e) Nonspecific cough and dyspnea
    - (2) It has not been determined whether any single drug is the causative agent or if the interaction of multiple antineoplastic agents results in enhanced toxicity (Desai et al., 2016; Leger et al., 2017).
    - (3) Concurrent chemotherapy and radiation therapy, especially with transplant therapies, has been associated with pneumonitis (Desai et al., 2016; Hanania et al., 2019).
    - (4) Increased toxicity with an increased dose results from drug accumulation in the lung. Two patterns of dose-related pulmonary toxicity are clinically observed (Leger et al., 2017).
      - (a) The threshold effect is the definitive increase in risk for pulmonary toxicity when a cumulative dose is reached.
        - i. Bleomycin: total lifetime dose exceeding 400 units (Hospira, 2021a)
        - ii. Busulfan: in the absence of other predisposing factors, a cumulative dose greater than 500 mg (Matijasic et al., 2019; Otsuka Pharmaceuticals, 2017)
        - iii. Mitomycin C: maximum dose of 30 mg/m<sup>2</sup> (Accord Healthcare, 2018)
        - iv. Lomustine: dose greater than 1,100 mg/m<sup>2</sup> (NextSource Biotechnology, 2018)
      - (b) The linear effect is the risk of increased pulmonary toxicity as more of the drug per dose is administered (e.g., carmustine at a cumulative dose greater than 1,400 mg/m<sup>2</sup>) (Amneal Pharmaceuticals, 2018).
    - (5) Risk with thoracic radiation therapy is related to exposure to ionizing radiation dose and fractionation (Arroyo-Hernández et al., 2021; Bledsoe et al., 2017).

**TABLE 17-1.** Pulmonary Toxicities of Antineoplastic Agents

| Classification             | Drug                                                               | Adverse Effects, Signs, and Symptoms                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                             |

| Alkylating agents<br>( <i>Cont.</i> ) | Temozolomide<br>(Temodar®) | Interstitial pneumonitis, alveolitis, pulmonary fibrosis, <i>Pneumocystis</i> pneumonia                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Establish baseline pulmonary function and reassess when any respiratory symptoms occur.<br>Advise patients of the increased risk of <i>Pneumocystis jirovecii</i> pneumonia and to contact their healthcare provider immediately for new or worsening pulmonary symptoms. (Merck, 2022c)                                                                                                                                                                                                                                                                                        |
| Antimetabolites                       | Capecitabine<br>(Xeloda®)  | Interstitial pneumonitis, dyspnea, cough, respiratory distress                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Advise patients to report symptoms of pulmonary toxicity. (Genentech, 2021e)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                                       | Cytarabine<br>(Cytosar®)   | Noncardiogenic pulmonary edema (previously known as cytarabine syndrome), a syndrome of sudden respiratory distress, rapidly progressing to pulmonary edema, capillary leak syndrome, respiratory failure, and ARDS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Continuous infusion cytarabine is associated with pulmonary toxicity (fluid overload). (Hospira, 2020; Nucci et al., 2015; Sanz & Montesinos, 2014)                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                                       | Fludarabine                | Severe pulmonary toxicity resulting in ARDS, respiratory distress, pulmonary hemorrhage, respiratory failure, pneumonitis, and pulmonary fibrosis<br>Pulmonary hypersensitivity reactions, such as dyspnea, cough, and interstitial pulmonary infiltrate                                                                                                                                                                                                                                                                                                                                                                                                                                             | Avoid concurrent use with pentostatin due to the risk of fatal pulmonary toxicity. (Hospira, 2018a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                                       | Gemcitabine<br>(Gemzar®)   | Pulmonary edema, ILD, pulmonary fibrosis, ARDS<br>The onset of pulmonary symptoms may occur up to 2 weeks after the final dose.<br>Severe pulmonary toxicities (including death) are likely related to bronchospastic events, capillary permeability-induced pulmonary edema, or diffuse alveolar hemorrhage.                                                                                                                                                                                                                                                                                                                                                                                        | Increased toxicity occurs with multiple weekly doses and prolonged infusion time beyond 60 minutes.<br>The drug should be discontinued for unexplained dyspnea or other evidence of severe pulmonary toxicity.<br>Advise patients of the risks of pulmonary toxicity, including respiratory failure and death. Instruct patients to immediately contact their healthcare provider with the development of shortness of breath, wheezing, or cough. (Eli Lilly and Company, 2019b)                                                                                               |
|                                       | Methotrexate               | Hypersensitivity pneumonitis, pulmonary fibrosis, organizing pneumonia; fever, dyspnea, cough (especially dry, nonproductive), nonspecific pneumonitis, or chronic interstitial obstructive pulmonary disease (deaths have been reported); pulmonary infiltrates<br>Acute or chronic interstitial pneumonitis and <i>Pneumocystis jirovecii</i> pneumonia may occur with methotrexate therapy.<br>A higher risk for complications is associated with older age, previous use of disease-modifying immunosuppressive drugs, pre-existing lung disease, abnormal baseline PFTs, daily dosing rather than weekly administration, and decreased elimination of methotrexate (e.g., renal insufficiency). | Methotrexate-induced lung disease, including acute or chronic interstitial pneumonitis, is a potentially dangerous condition that may occur acutely at any time during therapy and has been reported at low doses. It is not always fully reversible, and fatalities have been reported. Pulmonary symptoms (especially a dry, nonproductive cough) may require treatment interruption and careful investigation.<br>PFTs may be useful with suspected methotrexate-induced lung disease, especially if baseline measurements are available. (Balk, 2022; Fresenius Kabi, 2020) |

| <b>Chemotherapy Agents (Cont.)</b> |                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Antimetabolites<br>(Cont.)         | Pemetrexed<br>(Alimta®)               | Interstitial pneumonitis, including fatal cases<br>Alveolar hemorrhage (rare), ILD, and pleural effusions have been reported. Dyspnea, cough, and fever are presenting symptoms of interstitial pneumonitis.<br>ILD presents initially as dyspnea without pulmonary infiltrates and is reported within the first five courses of therapy.<br>Pulmonary infiltrates are diffuse with ground-glass opacities.<br>Pleural effusions occur in 7%–12% of patients and are more common if premedication with corticosteroids is not administered.                                                                                            | Establish baseline pulmonary function and imaging for comparison if respiratory symptoms develop.<br>Withhold pemetrexed for acute onset of new or progressive unexplained pulmonary symptoms, such as dyspnea, cough, or fever, pending diagnostic evaluation. If pneumonitis is confirmed, permanently discontinue pemetrexed.<br>(Adhikari et al., 2016; Breuer & Nechushtan, 2012; Eli Lilly and Company, 2019a; Hochstrasser et al., 2012; Tomii et al., 2017)                                                                                                      |
|                                    | Pentostatin<br>(Nipent™)              | Infection risk, cough<br>Increased risk of fatal pulmonary toxicity when used in combination with fludarabine<br>Acute pulmonary edema in the transplant setting                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Concurrent administration of fludarabine is not recommended due to severe or fatal pulmonary toxicity.<br>(Hospira, 2019)                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Antitumor antibiotics              | Bleomycin sulfate<br>(Blenoxane®)     | Hypersensitivity pneumonitis, pulmonary fibrosis, pulmonary VOD, organizing pneumonia, spontaneous pneumothorax<br>Characteristics of bleomycin-induced pneumonitis include dyspnea and fine rales.                                                                                                                                                                                                                                                                                                                                                                                                                                    | Early toxicity may be self-resolving. Monitor for early warning signs of toxicity to avoid irreversible pulmonary damage.<br>Chest x-rays should be taken every 1–2 weeks. If pulmonary changes are noted, treatment should be discontinued.<br>Increasing toxicity warrants prudently maintaining oxygen levels at room air (25%).<br>(Hospira, 2021b)                                                                                                                                                                                                                  |
|                                    | Mitomycin C<br>(Mitosol®, Mutamycin®) | Bronchospasm, noncardiogenic pulmonary edema, ILD, pulmonary VOD<br>Dyspnea, nonproductive cough, crackles, and capillary leak with progressive respiratory dysfunction indicate ILD.<br>Severe bronchospasm has been reported following administration of vinca alkaloids in patients who previously or simultaneously received mitomycin C. Acute respiratory distress occurring within minutes to hours after the vinca alkaloid injection has been reported. The total doses for each drug has varied considerably.<br>Pulmonary VOD occurs later after exposure (up to 10 years) and leads to symptoms of pulmonary hypertension. | Signs and symptoms of pneumonitis may be reversed if therapy is instituted early.<br>The drug may be discontinued if dyspnea occurs, even with a normal chest x-ray.<br>Caution should be exercised when using oxygen because toxic oxygen injury occurs without other medication-related etiologic precipitators.<br>Pulmonary toxicity with mitomycin can be severe and may be life threatening. Dyspnea with a nonproductive cough and radiographic evidence of pulmonary infiltrates may indicate mitomycin-induced pulmonary toxicity.<br>(Accord Healthcare, 2018) |
|                                    | Mitoxantrone<br>(Novantrone®)         | Hypersensitivity pneumonitis, ILD, organizing pneumonia, sudden-onset dyspnea and tachypnea with hypoxemia, patchy infiltrates on x-ray or computed tomography scan, cough<br>Toxicity usually only occurs when the drug is given with other potentially pulmonary toxic medications.<br>Interstitial pneumonitis has been reported in those receiving mitoxantrone as part of combination chemotherapy.                                                                                                                                                                                                                               | In severe cases, treatment with corticosteroids has produced a rapid response.<br>(Hospira, 2021c; Maldonado et al., 2022b)                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Chemotherapy Agents (Cont.)</b>  |                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Nitrosoureas<br>( <i>Cont.</i> )    | Carmustine<br>(BiCNU)<br>( <i>Cont.</i> )                       | developing pulmonary toxicity at total cumulative doses of 1,500 mg/m <sup>2</sup> . Risk factors include preexisting lung disease, smoking, cyclophosphamide therapy, and recent (within months) thoracic irradiation. Patients with baseline forced vital capacity or diffusing capacity of the lung for carbon monoxide < 70% of the predicted value are at high risk. Delayed toxicity after childhood treatment has increased mortality compared to toxicities from other causes. Other risks for increased pulmonary toxicity with carmustine include a history of lung disease and treatment duration.                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                                     | Lomustine<br>(Gleostine®)                                       | ILD, pulmonary fibrosis<br>Pulmonary toxicity onset is characterized by an interval of 6 months or longer from the start of therapy with cumulative doses of lomustine usually > 1,100 mg/m <sup>2</sup> . Delayed-onset pulmonary fibrosis occurring up to 17 years after treatment has been reported in patients who received nitrosoureas in childhood and early adolescence (aged 1–16 years) combined with cranial irradiation for intracranial tumors.                                                                                                                                                                                                                       | Establish baseline pulmonary function.<br>Monitor high-risk patients with PFTs.<br>Permanently discontinue if patient is diagnosed with pulmonary fibrosis.<br>(NextSource Biotechnology, 2018)                                                                                                                                                                                                                                                                                              |
| Plant alkaloids: epipodophylotoxins | Etoposide<br>(Toposar®),<br>etoposide phosphate<br>(Etopophos®) | Bronchospasm, interstitial pneumonitis, pulmonary fibrosis, pulmonary hypertension, pulmonary edema<br>Anaphylactic-like reactions have occurred during the initial infusion of etoposide. Facial or tongue swelling, coughing, diaphoresis, cyanosis, tightness in the throat, laryngospasm, back pain, and loss of consciousness have occurred. An apparent hypersensitivity-associated apnea has been reported rarely.<br>Toxicity is increased with low serum albumin and impaired renal function.<br>Increased methotrexate blood levels occurred when drugs were given concomitantly, but it is unclear whether this is due to etoposide interaction or decreased clearance. | Following bronchospasm, patients have been premedicated and successfully rechallenged with etoposide.<br>Chronic lung disease is difficult to identify, as this agent is usually administered with other pulmonary toxic agents.<br>(Bristol-Myers Squibb, 2019; Maldonado et al., 2022a)                                                                                                                                                                                                    |
| Plant alkaloids: taxanes            | Docetaxel<br>(Taxotere®)                                        | Bronchospasm, hypersensitivity pneumonitis, ILD, pleural effusion, noncardiogenic pulmonary edema                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Pleural effusions may be reversible with diuretics. Pulmonary fibrosis is not consistently responsive to corticosteroids. Hypersensitivity skin testing has been useful in the identification of reactions. Radiation pneumonitis may occur in patients receiving concomitant radiation therapy. The usual steroid dose to prevent pleural effusions is dexamethasone 4–8 mg the day prior to or the same day as docetaxel administration.<br>(Kuo et al., 2015; Sanofi-Aventis U.S., 2021b) |

|                                | Binimetinib (Mektovi <sup>®</sup> )  | ILD is a risk. Evaluate pulmonary symptoms that are new, unexplained, or progressive.                                                                                                                                                                                                                            | Hold drug during workup and permanently discontinue if determined to cause ILD or pneumonitis.<br>Instruct patients to report respiratory symptoms immediately.<br>(Array BioPharma, 2020)                                                                                                                                                                                                                                                                                                                                                                                                  |
|                                | Bortezomib (Velcade <sup>®</sup> )   | Pneumonitis; sudden respiratory distress with accompanying pulmonary infiltrates, interstitial pneumonia, ARDS, pulmonary hypertension, and acute diffuse infiltrative pulmonary disease; some of these events have been fatal. Toxicities have inconsistent reversibility or responsiveness to corticosteroids. | Immediate discontinuation of this drug is recommended when pulmonary symptoms occur.<br>(Maldonado et al., 2022a; Takeda Pharmaceuticals, 2021b)                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                                | Bosutinib (Bosulif <sup>®</sup> )    | Fluid retention, presenting as pulmonary edema or pleural effusion                                                                                                                                                                                                                                               | Advise patients to report shortness of breath and cough, especially with the presence of fluid retention.<br>(Pfizer, 2021a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                                | Brigatinib (Alunbrig <sup>®</sup> )  | ILD and pneumonitis usually occur early, within 9 days of initiation of medication. Adverse reactions, such as ILD and pneumonitis, can occur in varying grades of severity.                                                                                                                                     | Unlike similar kinase inhibitors, this drug has the potential for tolerization and continued dosing after pulmonary toxicity. Therefore, it should be initiated at a low dose and increased if tolerated without adverse effects in first 7 days. Monitor for new or worsening respiratory symptoms, such as dyspnea or cough, during the first week of treatment. If new or worsening respiratory symptoms occur, discontinue the drug and evaluate for ILD and pneumonitis. If ILD or pneumonitis is present, follow grade-specific dosage instructions.<br>(Ariad Pharmaceuticals, 2022) |
|                                | Capmatinib (Tabrecta <sup>®</sup> )  | ILD and pneumonitis (potentially fatal)                                                                                                                                                                                                                                                                          | Hold the drug during evaluation and discontinue permanently if ILD or pneumonitis occurs. Monitor for cough, dyspnea, and fever. Instruct patients to notify the healthcare team of respiratory symptoms.<br>(Novartis Pharmaceuticals, 2022e)                                                                                                                                                                                                                                                                                                                                              |
|                                | Carfilzomib (Kyprolis <sup>®</sup> ) | Potentially fatal respiratory events, including pulmonary toxicity (e.g., ARDS, acute respiratory failure, acute diffuse infiltrative pulmonary disease), pulmonary hypertension, and pulmonary hemorrhage                                                                                                       | Instruct patients to notify the healthcare team of respiratory symptoms.<br>(Onyx Pharmaceuticals, 2021)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                                | Ceritinib (Zykadia <sup>®</sup> )    | ILD and pneumonitis (potentially fatal)                                                                                                                                                                                                                                                                          | Discontinue medication for ILD or pneumonitis. Monitor for dyspnea, fever, and cough. Instruct patients to notify the healthcare team of respiratory symptoms.<br>(Novartis Pharmaceuticals, 2022h)                                                                                                                                                                                                                                                                                                                                                                                         |

|                                | Copanlisib<br>(Aliqopa®)   | Noninfectious pneumonitis                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Hold treatment if grade 1–2 adverse events occur. Resume treatment at 45 mg if recovery to grade 0 or 1. Discontinue if noninfectious pneumonitis recurs and is $\geq$ grade 3. Monitor for cough, dyspnea, hypoxia, or interstitial infiltrates on radiologic examination. Instruct patients to report any new or worsening respiratory symptoms.<br>(Bayer HealthCare Pharmaceuticals, 2022) |
|                                | Crizotinib<br>(Xalkori®)   | Dyspnea, ILD, pneumonitis, respiratory tract infections, ARDS, PE<br>ILD presents as dyspnea with pulmonary infiltrates. All cases of ILD presented within the first 2 months of therapy.<br>Reports of dyspnea warrant temporary discontinuation of agent until ILD can be ruled out.                                                                                                                                                                                                                                                                                                      | Coadministration of other pulmonary toxic agents or lung irradiation warrants frequent physical assessment and diagnostic tests, such as imaging or PFTs.<br>If treatment-related ILD is strongly suspected, permanent discontinuation of the drug is recommended.<br>(Kwon & Meagher, 2012; Pfizer, 2021c)                                                                                    |
|                                | Dacomitinib<br>(Vizimpro®) | ILD and pneumonitis are rare but serious and can be fatal, presenting as dyspnea, cough, and fever.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Advise patients to monitor respiratory status and to report new or worsening symptoms, including shortness of breath, cough, or fever. Discontinue the drug permanently if ILD is confirmed.<br>(Pfizer, 2020)                                                                                                                                                                                 |
|                                | Dasatinib<br>(Sprycel®)    | ILD, pleural effusion, pulmonary VOD, pulmonary arterial hypertension (e.g., dyspnea, fatigue, hypoxia, fluid retention), ARDS, PE<br>Most effusions are exudative and characterized by lymphocytic infiltration of the pleura. Lymphocytic effusion is associated with tumor response rates.<br>Most patients who develop grade 3–4 pleural effusions have accelerated- or blast-phase chronic myeloid leukemia.<br>Symptoms include dyspnea, cough, and chest pain.<br>Patients aged $\geq$ 65 years are more likely to experience pleural effusion, dyspnea, cough, and pulmonary edema. | Treatment may include interruption of medication and administration of diuretics or corticosteroids. Dose reduction may also be recommended.<br>(Bristol-Myers Squibb, 2021)                                                                                                                                                                                                                   |
|                                | Duvelisib<br>(Copiktra®)   | Serious and potentially fatal noninfectious pneumonitis cases are diagnosed between 4–9 months after treatment initiation and last for 1–2 months. Symptoms include cough, dyspnea, hypoxia, and interstitial infiltrates seen on radiology examination or decline in oxygen saturation of $> 5\%$ .                                                                                                                                                                                                                                                                                        | Hold the drug when grade 2 noninfectious pneumonitis occurs, and treat with corticosteroids. Resume at a reduced dose after resolution. If no response or recurrence, discontinue the drug.<br>Treat with systemic steroids and discontinue for severe or life-threatening pneumonitis. Educate patients to report new or worsening respiratory symptoms.<br>(Secura Bio, 2021)                |
|                                | Enasidenib<br>(Idhifa®)    | Acute respiratory distress, pulmonary infiltrates, pleural effusions, differentiation syndrome                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Monitor for signs of differentiation syndrome and symptoms of dyspnea, pleural effusion, and pulmonary edema.<br>(Celgene, 2020b)                                                                                                                                                                                                                                                              |

| <b>Targeted Agents (Cont.)</b> |                          |                                                                                                                                          |                                                                                                                                                                                                                                                              |
|                                | Lapatinib (Tykerb®)      | ILD and pneumonitis                                                                                                                      | Monitor for cough and dyspnea. Discontinue the drug in patients with $\geq$ grade 3 ILD or pneumonitis. (Novartis Pharmaceuticals, 2022f)                                                                                                                    |
|                                | Lorlatinib (Lorbrena®)   | ILD and pneumonitis                                                                                                                      | Hold the drug in patients with suspected ILD or pneumonitis. Permanently discontinue with ILD or pneumonitis of any severity. (Pfizer, 2021b)                                                                                                                |
|                                | Midostaurin (Rydapt®)    | Pulmonary complications include upper respiratory tract infection, dyspnea, and ILD and pneumonitis.                                     | Monitor for symptoms of pulmonary complications. Discontinue if noninfectious ILD or pneumonitis occurs. Advise patients to monitor for and report cough, chest discomfort, or dyspnea. (Novartis Pharmaceuticals, 2021c)                                    |
|                                | Mobocertinib (Exkivity®) | ILD and pneumonitis (potentially fatal)                                                                                                  | Hold the drug for suspected ILD or pneumonitis. Discontinue if confirmed. Advise patients to report cough, dyspnea, or chest pain. (Takeda Pharmaceuticals, 2021a)                                                                                           |
|                                | Olaparib (Lynparza®)     | Pneumonitis (potentially fatal), cough, dyspnea, fever, radiologic abnormalities, respiratory tract infections                           | Hold the drug for suspected ILD or pneumonitis. Discontinue if confirmed. Advise patients to report shortness of breath, fever, cough, or wheezing. (AstraZeneca Pharmaceuticals, 2022b)                                                                     |
|                                | Osimertinib (Tagrisso®)  | ILD or pneumonitis (potentially fatal), presenting as cough, dyspnea, fever                                                              | Discontinue permanently with the presence of ILD or pneumonitis. Advise patients to report cough, dyspnea, or fever. (AstraZeneca Pharmaceuticals, 2022c)                                                                                                    |
|                                | Palbociclib (Ibrance®)   | ILD or pneumonitis (severe and potentially fatal) when administered concurrently with endocrine therapy                                  | Hold the drug to evaluate respiratory symptoms. Permanently discontinue the drug with the presence of ILD or pneumonitis. Advise patients to report cough, dyspnea, or hypoxia. (Pfizer, 2019)                                                               |
|                                | Pazopanib (Votrient®)    | Pneumothorax may present as dyspnea, chest pain, and localized limb edema. ILD and pneumonitis present with cough, dyspnea, and hypoxia. | Permanently discontinue the drug with the presence of ILD or pneumonitis. Advise patients to report persistent cough and dyspnea. (Novartis Pharmaceuticals, 2022g)                                                                                          |
|                                | Pralsetinib (Gavreto®)   | ILD and pneumonitis (potentially fatal)                                                                                                  | Hold the drug with grade 1–2 pneumonitis. Resume at a reduced dose after resolution. Discontinue the drug for severe or life-threatening grade 3–4 pneumonitis. Advise patients to monitor for and report worsening respiratory symptoms. (Genentech, 2022a) |

| <b>Immunotherapy Agents (Cont.)</b> |                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Monoclonal antibodies: chimeric     | Brentuximab vedotin (anti-CD20 antibody; Adcetris®)                  | Upper respiratory tract infection, pneumonitis, pneumonia, cough, ILD, ARDS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Monitor patients for signs and symptoms of pulmonary toxicity, including cough and dyspnea.<br>If new or worsening pulmonary symptoms occur, hold the drug during evaluation until symptomatic improvement.<br>Concomitant use with bleomycin is contraindicated because of pulmonary toxicity. (Seagen, 2022)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                                     | Cetuximab (anti-epidermal growth factor receptor antibody; Erbitux®) | Dyspnea, cough, ILD (a fatality occurred in a clinical trial)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Premedicate with an H <sub>1</sub> receptor antagonist to decrease the risk of an infusion reaction.<br>For acute or worsening pulmonary symptoms, delay infusion 1–2 weeks; if the condition improves, continue at the dose being administered at the time of occurrence. If no improvement in 2 weeks or ILD is confirmed, discontinue the drug.<br>Advise patients to contact their healthcare provider immediately for new or worsening cough, chest pain, shortness of breath, and signs and symptoms of infusion reactions. (ImClone, 2021)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                                     | Isatuximab-irfc (Sarclisa®)                                          | Pneumonia, upper respiratory tract infection, bronchitis, cough (may be productive or allergic cough), dyspnea<br>The most common symptoms of an infusion-related reaction are dyspnea and cough.<br>Upper respiratory tract infections include acute sinusitis, chronic sinusitis, H1N1 influenza, H3N2 influenza, influenza, laryngitis, viral laryngitis, nasal herpes, nasopharyngitis, pharyngitis, pharyngotonsillitis, respiratory syncytial virus infection, rhinitis, bacterial sinusitis, tonsillitis, tracheitis, viral rhinitis, viral respiratory tract infection, and influenza-like illness.<br>Examples of pneumonia include atypical pneumonia, viral lower respiratory tract infection, <i>Pneumocystis jirovecii</i> pneumonia, influenzal pneumonia, <i>Legionella</i> pneumonia, <i>Streptococcus</i> pneumonia, respiratory syncytial virus, viral pneumonia, pulmonary sepsis, and pulmonary tuberculosis.<br>Bronchitis examples include viral bronchitis, respiratory syncytial virus bronchitis, chronic bronchitis, and tracheobronchitis. | Infusion-related reactions, including life-threatening anaphylactic reactions, have occurred. Severe signs and symptoms include bronchospasm and dyspnea.<br>To decrease the risk and severity of infusion-related reactions, premedicate patients with acetaminophen, H <sub>2</sub> antagonists, diphenhydramine or equivalent, and dexamethasone.<br>For patients with ≥ grade 2 reactions, interrupt the infusion and provide appropriate medical management. If symptoms improve to ≤ grade, restart infusion at half of the initial infusion rate, with supportive care as needed, and closely monitor patients.<br>If symptoms do not recur after 30 minutes, the infusion rate may be increased to the initial rate and then increased incrementally.<br>If symptoms do not improve after treatment interruption, persist or worsen despite appropriate medications, or require hospitalization, permanently discontinue the drug and institute appropriate management. If an anaphylactic or life-threatening (grade 4) infusion reaction occurs, permanently discontinue the drug.<br>Advise patients to contact their healthcare provider immediately for shortness of breath, wheezing, cough, trouble breathing, and signs and symptoms of infusion reactions. |                                                  | Rituximab and hyaluronidase (Rituxan Hycela <sup>®</sup> )       | Dyspnea, upper respiratory infection, pneumonia, bronchitis, cough, hypersensitivity reaction<br>Severe cytokine release syndrome is characterized by severe dyspnea, which is often associated with bronchospasm and hypoxia. This can also be related to respiratory failure and death. Patients with a history of pulmonary insufficiency or those with pulmonary tumor infiltration may be at a greater risk of poor outcomes.<br>Postmarketing studies have identified fatal bronchiolitis obliterans and ILD.                                                                                                                | Advise patients to contact their healthcare provider immediately for symptoms of infusion-related reactions, such as sudden cough and breathing problems, and infections, such as flu symptoms with cough. (Genentech, 2022c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Monoclonal antibodies: human                     | Daratumumab (anti-CD38 antibody; Darzalex <sup>®</sup> )         | Upper respiratory infection; pneumonia, infusion-related reactions; systemic administration-related reactions, including respiratory symptoms (e.g., bronchospasm, nasal congestion, cough [may be productive], throat irritation, allergic rhinitis, and wheezing); cough; dyspnea; pulmonary edema<br>Infections include bronchiolitis, bronchitis, viral bronchitis, respiratory syncytial virus, tracheobronchitis, atypical pneumonia, bronchopulmonary aspergillosis, lung infection, <i>Pneumocystis jirovecii</i> pneumonia, aspiration pneumonia, <i>Streptococcus</i> pneumonia, viral pneumonia, and pulmonary mycosis. | Postmedication recommended for patients with a history of COPD includes consideration of short- and long-acting bronchodilators and inhaled corticosteroids following the first 4 doses of medication. Consider discontinuing these additional postmedications if patients do not experience a major systemic administration-related reaction.<br>For infusion-related reactions of any grade or severity, immediately interrupt the infusion and manage symptoms.<br>For grade 1–2 (mild to moderate) events, once reaction symptoms resolve, resume the infusion at no more than half the rate at which the reaction occurred. If patients do not experience any further reaction symptoms, infusion rate escalation may resume at increments and intervals as clinically appropriate (up to the maximum rate of 200 ml/hour). |

| Monoclonal antibodies: human ( <i>Cont.</i> ) | Daratumumab (anti-CD38 antibody; Darzalex*) ( <i>Cont.</i> )               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | For grade 3 (severe) events, once symptoms resolve, consider restarting the infusion at no more than half the rate at which the reaction occurred. If patients do not experience additional symptoms, resume infusion rate escalation at increments and intervals as clinically appropriate. Repeat the procedure in the event of recurrence. Permanently discontinue the drug on the third occurrence of $\geq$ grade 3 reaction.<br>For grade 4 (life-threatening) events, permanently discontinue the drug.<br>Fatal infections were caused by pneumonia. (Janssen Biotech, 2022a)                                                                                          |
|                                               | Daratumumab and hyaluronidase-fihj (Darzalex Faspro®)                      | Upper respiratory infection is the most common adverse reaction and includes nasopharyngitis, respiratory syncytial virus infection, respiratory tract infection, rhinitis, tonsillitis, upper respiratory tract infection, and viral pharyngitis.<br>Pneumonia includes lower respiratory tract infection, lung infection, <i>Pneumocystis jirovecii</i> pneumonia, bacterial pneumonia, cough (may be productive), dyspnea, bronchitis, pulmonary edema, influenza, systemic administration-related reactions (e.g., respiratory symptoms, such as bronchospasm, nasal congestion, cough, throat irritation, allergic rhinitis, and wheezing), and respiratory failure. | Postmedication recommended for patients with a history of COPD includes consideration of short- and long-acting bronchodilators and inhaled corticosteroids following the first 4 doses of medication. Consider discontinuing these additional postmedications if patients do not experience a major systemic administration-related reaction. Advise patients to seek immediate medical attention for any signs and symptoms of systemic administration-related reactions, including cough, shortness of breath, or difficulty breathing. (Janssen Biotech, 2022b)                                                                                                            |
|                                               | Ofatumumab (anti-CD20 antibody; Arzerra®) for chronic lymphocytic leukemia | Upper and lower respiratory tract infections, pneumonia, cough, dyspnea, bronchitis, infusion-related reaction (e.g., bronchospasm, pulmonary edema, dyspnea)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Infusion-related reactions occur more frequently with the first 2 infusions. To prevent infusion-related reactions, premedicate with acetaminophen, an antihistamine, and a corticosteroid. Infusion-related reactions may occur despite premedication. Interrupt infusion for infusion-related reactions of any severity. Institute medical management for severe infusion-related reactions. If an anaphylactic reaction occurs, immediately and permanently discontinue the drug and initiate appropriate medical treatment. Advise patients to contact their healthcare provider for any signs of infections, including fever and cough. (Novartis Pharmaceuticals, 2021b) |

| Monoclonal antibodies: humanized ( <i>Cont.</i> ) | Obinutuzumab (Gazyva <sup>®</sup> )                                                                                                          | Cough, dyspnea, infusion-related reactions, respiratory symptoms (e.g., bronchospasm, larynx and throat irritation, wheezing, laryngeal edema), hypersensitivity reaction, upper and lower respiratory infection, pneumonia                                                                                                   | See package insert for instructions regarding premedication to prevent and treat infusion-related reactions. (Genentech, 2022b)                                                                                                                                                                                                                                                                                                                                                                                                              |
|                                                   | Pertuzumab (Perjeta <sup>®</sup> )                                                                                                           | Upper respiratory infection, dyspnea, cough, infusion-related reactions                                                                                                                                                                                                                                                       | Advise patients to contact their healthcare provider immediately for new-onset or worsening shortness of breath, or cough due to concern for left ventricular dysfunction. (Genentech, 2020d)                                                                                                                                                                                                                                                                                                                                                |
|                                                   | Pertuzumab, trastuzumab, and hyaluronidase-zxxf (Phesgo <sup>™</sup> )                                                                       | Dyspnea, cough, interstitial pneumonitis, pulmonary infiltrates, pleural effusions, non-cardiogenic pulmonary edema, pulmonary insufficiency and hypoxia, ARDS, pulmonary fibrosis                                                                                                                                            | Administration can result in serious and fatal pulmonary toxicity similar to trastuzumab. Patients with symptomatic ILD or with extensive tumor involvement of the lungs, resulting in dyspnea at rest, appear to have more severe toxicity. Discontinue the drug for anaphylaxis, angioedema, interstitial pneumonitis, or ARDS. (Genentech, 2020a)                                                                                                                                                                                         |
|                                                   | Polatuzumab vedotin-piiq (Polivy <sup>™</sup> ; CD79b-directed antibody–drug conjugate)                                                      | Pneumonia, dyspnea, infusion reaction with dyspnea, bronchospasm and wheezing, upper respiratory infection, pneumonitis                                                                                                                                                                                                       | For the first instance of grade 3 wheezing, bronchospasm, or generalized urticaria, permanently discontinue the drug. Permanently discontinue the drug for recurrent grade 2 wheezing or urticaria or for recurrence of any grade 3 symptoms. Fatal or severe infections have occurred, including opportunistic infections such as sepsis, <i>Pneumocystis jirovecii</i> pneumonia, and other fungal pneumonia. Administer prophylaxis for <i>Pneumocystis jirovecii</i> pneumonia and herpes virus throughout treatment. (Genentech, 2020c) |
|                                                   | Tafasitamab-cxix (Monjuvi <sup>®</sup> ; CD19-directed cytolytic antibody)                                                                   | Cough, respiratory tract infection, infusion reaction with dyspnea, bronchitis, pneumonia, exacerbation of COPD                                                                                                                                                                                                               | Fatal and severe infections have occurred, including opportunistic infection. Monitor patients for signs and symptoms of infection and manage infections as appropriate. Based on the severity of the infusion-related reaction, interrupt or discontinue the drug. (MorphoSys, 2021)                                                                                                                                                                                                                                                        |
|                                                   | Trastuzumab (Herceptin <sup>®</sup> )<br>HER2 receptor antagonist<br><br>Trastuzumab-pkrb (Herzuma <sup>®</sup> ; biosimilar to trastuzumab) | Infusion reaction, pulmonary toxicity, dyspnea, cough, interstitial pneumonitis, pulmonary infiltrates, pleural effusions, non-cardiogenic pulmonary edema, pulmonary insufficiency and hypoxia, ARDS, pulmonary fibrosis<br><br>These symptoms can occur as a result of an infusion reaction.<br>Upper respiratory infection | Stop the infusion for dyspnea or clinically significant hypotension concerning infusion reaction. Provide medical treatment as indicated, which may include epinephrine, corticosteroids, diphenhydramine, bronchodilators, and oxygen.<br>Discontinue medication for anaphylaxis, angioedema, interstitial pneumonitis, or ARDS.                                                                                                                                                                                                            |

Symptoms usually occur during or within 24 hours of administration. Patients with symptomatic ILD or with extensive tumor involvement of the lungs, resulting in dyspnea at rest, appear to have more severe toxicity. Discontinue for anaphylaxis, angioedema, interstitial pneumonitis, or ARDS. (Genentech, 2020b, 2021c)</p> <p>Advise patients to immediately report cough, dyspnea, fever, or any new or worsening respiratory symptoms. Monitor for and promptly investigate signs and symptoms, including cough, dyspnea, fever, and other new or worsening respiratory symptoms. Evaluate patients with suspected ILD by radiographic imaging and consider a consultation with a pulmonologist. For grade 1 asymptomatic ILD or pneumonitis, interrupt the drug until resolved to grade 0. If resolved in <math>\leq 28</math> days from onset, maintain the dose. If resolved <math>&gt; 28</math> days from onset, reduce the dose by one level. Consider corticosteroid treatment as soon as ILD and pneumonitis are suspected. Permanently discontinue the drug in all patients with a <math>\geq</math> grade 2 ILD or pneumonitis. Advise patients of the risk and to report symptoms immediately. Promptly initiate systemic corticosteroid treatment and continue for at least 14 days followed by a gradual taper for at least 4 weeks. (Daiichi Sankyo, 2021)</p> |

**TABLE 17-1.** Pulmonary Toxicities of Antineoplastic Agents (*Continued*)

| Classification                                             | Drug                                              | Adverse Effects, Signs, and Symptoms                                                                                                                 | Nursing Considerations                                                                                     |
|------------------------------------------------------------|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| <b>Immunotherapy Agents (Cont.)</b>                        |                                                   |                                                                                                                                                      |                                                                                                            |
| Chimeric anti-gen receptor T-cell therapy ( <i>Cont.</i> ) | Lisocabtagene maraleucel (Breyanzi <sup>®</sup> ) | Hypoxia, cough, dyspnea, pleural effusion, upper respiratory tract infection, cytokine release syndrome, infusion-related reaction                   | Manage cytokine release syndrome per medication prescribing information. (Juno Therapeutics, 2021)         |
|                                                            | Tisagenlecleucel (Kymriah <sup>®</sup> )          | Hypoxia, cough, dyspnea, pulmonary edema, pleural effusion, ARDS, lung infiltration, tachypnea, cytokine release syndrome, infusion-related reaction | Manage cytokine release syndrome per medication prescribing information. (Novartis Pharmaceuticals, 2022b) |

ARDS—acute respiratory distress syndrome; COPD—chronic obstructive pulmonary disease; ILD—interstitial lung disease; IV—intravenous; MASCC—Multinational Association of Supportive Care in Cancer; PE—pulmonary embolism; PFTs—pulmonary function tests; VOD—veno-occlusive disease

c) Risk factors for direct injury

- (1) Rare reports of interstitial pulmonary infiltrates and acute alveolitis with hydroxyurea have been noted.
- (2) Metabolic injury
  - (a) Metabolites of cyclophosphamide cause acute pneumonitis that may be hemorrhagic.
  - (b) Renal dysfunction may cause delayed drug excretion and increase the pulmonary toxicity of bleomycin, cyclophosphamide, and methotrexate (Leger et al., 2017; Stein et al., 2015).
- (3) Disruption of intracellular kinases
  - (a) Tyrosine kinase inhibitors (Ohmori et al., 2021; Teuwen et al., 2015)
  - (b) Epidermal growth factor receptor inhibitors (Tewwen et al., 2015)
  - (c) Mammalian target of rapamycin inhibitors: Genetic risks may be activated by these agents (Nishino et al., 2016; Teuwen et al., 2015; Willemsen et al., 2016).
- (4) Cytotoxic antigen-directed T-cell responses may drive lung changes with immunotherapy (Q. Zhang et al., 2021).
- (5) Pulmonary edema
  - (a) Interleukin-2 is associated with a high incidence of capillary leak syndrome. Pulmonary edema is a dose-limiting toxicity of high-dose interleukin-2 therapy. Severity depends on the route, dose, and administration schedule (Dhupkar & Gordon, 2017). It resolves quickly after therapy ends and diuresis begins.
  - (b) Docetaxel is associated with fluid retention, alveolar permeability, and

pulmonary infiltrates. These symptoms may be prevented with corticosteroid premedication and are treated with diuretics (Leger et al., 2017).

- (c) Cytosine arabinoside, intermediate and high dose, can affect pulmonary function (Nucci et al., 2015).
- (d) Leuprolide acetate has been reported to cause varying degrees of ILD (AbbVie, 2022).
- (e) Tyrosine kinase inhibitors cause capillary permeability, pulmonary edema, and effusions (Dasgupta et al., 2017; Medeiros et al., 2018; Teuwen et al., 2015).
- (6) Hypersensitivity pneumonitis
  - (a) Paclitaxel can cause acute pneumonitis, which no longer appears to be related to the drug's emulsification agents (polyoxyl 40 hydrogenated castor oil [Kolliphor<sup>®</sup> EL, formerly Cremophor<sup>®</sup> EL]) as originally postulated (Nakamura et al., 2021).
  - (b) Docetaxel has an increased risk of hypersensitivity pneumonitis with a higher total dose treatment schedule, preexisting lung disease (emphysematous or interstitial changes), and concurrent administration with gemcitabine or radiation (Genestreti et al., 2015; Grande et al., 2007).
  - (c) Gemcitabine-induced eosinophilic pneumonitis suggests that hypersensitivity may be an element of this drug reaction (De Giacomini et al., 2018).
  - (d) Acute methotrexate reaction is likely allergic (Fragoulis et al., 2019).

- (e) Pathologically confirmed hypersensitivity pneumonitis has occurred with agents such as bortezomib, imatinib, lenalidomide, mammalian target of rapamycin inhibitors, oxaliplatin, procarbazine, and thalidomide; however, no definite etiologic mechanisms have been identified (Kallel et al., 2021; Leger et al., 2017; Teuwen et al., 2015; Toma et al., 2017). This is not a comprehensive list. Please refer to Table 17-1 for specific agent information.
  - (f) Hypersensitivity skin testing can differentiate the etiology when multiple agents are implicated (Kuo et al., 2015).
- 5. Clinical manifestations: may be difficult to detect when subtle
  - a) Signs and symptoms (Brahmer et al., 2021; Johkoh et al., 2021; NCCN, 2022a; Rapoport et al., 2021)
    - (1) Dyspnea
    - (2) Dry cough
    - (3) Low-grade fever
    - (4) Low oxygen saturation and increased oxygen requirements
    - (5) Weight loss
    - (6) Fatigue
    - (7) Crackles, wheezing, or abnormal breath sounds
    - (8) Chest pain
  - b) Timing of signs and symptoms
    - (1) Respiratory signs and symptoms vary depending on the causative agent and type of ILD.
    - (2) Onset of ILD is sooner with chemotherapy than with targeted therapies (e.g., kinase inhibitors) and immune checkpoint inhibitors (Iwashita et al., 2021).
    - (3) Acute hypersensitivity pneumonitis reactions with chemotherapy agents, such as gemcitabine and methotrexate, may occur as early as hours to weeks after initial exposure (Samad et al., 2016; Thalambedu & El-Habr, 2020).
    - (4) Bleomycin-induced pulmonary toxicity presentation is usually subacute, with a median onset of approximately four months (O'Sullivan et al., 2003).
    - (5) Delayed toxicity may occur more than one year from drug initiation with some targeted therapies and immune checkpoint inhibitors (Skeoch et al., 2018).
- 6. Assessment
  - a) Past medical history
    - (1) Chemotherapy, targeted therapy, and immunotherapy drug exposure
    - (2) Other medications known to be associated with pulmonary toxicity (e.g., amiodarone, nitrofurantoin, disease-modifying antirheumatic drugs) (Skeoch et al., 2018)
    - (3) Radiation exposure
    - (4) Recent or chronic pulmonary conditions such as chronic obstructive pulmonary disease, preexisting ILD illness, or idiopathic pulmonary fibrosis (Skeoch et al., 2018)
    - (5) History of tobacco use (Skeoch et al., 2018)
    - (6) Advanced or metastatic cancers (Skeoch et al., 2018)
    - (7) Recent viral illnesses (e.g., COVID-19) (Cherri et al., 2021)
    - (8) Autoimmune diseases (Dodia et al., 2021)
    - (9) Occupational and environmental exposures (e.g., molds, gases, silica, asbestos, metal dust, coal) (Dodia et al., 2021; Glazer & Newman, 2004)
  - b) Physical examination (Conte et al., 2022; Johkoh et al., 2021; Leger et al., 2017)
    - (1) Tachypnea
    - (2) Crackles or wheezes on auscultation
    - (3) Cough or hemoptysis
    - (4) Accessory muscle use for breathing
    - (5) Evidence of poor tissue oxygenation in advanced cases (e.g., cyanosis, oliguria, decreased bowel sounds, altered mentation)
    - (6) Abnormal oxygen saturation readings
    - (7) Normal examination in asymptomatic patients
  - c) Performance status: Poor performance status correlates with increased risk of ILD and mortality in severe ILD (Kaku et al., 2022; Skeoch et al., 2018).
  - d) Diagnostic tests
    - (1) Diagnostic studies may show nonspecific findings, and ILD is often a diagnosis of exclusion.
    - (2) Diagnosis may be based on clinical, radiographic, and pathologic findings (Johkoh et al., 2021).
    - (3) A chest CT scan is the gold standard imaging study for drug-induced ILD (Rapoport et al., 2021).
      - (a) Chest CT scan patterns may vary based on the specific class of agents, and more than one pattern may be present (Johkoh et al., 2021).
      - (b) A CT scan may show organizing pneumonia, diffuse alveolar damage,

hypersensitivity pneumonitis, simple pulmonary eosinophilia, or nonspecific interstitial pneumonitis (Johkoh et al., 2021).

- (c) The most common pattern is hypersensitivity pneumonitis, followed by organizing pneumonia, and then diffuse alveolar damage (Kaku et al., 2022).
- (4) Pulmonary function test (PFT) for diagnosis of ILD may be useful but lacks specificity, and accuracy is variable (Skeoch et al., 2018).
  - (a) Baseline PFTs are recommended for patients with Hodgkin lymphoma prior to starting bleomycin-based therapy and can be considered after four cycles of doxorubicin, bleomycin, vinblastine, dacarbazine (NCCN, 2022b).
  - (b) If PFTs are performed, they should include spirometry and diffusing capacity of the lungs for carbon dioxide (DLCO) (Brahmer et al., 2021).
  - (c) Reductions in DLCO are the primary change noted in PFTs following bleomycin (Roncolato et al., 2016).
  - (d) PFTs are typically normal in immune checkpoint inhibitor pneumonitis (Rapoport et al., 2021).
- (5) Numerous biomarkers, including Krebs von den Lungen-6 (KL-6) and surfactant protein D (SP-D), and tissue-based genetic signatures have shown promise as a diagnostic tool for general ILD; however, no specific diagnostic biomarker exists for drug-induced ILD (Bowman et al., 2021; Okamoto et al., 2015).
  - (a) KL-6 has also been shown to be a predictive biomarker for ILD severity and poor outcomes (T. Zhang et al., 2021b).
  - (b) KL-6 to Sialyl-Lewis X antigen (SLX) (K/S) ratio may predict lung underlying idiopathic interstitial pneumonia in patients with cancer who are at higher risk for the development of drug-induced ILD (Kashiwabara et al., 2015).
  - (c) Whole-genome sequencing has been studied as a tool for pinpointing predictive biomarkers in drug-induced ILD (Udagawa et al., 2019).
- (6) A positron-emission tomography–CT scan has been evaluated in case series

of drug-induced interstitial pneumonitis from chemotherapy, immunotherapy, and targeted therapies (Dejust et al., 2018; Lu & Yang, 2021). The role of this diagnostic tool is still unclear, as findings from pneumonitis can mimic hypermetabolic findings present in infection and malignancy (Kalisz et al., 2019).

- (7) Bronchoscopy with lavage findings are usually nonspecific and primarily used to rule out other causes (e.g., infection, underlying malignancy) (NCCN, 2022a; Skeoch et al., 2018).
- (8) Open lung biopsy may also be useful in specific cases when other causes need to be ruled out; however, little evidence exists to support its use in most cases (Skeoch et al., 2018).
- 7. Collaborative management
  - a) PFTs should be considered for the following patients being evaluated for therapy.
    - (1) Patients with baseline lung disease (e.g., chronic obstructive pulmonary disease, ILD) and those with prior treatment-induced pulmonary toxicities (NCCN, 2022a)
    - (2) Prior to bleomycin-based chemotherapy for Hodgkin lymphoma (NCCN, 2022b)
  - b) Avoid exceeding maximum recommended doses.
    - (1) Bleomycin: 400 units total lifetime dose (Hospira, 2021a)
    - (2) Mitomycin C: 20 mg/m<sup>2</sup> (Accord Healthcare, 2018)
  - c) Consider alternative regimens and dosing schedules for high-risk patients.
    - (1) Bleomycin should be avoided in patients with testicular cancer older than age 50 years, who have underlying lung disease, or are at risk for pulmonary complications (NCCN, 2022c). Proceed with caution in patients with a prior heavy smoking history and underlying kidney disease.
    - (2) Bleomycin should be used with caution in patients with Hodgkin lymphoma aged 60 years and older. Alternative regimens without bleomycin should be considered (NCCN, 2022b).
    - (3) Eliminating bleomycin in a doxorubicin, bleomycin, vinblastine, and dacarbazine (ABVD) regimen after two cycles in Hodgkin lymphoma has resulted in reduced pulmonary toxicity without reduced efficacy (Johnson et al., 2016).
  - d) If pulmonary toxicity is suspected, hold the agent and notify the prescriber. Rechallenge with the

offending agent varies with toxicity severity, timing, probable mechanism of injury, and specific agent.

e) Consider PFTs for patients with new pulmonary symptoms suggestive of ILD or in asymptomatic individuals with radiographic findings of pneumonitis (Conte et al., 2022; Rapoport et al., 2021).

f) Administer oxygen for hypoxic patients (Conte et al., 2022).

(1) Patients who have received bleomycin should avoid high oxygen concentrations, including general anesthesia (Watson et al., 2018).

(2) Bleomycin produces free oxygen radicals, and high oxygen concentrations may cause respiratory complications. Case reports of respiratory failure in patients who received prior bleomycin have been reported (Brasher & Sood, 2020).

g) Mechanical ventilation may be required in severe cases, considering the patient's overall prognosis (Conte et al., 2022).

h) Establish fluid balance goals.

(1) Carefully record intake and output.

(2) Determine if fluid boluses or fluid restrictions are warranted.

(3) Consider using goal dry weight to target diuretic therapy. Weigh patients regularly.

i) Supportive care

(1) Oxygen therapy

(a) Establish a target level based on the degree of hypoxemia (Conte et al., 2022).

(b) Avoid high oxygen concentrations in patients who have received bleomycin (Watson et al., 2018).

(2) Dyspnea management (Shelton et al., 2019)

(a) Immediate-release opioids

(b) Fans

(c) Noninvasive ventilation

(d) Psychoeducational interventions

(e) Oral nutritional interventions

j) Treatment of ILD

(1) Administer corticosteroids as ordered. Corticosteroids usually are contraindicated for patients receiving lymphokines, such as aldesleukin (Dhupkar & Gordon, 2017).

(a) Corticosteroids are administered in low, moderate, or high doses.

(b) The risks and benefits of corticosteroids should be considered when treating pulmonary toxicities.

(c) Exact dosages remain controversial, but specific recommendations based

on toxicity grade have been established for immune checkpoint inhibitors (NCCN, 2022a).

(d) Consider adding infliximab, IV immunoglobulin, or mycophenolate mofetil for immune checkpoint inhibitor-induced ILD if there is no response to corticosteroids after 48 hours (NCCN, 2022a).

(2) Initiate antimicrobial therapy when infection superimposed on other lung toxicity is suspected (NCCN, 2022a).

k) Follow-up evaluation

(1) Frequency is based on the severity of and risk for ILD and may increase with cumulative dose or added risk factors.

(2) Patients should be followed for symptoms for at least two months after chemotherapy (Iwashita et al., 2021).

(3) Patients receiving targeted therapies and immune checkpoint inhibitors need to be followed longer given the later onset of pulmonary toxicities that can be seen with these agents (Iwashita et al., 2021).

(4) A post-treatment chest CT scan is recommended for patients receiving more than 300 units of bleomycin (Watson et al., 2018).

(5) Certain patients at risk for ILD should be periodically monitored with specific PFTs.

(a) Routine PFT screening may be useful in allogeneic hematopoietic stem cell transplantation (HSCT) recipients. The testing frequency has not been clearly determined, but some experts have recommended every three months for the first two years (Jamani et al., 2020; Thompson et al., 2014).

(b) A symptom-based follow-up approach is preferred over routine monitoring with PFTs in patients who have received bleomycin (Roncolato et al., 2016; Watson et al., 2018).

(c) PFTs should include spirometry and DLCO (Brahmer et al., 2021).

(d) Drug-induced ILD shows a restrictive spirometry picture with reductions in total lung capacity similar to other forms of ILD. DLCO is also reduced in drug-induced ILD, although the sensitivity for this measure may be low (Bui et al., 2020; Conte et al., 2022).

- (6) In patients with acute-onset symptomatic disorders, such as alveolar hemorrhage or acute hypersensitivity reaction, screening is not performed because of the usual acute presentation.
- (7) Late or delayed onset of lung toxicity may occur and be related to treatment and host factors, but plans for follow-up care are not clearly defined (Versluys & Bresters, 2016).

### C. Diffuse alveolar hemorrhage

#### 1. Pathophysiology

- a) Diffuse alveolar hemorrhage is a rare and life-threatening disease characterized by bleeding in the microvasculature of small airways. It is separated into four major groups.

- (1) Immune associated
- (2) Congestive heart failure associated
- (3) Miscellaneous (i.e., infection, trauma, clotting disorder, drugs, malignancy, and HSCT)
- (4) Idiopathic

- b) The major pathologic findings of diffuse alveolar hemorrhage include the following (J.A. Park, 2021).

- (1) Bland pulmonary hemorrhage is associated with the leaking of red blood cells into the alveoli without damage or inflammation. It commonly occurs with coagulopathies, anticoagulant therapy, heart failure, or renal failure.
- (2) Diffuse alveolar damage occurs due to direct lung injury that causes alveolar edema and the development of hyaline membranes and can lead to alveolar hemorrhage. Numerous causes include cytotoxic and noncytotoxic drugs, infections (e.g., COVID-19), and radiation treatment (e.g., thoracic or total body irradiation).
- (3) Antibody-mediated pulmonary capillaritis is characterized by neutrophilic infiltration of the interstitium of the lung and fibrinoid necrosis.

#### 2. Incidence

- a) Alveolar hemorrhage incidence rates have been reported as infrequent, occurring in 1.1% of autologous HSCT recipients and 7.2% in allogeneic HSCT recipients (Z. Zhang et al., 2021).
- b) Incidence is rare with other antineoplastic therapies.

#### 3. Risk factors

- a) Alveolar hemorrhage in patients with cancer is most commonly documented in HSCT. It is associated with allogeneic HSCT, myeloablative con-

ditioning, severe graft-versus-host disease, and older age. Mortality in HSCT recipients is more than 80% (Z. Zhang, 2021c).

- b) Alveolar hemorrhage has been rarely associated with standard doses of bevacizumab, bortezomib, crizotinib, cyclophosphamide, docetaxel, etoposide, everolimus, gefitinib, gemcitabine, lenalidomide, nilotinib, oxaliplatin, pemetrexed, rituximab, and sirolimus (Chatterjee et al., 2015; Donatelli et al., 2014; Kurimoto et al., 2015; Maldonado et al., 2022c; Mankikian et al., 2014; Ono et al., 2013; Sakai et al., 2015; Saleem et al., 2015; Specks, 2022; Sugita et al., 2015; Toma et al., 2017; Wirk, 2012; Willemsen et al., 2016).

- c) Concomitant pulmonary infection may be present with adenovirus, COVID-19, cytomegalovirus, dengue fever, Epstein-Barr virus, *Stenotrophomonas maltophilia*, and *Strongyloides* (parasite) (Loecher et al., 2021; J.A. Park, 2021).

- d) Non-oncologic drugs can cause alveolar hemorrhage (e.g., amiodarone, crack cocaine, nitrofurantoin, propylthiouracil, valproate) (J.A. Park, 2021).

- e) Unlike other bleeding syndromes, pulmonary hemorrhage is not always related to platelet counts or coagulation values (Nanjappa et al., 2016).

#### 4. Clinical manifestations (Loecher et al., 2021)

- a) Symptoms include dyspnea, fever, cough, chest discomfort, and profound hypoxemia.
- b) Hemoptysis occurs in up to one-third of patients. Pink, frothy sputum and blood in bronchoalveolar specimens may be found.
- c) Hypoxemia-related symptoms include agitation, confusion, air hunger, cyanosis, tachycardia, and bradycardia.

#### 5. Assessment

- a) Early crackles and diminished breath sounds as the airways become filled with bloody exudate
- b) Decreased oxygen saturation
- c) Increase in quantity and change in the quality of sputum
- d) Hemoglobin, platelet count, and coagulation parameters: Hemoglobin may not fall until bleeding is life threatening.
- e) Nonspecific findings of inflammation, including increased erythrocyte sedimentation rate and leukocytosis (if not marrow suppressed)
- f) PFTs (increased DLCO with hypoxemia) if patients can participate (Loecher et al., 2021)
- g) Chest x-ray or CT scan to evaluate for diffuse interstitial and alveolar infiltrates (typically nonspecific) (Loecher et al., 2021)
- h) Bronchoalveolar lavage (bloody returns that increase during lavage)

## 6. Collaborative management

- a) Corticosteroids are the standard treatment for diffuse alveolar hemorrhage, as it is thought to be inflammatory (Loecher et al., 2021). Methylprednisolone at doses of 30 mg/kg daily or 500–2,000 mg daily via IV for approximately three to five days followed by a taper is the typical treatment (J.A. Park, 2021). Further study is needed to determine the optimal dose of corticosteroids.
- b) Coagulation factors can be administered adjunctively, although no one therapy has proved effectively. Unproven coagulation therapies are IV aminocaproic acid and recombinant factor VIIa (Loecher et al., 2021).
- c) Etanercept is a tumor necrosis factor-alpha inhibitor that blocks pulmonary fibrosis formation and has been studied in patients with diffuse alveolar hemorrhage after HSCT with corticosteroids (Loecher et al., 2021).
- d) Consider noninvasive or invasive mechanical ventilation with positive pressure to produce intra-alveolar pressure and reduce bleeding (J.A. Park, 2021).
- e) Provide supportive management of dyspnea.

## D. Acute promyelocytic leukemia (APL) treatment-related differentiation syndrome (DS)

## 1. Pathophysiology

- a) APL treatment-related DS occurs with APL, a type of leukemia in which leukemic cells are halted at the promyelocyte stage. This DS was initially named retinoic acid syndrome because of its association with the administration of all-trans retinoic acid. This modified term was introduced because the syndrome occurs with any differentiating agents, such as arsenic trioxide (Stahl & Tallman, 2019). This syndrome has also been reported in patients with acute myeloid leukemia undergoing treatment with newer targeted agents, such as fms-related receptor tyrosine kinase 3 (FLT3) and isocitrate dehydrogenase (IDH) inhibitors (Fathi et al., 2021).
- b) The pathogenesis of APL treatment-related DS is complex and not completely understood. Interleukin-1, -6, and -8 and tumor necrosis factor-alpha lead to systemic inflammatory response syndrome. The release of cathepsin G leads to increased vascular permeability, which causes endothelial damage, and the increased adhesion of blast cells leads to leukostasis, endothelial damage, and organ infiltration (Stahl & Tallman, 2019).
- c) It is more a condition of tumor responsiveness to therapy than a toxicity.

## 2. Incidence

- a) APL treatment-related DS occurs in approximately 27%–48% of patients with APL receiving induction therapy (Elemam & Abdelmoety, 2013; Larson & Bag, 2022; Leblejian et al., 2013; Lengfelder et al., 2015).
- b) It is more prevalent in patients with high white blood cell counts (Watts & Tallman, 2014).
- c) The overall incidence of DS in patients with acute myeloid leukemia (non-APL) being treated with an IDH inhibitor is approximately 19% and is associated with a latent onset compared with APL (Fathi et al., 2021).
  - (1) Gilteritinib, an FLT3 inhibitor, includes a black box warning for DS. It promotes cellular differentiation to a more mature myeloid lineage. The time to onset is 2–75 days (Fathi et al., 2021).
  - (2) Ivosidenib, an IDH1 inhibitor, includes a black box warning for DS. The median time to onset is 29 days (range of 5–59 days). Enasidenib, another IDH1 inhibitor, is associated with a 14% incidence of DS (Fathi et al., 2021). DS has been observed as early as one day and up to five months after initiation of enasidenib (Celgene, 2020b).

## 3. Risk factors

- a) Increased body mass index is the only validated risk factor for DS (Breccia et al., 2012; Leblejian et al., 2013).
- b) High white blood cell count may be associated with increased risk. A rapid rise in white blood cell count, or a large percentage of immature cells, is related to the presence of APL treatment-related DS (Larson & Bag, 2022; Leblejian et al., 2013; Watts & Tallman, 2014).
- c) Acute myeloid leukemia, M3 subtype, expression of CD13 on APL blast cells (Breccia et al., 2014)
  - (1) The CD34/CD2 subgroup shows increased risk.
  - (2) CD56 expression with prevalent bcr3 expression shows increased risk.
- d) Treatment-specific variables include the following.
  - (1) All-trans retinoic acid treatment
  - (2) Arsenic trioxide
  - (3) Bortezomib
  - (4) Azacitidine (Laufer & Roberts, 2015)
  - (5) New targeted therapies (e.g., IDH1/2 inhibitors, FLT3 inhibitors)

## 4. Clinical manifestations (Stahl &amp; Tallman, 2019)

- a) Signs and symptoms include fever, dyspnea, cough, hypotension, crackles, hypoxemia, mus-

- culoskeletal pain (e.g., arthralgias, myalgias), effusions, edema, and a weight gain of more than 5 kg from baseline.
  - b) Rash can be diffuse, erythematous, and nonpruritic and is more common in severe cases (Larson & Bag, 2022).
  - c) Renal dysfunction may occur but often is slower in onset than other symptoms. It may be noted after recognizing the syndrome.
  - d) Approximately one-half of patients have symptoms within one week, and the rest develop symptoms between the third and fourth week of induction therapy (Sanz & Montesinos, 2014).
  - e) *Common Terminology Criteria for Adverse Events* grading (National Cancer Institute Cancer Therapy Evaluation Program, 2017)
    - (1) Weight gain
      - (a) Grade 1: 5% to less than 10% weight gain from baseline
      - (b) Grade 2: 10% to less than 20% weight gain from baseline
      - (c) Grade 3: greater than or equal to 20% weight gain from baseline
    - (2) The toxicity of DS is graded according to the severity of symptoms.
      - (a) Grade 1: fluid retention of less than 3 kg requiring intervention with fluid restriction or diuretics
      - (b) Grade 2: moderate signs and symptoms requiring steroid administration
      - (c) Grade 3: severe symptoms and hospitalization indicated
      - (d) Grade 4: life-threatening consequences with mechanical ventilation indicated
      - (e) Grade 5: death due to the disorder
5. Assessment
- a) Breath sounds and oxygen saturation
  - b) Intake and output (weight): monitoring of overhydration, may worsen respiratory symptoms
  - c) Laboratory studies
    - (1) White blood cell count with differential daily: Blast percentage should be assessed.
    - (2) Periodic assessment of hemoglobin, hematocrit, and platelet count: Anemia and thrombocytopenia are common.
    - (3) Periodic evaluation of coagulation parameters and platelet count: Disseminated intravascular coagulation can occur.
    - (4) Renal function tests to monitor for impairment: It is unclear if dysfunction is related to hypotension or thrombosis (Larson & Bag, 2022).
  - d) Chest x-ray or CT: nodular or ground-glass opacities with patchy bilateral distribution, consolidation, air bronchograms, prominent septal lines, and possible pleural or pericardial effusions (Stahl & Tallman, 2019)
6. Collaborative management
- a) Prevention
    - (1) Immediate administration of chemotherapy when white blood cell count rises
    - (2) Fluid management (strict intake and output)
  - b) Although no randomized studies compare patient treatment with or without steroids, retrospective studies have demonstrated that immediate use reduces DS-related mortality (Stahl & Tallman, 2019).
    - (1) If treatment with steroids is selected, the usual treatment is dexamethasone 10 mg IV twice daily. If no improvement is seen, the dexamethasone can be increased to 10 mg every six hours. Steroids can be discontinued or tapered once DS resolves.
    - (2) APL treatment-related DS presents concomitantly with infection, and a complete workup should be performed. Other diagnoses that need to be ruled out are pneumonia, heart failure, pulmonary embolism, and diffuse alveolar hemorrhage (Stahl & Tallman, 2019).
  - c) Noninvasive or invasive mechanical ventilation with positive pressure
  - d) Removal of pleural or pericardial effusions, if present
- E. Pleural effusions
1. Definition: Pleural effusions are the accumulation of excess fluid in the pleural space that impairs lung expansion. Four to six liters of pleural fluid usually pass through the potential space between the visceral and parietal pleura daily (Villena Garrido et al., 2014).
  2. Pathophysiology: Excess fluid is retained in the pleural space, restricting full alveolar expansion (Muzumdar, 2012; Villena Garrido et al., 2014).
    - a) Major causes of pleural effusion are an obstruction to fluid outflow and pleural irritation, leading to exudative capillary permeability into the space (Muzumdar, 2012).
      - (1) Mast cell degranulation may mediate pleural effusion and potential physiology for drug-related effusions (Giannou et al., 2015).
      - (2) Pleural effusions after HSCT may be multifactorial. Engraftment syndrome resulting from the treatment and cell engraft-

- ment has been associated with pleural effusions (Brownback et al., 2014).
- b) Transudative effusions are produced by passive capillary permeability and are characteristic of fluid overload, heart failure, or hypothyroidism (Dasanu et al., 2017; Kust et al., 2016).
  - c) Hydrophilic drugs with low plasma protein binding (e.g., methotrexate, pemetrexed) may accumulate in the pleural space, enhancing the incidence of pleural effusion and potentiating drug toxicity (Honoré et al., 2014).
3. Incidence of drug-related pleural effusions
    - a) Incidence varies and depends on the agent, dose, schedule, and comorbid conditions.
    - b) Incidence can be as high as 54% with some agents (Maldonado et al., 2022a, 2022b, 2022c).
  4. Risk factors
    - a) Pleural effusions are a common complication of cancer and other medical disorders, such as cirrhosis, gout, heart failure, infections, pneumonia, pulmonary embolism, renal failure, rheumatoid conditions, or hypothyroidism, and medications, such as valproate and clozapine (Jany & Welte, 2019).
    - b) When associated with chemotherapy and immunotherapy agents, pleural effusions result from capillary permeability temporally related to the administration of the offending agent. Most resolve with discontinuation of treatment.
    - c) Select chemotherapy and immunotherapy agents associated with the development of pleural effusions include the following.
      - (1) Antimetabolites and folate inhibitors (e.g., methotrexate, pemetrexed): eosinophilic pleural effusions (Cudzilo et al., 2014; Honoré et al., 2014)
      - (2) Bacillus Calmette Guérin: lymphocyte infiltration of the pleura (Tobieme et al., 2014)
      - (3) Bortezomib (Oudart et al., 2012)
      - (4) Cytosine arabinoside when combined with daunorubicin (He et al., 2014)
      - (5) Cyclophosphamide (high dose) (Nakazawa et al., 2014)
      - (6) BCR-ABL1 kinase inhibitors (e.g., dasatinib, which is the most common and significant in this drug class; imatinib; nilotinib); more common in second-generation agents (Chakraborty et al., 2013; Cortes et al., 2015; Eskazan et al., 2014; Schiffer et al., 2016)
      - (7) Docetaxel (S.I. Park et al., 2014)
      - (8) Fludarabine (Nakazawa et al., 2014)
      - (9) Gemcitabine (Kido et al., 2012)
      - (10) Immune checkpoint inhibitors (e.g., ipilimumab): late onset and uncommon; may be linked to drug-related hypothyroidism (Dasanu et al., 2017)
      - (11) Mammalian target of rapamycin inhibitors (e.g., everolimus, temsirolimus) (Fukushima et al., 2013; Willemsen et al., 2016)
      - (12) Sunitinib (Miura et al., 2014)
  5. Clinical manifestations and assessment
    - a) Patients present with tachypnea, dyspnea, increased work of breathing, abnormal chest excursion, pleuritic pain, and fatigue.
    - b) Onset varies by agent and mechanism of toxicity; hypersensitivity reactions may occur sooner than direct injury (Willemsen et al., 2016).
    - c) An upright chest x-ray documents large pleural effusions; smaller effusions are seen on a chest CT scan.
    - d) Tyrosine kinase inhibitor-induced pleural effusions are characterized by exudative features and lymphocytic infiltration of the pleura.
  6. Collaborative management (Jany & Welte, 2019)
    - a) In most cases, pleural effusions are uncomplicated and spontaneously resolve upon discontinuation of the causative agent.
    - b) Dose reduction has successfully eliminated pleural effusion related to some drugs.
    - c) Concomitant corticosteroids have effectively reduced the severity of pleural effusions related to docetaxel.
    - d) Other treatment strategies are albumin supplementation, fluid restrictions, diuretics, and corticosteroids, but these interventions do not have the evidence to support their use (Villena Garrido et al., 2014).
    - e) Medical or surgical pleurodesis is rarely required to treat drug-induced pleural effusion.
      - (1) On rare occasions, thoracentesis has been performed as a temporary measure or to rule out other causes of the effusion.
      - (2) Tunneled or temporary pleural catheters may be used with persistent pleural effusions.
- F. Patient and family education (Camp-Sorrell, 2018)
    1. Provide education regarding symptoms associated with pulmonary toxicity (e.g., cough, dyspnea, chest pain, shallow breathing, chest wall discomfort). Ensure all patients know to seek medical assistance immediately if symptoms occur.
    2. Advise smoking cessation or reduction, as any reduced exposure may reverse lung changes and slow the progression of ILD.
    3. Inform patients that treatment may be delayed or held until pulmonary symptoms resolve.

4. Explore patients' wishes regarding intubation and resuscitation status; establish advance directives.
5. Teach patients that raising the head of the bed may facilitate breathing.
6. Instruct patients to conserve energy by performing daily activities when their energy level is highest.
7. Teach patients and significant others methods to decrease symptoms of dyspnea (e.g., exercising to tolerance, practicing pursed-lip breathing, refraining from smoking, using a small fan).
8. Teach patients to take an opioid (e.g., morphine) as prescribed by their physician to relieve discomfort caused by air hunger.
9. Review the safety issues (e.g., flammability) related to oxygen administration.

## CHAPTER 18

# Hepatic Toxicities

### A. Overview

1. More than 1,300 drugs and toxins, including anti-neoplastics and herbs, may cause liver dysfunction (Mehta, 2019; Meuneir & Larrey, 2019; Postnikov et al., 2019).
2. Functions of the liver (Bunchorntavakul & Reddy, 2017; Kalra et al., 2021; Lee & Chan, 2016; Singh et al., 2021)
  - a) Filters toxic substances
  - b) Works with the spleen to eliminate damaged red blood cells
  - c) Produces bile, which aids in absorption and digestion of fats, allowing for excretion of waste products
  - d) Synthesizes procoagulant proteins, also referred to as clotting factors (e.g., II, V, VII, IX, X, XI), which promote the maintenance of healthy homeostasis (Kujovich, 2015)
  - e) Processes and stores vitamins, minerals, proteins, fats, and glucose

### B. Pathophysiology

1. Drug toxicity mechanisms (Andrade et al., 2019; Garcia-Cortes et al., 2020; Hoofnagle & Björnsson, 2019; Lisi, 2016; Maqbool et al., 2019; Mehta, 2019; Shehu et al., 2017; Stephens & Andrade, 2020)
  - a) Intrinsic: directly affect liver; liver toxicity induced by the drug that is predictable and dose related
  - b) Idiosyncratic: occur less frequently; associated with less consistent dose-toxicity relationship and varied presentation
2. Mechanisms of injury resulting from cancer therapies (Chen et al., 2015; Mehta, 2019; Mudd & Gudati, 2021)
  - a) Disruption of hepatocytes
    - (1) Adenosine triphosphate levels decrease because of the covalent binding of drugs to intracellular proteins, leading to actin disruption.
    - (2) Disassembling actin fibrils on hepatocyte surfaces causes blebs and membrane rup-

ture, resulting in hepatic injury, inflammation, fibrosis, and carcinogenesis (Mehta, 2019).

- b) Disruption of transport proteins
    - (1) Bile flow may be interrupted by drugs affecting transport proteins at the canalicular membrane.
    - (2) Loss of villous processes and transport pump interruption prevent bile excretion, causing cholestasis.
  - c) Cytolytic T-cell activation: Immune response is stimulated by the covalent binding of drugs with cytochrome P450 (CYP) enzymes acting as an immunogen, activating T cells and cytokines and resulting in an immune response to infection or tissue damage (Frick et al., 2017; Mehta, 2019).
  - d) Apoptosis of hepatocytes: Apoptotic pathways activated by the tumor necrosis factor- $\alpha$  receptor Fas may trigger a cascade of intercellular caspases, resulting in programmed cell death.
  - e) Disruption of mitochondria: Specific drugs inhibit the synthesis of nicotinamide adenine dinucleotide and flavin adenine dinucleotide, resulting in decreased adenosine triphosphate production and interference with lipid metabolism (Neuman, 2020).
  - f) Injury of bile ducts: Toxic metabolites excreted in bile can cause injury to the bile duct epithelium (Neuman, 2020).
  - g) Hypersensitivity and immune-mediated reactions: Antigen recognition by helper T cells occurs with key cytokines (Neuman, 2020).
  - h) Genetic differences in CYP protein: These differences can result in abnormal metabolic reactions to drugs; for example, increased toxicity can occur in genetically predisposed individuals such as females or obese individuals (Mehta, 2019; Stephens & Andrade, 2020).
3. Age-specific considerations
    - a) Pediatric considerations (Ali et al., 2014; Barrett et al., 2013; Benn, 2014; Postnikov et al., 2019)

- (1) Developmental changes in liver metabolism from birth to adolescence contribute to the increased sensitivity to toxins in the pediatric population, as drug half-life is more than two to three times longer (Benn, 2014).
- (2) Plasma protein binding and partitioning are different in the pediatric population and constantly fluctuate during early years, affecting how the drug is distributed (Ali et al., 2014; Postnikov et al., 2019).
- (3) Age-related differences in pharmacokinetics, particularly in infants and neonates, are important to recognize because pH and motility affect gastrointestinal absorption, body composition alters distribution, and clearance systems are not mature (Ali et al., 2014; Benn, 2014).
- (4) Drugs known to cause hepatotoxicity in children (Barrett et al., 2013; Chalasani et al., 2021; Chen et al., 2015)
  - (a) Analgesics
  - (b) Antimicrobials
  - (c) Anticonvulsants
  - (d) Antineoplastic drugs
- (5) Frequent monitoring of liver enzymes (Barrett et al., 2013; Urrutia-Maldonado et al., 2019)

*b) Considerations for older adult patients*

- (1) Developmental changes in liver metabolism, including a decline in physiologic functions in older adults (Lucena et al., 2020; Mehta, 2019)
  - (a) Increased risk of hepatic injury
  - (b) Decreased clearance
  - (c) Drug–drug interactions
  - (d) Reduced hepatic blood flow
  - (e) Varied drug binding
  - (f) Lower hepatic volume
  - (g) Age-related changes in body composition (decrease in lean body mass and higher adipose tissue) (Lucena et al., 2020)
  - (h) Decreased bile flow and bile acid secretion (Lucena et al., 2020)
- (2) Drugs known to cause hepatotoxicity in older adults (Lucena et al., 2020; Miller et al., 2020)
  - (a) Analgesics (e.g., nonsteroidal anti-inflammatory drugs)
  - (b) Non-narcotic pain medications (e.g., tricyclic antidepressants, muscle relaxants, benzodiazepines)
  - (c) Antibiotics
  - (d) Cardiovascular drugs

- (e) Herbal therapies and dietary supplements (Miller et al., 2020)
- (f) Psychoneurotic drugs
- (g) Antituberculosis drugs
- (h) Antineoplastic drugs

**C. Incidence (see Table 18-1)**

**D. Risk factors**

1. Race: variable toxicities (Chalasani et al., 2021; Mehta, 2019)
2. Age: rare in children; increased in older adults (Chalasani et al., 2021; Chen et al., 2015; Dass, 2020; Singh et al., 2021)
3. Sex: common in females (Mehta, 2019)
4. History of alcohol use (depletes glutathione), smoking, illicit drug use (Dass, 2020; Singh et al., 2021; Vicenzi et al., 2018)
5. History of liver disease (e.g., cirrhosis, Budd-Chiari syndrome, alpha-1 antitrypsin deficiency, hemochromatosis, Wilson disease) (Hoofnagle & Björnsson, 2019; Mehta, 2019)
6. History of infections (e.g., HIV, hepatitis B, hepatitis C) (Chalasani et al., 2021; Dass, 2020; Hoofnagle & Björnsson, 2019)
7. Genetic factors: The rate of metabolism of CYP enzymes differs among individuals (Chalasani et al., 2021; Chen et al., 2015; Hoofnagle & Björnsson, 2019; Mehta, 2019).
8. Comorbidities (e.g., obesity, malnutrition, diabetes mellitus) (Mehta, 2019)
9. Drug formulations (e.g., intrahepatic chemotherapy), drug interactions, polypharmacy (e.g., noncytotoxic hepatotoxic drugs or herbal products) (Chalasani et al., 2021; Chen et al., 2015; Hoofnagle & Björnsson, 2019; Mehta, 2019)
10. History of transplantation: liver, kidney, stem cell (Mehta, 2019)
11. Prior radiation therapy (Chen et al., 2015; Mehta, 2019)

**E. Clinical manifestations**

1. Variable from asymptomatic laboratory abnormalities to acute illness to overt hepatic failure (Mehta, 2019; Shehu et al., 2017; Vicenzi et al., 2018)
2. Elevations in aminotransferases (e.g., aspartate aminotransferase, alanine aminotransferase) indicative of hepatocellular injury; portal hypertension (Mehta, 2019; Shehu et al., 2017)
3. Elevations in bilirubin, alkaline phosphatase, and gamma-glutamyl transpeptidase activity suggestive of cholestasis (Neuman, 2020; Vicenzi et al., 2018)
4. Signs and symptoms of cancer treatment–related hepatotoxicity (Andrade et al., 2019; Mehta, 2019; Shehu et al., 2017; Vicenzi et al., 2016)

**TABLE 18-1.** Hepatotoxicity of Antineoplastic Agents

| Classification             | Drug                                     | Side Effects                                                                                                                                                                                                                                                                                                                | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Chemotherapy Agents</b> |                                          |                                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Alkylating agents          | Bendamustine (Bendeka®, Treanda®)        | Fatal and severe cases of liver injury due to confounding factors, including combination therapy, disease progression, or hepatitis B reactivation 3 months after treatment                                                                                                                                                 | Monitor LFTs prior to and during treatment.<br>No formal studies have been conducted on the impact of hepatic dysfunction on drug pharmacokinetics.<br>Avoid administration in patients with preexisting moderate to severe hepatic impairment (transaminases > 2.5 × ULN or total bilirubin > 1.5 × ULN). (Teva Pharmaceuticals, 2020)                                                                               |
|                            | Busulfan (IV: Busulfex®; oral: Myleran®) | Increased risk for SOS (AUC > 1,500 mcg × min) with 8% incidence in the setting of allogeneic HSCT; overall incidence of 7.7%–12%; jaundice, hepatic necrosis, hepatomegaly; SOS with an incidence of 20%–50% after HSCT                                                                                                    | Monitor transaminases, ALP, and bilirubin daily until day +28 post-HSCT to detect hepatotoxicity, which may indicate SOS.<br>Busulfan has not been studied in patients with hepatic dysfunction. Consider therapeutic drug monitoring with high doses. (National Institute of Diabetes and Digestive and Kidney Diseases, n.d.; Otsuka America Pharmaceutical, 2015)                                                  |
|                            | Chlorambucil (Leukeran®)                 | Jaundice, hepatotoxicity                                                                                                                                                                                                                                                                                                    | No formal studies have been conducted in patients with hepatic dysfunction. Monitor closely in patients with hepatic impairment.<br>Dose reduction may be considered, as no specific recommendations exist because of insufficient data. (GlaxoSmithKline, 2017)                                                                                                                                                      |
|                            | Cisplatin (Platinol®)                    | Increased aminotransferases, lactate dehydrogenase, and bilirubin; steatosis and cholestasis (rare)                                                                                                                                                                                                                         | Monitor LFTs. (Vicenzi et al., 2018; WG Critical Care, 2019)                                                                                                                                                                                                                                                                                                                                                          |
|                            | Cyclophosphamide (Cytoxan®)              | SOS (risk factor with a cytoreductive regimen for HSCT (10%–25%) using cyclophosphamide, total body irradiation, busulfan, or other agents; jaundice, cholestatic hepatitis, cytolytic hepatitis, hepatitis, cholestasis, hepatotoxicity with hepatic failure, hepatic encephalopathy, ascites, hepatomegaly, elevated LFTs | Dose reduction of 25% is recommended for serum bilirubin of 3.1–5 mg/dl or AST > 3 × ULN. Do not give if bilirubin > 5 mg/dl.<br>Hepatic impairment reduced conversion of the drug to the active metabolite, demonstrating possible decreased efficacy. Patients with severe hepatic dysfunction have a 40% decrease in total body clearance and 64% prolongation in elimination half-life. (Baxter Healthcare, 2013) |
|                            | Dacarbazine                              | Hepatic necrosis, hepatic vein thrombosis (0.01% incidence)                                                                                                                                                                                                                                                                 | Monitor for signs of liver toxicity. (Hospira, 2016)                                                                                                                                                                                                                                                                                                                                                                  |
|                            | Ifosfamide (Ifex®)                       | Hepatic failure, fulminant hepatitis, SOS, portal vein thrombosis, cytolytic hepatitis, cholestasis (1.8% incidence), jaundice, hepatorenal syndrome, elevated ALT/AST, ALP, gamma-glutamyl transferase, lactate dehydrogenase, and bilirubin                                                                               | Dose reduction of 25% is recommended with significant hepatic dysfunction (AST > 300 IU/L or bilirubin > 3 mg/dl).<br>No formal studies have been conducted in patients with hepatic dysfunction; use caution with administration. (Baxter Healthcare, 2018)                                                                                                                                                          |

| <b>Chemotherapy Agents (Cont.)</b>  |                                                |                                                                                                                                                                                                                                                                                                                                                                                                          |                                                                                                                                                                                                                                                                                                                             |
| Antimetabolites<br>( <i>Cont.</i> ) | 5-Fluorouracil<br>(Adrucil <sup>®</sup> )      | Transient elevations in aminotransferases associated with hepatic steatosis; rare cases of acute liver injury with jaundice                                                                                                                                                                                                                                                                              | Omit doses with liver failure (bilirubin > 5 mg/dl). No clear data exist on the monitoring of LFTs. (Spectrum Pharmaceuticals, 2016a)                                                                                                                                                                                       |
|                                     | Floxuridine<br>(FUDR <sup>®</sup> )            | Increased AST/ALT, ALP, and bilirubin; biliary sclerosis (1%–26%)                                                                                                                                                                                                                                                                                                                                        | Check LFTs at least weekly during therapy and after the drug has been discontinued if hepatotoxicity is evident. (Mayne Pharma, 2017)                                                                                                                                                                                       |
|                                     | Gemcitabine<br>(Gemzar <sup>®</sup> )          | Transient elevation in aminotransferases (up to 60%); liver failure and death (rare); increased ALP hepatic transaminitis (> 20%)                                                                                                                                                                                                                                                                        | Monitor liver function prior to starting and during treatment. Discontinue drug for severe hepatotoxicity. (Eli Lilly and Company, 2014; Vicenzi et al., 2018)                                                                                                                                                              |
|                                     | 6-Mercaptopurine<br>(Purinethol <sup>®</sup> ) | Intrahepatic cholestasis, parenchymal cell necrosis; jaundice (40%, appearing as early as 1 week or as late as 8 years after starting treatment), ascites, hepatic encephalopathy, hepatotoxicity most common when daily dose > 2 mg/kg, cholestatic liver damage and hepatocellular injury (30 days after initiation, moderate elevations in serum amino transaminases and ALP, bilirubin of 3–7 mg/dl) | Monitor LFTs prior to starting, then weekly, followed by monthly thereafter. Consider dose reduction in patients with hepatic impairment. Hold drug if signs of jaundice or hepatomegaly. Discontinue drug if LFTs continue to deteriorate and for toxic hepatitis or biliary stasis. (Nova Laboratories, 2014)             |
|                                     | Methotrexate                                   | Acute transaminitis (60%–80% in those receiving high-dose therapy, with a return to baseline in 1–2 weeks); risk for cirrhosis and fibrosis (in those receiving chronic low-dose therapy usually after > 2 years)                                                                                                                                                                                        | Obtain baseline hepatic enzyme levels prior to starting treatment, then every 1–2 months. Discontinue drug for moderate fibrosis. (Hospira, 2018)                                                                                                                                                                           |
|                                     | Nelarabine<br>(Arranon <sup>®</sup> )          | Elevated AST (6%), transaminases (12%), and bilirubin (10%) in pediatric patients                                                                                                                                                                                                                                                                                                                        | Monitor LFTs because of the risk for adverse reactions with severe hepatic impairment (total bilirubin > 3 × ULN). (GlaxoSmithKline, 2011)                                                                                                                                                                                  |
|                                     | Pemetrexed<br>(Alimta <sup>®</sup> )           | Elevated ALT/AST (8%–10%)                                                                                                                                                                                                                                                                                                                                                                                | Monitor LFTs periodically. Hold for hepatotoxicity for grade > 3, then resume upon recovery of LFTs to baseline or lower with 75% of the previous dose for bilirubin > 3 × ULN or transaminases > 5 × ULN. (Eli Lilly and Company, 2019)                                                                                    |
|                                     | Pentostatin<br>(Nipent <sup>™</sup> )          | Elevations in LFTs and hepatic disorders (2%)                                                                                                                                                                                                                                                                                                                                                            | Monitor LFTs. (Hospira, 2019)                                                                                                                                                                                                                                                                                               |
|                                     | Pralatrexate<br>(Foloty <sup>®</sup> )         | Liver abnormalities observed after drug administration                                                                                                                                                                                                                                                                                                                                                   | Monitor LFTs prior to starting the first and fourth dose of a given cycle. Consider dose modification with persistent LFT abnormalities. Do not give if bilirubin > 3–10 × ULN or transaminases > 5–20 × ULN. Discontinue treatment for bilirubin > 10 × ULN or transaminases > 20 × ULN. (Spectrum Pharmaceuticals, 2016b) |

**TABLE 18-1.** Hepatotoxicity of Antineoplastic Agents (*Continued*)

| Classification                                         | Drug                                                              | Side Effects                                                                                                                                             | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------------------|-------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Chemotherapy Agents (Cont.)</b>                     |                                                                   |                                                                                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Antitumor antibiotics: anthracyclines ( <i>Cont.</i> ) | Doxorubicin liposomal injection (Doxil <sup>®</sup> )             | Impaired liver function, hepatitis (< 1%)                                                                                                                | Monitor LFTs. Dose reduction of 50% is recommended for 1.2–3 mg/dl bilirubin, and 75% dose reduction is recommended for 3.1–5 mg/dl. Do not give if bilirubin > 5 mg/dl. (TTY Biopharm, 2019)                                                                                                                                                                                                                                             |
|                                                        | Epirubicin (Ellence <sup>®</sup> )                                | Elevated bilirubin or AST, which may delay drug clearance, increasing the risk of toxicity                                                               | Monitor bilirubin and AST before and during treatment. Avoid use in patients with hepatic impairment; no evaluations have been conducted. Dose reduction is recommended for elevated bilirubin or aminotransferase levels. If bilirubin is 1.2–3 mg/dl or AST > 2–4 × ULN, reduce dose to 50% of the recommended starting dose. If bilirubin > 3 mg/dl or AST > 4 × ULN, reduce dose to 25% of recommended starting dose. (Pfizer, 2014b) |
|                                                        | Idarubicin (Idamycin <sup>®</sup> )                               | Impaired drug metabolism caused by moderate to severe hepatic dysfunction, which may lead to elevated drug concentrations; severe hepatic changes (< 5%) | Monitor bilirubin prior to and during treatment. Drug pharmacokinetics have not been evaluated in patients with hepatic impairment. Consider dose reduction with elevated bilirubin. (Pfizer, 2014c)                                                                                                                                                                                                                                      |
| Miscellaneous                                          | Arsenic trioxide (Trisenox <sup>®</sup> )                         | Elevations in ALT/AST (> 5%)                                                                                                                             | Monitor LFTs in patients with severe hepatic impairment. (Teva Pharmaceuticals, 2015)                                                                                                                                                                                                                                                                                                                                                     |
|                                                        | L-Asparaginase (Elspar <sup>®</sup> )                             | Fulminant hepatic failure; moderate reversible elevation of aminotransferases, bilirubin, and ALP                                                        | Monitor LFTs at baseline and periodically during treatment. (Merck, 2013)                                                                                                                                                                                                                                                                                                                                                                 |
|                                                        | Asparaginase <i>Erwinia chrysanthemi</i> (Erwinaze <sup>®</sup> ) | Mild elevations in bilirubin and transaminases (4%)                                                                                                      | Monitor LFTs at baseline and periodically during treatment. (Jazz Pharmaceuticals, 2016)                                                                                                                                                                                                                                                                                                                                                  |
|                                                        | Bexarotene (Targretin <sup>®</sup> )                              | Elevations of ALT (2%–9%), AST (5%–7%), and bilirubin (0%–6%)                                                                                            | Monitor LFTs at baseline, after weeks 1, 2, and 4, and if stable, then every 8 weeks thereafter. Consider holding or discontinuing the drug if ALT/AST or bilirubin > 3 × ULN. No studies have been done in patients with hepatic insufficiency. (Valeant Pharmaceuticals North America, 2015)                                                                                                                                            |
|                                                        | Eribulin mesylate (Halaven <sup>®</sup> )                         | Grade 2 or elevated ALT (18%); elevated bilirubin; mild to moderate hepatic dysfunction (an increase of drug exposure by 1.8–2.5-fold)                   | Dose reduction is recommended in patients with hepatic dysfunction, with a dose of 1.1 mg/m <sup>2</sup> in mild (Child-Pugh A) and 0.7 mg/m <sup>2</sup> in moderate (Child-Pugh B) hepatic impairment. No studies have been conducted in patients with severe hepatic impairment. (Eisai, 2016)                                                                                                                                         |

| <b>Chemotherapy Agents (Cont.)</b>           |                                                                                                   |                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Plant alkaloids: taxanes<br>( <i>Cont.</i> ) | Docetaxel (Taxotere <sup>®</sup> )                                                                | Transient elevations in ALP, ALT/AST, and bilirubin (5%–20%); decreased clearance with elevated bilirubin or transaminases | Monitor LFTs prior to each cycle of treatment. It is recommended not to give the drug if baseline bilirubin is $> \text{ULN}$ or $\text{AST} > 1.5 \times \text{ULN}$ with $\text{ALP} > 2.5 \times \text{ULN}$ . Reduce dose by 20%–40% with grade 2–3 elevations in aminotransferases $> 2.5$ to $< 5 \times \text{ULN}$ at baseline with elevated ALP. Discontinue drug if $\text{ALT/AST} > 5 \times \text{ULN}$ or $\text{ALP} > 5 \times \text{ULN}$ . (Sanofi-Aventis U.S., 2020b)                                                                                                                                                                                         |
|                                              | Paclitaxel (Taxol <sup>®</sup> )                                                                  | Transient elevations in ALP, AST, and bilirubin (5%–20%); for high doses, up to 37%; hepatic necrosis and encephalopathy   | Monitor LFTs. Dose modifications for preexisting liver disease include a total dose of $175 \text{ mg/m}^2$ for bilirubin $\leq 1.25 \times \text{ULN}$ and $\text{AST} < 10 \times \text{ULN}$ ; a total dose of $135 \text{ mg/m}^2$ for bilirubin $1.26\text{--}2 \times \text{ULN}$ and aminotransferases $< 10 \times \text{ULN}$ ; and total dose of $90 \text{ mg/m}^2$ for bilirubin $2.01\text{--}5 \times \text{ULN}$ and aminotransferases $< 10 \times \text{ULN}$ . The drug is not recommended in patients with bilirubin $> 5\text{--}7.5 \times \text{ULN}$ or aminotransferases $\geq 10 \times \text{ULN}$ . (Bristol-Myers Squibb, 2011; Vicenzi et al., 2018) |
| Plant alkaloids: topoisomerase 1 inhibitor   | Topotecan (Hycamtin <sup>®</sup> )                                                                | Increased aminotransferases and ALP (up to 5%–8%)                                                                          | Monitor LFTs periodically prior to and during treatment. (Novartis Pharmaceuticals, 2018b; Vicenzi et al., 2018)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Plant alkaloids: vinca alkaloids             | Vincristine sulfate (Oncovin <sup>®</sup> ), Vincristine sulfate liposome (Marqibo <sup>®</sup> ) | Severe hepatotoxicity when given with irradiation; SOS, particularly in pediatric patients; elevated AST                   | Monitor LFTs. Dose reduction of 50% is recommended with bilirubin $> 3 \text{ mg/dL}$ . (Acrotech Biopharma, 2020; Hospira, 2014)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Targeted Therapy Agents</b>               |                                                                                                   |                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Small molecule inhibitors                    | Afatinib (Gilotrif <sup>®</sup> )                                                                 | Liver abnormalities (10.1%) with fatal hepatic impairment (0.18%)                                                          | Monitor LFTs periodically. No dosing adjustment is recommended for mild (Child-Pugh A) or moderate (Child-Pugh B) hepatic dysfunction. No studies have been done on severe (Child-Pugh C) hepatic dysfunction. Hold or discontinue for severe LFT changes. (Boehringer Ingelheim, 2018)                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Targeted Therapy Agents (<i>Cont.</i>)</b> |                                        |                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Small molecule inhibitors<br>( <i>Cont.</i> ) | Alectinib<br>(Alecensa <sup>®</sup> )  | Elevations of ALT > 5 × ULN (5.3%), AST > 5 × ULN (4.6%), and bilirubin > 3 × ULN (3.7%) | Monitor LFTs every 2 weeks for the first 2 months of treatment, then periodically thereafter; increase frequency with noted ALT/AST or bilirubin elevations. No dose adjustment is recommended for mild hepatic dysfunction (bilirubin ≤ ULN and AST > ULN or bilirubin 1–1.5 × ULN with any AST). For ALT/AST > 5 × ULN with bilirubin ≤ 2 × ULN, hold drug until patient recovers to baseline or ≤ 3 × ULN, and resume at dose reduction of 450 mg twice daily. For ALT/AST > 3 × ULN with bilirubin > 2 × ULN without cholestasis or hemolysis, discontinue drug. For bilirubin > 3 × ULN, hold drug until patient recovers to baseline or ≤ 1.5 × ULN, and resume at dose reduction of 450 mg twice daily. Depending on the severity of hepatic dysfunction, consider discontinuation of the drug.<br>(Genentech, 2017a) |
|                                               | Axitinib<br>(Inlyta <sup>®</sup> )     | Elevated ALT/AST more frequent than elevated ALP                                         | Monitor ALT/AST and bilirubin prior to starting treatment, then periodically throughout treatment. No dose adjustment is recommended in mild hepatic impairment (Child-Pugh A). The initial dose should be reduced by 50% in patients with moderate hepatic dysfunction (Child-Pugh B).<br>(Pfizer, 2020a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                                               | Belinostat<br>(Beleodaq <sup>®</sup> ) | Fatal hepatotoxicity and liver abnormalities                                             | Monitor LFTs. For grade 3–4 hepatotoxicity, reduce dose by 25% (750 mg/m <sup>2</sup> ). For recurrence of grade 3–4 hepatotoxicity, after 2 dose reductions, discontinue drug.<br>(Spectrum Pharmaceuticals, 2014)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                                               | Bortezomib<br>(Velcade <sup>®</sup> )  | Acute liver failure, hepatitis, and elevated ALT/AST and bilirubin                       | Monitor LFTs during treatment. No dosing adjustment is recommended with mild hepatic impairment (bilirubin < 1–1.5 × ULN or AST > ULN). In patients with moderate or severe hepatic dysfunction (bilirubin > 1.5–3 × ULN or bilirubin > 3 × ULN with any AST), start at a lower dose of 0.7 mg/m <sup>2</sup> for the first cycle and escalate to 1 mg/m <sup>2</sup> or reduce to 0.5 mg/m <sup>2</sup> based on tolerance.<br>(Millennium Pharmaceuticals, 2014)                                                                                                                                                                                                                                                                                                                                                           |
|                                               | Bosutinib<br>(Bosulif <sup>®</sup> )   | Elevated ALT/AST, bilirubin, and ALP                                                     | Monitor LFTs at least monthly for 3 months, then as needed. For baseline hepatic dysfunction, reduce dose to 200 mg daily. For elevated transaminases > 5 × ULN, hold drug until the patient recovers to < 2.5 × ULN and resume at 400 mg daily. Discontinue drug if recovery takes > 4 weeks. Discontinue drug if transaminases > 3 × ULN with bilirubin > 2 × ULN and ALP < 2 × ULN.<br>(Pfizer, 2017a)                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Small molecule inhibitors<br>( <i>Cont.</i> ) | Dasatinib (Sprycel®)                                                  | Elevated transaminases and bilirubin, ascites, cholestasis, cholecystitis, hepatitis                                                                                       | Use caution with hepatic impairment. Consider holding and reducing dose with persistent elevation of ALT/AST > 5 × ULN or bilirubin > 3 × ULN. (Bristol-Myers Squibb, 2017)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                                               | Duvelisib (Copiktra®)                                                 | The median time to onset of any grade transaminase elevation was 2 months (range: 3 days to 26 months), with median event duration of 1 month (range: 1 day to 16 months). | For grade 2 ALT/AST elevation (> 3–5 × ULN), maintain dose and monitor at least weekly until return to < 3 × ULN.<br>For grade 3 ALT/AST elevation (> 5–20 × ULN), withhold and monitor at least weekly until return to < 3 × ULN. Resume at the same dose (first occurrence) or at a reduced dose for subsequent occurrence.<br>For grade 4 ALT/AST elevation (> 20 × ULN), discontinue drug. (Verastem, 2019)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                                               | Eltrombopag (Promacta®)                                               | Increased risk of severe and potentially life-threatening hepatotoxicity                                                                                                   | Measure serum ALT, AST, and bilirubin prior to starting treatment, every 2 weeks during the dose adjustment phase, and monthly following the establishment of a stable dose.<br>Eltrombopag inhibits UGT1A1 and OATP1B1, which may lead to indirect hyperbilirubinemia. If bilirubin is elevated, perform fractionation. Evaluate abnormal serum liver tests with repeat testing within 3–5 days. If the abnormalities are confirmed, monitor serum liver tests weekly until resolved or stabilized.<br>Discontinue therapy if ALT levels ≥ 3 × ULN in patients with normal liver function or ≥ 3 × baseline (or > 5 × ULN, whichever is the lower) in patients with pre-treatment elevations in transaminases that are progressively increasing, persistent for ≥ 4 weeks, accompanied by increased direct bilirubin, or accompanied by clinical symptoms of liver injury or evidence for hepatic decompensation.<br>If the potential benefit of reinitiating treatment outweighs the risk for hepatotoxicity, consider cautiously reintroducing therapy and measuring serum liver tests weekly during the dose adjustment phase. Hepatotoxicity may recur. (Novartis Pharmaceuticals, 2021) |
|                                               | Erlotinib (Tarceva®)                                                  | Hepatic failure and hepatorenal syndrome reported                                                                                                                          | Monitor LFTs periodically. Increase frequency with noted elevated LFTs. Closely monitor if patient has Child-Pugh A, B, or C cirrhosis.<br>Interrupt or discontinue treatment if bilirubin > 3 × ULN or elevated aminotransferases > 5 × ULN.<br>Discontinue drug with hepatic failure. (Astellas Pharma US, 2016)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                                               | Everolimus (Afinitor®, Afinitor Disperz® tablets for oral suspension) | Risk for reactivation of viral hepatitis                                                                                                                                   | Dose reduction of 25% is recommended for patients with Child-Pugh A cirrhosis. A 50% reduction is recommended for Child-Pugh B cirrhosis. Dose reduction to 5 mg daily is recommended for Child-Pugh B.<br>Avoid use in patients with severe hepatic dysfunction (Child-Pugh C). (Novartis Pharmaceuticals, 2018a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Small molecule inhibitors<br>( <i>Cont.</i> ) | Pexidartinib<br>(Turalio™) | Serious and potentially fatal liver injury; only available through a restricted risk evaluation and mitigation strategy program | Taking with food increases drug exposure by 100% and may increase the risk of hepatotoxicity. Administer on an empty stomach, either 1 hour before or 2 hours after a meal or snack.<br>Monitor LFTs prior to starting treatment, weekly for the first 8 weeks, every 2 weeks for the next month, and every 3 months thereafter. Withhold and dose reduce, or permanently discontinue based on the severity of the hepatotoxicity. Rechallenge with a reduced dose may result in a recurrence of increased serum transaminases, bilirubin, or ALP. Monitor LFTs weekly for the first month after rechallenge.<br>(Daiichi Sankyo, 2020)   |
|                                               | Ponatinib<br>(Iclusig®)    | Elevated ALT/AST                                                                                                                | Monitor LFTs prior to, monthly, and as clinically indicated during treatment. Hold drug with elevation of transaminases $> 3 \times \text{ULN}$ ( $\geq$ grade 2) until patient recovers to $< 3 \times \text{ULN}$ (grade 1), then resume drug at a reduced dose. Discontinue drug with elevations of ALT/AST $> 3 \times \text{ULN}$ with elevated bilirubin $> 2 \times \text{ULN}$ and ALP $< 2 \times \text{ULN}$ .<br>Avoid giving the drug in patients with moderate to severe (Child-Pugh B or C) hepatic dysfunction.<br>(ARIAD Pharmaceuticals, 2016)                                                                           |
|                                               | Pralsetinib<br>(Gavreto™)  | Elevated transaminases                                                                                                          | Monitor ALT/AST prior to starting treatment, every 2 weeks during the first 3 months, then monthly thereafter and as clinically indicated. Withhold, reduce dose, or permanently discontinue drug based on severity (Genentech, 2021).                                                                                                                                                                                                                                                                                                                                                                                                    |
|                                               | Regorafenib<br>(Stivarga®) | Elevated LFTs; hepatocellular necrosis                                                                                          | Obtain baseline LFTs prior to starting treatment, at least every 2 weeks during the first 2 months of treatment, then monthly.<br>Dose reduction is recommended for grade 2 hepatic impairment.<br>Discontinue drug for ALT/AST $> 20 \times \text{ULN}$ or ALT/AST $> 3 \times \text{ULN}$ with bilirubin $> 2 \times \text{ULN}$ or recurrence of ALT/AST $> 5 \times \text{ULN}$ despite dose reduction.<br>Drug is not recommended for patients with severe hepatic impairment (Child-Pugh C).<br>(Bayer HealthCare Pharmaceuticals, 2020)                                                                                            |
|                                               | Ribociclib<br>(Kisqali®)   | Elevated ALT/AST (7%–10%; grade 3–4) and bilirubin (1%)                                                                         | Monitor LFTs at baseline, every 2 weeks for the first 2 cycles, at the beginning of each subsequent 4 cycles, then as clinically indicated.<br>Dose reduce to 400 mg in patients with moderate to severe hepatic impairment (Child-Pugh B or C).<br>Hold for ALT/AST $> 3\text{--}20 \times \text{ULN}$ until patient recovers to baseline or $<$ grade 2–3 toxicity. Consider resuming at the same dose or reducing the dose depending on toxicity.<br>Discontinue drug for elevated ALT/AST $> 3 \times \text{ULN}$ with bilirubin $> 2 \times \text{ULN}$ or if ALT/AST $> 20 \times \text{ULN}$ .<br>(Novartis Pharmaceuticals, 2017) |

**TABLE 18-1.** Hepatotoxicity of Antineoplastic Agents (*Continued*)

| Classification                                          | Drug                      | Side Effects                                                                                                                                                                                   | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------------------------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Targeted Therapy Agents (Cont.)</b>                  |                           |                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Small molecule inhibitors<br>( <i>Cont.</i> )           | Umbralisib (Ukoniq™)      | Elevated transaminases                                                                                                                                                                         | Monitor liver function at baseline and during treatment. For ALT/AST greater than 5 to less than 20 × ULN, withhold until return to < 3 × ULN, then resume at a reduced dose. For ALT/AST elevation > 20 × ULN, discontinue drug. (TG Therapeutics, 2021)                                                                                                                                                                                                                                                                                                                                                    |
|                                                         | Vandetanib (Caprelsa®)    | Elevated ALT/AST (20%) and bilirubin                                                                                                                                                           | Dose reduction is recommended for ≥ grade 3 toxicity. The drug is not recommended in patients with moderate or severe hepatic impairment. It is recommended to avoid use in patients with severe hepatic impairment (Child-Pugh B or C cirrhosis). (AstraZeneca Pharmaceuticals, 2014)                                                                                                                                                                                                                                                                                                                       |
|                                                         | Vemurafenib (Zelboraf®)   | Elevated ALT/AST, ALP, and bilirubin                                                                                                                                                           | Monitor LFTs prior to starting therapy and monthly during therapy or as clinically indicated. Hold drug for grade 2–3 toxicities until patient recovers to < grade 1 toxicity or baseline. Resume at recommended dose reductions. Discontinue drug for grade 4 toxicities. (Genentech, 2017c)                                                                                                                                                                                                                                                                                                                |
| <b>Immunotherapy Agents</b>                             |                           |                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Checkpoint inhibitors: cytotoxic T-lymphocyte antigen 4 | Ipilimumab (Yervoy®)      | Immune-related hepatitis T-cell activation and proliferation, leading to immune-mediated organ failure, increased aminotransferases, and hyperbilirubinemia                                    | Monitor LFTs and assess for signs and symptoms of hepatotoxicity prior to each dose. No dose adjustment is recommended for mild hepatic dysfunction (bilirubin > 1–1.5 × ULN or ALT/AST > ULN). Hold drug for grade 2 toxicities. Discontinue drug for grade 3–4 toxicities; initiate steroids (1–2 mg/kg prednisone daily or equivalent) until LFTs return to baseline or evidence of sustained improvement is seen. Taper steroids over 1 month. Mycophenolate has been given in the setting of persistent severe hepatitis despite high-dose steroids. (Bristol-Myers Squibb, 2020; Vicenzi et al., 2018) |
| Checkpoint inhibitors: programmed cell death protein 1  | Nivolumab (Opdivo®)       | Elevated ALT (16%), AST (28%), ALP (22%), and bilirubin (9%); immune-mediated hepatitis (1.1%)                                                                                                 | Monitor LFTs prior to and periodically during treatment. For ≥ grade 2 elevations in transaminases or bilirubin, initiate steroids 1–2 mg/kg prednisone daily or equivalent. Discontinue drug for grade 3–4 hepatitis. (Bristol-Myers Squibb, 2021)                                                                                                                                                                                                                                                                                                                                                          |
|                                                         | Pembrolizumab (Keytruda®) | Immune-mediated hepatitis (0.7%; grade 2: 0.1%; grade 3: 0.4%; grade 4: < 0.1%), elevated ALP (26%; grade 3–4: 3.1%), elevated AST (22%; grade 3–4: 2.1%), elevated ALT (21%; grade 3–4: 1.8%) | Monitor for LFT changes. For grade 2 LFT changes, initiate steroids 0.5–1 mg/kg daily; for ≥ grade 3, initiate steroids 1–2 mg/kg prednisone daily or equivalent followed by a taper. Depending on severity of LFT changes, hold or discontinue drug. (Merck, 2021)                                                                                                                                                                                                                                                                                                                                          |

| <b>Immunotherapy Agents (Cont.)</b>                   |                           |                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Checkpoint inhibitors: programmed cell death-ligand 1 | Atezolizumab (Tecentriq®) | Across clinical trials (N = 1,978): grade 3–4 elevations in ALT (2.5%), AST (2.3%), and total bilirubin (1.6%); in patients with urothelial carcinoma (n = 523): immune-mediated hepatitis (1.3%), grade 3–4 elevations in ALT (2.5%), AST (2.5%), and total bilirubin (2.1%), with median time to onset of 1.1 months (range: 0.4–7.7 months) | Monitor for LFT changes, including signs and symptoms of hepatitis. Monitor AST, ALT, and bilirubin prior to and periodically during treatment. Administer corticosteroids at dose of 1–2 mg/kg prednisone daily equivalents for ≥ grade 2 transaminase elevations, with or without concurrent total bilirubin elevation, followed by corticosteroid taper. Hold drug for moderate hepatic impairment (ALT or AST > 3–5 × ULN or total bilirubin > 1.5–3 × ULN). Permanently discontinue drug for severe or life-threatening hepatic impairment (AST or ALT > 5 × ULN or total bilirubin > 3 × ULN). (Genentech, 2018b)                                                    |
|                                                       | Avelumab (Bavencio®)      | Immune-mediated hepatitis (0.9%; grade 3: 0.6%; grade 5: 0.1%; median time to onset 3.2 months [range 1 week to 15 months]; median duration 2.5 months [range 1 day to 7+ months]); grade 3–4 elevations in AST (1%), ALT (5%), and total bilirubin (1%)                                                                                       | Monitor patients for abnormal LFTs prior to and periodically during treatment. Administer corticosteroids (initial dose of 1–2 mg/kg prednisone daily or equivalent, followed by a corticosteroid taper) for ≥ grade 2 hepatitis. Withhold drug for moderate (grade 2; AST/ALT 3–5 × ULN or total bilirubin > 1.5 and up to 3 × ULN) or immune-mediated hepatitis until resolution, and permanently discontinue for severe (grade 3 ALT/AST > 5 × ULN or total bilirubin > 3 × ULN) or life-threatening (grade 4) immune-mediated hepatitis. (EMD Serono & Pfizer, 2019)                                                                                                   |
|                                                       | Durvalumab (Imfinzi®)     | Immune-mediated hepatitis (1.1%; grade 3: 0.6%; median time to onset of 51.5 days [range: 15–312 days]); grade 3–4 elevations in ALT (3%), AST (4.3%), and total bilirubin (2.8%)                                                                                                                                                              | Monitor LFTs for changes in each cycle during treatment. For grade 2–3 elevations in transaminases with or without concurrent total bilirubin elevation, initiate dose of 1–2 mg/kg prednisone daily or equivalent followed by taper. Hold drug for moderate hepatic impairment (grade 2 ALT/AST > 3–5 × ULN or total bilirubin > 1.5–3 × ULN; grade 3 ALT/AST ≤ 8 × ULN or total bilirubin ≤ 5 × ULN). Permanently discontinue drug for severe or life-threatening hepatic impairment (grade 3 ALT or AST > 8 × ULN or total bilirubin > 5 × ULN; concurrent ALT or AST > 3 × ULN and total bilirubin > 2 × ULN with no other cause). (AstraZeneca Pharmaceuticals, 2020) |
|                                                       | Cemiplimab (Libtayo®)     | Immune-mediated hepatitis (2.1%); grade 3 (1.7%), grade 4–5 (0.2%); grade 3 AST (3%)                                                                                                                                                                                                                                                           | Withhold drug if ALT/AST increases to > 3–10 × ULN or if total bilirubin increases up to 3 × ULN. Permanently discontinue drug if AST/ALT increases to > 10 × ULN or total bilirubin increases to > 3 × ULN. Systemic corticosteroids were required in all patients with hepatitis, including 91% who received prednisone ≥ 40 mg daily or equivalent. (Morgado et al., 2020; Regeneron Pharmaceuticals, 2021)                                                                                                                                                                                                                                                             |

| <b>Immunotherapy Agents (Cont.)</b>                           |                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Cytokines: interferons                                        | Pegylated interferon alfa-2a (Pegasys®); pegylated interferon alfa-2b (Sylatron™) | Significant elevation in aminotransferases ( $> 10 \times \text{ULN}$ )                                                                                                                                                                                                                                                                                                                 | Monitor LFTs on weeks 1, 2, 4, 6, and 8; then every 4–6 weeks; and more frequently if abnormalities. It is recommended to hold dose if aminotransferases $> 5 \times \text{ULN}$ until resolution to grade 1, then reduce dose by 33%. (Hoffmann-La Roche, 2011; Merck, 2015a)                                                                                                                                                                                                                                                                                  |
| Cytokines: interleukins                                       | Interleukin-2, aldesleukin (Proleukin®)                                           | Hepatitis, hepatosplenomegaly, cholecystitis                                                                                                                                                                                                                                                                                                                                            | Monitor LFTs prior to starting therapy, then daily during treatment. (Bayer HealthCare Pharmaceuticals, 2012)                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Interleukin-3 receptor alpha chain (CD123)-directed cytotoxin | Tagraxofusp-erzs (Elzonris™)                                                      | Hepatotoxicity                                                                                                                                                                                                                                                                                                                                                                          | Monitor ALT/AST prior to each infusion. Withhold therapy if ALT/AST increases $> 5 \times \text{ULN}$ . Treatment can resume when transaminase elevations are $\leq 2.5 \times \text{ULN}$ . (Stemline Therapeutics, 2018)                                                                                                                                                                                                                                                                                                                                      |
| Immunomodulators                                              | Lenalidomide (Revlimid®)                                                          | Hepatic failure, including fatalities (15% with hepatocellular, cholestatic, and mixed characteristic); patients with multiple myeloma (2%) and myelodysplasia (1%) with hepatotoxicity events (e.g., hyperbilirubinemia, cholecystitis, acute cholecystitis, hepatic failure); risk factors: preexisting viral liver disease, elevated baseline liver enzymes, concomitant medications | Monitor LFTs periodically; stop drug and evaluate if hepatotoxicity is suspected. Treatment at lower dose may be considered if LFTs return to baseline values. (Celgene, 2013)                                                                                                                                                                                                                                                                                                                                                                                  |
|                                                               | Pomalidomide (Pomalyst®)                                                          | Elevated bilirubin                                                                                                                                                                                                                                                                                                                                                                      | Avoid in patients with bilirubin $> 2 \text{ mg/dl}$ or ALT/AST $> 3 \times \text{ULN}$ . Dose reduction of 25% is recommended for mild or moderate (Child-Pugh A or B) hepatic impairment; 50% dose reduction is recommended for severe (Child-Pugh C) hepatic impairment. (Celgene, 2017)                                                                                                                                                                                                                                                                     |

| <b>Immunotherapy Agents (Cont.)</b>               |                                                 |                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Monoclonal antibodies: humanized ( <i>Cont.</i> ) | Obinutuzumab (Gazyva <sup>®</sup> )             | Hepatitis B virus reactivation, with some cases resulting in fulminant hepatitis, hepatic failure, and death                     | Screen for hepatitis B infection (hepatitis B surface antigen and hepatitis B core antibody) prior to starting treatment; if patient is positive for hepatitis B infection, consult expert for monitoring and consideration of antiviral therapy. Monitor patients with current or prior hepatitis B infection for signs of hepatitis or hepatitis B reactivation during therapy and for several months after treatment. Discontinue drug for hepatitis B reactivation while on treatment. Insufficient data exist on safety of resuming drug in patients with hepatitis B reactivation. (Genentech, 2017b)                                                                                                                     |
|                                                   | Ofatumumab (Arzerra <sup>®</sup> )              | Hepatitis B virus reactivation, fulminant hepatitis                                                                              | Screen high-risk patients prior to starting treatment. Monitor carriers of hepatitis B closely for clinical and laboratory signs of active infection during treatment and for 6–12 months following final dose. Discontinue drug in patients who develop viral hepatitis or viral hepatitis reactivation. (GlaxoSmithKline, 2014a)                                                                                                                                                                                                                                                                                                                                                                                              |
|                                                   | Polatuzumab vedotin-piiq (Polivy <sup>™</sup> ) | Preexisting liver disease, elevated baseline liver enzymes, and concomitant medications that increase the risk of hepatotoxicity | Monitor liver enzymes and bilirubin levels. (Genentech, 2020)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Hormone Therapy Agents</b>                     |                                                 |                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Androgen inhibitor                                | Abiraterone acetate (Zytiga <sup>®</sup> )      | Elevated ALT/AST and bilirubin                                                                                                   | Monitor ALT/AST and bilirubin prior to starting therapy, every week for the first month, every 2 weeks for the following 2 months of treatment, then monthly thereafter. For moderate hepatic impairment, reduce dose to 250 mg daily. Hold drug if ALT/AST > 5 × ULN or bilirubin > 3 × ULN until patient recovers to baseline or ALT/AST ≤ 2.5 × ULN or bilirubin ≤ 1.5 × ULN. Resume at reduced dose of 750 mg daily at first occurrence and 500 mg daily at second occurrence. Discontinue if ALT/AST > 5 × ULN or bilirubin > 3 × ULN with moderate hepatic impairment or if the patient is unable to tolerate 500 mg daily. Avoid drug in patients with severe hepatic impairment (Child-Pugh C). (Janssen Biotech, 2020) |

*Note.* Review package inserts for dosing and prescribing information.

ALP—alkaline phosphatase; ALT—alanine aminotransferase; AST—aspartate aminotransferase; AUC—area under the plasma concentration versus-time curve; HSCT—hematopoietic stem cell transplantation; LFTs—liver function tests; SOS—sinusoidal obstruction syndrome; ULN—upper limit of normal

- a) Malaise, myalgia, arthralgia, low-grade fever
  - b) Gastrointestinal symptoms (e.g., anorexia, nausea, vomiting, right upper quadrant pain, acholic stools that are pale, clay-like, or putty-colored due to problems in the biliary system)
  - c) Jaundice, hyperpigmentation, ascites
  - d) Dark-colored urine
  - e) Pruritus
  - f) Hepatomegaly
  - g) Coagulopathy; bruising or bleeding
  - h) Hepatic encephalopathy
  - i) Hypersensitivity reactions (e.g., fever, rash, mononucleosis illness, additional evidence of toxicity to other organs)
- F. Pathologic manifestations associated with drug toxicity in the liver (Botti et al., 2016; Gordon et al., 2017; Mehta, 2019; Tewari et al., 2017)
1. Acute hepatocellular injury
    - a) Incidence: 90% of cases (Mehta, 2019)
    - b) Pathophysiology
      - (1) Hepatocellular apoptosis, steatosis, or cellular degeneration can occur.
      - (2) Liver cells appear spotty (minute clusters of hepatocytes) or confluent (larger groups of hepatocytes involving multiple lobules under microscopy) (Krishna, 2017).
      - (3) The hepatic acinus is the functional unit in the liver that is divided into different zones.
        - (a) Zone 1 encircles the portal tracts, where oxygenated blood from hepatic arteries enters. Zone 3 is located around the central veins, where oxygenation is poor. Zone 2 is located between zones 1 and 3.
        - (b) Zone 3 is most commonly affected.
          - i. Zonal necrosis occurs with compounds with predictable, dose-dependent, and intrinsic toxicity.
          - ii. Nonzonal necrosis (diffuse, irregular, patchy injury involving all parts of the acinus) occurs with compounds with unpredictable idiosyncratic injury (Fisher et al., 2015).
      - (4) Most recover without developing significant fibrosis.
    - c) Signs and symptoms include jaundice, painful hepatomegaly, abdominal distension, nausea and vomiting, malaise, confusion, and sleepiness.
  2. Chronic hepatocellular injury
    - a) Incidence: 5%–10% of cases (Mehta, 2019)
    - b) Pathophysiology
      - (1) Pigment accumulation (excessive iron): Lipofuscin (fine yellow-brown pigment granules) is found in hepatic cells as a result of certain drugs. Excessive iron may accumulate in the liver due to over ingestion or parenteral therapy (Mehta, 2019).
      - (2) Steatosis, steatohepatitis, phospholipidosis
      - (3) Hepatic fibrosis, cirrhosis
    - c) Signs and symptoms include nausea, diarrhea, poor appetite, weight loss, fatigue, jaundice, easy bruising or bleeding, pruritus, and lower extremity swelling.
  3. Acute cholestasis: decrease in bile flow due to impaired secretion by hepatocytes or bile flow obstruction through intra- or extrahepatic bile ducts (Gasmi & Kleiner, 2020; Mehta, 2019; Nazer, 2017)
    - a) Incidence: 2%–5% of cases (Mehta, 2019)
    - b) Pathophysiology (Gasmi & Kleiner, 2020; Mehta, 2019; Nazer, 2017)
      - (1) Reduction in bile flow due to decreased secretion or biliary tree obstruction
      - (2) Pure cholestasis (canalicular, bland, or noninflammatory) characterized by prominent hepatocellular or canalicular cholestasis with minimal hepatocellular injury or inflammation
      - (3) Cholestatic hepatitis (hepatocanalicular, cholangiolitic, or inflammatory) characterized by inflammation, prominent cholestasis, and hepatocellular injury
    - c) Signs and symptoms include pruritus, jaundice, pale stools, and dark urine.
  4. Chronic cholestasis
    - a) Incidence
      - (1) Approximately 1% of cases
      - (2) Progresses to cirrhosis in rare cases (Mehta, 2019)
    - b) Pathophysiology (Mehta, 2019)
      - (1) Bile duct loss or cholate stasis (the rim of pale hepatocytes adjacent to portal tracts)
      - (2) Prolonged damage leading to bile duct loss and overt ductopenia
    - c) Signs and symptoms include pruritus, jaundice, pale stools, and dark urine.
  5. Steatosis: infiltration of liver cells with fat, which is associated with metabolism being disturbed by drug therapy and mitochondrial function (Mehta, 2019; Meunier & Larrey, 2020)
    - a) Incidence: 20%–30% of cases (Meunier & Larrey, 2020)
    - b) Pathophysiology
      - (1) Acute steatosis causes hepatic cells to appear microvesicular (small vesicles of fat droplets). In contrast, chronic steatosis causes hepatic cells to appear macrovesic-

- ular (large vesicles of fat droplets) under microscopy (Gasmi & Kleiner, 2020).
- (2) Hepatocytes are filled with excess fatty cells composed of triglycerides (Marchisello et al., 2019).
- (3) Disruption occurs in mitochondrial beta-oxidation of lipids.
- (4) Steatohepatitis includes variable steatosis, lobular inflammation, and hepatocellular injury.
- c) Signs and symptoms include ascites, jaundice, confusion, and tendency to bleed easily.
- 6. Granulomas: macrophages that have accumulated in the liver because of chronic exposure to drug therapy (Culver et al., 2016; Mehta, 2019)
  - a) Incidence: 2%–15% of cases (Ortiz-Brizuela et al., 2019)
  - b) Pathophysiology
    - (1) Inflammatory process
    - (2) Seen in periportal and portal areas
    - (3) Temporary injury
  - c) Signs and symptoms include fevers, myalgias, fatigue, right upper quadrant abdominal pain, elevated liver function tests, and jaundice (Culver et al., 2016).
- 7. Budd-Chiari syndrome: hepatic venous outflow obstruction (Mehta, 2019)
  - a) Incidence: 17% of cases (Khan et al., 2019)
  - b) Pathophysiology
    - (1) Drug-induced thrombosis of hepatic veins or inferior vena cava
    - (2) Centrizonal congestion, hepatocellular necrosis, hemorrhage
    - (3) Large regenerative nodules and obstructive portal venopathy
    - (4) Budd-Chiari syndrome includes classical (obstruction occurs within the hepatic vein and is more common in women), hepatic vena cava (inferior vena cava obstruction with or without the involvement of the hepatic veins and small vessel and more common in men), and small vessel versions (very rare; hepatic outflow obstruction limited to small intrahepatic veins) (Khan et al., 2019).
  - c) Signs and symptoms include painful hepatomegaly, jaundice, ascites, fever, pedal edema, dilated truncal veins, esophageal bleeding (less common), and hepatic encephalopathy (less common) (Khan et al., 2019).
- 8. Hepatic sinusoidal obstruction syndrome (SOS; formerly known as veno-occlusive disease): syndrome comprising weight gain, ascites, painful hepatomegaly, and jaundice caused by damage to the sinusoidal endothelial cells and leading to obstruction of the hepatic vessels (Botti et al., 2016; Corbacioglu et al., 2019; Gasmi & Kleiner, 2020; Mehta, 2019; Mohty et al., 2016; Nasserredine et al., 2018; Shehu et al., 2017; Tewari et al., 2017; Valla & Cazals-Hatem, 2016)
  - a) Incidence: approximately 14% of patients following allogeneic hematopoietic stem cell transplantation (HSCT) (range 0%–62%, depending on the series) (Corbacioglu et al., 2020)
    - (1) SOS is a complication of HSCT that most often occurs 20–30 days after receiving the conditioning regimen (Valla & Cazals-Hatem, 2016).
    - (2) The incidence of SOS following allogeneic HSCT has diminished, and outcomes have improved over the past decade (Nasserredine et al., 2018).
  - b) Pathophysiology
    - (1) Injury occurs to the sinusoids, hepatic veins, and hepatic arteries.
    - (2) Luminal narrowing of sinusoids leads to increased resistance to blood flow, resulting in hepatic congestion, sinusoidal dilation, and portal hypertension culminating in fibrosis.
    - (3) Thrombi may be seen in larger veins (Gasmi & Kleiner, 2020).
  - c) Risk factors (Corbacioglu et al., 2019)
    - (1) Patient-related factors
      - (a) Age
      - (b) Preexisting liver disease
      - (c) Underlying diagnosis (leukemia), advanced disease status
      - (d) Previous treatment (e.g., gemtuzumab ozogamicin, inotuzumab ozogamicin)
      - (e) Other previous organ toxicities (e.g., pulmonary, abdomen)
      - (f) Poor performance status
      - (g) Genetic factors
      - (h) Elevated ferritin
    - (2) Transplantation-related factors
      - (a) Allogeneic donor
      - (b) Previous transplant
      - (c) Myeloablative conditioning
      - (d) Graft-versus-host disease prophylaxis
      - (e) Antithymocyte globulin (horse)
  - d) Signs and symptoms include painful hepatomegaly, ascites, abdominal pain, weight gain, and hyperbilirubinemia (Corbacioglu et al., 2020; Hoofnagle & Björnsson, 2019; Tewari et al., 2017).
  - e) Assessment: Two grading systems have historically been used to diagnose and stage SOS—the Baltimore criteria (Bonifazi et al., 2020) and the modified Seattle criteria (Cairo et al., 2020; Corbacioglu et al., 2019).

- (1) The Baltimore criteria are more stringent, with an absolute requirement for hyperbilirubinemia. The severity of SOS can be classified retrospectively using the Seattle criteria (Nassereddine et al., 2018).
    - (2) The European Group for Blood and Marrow Transplantation (formerly the European Society for Blood and Marrow Transplantation) has proposed revised criteria for diagnosis and grading in adults and children (Corbacioglu et al., 2019; Faraci et al., 2019; Mohty et al., 2016; see Table 18-2).
  9. Neoplastic lesions: Focal nodular hyperplasia and hepatocellular adenomas have been seen with hepatotoxic drugs (Mehta, 2019).
    - a) Incidence: 6% of cases (Mehta, 2019)
    - b) Pathophysiology: focal nodular hyperplasia, hepatocellular adenomas
    - c) Signs and symptoms include abdominal distension, jaundice, weight loss, easy bruising, and right upper quadrant pain.
  10. Immune-related adverse events (Ellithi et al., 2020; Gordon et al., 2017)
    - a) Incidence: 2%–10% cases (Park et al., 2021)
      - (1) May occur with checkpoint inhibitors (e.g., cytotoxic T-lymphocyte antigen 4–blocking antibodies, programmed cell death protein 1 inhibitors, programmed cell death-ligand 1 inhibitors), chimeric antigen receptor T-cell therapies, monoclonal antibodies (Sosa et al., 2018; Spain et al., 2016; Winer et al., 2018)
      - (2) May present 6–14 weeks after initiation of therapy (Durrechou et al., 2020)
    - b) Pathophysiology
      - (1) Inflammation of hepatocytes or bile ducts
      - (2) Diffuse T-cell infiltrates of the liver
      - (3) Portal fibrosis (Nishida & Kudo, 2019)
    - c) Signs and symptoms include asymptomatic elevations in liver enzymes (at least three times the upper limit of normal of aspartate aminotransferase and alanine aminotransferase or twice the total bilirubin), hepatomegaly, and enlarged perihepatic lymph nodes.
- G. Assessment (Bhandari et al., 2018; Botti et al., 2016; Chalasani et al., 2021; Haanen et al., 2017; Helissey et al., 2016; Herrine, 2016; Kwo et al., 2017; Meunier & Larrey, 2019; Newsome et al., 2018; Skood, 2019; Sosa et al., 2018; Spain et al., 2016; Winer et al., 2018)
1. Medical history
    - a) Previous medications (e.g., prescription, illicit or recreational, herbal, dietary supplements) (Miller et al., 2020)
    - b) Alcohol use
    - c) Hepatitis
    - d) Familial history of liver disease
    - e) Risk factor exposure for viral hepatitis (e.g., IV drug use, transfusions, travel, sexual contacts, occupation, body piercings, tattoos)
    - f) Exposure to hepatic toxins
    - g) Organ transplants
    - h) Previous complications (e.g., bleeding, infection, renal failure)
    - i) Other conditions (e.g., congestive hepatopathy, diabetes, skin pigmentation, arthritis, hypogonadism and dilated cardiomyopathy, obesity, primary sclerosing cholangitis, early-onset emphysema, celiac disease, thyroid disease)
  2. Vital signs (e.g., fever, hypotension, hypertension, bradycardia, tachycardia)
  3. Laboratory testing should be obtained prior to each treatment and every 6–12 weeks for the first six months following completion of cancer therapies. Depending on treatment response or occurrence of toxicities, increased frequency of follow-up testing may be necessary.
    - a) Complete blood counts (including eosinophil count) (Chalasani et al., 2021)
    - b) Thyroid function tests
    - c) Liver function tests (e.g., bilirubin, alanine aminotransferase, aspartate aminotransferase, lactate dehydrogenase, alkaline phosphatase)
    - d) Complete metabolic panels
    - e) Coagulation factors
    - f) Hepatitis titers and viral hepatitis serologies (e.g., anti-hepatitis A immunoglobulin M antibody, surface antigen of the hepatitis B virus [HBsAg], anti-hepatitis B core antigen immunoglobulin M, anti-hepatitis C, hepatitis B RNA) (Chalasani et al., 2021)
  4. Physical examination should include a thorough head-to-toe assessment to identify signs and symptoms of hepatotoxicity.
    - a) Neurologic examination: Assess level of consciousness, orientation, and behavioral changes.
    - b) Examination of skin and head, eyes, ears, nose, and throat: Assess for jaundice of the skin, sclerae (icteric), and mucous membranes; rash; ecchymosis; and petechiae.
    - c) Cardiac and pulmonary examination: Assess for hypotension or hypertension, bradycardia or tachycardia, jugular venous distension, peripheral edema, crackles and rales, and weight gain.
    - d) Abdominal examination: Assess for bowel sounds, ascites, hepatosplenomegaly, abdominal pain, and hematemesis.

**TABLE 18-2.** Diagnosis and Grading of Sinusoidal Obstruction Syndrome

| System                                                                                                                                                                               | Diagnostic Criteria                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Grading and Severity                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## H. Collaborative management (Lee & Chan, 2016; Vicenzi et al., 2016)

1. An interprofessional approach and collaboration among providers, nurses, patients, caregivers, and consultants are essential in managing patients who may develop hepatotoxicity. Liver abnormalities may increase, fluctuate, or possibly resolve without intervention (Economopoulou & Psyrri, 2016; Trinh et al., 2019).

a) Monitoring of liver function tests should be more frequent (every one to three days) until stabilization, followed by weekly monitoring (Trinh et al., 2019).

b) Nurses should rule out other causes, such as disease progression, infection, effects of other medications, hemochromatosis, or alcohol use (Sosa et al., 2018; Spain et al., 2016; Winer et al., 2018).

c) Standardized toxicity grading tools should be used.

(1) The National Cancer Institute Cancer Therapy Evaluation Program's (2017) *Common Terminology Criteria for Adverse Events* is a standardized classification to quantify or grade the severity of treatment-related adverse effects, including liver enzyme elevations (see Table 18-3).

(2) The Child-Pugh classification is a scoring system used to measure the severity of chronic liver disease, including cirrhosis, and provides clinicians a way to communicate objectively about liver function (Peng et al., 2016; see Table 18-4). The modified Child-Pugh score classifies liver disease severity according to the degree of ascites, serum concentrations of bilirubin and albumin, prothrombin time, and degree of encephalopathy.

d) Consider an autoimmunity workup, including serum antinuclear antibody, smooth muscle antibody, antimitochondrial antibodies, anti-soluble liver antigen/liver-pancreas antibodies, anti-liver-kidney microsomal type 1 antibodies, and additional studies as appropriate.

e) Consider viral screening, including Epstein-Barr virus, cytomegalovirus, hepatitis B and C, and hepatitis A, D, and E if the patient has a recent history of travel outside of the country (DeSouza & Savva, 2016).

f) Additional laboratory tests include complete metabolic panel, complete blood counts, ammonia level, coagulation factors, novel biomarkers (microRNA-122, cytokeratin 18, glutamate dehydrogenase, macrophage-colony-stimulating factor receptor 1, bile acids), and pharmacogenetic

markers (Chalasani et al., 2021; Meunier & Larrey, 2019).

g) Consider consultation with a gastroenterologist or hepatologist.

h) Consider imaging (DeSouza & Savva, 2016; Gordon et al., 2017).

(1) Ultrasound of the liver with or without Doppler can rule out obstruction of the biliary tree and assess for masses in the liver parenchyma (Chalasani et al., 2021).

(2) A computed tomography scan may identify hepatomegaly, periportal edema, or periportal lymphadenopathy. Other findings that may be noted include liver abnormalities, such as fatty liver, pseudo-cirrhosis, biliary sclerosis, and SOS (Torri et al., 2021).

(3) Magnetic resonance imaging with or without magnetic resonance cholangiopancreatography can evaluate the liver, gallbladder, bile ducts, pancreas, and pancreatic duct for disease (Chalasani et al., 2021).

i) A liver biopsy may be considered if the diagnosis remains unclear (DeSouza & Savva, 2016; Postow, 2015).

(1) Autoimmune hepatitis and drug-induced liver injury may present similarly, and a liver biopsy would provide a definitive diagnosis of the causative agent (Zen & Yeh, 2019). Severe inflammation of the lobules in the liver with thickening of the surrounding hepatic veins has been seen, leading to necrosis.

(2) Primary biliary pattern with mild portal mononuclear infiltration around proliferated bile ductules has been seen.

(a) Consider dose adjustment of drugs if hepatic dysfunction is noted at baseline (Wilkes & Barton-Burke, 2020).

(b) Consider avoiding hepatotoxic drugs in patients with preexisting liver dysfunction (Shehu et al., 2017).

(c) Consider withdrawal of the offending hepatotoxic drug and monitoring for normalization of liver function tests.

## 2. Management of immune-mediated hepatitis

a) The primary mode of treatment for hepatotoxicity is the withdrawal of the offending drug. Management algorithms have been developed based on the severity of the toxicity (Darnell et al., 2020; Ellithi et al., 2020; Fay et al., 2016; Jennings et al., 2019; Kwo et al., 2017; Mistry et al., 2017; Morgado et al., 2020; Naidoo et al., 2015; Newsome et al., 2018; Park et al., 2021; Sosa et al.,

- 2018; Spain et al., 2016; Thompson et al., 2019; Villadolid & Amin, 2015; Winer et al., 2018).
- b) Mild (grade 1) immune-related adverse events warrant close monitoring of liver enzymes and supportive care (Ellithi et al., 2020).
- c) Moderate or severe (grade 2) immune-related adverse events necessitate holding the drug and initiating corticosteroids (Economopoulou & Psyrris, 2016).
- d) The drug is resumed when toxicity is grade 1 or less.
- e) Severe or life-threatening (grade 3–4) immune-related adverse events require permanent discontinuation of the drug and initiation of high-dose corticosteroids.
- f) Steroids are tapered gradually over at least one month.
- g) In the presence of steroid-refractory hepatitis, mycophenolate or antithymocyte globulin, tacrolimus, and azathioprine should be considered (Choi & Lee, 2020; DeSouza & Savva, 2016; Economopoulou & Psyrris, 2016; Eigentler et al., 2016; Lampson et al., 2016; Sanjeevaiah et al., 2018).
- I. Patient and family education (Chalasani et al., 2021; Champiat et al., 2016; Economopoulou & Psyrris, 2016)
  - 1. Patient and caregiver education about the potential side effects of drugs is essential. Communication is critical, including an emphasis on the importance of

Note. Based on information from Durand & Valla, 2005; Pugh et al., 1973.

prompt identification and reporting of the following signs and symptoms:

- Change in level of consciousness (e.g., increased sedation, confusion)
  - Malaise, fever
  - Jaundice, icteric sclera
  - Abdominal pain, bleeding or persistent bruising, hematemesis, changes in stool or urine (including the presence of blood)
  - Edema of extremities, weight gain
- Items to include in patient instructions
    - Avoidance of other hepatotoxins, including herbal and dietary supplements and over-the-counter medications
    - Close follow-up with healthcare providers, including periodic monitoring of liver function studies
    - Maintenance of a well-balanced diet and hydration
    - Skin care (e.g., avoidance of scratching, use of lotions, daily showers)
    - Fall prevention

## CHAPTER 19

# Genitourinary Toxicities

### A. Overview

1. The kidneys have multiple roles within the human body, with their primary functions including blood filtration, metabolism, excretion of endogenous and exogenous compounds, and endocrine functions (Perlman & Heung, 2019).

- a) Anatomically, the kidney comprises roughly one million nephrons, each of which includes a glomerulus (the site of blood filtration) and a renal tubule, where water and salts are reclaimed (Perlman & Heung, 2019).

- b) Many anticancer treatments, including specific chemotherapy and immunotherapy agents, are considered nephrotoxic because they are metabolized via the renal system. Therefore, many therapies necessitate careful monitoring and possible dose modifications to prevent kidney injury, which can be irreversible in some cases (Shahinian et al., 2017).

2. The bladder consists of three layers: the mucosa, submucosa, and muscularis. Chemotherapy drugs can result in the recruitment of inflammatory mediators, including myeloperoxidase, interleukin-1-beta, and interleukin-6, which result in edema, hemorrhage, and vascular permeability in the bladder layers (Dornelas-Filho et al., 2018). Radiation therapy can induce a hypoxic injury, resulting in endarteritis in small vessels and fibrotic changes to the mucosa and submucosa layers (Tanaka et al., 2019).

### B. Antineoplastic-associated genitourinary toxicities

#### 1. Acute kidney injury (AKI)

##### a) Definition and pathophysiology

- (1) AKI is a sudden loss of kidney function over hours to days, resulting in fluid and electrolyte imbalances, acid-base irregularity, and retention of nitrogenous waste products in the blood (Mercado et al., 2019).

- (2) A universal definition and staging system were developed by the collaborative efforts

of KDIGO (Kidney Disease: Improving Global Outcomes), RIFLE (Risk, Injury, Failure, Loss, End-stage renal disease), and the Acute Kidney Injury Network.

- (3) AKI includes an increase in serum creatinine by greater than or equal to 0.3 mg/dl within 48 hours or an increase in serum creatinine by greater than or equal to 1.5 times baseline, which is known or presumed to have occurred within the prior seven days, or urine volume less than 0.5 ml/kg/hour for six hours.

- (4) AKI staging increases with an escalating insult to creatinine and a reduction in urine output (International Society of Nephrology, 2012; Mercado et al., 2019; see Figure 19-1).

- b) AKI etiology is multifactorial and includes prerenal, intrinsic, or postrenal causes.

- (1) Prerenal causes occur with decreased perfusion and subsequent glomerular filtration rate (GFR).

- (a) Etiology includes any insult that would cause intravascular volume depletion, such as hypovolemia, peripheral vasodilation, decreased arterial pressures, or impaired cardiac function.

- (b) Infections, such as sepsis and drugs lowering renal perfusion, are also associated with prerenal etiology.

- (2) Intrinsic causes include injury to the glomerulus, tubule, tubular interstitial, and kidney microvasculature. A disease affecting the vasculature of the kidney, such as renal artery thrombosis, will also result in intrinsic injury.

- (3) Postrenal causes include any injury induced by obstruction of urinary flow, such as prostatic hypertrophy or extra-renal compression from a bladder

**FIGURE 19-1.** Definition of Acute Kidney Injury**Section 2: AKI Definition**

2.1.1: AKI is defined as any of the following (Not Graded):

- Increase in SCr by  $\geq 0.3$  mg/dl ( $\geq 26.5$   $\mu\text{mol/L}$ ) within 48 hours; or
- Increase in SCr to  $\geq 1.5$  times baseline, which is known or presumed to have occurred within the prior 7 days; or
- Urine volume  $< 0.5$  ml/kg/h for 6 hours.

2.1.2: AKI is staged for severity according to the following criteria (Table 2). (Not Graded)

**Table 2 | Staging of AKI**

| Stage | Serum creatinine                                                                                                                                                                                                                                          | Urine output                                                            |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| 1     | 1.5–1.9 times baseline<br>OR<br>$\geq 0.3$ mg/dl ( $\geq 26.5$ $\mu\text{mol/L}$ ) increase                                                                                                                                                               | $< 0.5$ ml/kg/h for 6–12 hours                                          |
| 2     | 2.0–2.9 times baseline                                                                                                                                                                                                                                    | $< 0.5$ ml/kg/h for $\geq 12$ hours                                     |
| 3     | 3.0 times baseline<br>OR<br>Increase in serum creatinine to $\geq 4.0$ mg/dl ( $\geq 353.6$ $\mu\text{mol/L}$ )<br>OR<br>Initiation of renal replacement therapy<br>OR, In patients $< 18$ years, decrease in eGFR to $< 35$ ml/min per $1.73\text{ m}^2$ | $< 0.3$ ml/kg/h for $\geq 24$ hours<br>OR<br>Anuria for $\geq 12$ hours |

AKI—acute kidney injury; eGFR—estimated glomerular filtration rate

Note. From "KDIGO Clinical Practice Guideline for Acute Kidney Injury," by Kidney Disease: Improving Global Outcomes (KDIGO) CKD Work Group, 2012, *Kidney International Supplements*, 2(1), p. 8 (<https://kdigo.org/wp-content/uploads/2016/10/KDIGO-2012-AKI-Guideline-English.pdf>). Copyright 2012 by KDIGO. Reprinted with permission.

or retroperitoneal tumor (Mercado et al., 2019).

- (4) Increases in mortality, length of hospital stay, and chemotherapy dose reductions are associated with AKI in patients with cancer, making prevention and effective monitoring crucial to oncology nursing practice.
- (5) Due to the varying definitions of AKI and changes in treatment patterns, the exact incidence is unknown; however, recent studies suggest incidence is 11%–20%, with a higher risk associated with hematologic malignancy (Rosner et al., 2017).
- (6) Overall, renal cell cancer, liver cancer, multiple myeloma, leukemia, and hematopoietic stem cell transplantation (HSCT) are associated with the highest incidences (Rosner et al., 2017; see Table 19-1).

c) Risk factors

(1) Pharmacologic agents

(a) Chemotherapy

- i. Conventional chemotherapies result in direct cellular toxicity, oxidative stress, mitochondrial injury, and apoptosis.

ii. Acute tubular injury can be seen with platinum agents, ifosfamide, and pemetrexed.

iii. Interstitial nephritis can also be associated with conventional agents, such as doxorubicin (Rosner et al., 2017).

(b) Targeted therapies

i. Targeted agents may be associated with AKI, proteinuria, hypertension, and electrolyte disturbances.

ii. Thrombotic microangiopathy may occur with antiangiogenesis drugs targeting vascular endothelial growth factors.

iii. BRAF inhibitors, such as vemurafenib and dabrafenib, are associated with dose-related AKI that can often resolve with drug discontinuation.

iv. Tubulointerstitial injury is only partially reversible with crizotinib (Rosner et al., 2017).

**TABLE 19-1.** Genitourinary Toxicities

| Classification             | Drug                                | Side Effects and Toxicities                                         | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------|-------------------------------------|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Chemotherapy Agents</b> |                                     |                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Alkylating agents          | Bendamustine (Bendeka®)             | Increased serum creatinine                                          | The drug is associated with TLS when given in patients with increased tumor burden.<br>Use with caution in patients with mild to moderate renal impairment.<br>The drug is not recommended in patients with CrCl < 30 ml/min. (Teva Pharmaceuticals, 2021)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                            | Carboplatin                         | AKI                                                                 | The drug exhibits less renal toxicity than cisplatin.<br>Check creatinine level before each dose (for area under the curve dosing). Refer to Chapter 11. (Teva Pharmaceuticals, 2016a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                            | Cisplatin (Platinol®, Platinol®-AQ) | Severe dose-related and cumulative renal toxicity, including AKI    | Monitor creatinine, blood urea nitrogen, CrCl, and electrolytes. Ensure adequate hydration prior to, during, and postadministration.<br>Monitor urinary output and ensure magnesium repletion as needed.<br>Renal toxicity typically presents the second week after administration.<br>Older adult patients and those with preexisting renal impairment are more susceptible to renal toxicity.<br>Dose reductions are needed in the setting of baseline renal impairment or following significant CrCl reductions during treatment.<br>Consideration of alternative therapies is also appropriate.<br>Dose reductions for curative intent therapy should begin with GFR 50–59 ml/min/1.73m <sup>2</sup> .<br>Therapy is not recommended at GFR < 40 ml/min/1.73 m <sup>2</sup> .<br>For palliative intent, dose reductions begin at GFR 50–59 ml/min/1.73 m <sup>2</sup> .<br>In this setting, therapy is not recommended at GFR < 50 ml/min/1.73 m <sup>2</sup> .<br>(Krens et al., 2019; WG Critical Care, 2019) |
|                            | Cyclophosphamide (Cytoxan®)         | Renal toxicity, hemorrhagic cystitis, SIADH, dose-related sterility | Dose adjust for CrCl beginning at ≤ 29 ml/min. See drug-specific criteria.<br>Dose reductions are required for hemodialysis and peritoneal dialysis. No dose reduction is required for continuous renal replacement therapy.<br>Increase fluid intake 1–2 days after the dose to avoid bladder toxicity (hemorrhagic cystitis).<br>In hematopoietic stem cell transplantation, mesna and hyperhydration with or without forced diuresis are recommended for high-dose cyclophosphamide.<br>(Baxter Healthcare, 2017; Hensley et al., 2009; Krens et al., 2019)                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                            | Ifosfamide (Ifex®)                  | Hemorrhagic cystitis                                                | The drug may cause severe nephrotoxicity, resulting in renal failure.<br>The drug is associated with proteinuria and SIADH.<br>Mesna should be used to reduce the incidence of hemorrhagic cystitis.<br>(Baxter Healthcare, 2018)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                            | Melphalan (Alkeran®, Evomela®)      | Hypokalemia, renal failure or insufficiency                         | The drug is associated with SIADH.<br>Dose reductions should be considered in patients receiving palliative treatment with renal insufficiency.<br>(Spectrum Pharmaceuticals, 2016)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**TABLE 19-1. Genitourinary Toxicities (Continued)**

| Classification                     | Drug                            | Side Effects and Toxicities                                                           | Nursing Considerations                                                                                                                                                                                                                                                                                                                |
|------------------------------------|---------------------------------|---------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Chemotherapy Agents (Cont.)</b> |                                 |                                                                                       |                                                                                                                                                                                                                                                                                                                                       |
| Alkylating agents (Cont.)          | Oxaliplatin (Eloxatin®)         | Acute tubular necrosis, acute interstitial nephritis, AKI, increased serum creatinine | The drug is associated with hypokalemia and dehydration. Dose adjust for CrCl < 30 ml/min. (Sanofi-Aventis U.S., 2020b)                                                                                                                                                                                                               |
| Antimetabolites                    | Azacitidine (Vidaza®)           | Renal failure                                                                         | Monitor serum creatinine. The drug is primarily excreted by the kidneys. The drug is associated with TLS in patients with high tumor burden. Dose reductions may be necessary for patients with serum creatinine or blood urea nitrogen elevations. (Celgene, 2020)                                                                   |
|                                    | Capecitabine (Xeloda®)          | Dehydration, renal insufficiency                                                      | Monitor for and correct dehydration. Dose reductions are indicated in patients with moderate renal impairment. The drug is contraindicated in patients with CrCl < 30 ml/min. The drug is associated with the risk of dehydration resulting in AKI. Exercise caution with concomitant use with nephrotoxic agents. (Genentech, 2021c) |
|                                    | Clofarabine (Clolar®)           | AKI                                                                                   | Monitor renal function during the days of administration. Dose reduction is necessary for patients with renal impairment (< 60 ml/min). (Sanofi-Aventis U.S., 2016)                                                                                                                                                                   |
|                                    | Fludarabine                     | Renal failure or insufficiency                                                        | Monitor CrCl. Dose adjust for patients with moderate impairment of renal function. (Teva Pharmaceuticals, 2017)                                                                                                                                                                                                                       |
|                                    | Gemcitabine (Gemzar®)           | Renal failure or insufficiency, proteinuria, hemolytic uremic syndrome                | Monitor serum creatinine and blood urea nitrogen. Permanently discontinue for hemolytic uremic syndrome or severe renal impairment. (Eli Lilly and Company, 2019b)                                                                                                                                                                    |
|                                    | Hydroxyurea (Hydrea®, Mylocel®) | Renal failure                                                                         | Reduce the dose of hydroxyurea in patients with creatinine clearance < 60 ml/min. (Bristol-Myers Squibb, 2017)                                                                                                                                                                                                                        |
|                                    | Methotrexate                    | AKI (dose dependent)                                                                  | The drug can cause crystal nephropathy when given at high doses. Maintain adequate hydration and urinary alkalization. Renal excretion is the primary route of elimination, and impaired renal function increases the risk of methotrexate toxicity. (Fresenius Kabi, 2020)                                                           |
|                                    | Nelarabine (Arranon®)           | Renal impairment                                                                      | Closely monitor patients with moderate or severe renal impairment for toxicities. (Novartis Pharmaceuticals, 2019)                                                                                                                                                                                                                    |
|                                    | Pemetrexed (Alimta®)            | Renal failure                                                                         | The drug is not recommended in patients with CrCl < 45 ml/min. Ibuprofen drug interaction can cause increased toxicity in patients with mild or moderate renal impairment. Avoid ibuprofen for 2 days prior to, the day of, and 2 days following administration of pemetrexed. (Eli Lilly and Company, 2019a)                         |

**TABLE 19-1.** Genitourinary Toxicities (*Continued*)

| Classification                                | Drug                         | Side Effects and Toxicities                                                                       | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------|------------------------------|---------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Targeted Therapy Agents (Cont.)</b>        |                              |                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Small molecule inhibitors<br>( <i>Cont.</i> ) | Carfilzomib (Kyprolis®)      | AKI                                                                                               | Nephrotoxicity has been reported and may cause fatal events. Monitor serum creatinine regularly. Renal failure is greater when patients have a baseline reduced CrCl. (Amgen, 2021)                                                                                                                                                                                                                                                     |
|                                               | Crizotinib (Xalkori®)        | Electrolyte abnormalities, renal cysts, AKI, GFR reductions beginning 2 weeks into therapy        | Monitor electrolytes, serum creatinine, and GFR. Dose reductions are recommended with severe renal impairment (CrCl < 30 ml/min). See package insert for further details. (Pfizer, 2021c)                                                                                                                                                                                                                                               |
|                                               | Dabrafenib (Tafinlar®)       | Hyponatremia, hypophosphatemia, hyperkalemia, increased creatinine, urinary tract infections, AKI | Monitor electrolytes and renal function. Dose reductions are not currently recommended for mild to moderate renal impairment; however, formalized pharmacokinetic studies are needed. Dose is not established for severe renal impairment. (Novartis Pharmaceuticals, 2021c)                                                                                                                                                            |
|                                               | Enasidenib (Idhifa®)         | Differentiation syndrome, which can be associated with renal insufficiency                        | Monitor for and treat differentiation syndrome if it occurs. (Celgene, 2021)                                                                                                                                                                                                                                                                                                                                                            |
|                                               | Erlotinib (Tarceva®)         | AKI, hepatorenal syndrome, renal insufficiency, urinary tract infection (< 4%)                    | Monitor serum creatinine and electrolytes. (Genentech, 2016)                                                                                                                                                                                                                                                                                                                                                                            |
|                                               | Everolimus (Afinitor®)       | AKI, proteinuria                                                                                  | Monitor drug levels as evidence shows trough levels > 26.3 ng/ml are associated with 4-fold increased risk of toxicity, and levels < 11.9 ng/ml are associated with a 3-fold increased risk of progression. Monitor renal function at baseline and at least every 6 months in those with risk factors. See package insert for guidelines on dose adjustments for toxicity. (Deppenweiler et al., 2017; Novartis Pharmaceuticals, 2021a) |
|                                               | Fedratinib (Inrebic®)        | Dysuria, urinary tract infections, renal insufficiency                                            | Monitor blood urea nitrogen, creatinine, and CrCl. Dose modifications are needed for severe renal impairment (CrCl 15–29 ml/min). See package insert for details. (Celgene, 2019a)                                                                                                                                                                                                                                                      |
|                                               | Gilteritinib (Xospata®)      | Renal insufficiency associated with differentiation syndrome                                      | Monitor for differentiation syndrome. Monitor serum creatinine. (Astellas Pharma, 2019)                                                                                                                                                                                                                                                                                                                                                 |
|                                               | Glasdegib (Daurismo®)        | AKI oliguria and renal failure, electrolyte abnormalities                                         | Monitor electrolytes, creatinine, and CrCl prior to, weekly for the first month, and monthly for the duration of therapy. (Pfizer, 2020a)                                                                                                                                                                                                                                                                                               |
|                                               | Imatinib mesylate (Gleevec®) | Increased serum creatinine, nephrotoxicity (including genitourinary)                              | The drug is associated with AKI and SIADH. Dose adjust for CrCl ≤ 39 ml/min. (Novartis Pharmaceuticals, 2020)                                                                                                                                                                                                                                                                                                                           |
|                                               | Infigratinib (Truseltiq®)    | Hyperphosphatemia, renal insufficiency                                                            | See package insert for specific instructions on dose adjustments for serum phosphorus starting at > 5.5 mg/dl. Dose reductions are needed for mild to moderate renal impairment (CrCl 30–89 ml/min). Dose is not established for severe or end-stage renal failure. (QED Therapeutics, 2021)                                                                                                                                            |

**TABLE 19-1.** Genitourinary Toxicities (*Continued*)

| Classification       | Drug                      | Side Effects and Toxicities                                                                            | Nursing Considerations                                                                                                                                                                                                                                                                                                                                                          |
|----------------------|---------------------------|--------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Miscellaneous</b> |                           |                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                 |
| Bisphosphonates      | Pamidronate (Aredia®)     | Increased serum creatinine, renal insufficiency                                                        | The drug can cause electrolyte abnormalities. For CrCl < 30 ml/min or creatinine > 3 mg/dl, use may be not recommended or dose reduced depending on the disease process. Limited data are available in the setting of dialysis. (Bedford Laboratories, 2009)                                                                                                                    |
|                      | Zoledronic acid (Zometa®) | Increased serum creatinine, renal insufficiency (higher in patients with abnormal baseline creatinine) | Risk of AKI is increased with abnormal baseline creatinine. Monitor serum creatinine before each dose. Do not use doses > 4 ml in patients with renal impairment. Administration over 15 minutes has been associated with reduced renal failure. Limited pharmacokinetic data exist in patients with CrCl < 30 ml/min or with evidence of AKI. (Novartis Pharmaceuticals, 2016) |

AKI—acute kidney injury; CrCl—creatinine clearance; eGFR—estimated glomerular filtration rate; GFR—glomerular filtration rate; min—minute; SIADH—syndrome of inappropriate antidiuretic hormone secretion; TLS—tumor lysis syndrome; ULN—upper limit of normal

## (c) Immunotherapy agents

- i. Interferons and high-dose interleukin-2 induce AKI.
- ii. Immune checkpoint inhibitors, such as ipilimumab, nivolumab, and pembrolizumab, can lead to acute interstitial nephritis.
- iii. Chimeric antigen receptor T cells can cause a capillary leak and subsequent AKI (Rosner et al., 2017).

## (d) Other drugs

- i. Zoledronate, nonsteroidal anti-inflammatory agents, angiotensin-converting enzyme inhibitors, angiotensin II receptor blockers, and iodinated contrast can affect the kidneys (Rosner et al., 2017).
- ii. Antimicrobial drugs, such as aminoglycosides, sulfonamides, and ciprofloxacin; antivirals, such as acyclovir; and antifungals, such as amphotericin B and liposomal formulation, are associated with tubular injury.
- iii. Calcineurin inhibitors used to prevent graft-versus-host disease (GVHD) can induce AKI and thrombotic microangiopathy by promoting arteriolar vasoconstriction (Renaghan et al., 2020).

## (e) HSCT regimens

- i. AKI and long-term renal dysfunction: Myeloablative allogeneic HSCT is associated with the highest risk, followed by nonmyeloablative allogeneic and myeloablative autologous HSCT. Causes include chemotherapy, high-dose radiation accompanied by fluid loss, sepsis, or nephrotoxic drugs used for supportive therapy. Other causes of renal dysfunction in patients receiving HSCT include stem cell infusion toxicity, hepatic sinusoidal obstruction syndrome (or veno-occlusive disease), thrombotic microangiopathy, and GVHD (Kemmner et al., 2017).
- ii. The use of cyclosporine in patients with diabetes mellitus shows a significant association with AKI in the first 100 days following transplant (Renaghan et al., 2020).
- iii. Risk for AKI in nonmyeloablative allogeneic regimens includes diabetes mellitus, more than three cycles of chemotherapy, and methotrexate for GVHD (Renaghan et al., 2020).

## (2) Preexisting conditions

- (a) Syndrome of inappropriate antidiuretic hormone secretion (SIADH)
  - (b) Tumor lysis syndrome
  - (c) Preexisting renal disease
  - (d) Chronic comorbidities (e.g., diabetes, chronic kidney disease [CKD], hypertension, cardiac insufficiency, autoimmune disease)
  - (e) Urinary stones
  - (f) Urinary tract infections
  - (g) Lower urinary tract obstruction
  - (h) Hydronephrosis
  - (i) Neutropenic sepsis
  - (j) Hypercalcemia
  - (k) Volume depletion (e.g., nausea, vomiting, diarrhea)
  - (l) Disseminated intravascular clotting
- (3) Cancer types: hematologic malignancies, especially multiple myeloma, and solid malignancies with renal involvement of tumor (Rosner et al., 2017)
- (4) Patient characteristics
  - (a) Age older than 65 years
  - (b) Family history of CKD
  - (c) Female sex (Rosner et al., 2017)
- d) Clinical manifestations (Perlman & Heung, 2019)
  - (1) Initial symptoms
    - (a) Fatigue
    - (b) Malaise
    - (c) Oliguria: common but not always present with onset of AKI
  - (2) Later symptoms
    - (a) Dyspnea
    - (b) Orthopnea
    - (c) Rales
    - (d) Third heart sounds ( $S_3$ )
    - (e) Peripheral edema
    - (f) Hypertension
    - (g) Altered mental status
    - (h) Weight gain
- e) Assessment
  - (1) Laboratory assessment
    - (a) Serum creatinine must be evaluated along with creatinine clearance, as this level may take 24–72 hours to reflect AKI (Mercado et al., 2019).
    - (b) Creatinine clearance is measured using Cockcroft and Gault estimated creatinine clearance (CG eCRCL) (Sprangers et al., 2021).
    - (c) Urinalysis and microscopy
      - i. Glomerular injury is associated with acanthocytes and red blood cell casts.
      - ii. Drug-induced injury and crystalline nephropathy are associated with crystal casts.
      - iii. Tubulointerstitial injury is associated with leukocyturia, tubular epithelial cells, and granular casts.
      - iv. Ischemic injury is associated with renal tubular epithelial cells and casts, including muddy brown casts (Mercado et al., 2019).
  - (d) Electrolyte abnormalities (urine electrolytes) include azotemia, which can be calculated by excretion of sodium and urea.
  - (e) Albumin
- (2) Imaging: A renal ultrasound is used to evaluate for postrenal causes of AKI.
- (3) Renal biopsy: This procedure is reserved for unclear etiology of AKI (Mercado et al., 2019).
- (4) Physical assessment
  - (a) Intake and output
  - (b) Vital signs
  - (c) Daily weights
  - (d) Edema
  - (e) Costovertebral angle tenderness
- f) Collaborative management
  - (1) Assess for risk factors prior to initiating nephrotoxic agents. Consult with the pharmacy prior to starting any such agents to determine if there is an alternative or if a dose reduction should be considered.
  - (2) Optimize hydration status and evaluation prior to starting therapy.
  - (3) Follow dosing adjustments for patients with impaired renal function.
  - (4) Treat the underlying cause.
  - (5) Monitor for hyperglycemia and consult a clinical nutritionist or registered dietitian for evaluation and planning. Manage comorbid conditions, such as hypertension.
  - (6) Consult with nephrology within 48 hours of initial AKI for lack of response to therapy, unclear etiology, stage 3 or higher AKI, or any other high-risk disease, such as multiple myeloma or in the transplant setting (Mercado et al., 2019).
  - (7) Consider renal replacement therapy for life-threatening conditions, such as anuria, severe hyperkalemia, azotemia with urea concentrations greater than 84 mg/dL,

severe metabolic acidosis, oliguria less than 200 ml over 12 hours, uremia resulting in encephalopathy, neuropathy, pericarditis, and volume overload (Mercado et al., 2019).

g) Patient and family education

- (1) Educate patients and families regarding the risk of AKI with cytotoxic agents.
- (2) Educate patients and families on the signs and symptoms of AKI.
- (3) Instruct patients to notify the healthcare team if the following symptoms occur (Forman, 2021):
  - (a) No urine output for more than 12 hours
  - (b) Very small amounts of dark urine
  - (c) Dark, concentrated, cloudy, or bloody urine
  - (d) Occurrence of edema or acute weight gain
- (4) Encourage patients to monitor their blood pressure at home.
- (5) Educate patients and families about the importance of adequate oral hydration of up to 3 L daily while they are receiving nephrotoxic cytotoxic agents (e.g., cisplatin, methotrexate) (Almanric et al., 2017; Howard et al., 2016).

## 2. SIADH

a) Definition and pathophysiology

- (1) SIADH is a paraneoplastic syndrome characterized by impaired water excretion second to excess antidiuretic hormone, which causes the kidneys to reabsorb water. Water retention, in turn, leads to hyponatremia.
- (2) Paraneoplastic SIADH is thought to result from ectopic secretion of antidiuretic hormone from tumor cells.
- (3) The principle difference between SIADH and cerebral salt wasting is that SIADH occurs in the setting of euvolemia (Kitchlu & Rosner, 2019).

b) Diagnostic criteria (Workeneh et al., 2020)

- (1) Plasma sodium less than 135 mEq/L
- (2) Plasma osmolality less than 275 mOsm/kg
- (3) Urine osmolality greater than 100 mOsm/kg
- (4) Clinical euvolemia
- (5) Urine sodium concentration greater than 30 mmol/L with normal dietary salt and water intake
- (6) Adrenal, thyroid, and renal function to identify contributing causes (Workeneh et al., 2020)

(7) No recent diuretic agents

- c) Incidence: Hyponatremia is the most common electrolyte alteration in patients with cancer. Incidence varies by type of cancer; however, lung cancers are associated with a higher risk (25%–45%) (Kitchlu & Rosner, 2019).

d) Risk factors

(1) Pharmacologic agents

- (a) Chemotherapy: vinka alkaloids (e.g., vincristine, vinblastine), alkylating agents (e.g., cyclophosphamide, ifosfamide), platinum compounds (e.g., cisplatin, carboplatin, methotrexate)
- (b) Immunotherapy: Interferon drugs can cause hypophysitis, an inflammation of the pituitary gland. When the pituitary gland is inflamed, normal body functions can be significantly altered, such as endocrine system regulation and storage of hormones produced by the hypothalamus (Vazquez, 2017).
- (c) Other drugs: amiodarone, amitriptyline, ciprofloxacin, haloperidol, imatinib, nonsteroidal anti-inflammatory drugs, selective serotonin reuptake inhibitors, thiazides

- (2) Preexisting conditions: cerebrovascular accident, infection, mental illness, hypopituitarism, hypothyroidism, HIV (Sterns, 2021)

- (3) Cancer types: small cell lung, prostate, breast, adrenal, head and neck, olfactory neuroblastoma, malignancies with brain involvement (primary or metastatic), malignancies with pulmonary involvement (primary or metastatic) (Workeneh et al., 2020)

- (4) Patient characteristics: age older than 65 years

e) Clinical manifestations: dependent on serum sodium concentration

- (1) Serum sodium 125–135 mEq/L: increased thirst, anorexia, nausea, weakness, fatigue, muscle cramps, headache (Dimitriadis et al., 2017)
- (2) Serum sodium less than 125 mEq/L: altered mental status, seizures, coma, respiratory collapse (Dimitriadis et al., 2017)

f) Assessment

(1) Laboratory assessment

- (a) Serum sodium
- (b) Serum osmolality
- (c) Urine sodium
- (d) Urine osmolality

- (e) Serum cortisol
- (f) Thyroid-stimulating hormone, free thyroxine ( $T_4$ )
- (g) Creatinine clearance
- (2) Imaging: brain magnetic resonance imaging if concern for SIADH secondary to immune-related hypophysitis
- (3) Physical assessment
  - (a) Thorough patient history, including current medications and comorbidities
  - (b) Neurologic examination
  - (c) Assessment for signs and symptoms of fluid volume overload
    - i. Hypertension
    - ii. Edema
    - iii. Weight gain
    - iv. Decreased urine output
    - v. Altered respiratory status
- g) Collaborative management (Kitchlu & Rosner, 2019)
  - (1) Consulting endocrinologists has been shown to improve patient outcomes.
  - (2) Special care must be taken to not over rapidly correct sodium, as this may result in osmotic demyelination syndrome.
    - (a) The general recommendation is to restrict to 500 ml less than daily urine output. The fluid restriction will result in sodium improvements of 2–4 mEq/L daily (Kitchlu & Rosner, 2019).
    - (b) If serum sodium is less than 125 mEq/L or greater than or equal to 125 mEq/L with severe symptoms, raise serum sodium by 4–6 mEq/L over one to two hours, followed by slower correction over 48 hours.
    - (c) Tolvaptan is an antagonist of vasopressin 2 receptor in the distal tubule responsible for free water retention. It is indicated for clinically significant hypovolemic and euvoletic hyponatremia. Consider when serum sodium is not corrected with other therapies or there is a need to correct preprocedure or surgery.
    - (d) Salt tablets
    - (e) Loop diuretics
    - (f) Urea induces osmotic excretion of free water without electrolyte depletion. General dosing is 15–30 g daily or a dose of 0.25–0.50 g/kg.
    - (g) Demeclocycline reduces the loss of sodium in the renal inner medulla; however, efficacy is variable and cannot be routinely recommended.
- (h) If related to hypophysitis, treat with corticosteroids (Vazquez, 2017).
- h) Patient and family education
  - (1) Educate patients and families on the risk factors for SIADH.
  - (2) Educate patients and families on the clinical signs and symptoms of SIADH, and stress the importance of notifying the healthcare team if signs or symptoms appear.
- 3. Tumor lysis syndrome (TLS)
  - a) Definition and pathophysiology
    - (1) TLS is an oncologic emergency that results when many tumor cells are killed (or lysed), causing the intracellular components to be dumped into circulation.
    - (2) This can lead to various metabolic abnormalities, including hyperkalemia, hyperphosphatemia, hypocalcemia, and hyperuricemia, which can cause AKI (Puri et al., 2020).
    - (3) The syndrome is most commonly seen in hematologic malignancies treated with cytotoxic therapies and chemotherapy; however, it can also occur in solid tumors with a significant tumor burden and strong chemosensitivity (Rahmani et al., 2019).
    - (4) Early identification and treatment are critical to avoid life-threatening consequences.
  - b) Diagnostic criteria: Cairo and Bishop (2004) described the most widely accepted definition of TLS with laboratory and clinical considerations. The following laboratory results and clinical data must occur within three days before or seven days after cytotoxic therapy (Cairo & Bishop, 2004).
    - (1) Cairo Bishop laboratory TLS must contain two or more of the following (Cairo & Bishop, 2004; Rahmani et al., 2019):
      - (a) Uric acid 8 mg/dl or higher, or 25% increase from baseline
      - (b) Potassium 6 mEq/L or higher, or 25% increase from baseline
      - (c) Phosphorus 4.5 mg/dl or higher, or 25% increase from baseline
      - (d) Calcium 7 mg/dl or lower, or 25% decrease from baseline
    - (2) Cairo Bishop grading of clinical TLS requires one or more clinical manifestations along with criteria for laboratory TLS. Select the maximal renal, cardiac, or

neurologic clinical TLS manifestation to define the grade.

- (a) Grade 0: creatinine less than or equal to 1.5 times upper limit of normal (ULN)
- (b) Grade 1: creatinine 1.5 times ULN
  - i. Intervention is not indicated for cardiac arrhythmia or seizures in grade 1.
  - ii. Neither creatinine nor cardiac arrhythmia is attributable to chemotherapy agents (Cairo & Bishop, 2004; Rahmani et al., 2019).
- (c) Grade 2: creatinine greater than 1.5–3 times ULN
  - i. Cardiac arrhythmia: nonurgent medical intervention indicated
  - ii. Seizures: one brief generalized seizure and seizures that are well controlled with use of anticonvulsants or focal motor seizures that are infrequent and do not interfere with activities of daily living
  - iii. Neither creatinine, cardiac arrhythmia, or seizure are attributable to chemotherapy agents (Cairo & Bishop, 2004; Rahmani et al., 2019).
- (d) Grade 3: creatinine greater than 3–6 times ULN
  - i. Cardiac arrhythmia: symptomatic and incompletely controlled medically or controlled with a device such as a defibrillator
  - ii. Seizures: may occur where consciousness is altered or is poorly controlled despite medical intervention
  - iii. Neither creatinine, cardiac arrhythmia, or seizure are attributable to chemotherapy agents (Cairo & Bishop, 2004; Rahmani et al., 2019).
- (e) Grade 4: creatinine greater than 6 times ULN
  - i. Cardiac arrhythmia: life threatening (i.e., arrhythmia associated with heart failure, hypotension, syncope, or shock)
  - ii. Seizures: of any kind which are prolonged, repetitive, or difficult to control (i.e., status epilepticus, intractable epilepsy)

- iii. Neither creatinine, cardiac arrhythmia, or seizure are attributable to chemotherapy agents (Cairo & Bishop, 2004; Rahmani et al., 2019).

- (f) Grade 5: Death can be attributable to chronic TLS (Cairo & Bishop, 2004; Rahmani et al., 2019).

c) Incidence: Exact incidence is unknown. TLS remains the most common oncologic emergency in adult and pediatric patients with a hematologic malignancy (Rahmani et al., 2019).

d) Risk factors: Medications, radiation, and steroids cause TLS through rapid cell death. Bulky disease, significant areas of tumor necrosis, highly treatment-sensitive tumors, and those with a highly proliferative rate present an increased risk. TLS can also occur spontaneously without intervention (Rahmani et al., 2019).

(1) Pharmacologic agents

(a) Chemotherapy (e.g., alemtuzumab, cisplatin, cladribine, cytarabine, doxorubicin, etoposide, fludarabine, gemtuzumab, idarubicin, imatinib mesylate, mitoxantrone, paclitaxel, rituximab, tamoxifen)

(b) Radiation (e.g., total body irradiation)

(c) Other drugs (e.g., corticosteroids)

(2) Cancer types, rate of differentiation (acute vs. chronic), degree of white blood cell (WBC) and lactate dehydrogenase (LDH) elevation, age, comorbid conditions, and cancer therapy should be taken into account when determining the risk of TLS (Rahmani et al., 2019).

(a) Cancers associated with a higher risk of developing TLS are defined as a greater than 5% risk and include the following (Rahmani et al., 2019):

i. Leukemias

- Any Burkitt leukemia
- Acute lymphoblastic leukemia with a WBC count greater than or equal to 100,000/mm<sup>3</sup> or serum LDH level greater than or equal to two times ULN
- Acute myeloid leukemia with WBC count greater than or equal to 100,000/mm<sup>3</sup>
- Chronic lymphocytic leukemia with bulky features: greater than or equal to 10 cm or lymph nodes greater

- than or equal to 5 cm, absolute lymphocyte count greater than or equal to 25,000/mm<sup>3</sup>, elevated uric acid
- ii. Lymphomas
  - Advanced stage Burkitt lymphoma or lymphoblastic lymphoma or early stage for either with LDH two times ULN
  - Adult T-cell, diffuse large B-cell, peripheral T-cell, transformed, or mantle cell lymphomas with elevated LDH and significant tumor burden
  - Pediatric stage III–IV diffuse large B-cell lymphoma with LDH greater than or equal to two times ULN
- (b) Cancers associated with an intermediate risk of developing TLS (1%–5%) include the following (Rahmani et al., 2019):
  - i. Leukemias
    - Acute lymphoblastic leukemia with WBC count less than 100,000/mm<sup>3</sup> or serum LDH level less than two times ULN
    - Acute myeloid leukemia with WBC 25,000–100,000/mm<sup>3</sup>
  - ii. Bulky solid tumors sensitive to chemotherapy, including neuroblastoma, germ cell cancer, and small cell lung cancer
  - iii. Lymphomas
    - Adult T-cell, diffuse large B-cell, peripheral T-cell, transformed, or mantle cell leukemias or early-stage Burkitt type with LDH two times ULN
    - Pediatric stage III–IV anaplastic large cell lymphoma with LDH greater than or equal to two times ULN
    - Early-stage lymphoblastic lymphomas with LDH less than two times ULN
  - iv. Chronic lymphocytic leukemia and small lymphocytic lymphomas present a risk in the setting of lymph nodes greater than or equal to 5 cm or an absolute lymphocyte count greater than or equal to 25,000/mm<sup>3</sup> or a WBC greater than or equal to 50,000/mm<sup>3</sup> and treated with fludarabine, rituximab, lenalidomide, or venetoclax.
- (c) Cancers associated with a low risk of developing TLS (less than 1%) include the following (Rahmani et al., 2019):
  - i. Acute myeloid leukemia with WBC less than 25,000/mm<sup>3</sup> and serum LDH less than two times ULN
  - ii. Chronic lymphocytic leukemias and small lymphocytic lymphomas with WBC less than or equal to 50,000/mm<sup>3</sup> without any treatment with fludarabine, rituximab, or venetoclax
  - iii. Multiple myeloma and chronic myeloid leukemia
  - iv. Any other non-Hodgkin lymphoma with normal LDH and any other solid tumor
- (3) Patient characteristics may include acidic urine, dehydration, extensive lymph node involvement, hyperuricemia, increased LDH, leukocytosis, hyperkalemia, hyperphosphatemia, large tumor burden, nephrotoxic agent exposure, oliguria, renal dysfunction, and renal involvement of cancer at diagnosis (Kaplow & Iyere, 2016).
- e) Clinical manifestations resulting from metabolic abnormalities (Klemencic & Perkins, 2019; Rahmani et al., 2019)
  - (1) Weakness
  - (2) Nausea and vomiting
  - (3) Diarrhea
  - (4) Electrocardiogram abnormalities
  - (5) Muscle twitching
  - (6) Confusion and delirium
  - (7) Seizures
  - (8) Peripheral edema
  - (9) Oliguria and hematuria
  - (10) Flank pain
  - (11) Paralysis
  - (12) Paresthesias
  - (13) Muscle cramps
- f) Assessment
  - (1) Laboratory assessment: complete blood count, comprehensive metabolic panel,

magnesium, phosphorus, uric acid, LDH, urinalysis, arterial blood gases, creatinine clearance (using Cockcroft-Gault formula)

(2) Imaging: electrocardiogram

(3) Physical examination

(a) Vital signs

(b) Chvostek sign: contraction of the ipsilateral facial muscles elicited by tapping the facial nerve just in front of the ear (Goltzman, 2021)

(c) Trousseau sign: adduction of the thumb, flexion of wrist and metacarpophalangeal joints, and extension of the interphalangeal joints as induced by a blood pressure cuff inflated above systolic blood pressure on the upper arm for three minutes (Goltzman, 2021)

(d) Weight changes

(e) Daily intake and output

(f) Changes in mental status

g) Collaborative management

(1) Prevention: Close monitoring and assessment of high-risk patients are essential to prevent and treat TLS (Puri et al., 2020).

(2) Treatment and management: A combination of monitoring, hydration, and hypouricemic therapy are essential for prevention, management, and treatment (Puri et al., 2020).

(a) Hydration

i. General recommendations include 2–3 L/m<sup>2</sup> of IV crystalloids daily to promote glomerular filtration and subsequent urine output. Urine output should generally be maintained at 70–100 ml/m<sup>2</sup> per hour. IV hydration can be discontinued when LDH normalizes or with resolution of tumor burden. Volume status and comorbid conditions must be considered (Puri et al., 2020).

ii. Diuretics may be considered to maintain adequate urine output after hypovolemia and obstructive uropathy are ruled out (Puri et al., 2020).

(b) Alkalinization: The role of alkalization is controversial given the risk of calcium phosphate precipitation, worsening kidney function, and hypocalcemia (Puri et al., 2020).

(c) Allopurinol

i. Prevents the conversion of purine metabolites to uric acid

ii. Used in combination with vigorous hydration in low-risk patients (Shaikh et al., 2018) and is the drug of choice in intermediate-risk patients (Puri et al., 2020)

iii. Allopurinol oral dosing: 100 mg/m<sup>2</sup> every eight hours (maximum 800 mg daily) in adults (Puri et al., 2020)

(d) Recombinant urate oxidase (rasburicase)

i. The U.S. Food and Drug Administration approved rasburicase in 2002 to manage TLS. Rasburicase works by rapidly reducing uric acid levels to prevent or reverse AKI (Shaikh et al., 2018).

ii. Rasburicase is used in high-risk patients and is contraindicated in patients with glucose-6-phosphate dehydrogenase deficiency. Side effects include methemoglobinemia, hemolysis, and anaphylaxis (Puri et al., 2020).

iii. Dosing is a 6 mg flat dose; however, recent evidence has suggested a 3 mg flat dose is noninferior for patients with uric acid levels of 8–15 mg/dl (Shaikh et al., 2018).

(3) Nursing considerations

(a) Monitor for cardiac arrhythmias.

(b) Closely monitor laboratory results, specifically paying attention to electrolytes, uric acid, and renal function.

(c) Ensure adequate hydration of at-risk patients.

(d) Closely monitor for changes in cognition or mental status.

h) Patient and family education

(1) Educate patients and families on the risk factors and treatment strategies for TLS.

(2) Educate patients and families on the clinical signs and symptoms of TLS and stress the importance of notifying the healthcare team if these appear.

4. CKD (see Figure 19-2)

a) Definition and pathophysiology

**FIGURE 19-2.** Chronic Kidney Disease Nomenclature

**CURRENT CHRONIC KIDNEY DISEASE (CKD) NOMENCLATURE  
USED BY KDIGO**

CKD is defined as abnormalities of kidney structure or function present for > 3 months, with implications for health and CKD is classified based on cause, GFR category, and albuminuria category (CGA).

**Prognosis of CKD by GFR and albuminuria category**

| Prognosis of CKD by GFR<br>and Albuminuria Categories:<br>KDIGO 2012  |     |                                  |       | Persistent albuminuria categories<br>Description and range |                             |                          |
|-----------------------------------------------------------------------|-----|----------------------------------|-------|------------------------------------------------------------|-----------------------------|--------------------------|
|                                                                       |     |                                  |       | A1                                                         | A2                          | A3                       |
|                                                                       |     |                                  |       | Normal to mildly increased                                 | Moderately increased        | Severely increased       |
|                                                                       |     |                                  |       | <30 mg/g<br><3 mg/mmol                                     | 30–300 mg/g<br>3–30 mg/mmol | >300 mg/g<br>>30 mg/mmol |

- (1) CKD is defined as abnormalities of kidney structure or function, present for longer than three months, with health implications. It is classified based on cause, GFR category, and albuminuria category (International Society of Nephrology, 2013).
- (2) CKD is further distinguished by the irreversible loss of nephrons with subsequent glomerular sclerosis characterized by fibrotic changes to remaining nephrons.
- (3) Clinical sequela of the disease state is a determinant of the stage of the disease, with later stages being more severe.
- (4) Given the complex role of the kidney in maintaining homeostasis, CKD is characterized as a systemic disease.
- (5) Uremia results in retention of otherwise normally excreted products, a rise in physiologic hormones, and an overall loss in kidney function, such as erythropoietin production (Perlman & Heung, 2019).
- (6) Reductions in GFR lead to sodium and water retention and the lack of potassium excretion, resulting in hypertension, edema, heart failure, and life-threatening arrhythmias.

- (7) Metabolic acidosis occurs second to the diminished ability to generate bicarbonate and excrete acid.
  - (8) Significant risk for osteomalacia of the bones occurs due to decreased production of vitamin D. Elevated levels of phosphorus, coupled with decreased absorption of calcium, results in overcompensation by the parathyroid to resorb calcium from bones.
  - (9) Decreased erythropoietin production results in anemia, and uremic toxins suppress platelet aggregation and leukocyte function.
  - (10) A cascade of skin changes occurs related to pigmented metabolites.
  - (11) Decreases in estrogen and testosterone from uremic products may result in amenorrhea and overall infertility (Perlman & Heung, 2019).
  - b) Incidence: CKD in patients with cancer occurs with a prevalence rate of 12%–53% upon initial diagnosis (Sprangers et al., 2019).
  - c) Risk factors
    - (1) Chemotherapy: cisplatin, ifosfamide, melphalan, methotrexate, vinblastine, vincristine, vinorelbine
    - (2) Preexisting conditions: diabetes, hypertension, cardiovascular disease, HIV, hepatitis C virus, malignancy, autoimmune diseases, nephrolithiasis, recurrent urinary tract infections, family history of renal disease (Ammirati, 2020)
    - (3) Cancer types: solid tumor malignancies, multiple myeloma, bone metastasis
    - (4) Patient characteristics
      - (a) Age older than 70 years
      - (b) Male sex
      - (c) Cigarette use
  - d) Clinical manifestations
    - (1) Hypertension
    - (2) Edema
    - (3) Weight gain
    - (4) Decreased urine output
  - e) Assessment
    - (1) Laboratory assessment (Ammirati, 2020)
      - (a) Serum creatinine
      - (b) Blood urea nitrogen
      - (c) Creatinine clearance using Cockcroft-Gault formula or 24-hour urine (Cockcroft & Gault, 1976)
      - (d) Proteinuria: best assessed with 24-hour urine
      - (e) Comprehensive metabolic panel: calcium, phosphorus, alkaline phosphatase
    - (f) Albumin
    - (g) Complete blood count
    - (h) Parathyroid hormone
    - (i) Vitamin D
    - (j) Venous blood gas
    - (k) Lipids
    - (l) Virology studies: hepatitis B
  - (2) Imaging: renal ultrasound, echocardiogram, electrocardiogram
  - (3) Physical assessment
    - (a) Intake and output
    - (b) Vital signs
    - (c) Daily weights
    - (d) Edema
    - (e) Costovertebral angle tenderness
  - f) Collaborative management
    - (1) Patients with preexisting CKD should be followed by a nephrologist while undergoing cancer treatment.
    - (2) Criteria for referral include GFR less than 30 ml/min/1.73 m<sup>2</sup>, a decrease greater than or equal to 25% in the GFR, progression of CKD with a yearly decrease of more than 5 ml/min, significant albuminuria, persistent hematuria without a clear cause, persistent metabolic acidosis, anemia of CKD, resistant hypertension, recurrent nephrolithiasis, or hereditary kidney disease (Ammirati, 2020).
    - (3) Renal replacement therapy should be considered with a GFR less than 20 ml/min and with progressive disease.
    - (4) Procedural therapeutics, such as peritoneal or hemodialysis, should be determined on an individualized basis according to risks and benefits (Ammirati, 2020).
  - g) Patient and family education
    - (1) Educate patients and families regarding CKD risk with cytotoxic agents.
    - (2) Educate patients and families on the signs and symptoms of worsening CKD and the treatment goals to slow CKD progression and manage comorbid conditions.
    - (3) Encourage patients to monitor their blood pressure at home.
    - (4) Educate patients and families on the importance of continued follow-up with a nephrologist while undergoing cancer treatment.
5. Hemorrhagic cystitis
- a) Definition and pathophysiology
    - (1) Hemorrhagic cystitis is a diffused inflammatory condition of the urinary bladder due to an infection or noninfectious etiology, resulting in bleeding from

the bladder mucosa (Manikandan et al., 2010).

- (2) Treatment-related causes include chemotherapy and pelvic radiation (Dautruche & Delouya, 2018).
- (3) Although bacteria and fungi pathogens promote inflammation of the urinary tract, they seldom cause hemorrhagic cystitis.
- (4) Viruses have a high incidence of causing hemorrhagic cystitis in immunocompromised patients.
- (5) Hemorrhagic cystitis can be acute or chronic. The severity can range from mild discomfort in the lower abdomen to severe life-threatening hemorrhage characterized by urinary frequency, lower abdominal pain, and dysuria (Dosin et al., 2017; Schneidewind et al., 2018).

#### b) Incidence

- (1) Hemorrhagic cystitis may affect up to 70% of the immunocompromised population and up to 66% of HSCT recipients (Cesaro et al., 2018; Ruggeri et al., 2015).
- (2) BK virus occurs in 50% of HSCT recipients and can lead to BK polyomavirus-associated hemorrhagic cystitis in up to 20% (Atilla et al., 2020).
- (3) The incidence of hemorrhagic cystitis in the adult and pediatric population after HSCT ranges from 10% to 70% in the literature (Au et al., 2017; Cesaro et al., 2018).
- (4) Early-onset hemorrhagic cystitis, occurring as early as 48 hours after HSCT conditioning, is usually associated with thrombocytopenia, conditioning regimens with high-dose alkylating chemotherapy agents, and radiation therapy. Delayed-onset hemorrhagic cystitis occurs between two weeks and six months post-transplant, is usually caused by viral infections due to depressed immune cell response or GVHD, and is often fatal (Au et al., 2017; Cesaro et al., 2018).

#### c) Risk factors

##### (1) Pharmacologic agents

- (a) Chemotherapy agents are known to cause hemorrhagic cystitis due to hepatic breakdown of antineoplastic agents to toxic compounds that affect the internal membrane of the bladder or urothelium (Johnston et al., 2015).
  - i. Cyclophosphamide and ifosfamide are metabolized by the

liver and converted into anti-neoplastic agents, such as nitrogen mustard, and phosphoramide mustard, respectively, and into a compound called acrolein responsible for injury to the urothelium in the bladder (Almalag et al., 2021; Matz & Hsieh, 2017). Accumulation of acrolein in the bladder induces the release of inflammatory mediators, including tumor necrosis factor-alpha, interleukin-1-beta, and endogenous nitric oxide. This provokes vascular dilation, mucosal inflammation, and increased capillary fragility, causing bladder mucosal ulceration and hemorrhage (Matz & Hsieh, 2017).

- ii. Busulfan and thiotepea are alkylating agents known to induce trauma to the urothelium wall of the bladder. These are often used in the conditioning regimen for HSCT (Lam et al., 2017).

(b) Pelvic radiation therapy, with or without chemotherapy, causes hemorrhagic cystitis in patients with cancer (Halder et al., 2014). The effect of high-energy radiation can cause cell death through DNA damage and increased permeability of cell membranes, leading to activation of DNA damage repair genes and apoptosis in a continuous cycle that depletes the energy sources of the cells and results in loss of bladder muscle expansion, hyperplasia, and progressively worsening hemorrhagic cystitis (Halder et al., 2014; Zwaams et al., 2018).

- i. External beam radiation causes tissue damage, resulting in impaired healing and necrosis of the bladder mucosa. Telangiectasia (permanent dilation of blood vessels, usually in the mucous membranes) develops and can cause bleeding and pain (Zwaams et al., 2018).
- ii. Radiation causes cellular depletion, fibrosis, and oblit-

erative endarteritis (inflammation of the inner lining of the artery) of the urothelial wall in the bladder, resulting in atrophy and fibrosis and causing late-onset hemorrhagic cystitis (Thompson et al., 2014; Zwaams et al., 2018).

(2) Preexisting conditions

(a) GVHD, a complication after HSCT, is a condition in which the matured T cells from the transplant attack the host tissues of the recipient.

i. GVHD in the bladder may also cause hemorrhagic cystitis as T lymphocytes induce urothelial damage and hematuria (Lunde et al., 2015; Peterson et al., 2016).

ii. Immunosuppressive therapies to treat GVHD aid in microorganism infections that exacerbate hemorrhagic cystitis (Lunde et al., 2015; Raaijmakers, 2021).

(b) Infection may lead to hemorrhagic cystitis by acquired or reactivation of microorganisms in a sustained immunocompromised state (Peterson et al., 2016; Schneidewind et al., 2017).

i. BK virus, JC virus, adenovirus type 11, cytomegalovirus, and herpesvirus play a crucial role in inflammatory processes and breakdown of the bladder mucosa epithelial cells, leading to painful hematuria in patients with cancer (Atilla et al., 2020; Dosin et al., 2017).

ii. Fungal organisms, such as *Candida albicans*, *Candida tropicalis*, *Cryptococcus neoformans*, *Aspergillus fumigatus*, and *Torulopsis glabrata*, cause inner bladder inflammation and damage to the urothelium in the bladder (Cesaro et al., 2018; Pappas et al., 2016).

iii. Bacterial infections affecting the bladder mucosa, specifically *Escherichia coli*, *Staphylococcus saprophyticus*, *Proteus mirabilis*, and *Klebsiella*,

contribute to the loss of cellular urothelial protective function in the bladder (Cesaro et al., 2018).

d) Clinical manifestations

(1) Signs and symptoms of patients presenting with hemorrhagic cystitis should be classified based on the bleeding grade to provide a prognosis of survival and treatments. Grading ranges from 1 to 4; a higher grade indicates a higher mortality risk (Au et al., 2017).

(a) Grade 1: presenting microscopic hematuria

(b) Grade 2: macroscopic hematuria

(c) Grade 3: macroscopic hematuria with small clots

(d) Grade 4: gross hematuria with clots causing urinary tract obstruction requiring clot evacuation

(2) The *Common Terminology Criteria for Adverse Events* uses grading criteria based on the level of intervention required for therapy (National Cancer Institute Cancer Therapy Evaluation Program, 2017; see Table 19-2).

(3) In addition to the severity of bleeding, hemorrhagic cystitis is classified according to the time of occurrence after cancer treatments.

(a) Early stage is within 48 hours.

(b) Late stage is after the first 72 hours post-treatment.

(c) Patients may present with late-stage hemorrhagic cystitis two to three weeks after initial treatment.

(d) Patients experiencing hemorrhagic cystitis may present with pain in the lower abdominal area, fever, weakness, palpitations, and frustration due to the prolonged period of discomfort (Au et al., 2017; Dosin et al., 2017).

e) Assessment

(1) Review past infections that a neutropenic state or immunosuppression may reactivate to prevent GVHD, such as BK virus (Graham, 2017; Karagun et al., 2021).

(2) Collaborate with medical teams to expedite obtaining urine culture and polymerase chain reaction to identify pathogen infections and viral load (Klein et al., 2015).

(3) Assess renal function by obtaining laboratory levels of GFR, blood urea nitrogen,

**TABLE 19-2.** Common Terminology Criteria for Adverse Events Grading for Cystitis Noninfective

| Adverse Event         | Grade                                                                                                          |                                                                                                                                                                                                               |                                                                                                                               |                                                              |       |
|-----------------------|----------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|-------|
|                       | 1                                                                                                              | 2                                                                                                                                                                                                             | 3                                                                                                                             | 4                                                            | 5     |
| Cystitis noninfective | Microscopic hematuria; minimal increase in frequency, urgency, dysuria, or nocturia; new onset of incontinence | Moderate hematuria; moderate increase in frequency, urgency, dysuria, nocturia, or incontinence; urinary catheter placement or bladder irrigation indicated; limiting instrumental activities of daily living | Gross hematuria; transfusion, intravenous medications, or hospitalization indicated; elective invasive intervention indicated | Life-threatening consequences; urgent intervention indicated | Death |

creatinine, and urinalysis. Collaborate in obtaining an interstitial biopsy to verify and monitor bladder and renal infections (Cesaro et al., 2018; Klein et al., 2015).

- (4) Identify drinking and voiding patterns to formulate plans of care in the presence of possible hemorrhagic cystitis.
- (5) Assess menstrual cycle to prevent misinterpretation with hematuria.
- (6) Review treatment plans to correlate potential risk factors for hemorrhagic cystitis, including chemotherapy agents, radiation therapy, pathogen infections, and neutropenia. Identify antineoplastic therapies associated with hemorrhagic cystitis (e.g., cyclophosphamide, ifosfamide, radiation) and monitor for clinical manifestations.

f) Monitoring

- (1) Monitor urinalysis to identify possible occurrences of hematuria (Thompson, 2017).
- (2) Monitor urinalysis and sensitivity to screen for potential pathogens associated with hemorrhagic cystitis (Thompson, 2017).
- (3) Monitor complete blood count to anticipate risks of anemia, neutropenia, and thrombocytopenia in the presence of hemorrhagic cystitis (Cesaro et al., 2018; Thompson, 2017; Wilkinson et al., 2015).
- (4) Monitor fluid intake and output to maintain fluid balance at all times (Thompson, 2017).

g) Treatment: Management of hemorrhagic cystitis varies depending on etiology and symptom-

atic presentation. Some antineoplastic protocols include initiating continuous bladder irrigation in the presence of conditioning regimens known to cause hemorrhagic cystitis.

- (1) Bladder irrigation: Manual or continuous bladder irrigation remains a treatment of choice for hemorrhagic cystitis. A three-way urethral catheter that allows manual piston saline irrigation or continuous bladder irrigation will decompress any clots formed and often stop the bleeding (Yang et al., 2020). In addition, continuous bladder irrigation decreases the concentration of acrolein and its contact time with the bladder urothelium. Some antineoplastic protocols include initiating it prior to cyclophosphamide chemotherapy or in combination with the bladder protectant mesna, hyperhydration with forced diuresis and frequent voiding, antibiotic prophylaxis with fluoroquinolones, and urethral catheterization (Gonella et al., 2015; Yang et al., 2020).

- (a) Continuous bladder irrigation with 0.9% sodium chloride isotonic solution or manual irrigation of clots reduces bleeding by removing urokinase, an anticoagulant substance secreted into the urine by the kidney (Gonella et al., 2015; Yang et al., 2020). Continuous bladder irrigation has not been shown in recent studies to decrease the incidence of hemorrhagic cystitis but did decrease the duration of hemorrhagic cystitis (Cesaro et al., 2018).

- (b) Alum may be added to bladder irrigation to cause reduced protein precipitation, vasoconstriction, and decreased capillary permeability (Ziegelmann et al., 2017).
  - (c) Silver nitrate bladder instillation causes chemical coagulation and scarring at the bleeding site (Ziegelmann et al., 2017).
  - (d) Formalin bladder instillation stops bleeding by causing chemical corrosion in the bladder mucosa without scar tissue formation (Ziegelmann et al., 2017).
- (2) 2-Mercaptoethane sodium sulfonate (mesna) is the most widely used uroprotective agent that neutralizes the corrosive metabolite acrolein, which is responsible for the induction of hemorrhagic cystitis. Different dosages and timings of mesna and hyperhydration have been tested as prophylaxis against hemorrhagic cystitis. In 2008, the American Society of Clinical Oncology updated clinical practice guidelines for the use of mesna (Hensley et al., 2009).
- (a) Mesna dosing with ifosfamide therapy
    - i. With a standard dose of ifosfamide less than 2.5 g/m<sup>2</sup> daily, mesna dosing should equal 60% of the total daily dose of ifosfamide and be divided between three bolus doses administered 15 minutes before and four and eight hours after the administration of each dose of ifosfamide (Hensley et al., 2009; Matz & Hsieh, 2017).
    - ii. For an ifosfamide dosage greater than 2.5 g/m<sup>2</sup> daily, mesna dosing has not been established, although it has been given in divided doses equivalent to 60%–160% of the ifosfamide daily dose. An example regimen includes the following:
      - Before ifosfamide: mesna equivalent of 20% of the total daily ifosfamide dose given as IV bolus
      - During ifosfamide: mesna equivalent of 100%–120% of the total daily ifosfamide dose given as IV infusion over 24 hours (mixed in bags with ifosfamide)
      - After ifosfamide: mesna equivalent of 60% of the total daily ifosfamide dose given as IV infusion over 12 hours
      - Alternatively, mesna can be administered via IV at a dose equivalent to 20% of the ifosfamide dosage, followed by two oral doses, each equivalent to 40% of the antineoplastic agent. Mesna oral doses should be administered two and six hours after each dose of ifosfamide (Hensley et al., 2009).
  - (b) Mesna dosing with cyclophosphamide therapy
    - i. Mesna dosing with high-dose cyclophosphamide (greater than 1 g/m<sup>2</sup>; HSCT mobilization with cyclophosphamide 1.5 g/m<sup>2</sup>) requires mesna equivalent to 60%–160% of the total dose of cyclophosphamide daily given via IV. Mesna must be given by IV administration in three to five divided doses or by continuous infusion. Mesna should be administered each day cyclophosphamide is administered and continued for at least 24 hours after cyclophosphamide is discontinued (Hensley et al., 2009).
    - ii. Post-transplant cyclophosphamide can be used as a therapy to prevent GVHD and graft failure in haplo-identical HSCT. Given the increased risk of more severe cases of hemorrhagic cystitis in this population, mesna and hyperhydration have also been used as preventive strategies. Although insufficient evidence exists to suggest an optimal dose and administration schedule, IV mesna at 20 mg/kg bolus every three hours for

a total of 16 doses (equivalent to 320% of the total daily dose of cyclophosphamide) resulted in a lower incidence of hemorrhagic cystitis when compared to other studies (Mac et al., 2021).

iii. Mesna administration

- Mesna can be given by mouth, considering its bioavailability and half-life are approximately 50% of those observed after IV infusion (Jeelani et al., 2017).
- In patients receiving cyclophosphamide for HSCT, mesna plus saline diuresis is recommended to prevent hemorrhagic cystitis (Matz & Hsieh, 2017).

(c) Hyperbaric oxygen therapy may be used, as it causes vasoconstriction, enhances angiogenesis and granulation tissue formation, and optimizes immune function at the cellular level to the urothelial mucosa (Cesaro et al., 2018; Dautruche & Delouya, 2018).

(d) Surgical interventions

- i. Cystoscopy and fulguration using high-frequency energy channeled via electrocautery or laser
- ii. Intravesical formalin instillation using a large-bore catheter and cystogram under general anesthesia (Ziegelmann et al., 2017)
- iii. Cystectomy with urinary diversion (Au et al., 2017)

(3) Care coordination: Coordinate care with social work services, case management, home health, and pharmacy for patients undergoing hemorrhagic cystitis treatment.

h) Patient and family education

- (1) Educate patients and caregivers about the importance of actively participating in preventing and managing hemorrhagic cystitis.
- (2) Explain the importance of oral hydration, if not contraindicated, to stimulate frequent voiding while receiving oncologic treatments. Polyuria minimizes the time that acrolein and microorganisms are in the bladder.

(3) Teach patients and families neutropenic precautions to avoid new and recurrent infections that may exacerbate hemorrhagic cystitis during the recovery state.

(4) Educate about the importance of assessing urine and symptoms associated with hemorrhagic cystitis (e.g., pink and dark color, burning sensation while voiding, difficulty voiding, lack of sensation to urinate, frequency, lower abdomen pain).

(5) Explain to patients and caregivers continuous bladder irrigation and symptom management (Thompson, 2017; Wilkinsson et al., 2015).

C. Drug-specific considerations

1. Chemotherapy

a) Cisplatin is a platinum-based antineoplastic agent used in many different malignancies. Nephrotoxicity is the primary dose-limiting toxicity, and thus treatment with cisplatin-based regimens necessitates careful evaluation, prevention, and management of associated nephrotoxicity (Crona et al., 2017). Although multiple mechanisms of injury exist, rapid distribution into the kidneys, particularly increased concentration of cisplatin in the tubules, may account for such toxicity (Dahal et al., 2016). Cisplatin can also cause SIADH, salt wasting, magnesium wasting, and hypokalemia, leading to nephrotoxicity (Almanric et al., 2017).

(1) Incidence

(a) In a landmark article on cisplatin toxicity, approximately 28%–36% of patients treated with cisplatin therapy experience nephrotoxicity and 20% can be severe (Yao et al., 2007).

(b) Data on incidence are limited because studies use different renal evaluation metrics, such as serum creatinine, estimated GFR, and creatinine clearance.

(c) A recent meta-analysis comparing cisplatin-based to non-cisplatin-based regimens sought to determine the best method for measuring the true nephrotoxicity of cisplatin. Results revealed the incidence of nephrotoxicity when measured by serum creatinine alone was 1.82% for the cisplatin group compared to 0.23% for the non-cisplatin group.

(d) The incidence of severe nephrotoxicity, when measured by creatinine

clearance, was 1.09% in the cisplatin group compared to 0.72% in the non-cisplatin group.

- (e) In studies where either method was used, the incidence of severe nephrotoxicity was 0.88% with cisplatin-containing regimens and 0.45% with non-cisplatin regimens. This study suggested that using creatinine alone compared to metrics that estimate renal function, such as estimated GFR and creatinine clearance, can result in higher nephrotoxicity. Thus, estimated GFR or creatinine clearance would be the preferred evaluation metric in future studies. (Dahal et al. 2016).
  - (2) Risk factors (Almanric et al., 2017)
    - (a) Pharmacologic agents
      - i. Chemotherapy: previous cisplatin exposure
      - ii. Other agents: angiotensin-converting enzyme inhibitors, angiotensin receptor blockers, hydrochlorothiazide
    - (b) Preexisting conditions: hypertension, arteriosclerotic heart disease, myocardial infarction, coronary artery bypass surgery, type 2 diabetes
    - (c) Patient characteristics: hypomagnesemia, hypokalemia
  - (3) Clinical manifestations
    - (a) Hypertension
    - (b) Electrolyte disturbances
    - (c) Edema
  - (4) Assessment: Assess creatinine clearance using the Cockcroft-Gault formula prior to cisplatin administration.
  - (5) Collaborative management
    - (a) For hydration, patients should receive 2–4 L of normal saline over two to six hours with cisplatin administration (Crona et al., 2017; Duffy et al., 2018).
    - (b) Mannitol reduces the concentration of cisplatin in the kidneys; some studies suggest it should only be used for high-dose cisplatin (100 mg/m<sup>2</sup>) or with preexisting hypertension (Crona et al., 2017; Duffy et al., 2018).
    - (c) Electrolytes, specifically magnesium and potassium, should be monitored; add to IV hydration accordingly (Duffy et al., 2018).
- b) Methotrexate is an antimetabolite chemotherapy drug that disrupts folic acid metabolism and is used for different malignancies. AKI is a well-documented toxicity, and methotrexate, as with cisplatin, requires close monitoring and prompt intervention to avoid kidney damage (Howard et al., 2016). Nephrotoxicity occurs through crystal nephropathy, resulting from methotrexate and its metabolites forming precipitate within the renal tubules. Crystal-induced nephropathy initially might cause an elevation in serum creatinine and then progress to tubular necrosis (Howard et al., 2016; Sales & Foresto, 2020).
    - (1) Incidence: Doses greater than 500 mg/m<sup>2</sup> are associated with a 2%–12% incidence of AKI (Howard et al., 2016).
    - (2) Risk factors
      - (a) Pharmacologic agents
        - i. Chemotherapy: high-dose methotrexate dosing
        - ii. Other agents: concurrent use of drugs that impair methotrexate clearance, such as non-steroidal anti-inflammatory drugs, penicillin, salicylates, probenecid, gemfibrozil, trimethoprim-sulfamethoxazole, proton pump inhibitors, levetiracetam, amphotericin, aminoglycosides, and radiographic contrast dyes (Howard et al., 2016)
      - (b) Preexisting conditions: history of nephrotoxicity with previous methotrexate therapy
      - (c) Cancer types: lymphomas
      - (d) Patient characteristics: volume depletion
    - (3) Clinical manifestations
      - (a) Edema
      - (b) Electrolyte disturbances
      - (c) Hypertension
    - (4) Assessment
      - (a) Laboratory assessment
        - i. Monitor blood urea nitrogen and creatinine.
        - ii. Monitor urine pH and maintain greater than 7.
      - (b) Physical assessment
        - i. Assess for signs and symptoms of fluid overload.
        - ii. Perform strict intake and output monitoring.
    - (5) Collaborative management (Howard et al., 2016)

- (a) Discontinue medications that interfere with methotrexate elimination.
- (b) For hydration, administer prehydration with IV fluids containing bicarbonate at a rate of 150–200 ml/hr up to 2 L prior to high-dose methotrexate administration (Howard et al., 2016).
- (c) Perform strict monitoring of intake and output during and after high-dose methotrexate infusion.
- (d) Because methotrexate and its metabolites are poorly soluble in an acidic pH, using sodium bicarbonate for hydration increases urine pH to 7 and thus increases the solubility of methotrexate, minimizing the risk of intratubular crystal formation (Howard et al., 2016).
- (e) Monitor plasma methotrexate levels closely and adjust leucovorin dosing accordingly.
- (f) Glucarpidase is the antidote for methotrexate and is indicated only for toxic methotrexate plasma concentrations greater than 1  $\mu\text{mol/L}$  in patients with delayed clearance due to renal impairment (Ramsey et al., 2018).

## 2. Immunotherapy

- a) Immune checkpoint inhibitors, first approved for melanoma, have quickly emerged in treatment of several neoplasms. They work by enhancing tumor-directed immune response by targeting inhibitory receptors seen on T cells and other tumor cells (Cortazar et al., 2016). The toxicities associated with immunotherapy agents are immune-related events with cytotoxic T-lymphocyte-associated protein inhibitors (e.g., ipilimumab) and programmed cell death-ligand 1 inhibitors (e.g., nivolumab, pembrolizumab) causing interstitial nephritis and glomerulonephritis (Sales & Foresto, 2020).
- b) Management: Although no standard of care exists for immune-related nephritis, as with other immune-related toxicities, it is typically managed with steroids (Cortazar et al., 2016; Izzedine et al., 2014; Thajudeen et al., 2015). Once immune-related etiology is confirmed, usually via biopsy, patients are treated with prednisone or equivalent at a 1 mg/kg dose (Izzedine et al., 2014; Sales & Foresto, 2020). Immune-mediated toxicity may require temporary or permanent discontinuation of the offending agent.
- c) Patient and family education
  - (1) Educate patients and families regarding the risks of nephrotoxicity with the specific antineoplastic or cytotoxic regimens.
  - (2) Provide patients with a list of warning signs and symptoms that necessitate contacting their provider.
  - (3) Educate patients and families regarding the need for extraoral hydration while receiving nephrotoxic therapies.
  - (4) Provide patients with a list of drugs to avoid to decrease the risk of nephrotoxicity.

## CHAPTER 20

# Altered Sexual and Reproductive Functioning

### A. Alterations in sexual functioning

#### 1. Overview

- a) Sexuality is both a high priority and an unmet need for patients undergoing cancer treatment and cancer survivors (Almont et al., 2017).
- b) Sexual dysfunction after cancer is frequently reported and is associated with poor quality of life among survivors (Sears et al., 2018).
- c) Sexuality, and therefore sexual toxicities, are a concern for individuals across the age spectrum.
  - (1) Most patients are concerned about sexuality despite their prognosis, and younger patients are more likely to experience persistently impaired sexuality following cancer treatment (Almont et al., 2017; Farthmann et al., 2016).
  - (2) Studies suggest that despite knowing about the impacts of cancer and its treatment on sexuality, patients are often not provided with adequate information and resources (Pitcher et al., 2020). This lack of education results in missed opportunities for sexual rehabilitation (Almont et al., 2017).
  - (3) Approximately 20% of men with treatment-related issues consult with a healthcare provider about sexuality. Healthcare providers tend to ask women about sexuality less frequently than men (Ben Charif et al., 2016; Schover, 2016).
- d) More research is needed on the effects of cancer and sexuality in the LGBTQ+ community (Schabath et al., 2019). Despite an estimated 100,000 cancer diagnoses annually within the LGBTQ+ community, limited efforts have been made to address sexual disparities in this population (Schabath et al., 2019).

#### 2. Pathophysiology

- a) Sexual dysfunction related to cancer and its treatment results from chemotherapy, surgery, and radiation therapy (Priviero & Webb, 2021). These

treatment modalities cause disruptions to blood vessels, nerves, and hormones that contribute to sexual dysfunction (Priviero & Webb, 2021). Women and men can experience different forms of sexual dysfunction.

##### (1) Women

- (a) Premature ovarian failure resulting in loss of ovarian androgen and precursor sex hormones (i.e., estrogen, progesterone, and testosterone) (N. Bennett et al., 2016)
- (b) Neurotoxic chemotherapy hypothesized to damage genital sensory neurons (Marchand & Bradford, 2017)
- (c) Estrogen deprivation resulting from hormone manipulation (N. Bennett et al., 2016)

##### (2) Men

- (a) Alterations in testosterone levels caused by disease or cancer treatments
- (b) Chemotherapy that may be neurotoxic to erectile nerves and affect penile blood supply, causing erectile problems (Voznesensky et al., 2016)
- (c) Erectile dysfunction is classified as a psychogenic, vasculogenic, neurogenic, endocrinologic, end-organ disease, or iatrogenic condition (McMahon, 2019).

##### i. Psychogenic

- Dysfunction may result from anxiety, fatigue, or depression that often manifests as a lack of interest in sexual activity or a decline in arousal ability.
- Anxiety may be related to a relationship, sexual performance, or depression.

##### ii. Vasculogenic

- Dysfunction is associated with alterations in penile blood flow or damage to the pudendal or penile arteries.
- Veno-occlusive dysfunction also may occur. It is caused by a failure of the passive venous outflow obstructive mechanism, resulting in the inability of sinusoids to trap blood.

### iii. Neurogenic

- Dysfunction is associated with any disease or dysfunction involving the brain, spinal cord, or cavernous and pudendal nerves.
- Causes can include pelvic surgery, spinal cord injury, and multiple sclerosis (McMahon, 2019).

### iv. Endocrinologic

- It is associated with hypogonadism and testosterone deficiencies.
- Testosterone is associated with all stages of physiologic development in males, including sexual development (Mirone & La Rocca, 2020).
- Testosterone production can be influenced by tumor growth or cancer treatment that contributes to hypogonadism.
- Treatment-related hyperprolactinemia may suppress the production of testosterone.
- Pure hormone-driven erectile dysfunction is rare.

(d) End-organ disease is associated with pelvic or genital radiation therapy and Peyronie disease (McMahon, 2019).

(e) Iatrogenic dysfunction is associated with side effects of certain medications, such as thiazide diuretics and selective serotonin reuptake inhibitor antidepressants (McMahon, 2019).

## 3. Incidence

a) General: Sexual dysfunction reporting in cancer survivors is 17%–100% (Priviero & Webb, 2021). Patients with cancer and survivors can experience sexual alterations regardless of cancer type.

These alterations are commonly related to cancer treatments (American Cancer Society, 2019). Up to 68% of childhood cancer survivors report sexual dysfunction (Priviero & Webb, 2021). The probability of sexual dysfunction increases over time for young adults (Acquati et al., 2018).

### b) Women

- (1) The incidence of sexual dysfunction is 35%–94% across female cancer survivors and often goes unaddressed (Falk & Dizon, 2020; Miller et al., 2019).
- (2) In women with gynecologic cancers, 40%–100% report sexual dysfunction after cancer treatment (Pitcher et al., 2020).
- (3) Among young adult breast cancer survivors, 52% report sexual dysfunction (Acquati et al., 2018).
- (4) A decrease in sexual desire and libido occurs in over half of women with ovarian or breast cancers (Whicker et al., 2017; Widiarti et al., 2019). Studies have shown that sexual desire is directly related to side effects of chemotherapy, as well as social support and body image (Widiarti et al., 2019).
- (5) Dyspareunia or pain during intercourse has been reported by women after various cancer diagnoses and treatment modalities (Duimering et al., 2020).
- (6) Vaginal stenosis is a known toxicity of radiation treatment in patients with endometrial and cervical cancers, with an average incidence of about 73% (Campitelli et al., 2018; de Moraes Siqueira et al., 2021).

### c) Men

- (1) Approximately 30.9% of men with cancer are dissatisfied with sexual functioning, whereas 18.2% of women with cancer are dissatisfied (Jackson et al., 2016).
- (2) Erectile dysfunction
  - (a) The incidence of cancer-related erectile dysfunction is 24%–87% (Madan et al., 2020).
  - (b) Erectile dysfunction is the most common sexual side effect for men receiving cancer treatment, but it is often underreported (Madan et al., 2020; Mayo Clinic, 2020a).
  - (c) Following radical prostatectomy, 79% of men reported erectile dysfunction two years after surgery and 72% five years after surgery (Madan et al., 2020). Approximately 9%–40% of men regain sexual function following a prostatectomy.

- (d) Following radiation therapy for prostate cancer, 60% of men reported erectile dysfunction two years after treatment and 72% five years after treatment (Madan et al., 2020).
  - (e) Long-term survivors (more than 15 years) reported erectile dysfunction consistent with their five-year follow-up (Madan et al., 2020).
  - (3) Reduced penile length is reported in men following prostatectomies and cystectomies (Madan et al., 2020).
  - (4) Approximately 11% of testicular cancer survivors report loss of desire, and 51% report ejaculation problems (Acquati et al., 2018).
4. Risk factors
- a) General (Falk & Dizon, 2020)
    - (1) Individuals with cancer and other chronic illness states, specifically uncontrolled hypertension, thyroid dysfunction, hyperlipidemia, anemia, fatigue, and depression, are at an increased risk for sexual dysfunction. Uncontrolled diabetes can also cause vascular dysfunction and decreased blood flow to the pelvic region, inhibiting engorgement and excitement.
      - (a) Diuretics and antihypertensive medications are associated with decreased libido and orgasm.
      - (b) Similarly, selective serotonin reuptake inhibitors and other antidepressants may inhibit sexual desire, arousal, and orgasm.
    - (2) A higher probability of reporting sexual dysfunction exists in patients who are female, older, married, treated with chemotherapy, and reported comorbid psychological distress and lower social support (Aquatic et al., 2018).
    - (3) Gender and sexual minorities are at a higher risk for cancer effects on sexual dysfunction due to a lack of knowledge and skill from providers (Kamen et al., 2018).
    - (4) Sexual dysfunction related to antineoplastic agents is common among cancer survivors treated as adults and adults treated as children (Priviero & Webb, 2021). The following agents are used in various combinations; thus, sexual side effects may be cumulative.
      - (a) Alkylating agents (e.g., busulfan, cyclophosphamide, ifosfamide, nitrogen mustard, platinum-based chemotherapies) cause nausea and vomiting, which can significantly decrease sexual desire (Falk & Dizon, 2020; Weitzner et al., 2019).
      - (b) Antimetabolites (e.g., cladribine, cytarabine, hydroxyurea, methotrexate) cause malaise, mucositis, nausea, and vomiting (Davis & Howard, 2019).
      - (c) Antitumor antibiotics (e.g., daunorubicin, doxorubicin, mitoxantrone) cause nausea, vomiting, and mucositis (Davis & Howard, 2019).
      - (d) Vinca alkaloids (e.g., vincristine, vinblastine, vinorelbine) cause peripheral neuropathy, which may affect sensation in the hands and fingers and decrease sexual desire (Davis & Howard, 2019).
      - (e) Most immunotherapy agents can cause fatigue, flu-like symptoms, and changes to body image (Abueg & Keith, 2019).
      - (f) Targeted therapy can cause fatigue, diarrhea, and rash with the potential to affect body image (Abueg & Keith, 2019).
  - b) Women
    - (1) Disease factors (Falk & Dizon, 2020)
      - (a) The risk of sexual dysfunction increases for women with rectal, gynecologic, or breast cancers, especially hormone-sensitive cancers (Mayo Clinic, 2020b).
      - (b) The risk for premature or permanent ovarian failure increases with age.
    - (2) Antineoplastic therapies
      - (a) Chemotherapy (Falk & Dizon, 2020; see Chapter 6)
        - i. Chemotherapy can cause hair loss, nausea and vomiting, diarrhea, or constipation, which may decrease sexual desire and frequency.
        - ii. Chemotherapy can cause direct toxicity to the pelvis and vagina.
      - (b) Hormone therapy (see Chapter 7)
        - i. Aromatase inhibitor risk to sexual health is higher than estrogen receptor modulators, causing vaginal dryness, atrophy, and dyspareunia (Sánchez-Rovira et al., 2020). Aromatase inhibitors are preferred for postmenopausal women

- with estrogen-sensitive cancers (Advani et al., 2017).
- ii. Estrogen receptor modulators, such as tamoxifen, can cause dyspareunia (painful intercourse) regardless of menopause status (Falk & Dizon, 2020).
- (c) Pelvic or anal irradiation contributes to ovarian failure (Falk & Dizon, 2020).
- (d) Bilateral oophorectomy (for cancer treatment or prevention) is equivalent to ovarian failure.
- (e) Gonadotropin-releasing agonists or antagonists for ovarian suppression can increase the risk of permanent ovarian failure (Falk & Dizon, 2020).
- (3) Systemic graft-versus-host disease can make vaginal intercourse impossible because of severe tissue damage to the vulva and vagina (Skorupska et al., 2019).
- (4) Subjectively, women report that fatigue, anxiety, depression, compromised self-esteem, general pain, appearance changes, and feelings of unattractiveness contribute to changes in sexual frequency and activities (Almont et al., 2017; Mollaioli et al., 2020; Widiанти et al., 2019).
- c) Men (Mayo Clinic, 2020a)
  - (1) Disease factors
    - (a) History of pelvic cancers (e.g., bladder, colorectal, prostate)
    - (b) Hypogonadism
  - (2) Antineoplastic therapies
    - (a) Surgery for bladder or rectal cancer
    - (b) Chemoradiation therapy for anal cancer
    - (c) Prostatectomy (both radical and nerve sparing)
    - (d) Damage to pelvic nerves
    - (e) Pelvic or total body irradiation
  - (3) Multimodal treatment (chemoradiation therapy) is more likely to cause sexual problems (Capogrosso et al., 2016).
  - (4) Subjectively, men report that erectile dysfunction, fatigue, pain, surgery, decreased body image, and aging were the primary causes of changes in sexual functioning (Mayo Clinic, 2020a).
- 5. Clinical manifestations
  - a) Sexual dysfunction is associated with fatigue, pain, nausea, incontinence, depression, and anxiety that can result in the discontinuation of sexual activity (McMahon, 2019).
  - b) Men and women report a decrease in sexual frequency and satisfaction following a cancer diagnosis and associated treatment (Olsson et al., 2018).
  - c) Women (Falk & Dizon, 2020)
    - (1) Most common manifestations
      - (a) Dyspareunia
      - (b) Vaginal dryness
      - (c) Decreased libido
    - (2) Effects may also include difficulty with sexual self-image, arousal, feeling pleasure, or achieving orgasm during sexual activity. Hair loss due to chemotherapy can contribute to negative body image, affecting sexual desire.
    - (3) Symptoms of chemotherapy-induced menopause are dramatic and may be worse for premenopausal women when diagnosed. Symptoms include the following (Farthmann et al., 2016; Valpey et al., 2019):
      - (a) Menstrual cycle changes with eventual cessation
      - (b) Hot flashes and insomnia
      - (c) Vaginal or vulvar dryness
      - (d) Dyspareunia
      - (e) Weight gain
      - (f) Mood changes and cognitive effects
  - d) Men (Madan et al., 2020)
    - (1) Most common manifestations are loss of libido and erectile dysfunction.
    - (2) Additional possible manifestations
      - (a) Perceived loss of genital length or penile shrinkage (Gentili et al., 2019)
      - (b) Changes in quality of and ability to achieve orgasm and pain associated with orgasm
      - (c) Feminization because of androgen deprivation (Gentili et al., 2019)
- 6. Collaborative management
  - a) A multimodal approach is needed to address all aspects of sexual dysfunction related to cancer treatment (Whicker et al., 2017).
    - (1) Screening for sexual dysfunction is essential for survivorship and patient quality of life (Falk & Dizon, 2020).
    - (2) Based on the individual, referrals may be needed to gynecology, urology, mental health, and internal medicine (Falk & Dizon, 2020).
    - (3) Sexual rehabilitation should be presented and offered to all patients with cancer.
    - (4) Quality of life restoration is an essential aspect of survivorship (Madan et al., 2020).
    - (5) Management of treatment-related sexual dysfunction should involve an interpro-

fessional approach consisting of medical and mental health components (Falk & Dizon, 2020).

- (6) This is important because sexual dysfunction emerges from physiologic changes related to cancer and its treatment and from the psychological sequelae of cancer, including negative body image and depression.

*b) General recommendations*

- (1) Address sexual health before cancer treatment rather than sexual dysfunction after it has progressed (Falk & Dizon, 2020).
- (2) Obtain a prior history of sexual experience, avoiding assumptions about sexual orientation and gender identity. Ask open-ended questions (Falk & Dizon, 2020).
- (3) Become knowledgeable about sexual orientation and gender identity before addressing the sexual needs of each patient (Schabath et al., 2019).
- (4) Focus on communication between patients and partners (Falk & Dizon, 2020).
- (5) Emphasize that sexual pleasure and intimacy can be found beyond penetrative intercourse (Falk & Dizon, 2020).
- (6) Identify coping mechanisms for the limitations of sex after cancer (Falk & Dizon, 2020).
- (7) Educate patients on the need for safe sex practices throughout cancer treatment (Frederick et al., 2020).
  - (a) Patients are usually advised to use a barrier (condom or dental dam) for penetrative intercourse and oral sex to protect their partner from exposure to metabolites of chemotherapy.
  - (b) Barrier protection should be used on the day of and for a week after chemotherapy administration.

*c) Women*

- (1) In addition to a physical examination, psychosocial assessment should focus on changes in spontaneous versus receptive sexual desire, barriers to sexual activity (e.g., pain), changes in relationship adjustment (if applicable), and assessment of risk factors (Marchand & Bradford, 2017). Validated instruments include the following:
  - (a) Female Sexual Function Index (Duijmering et al., 2020)
  - (b) Sexual Activity Questionnaire (Oppenheimer et al., 2019)

(c) Menopausal Sexual Interest Questionnaire (Advani et al., 2017)

(d) Patient-Reported Outcomes Measurement Information System Sexual Interest and Satisfaction Measure (PROMIS-SexFS) (Agochukwu et al., 2019)

- (2) Psychosocial counseling is recommended to improve desire, arousal, orgasm, intimacy in relationships, and body image. Couple-based interventions have demonstrated efficacy in improving sexual functioning (Barbera et al., 2017).
- (3) Distinct from psychosocial counseling, sex therapy may use a multimodal approach (e.g., education, communication, sensate focus, mindfulness) to enhance sexual desire (Marchand & Bradford, 2017).
- (4) Physical interventions
  - (a) Regular stimulation (e.g., masturbation) can also help to improve sexual response.
  - (b) Physical exercise or pelvic floor exercises can be helpful.
- (5) The first-line choice for managing menopausal symptoms should be nonhormone. Four nonhormone treatments appear to be beneficial for managing vasomotor symptoms (hot flashes) (Szabo et al., 2019).
  - (a) Gabapentin and pregabalin reduce vasomotor symptoms in breast cancer survivors.
  - (b) Selective serotonin reuptake inhibitors (e.g., citalopram, escitalopram, sertraline, fluoxetine, paroxetine) have been shown to reduce vasomotor symptoms in patients with breast cancer by 10%–40%. Tamoxifen competes for the same metabolic pathway as paroxetine and fluoxetine; therefore, those agents should not be used in women receiving tamoxifen therapy for breast cancer.
  - (c) Serotonin noradrenaline reuptake inhibitors, including venlafaxine and desvenlafaxine, have reduced vasomotor symptoms.
  - (d) Clonidine, an alpha-2 adrenergic agonist, is used as an antihypertensive medication and to treat vasomotor symptoms.
- (6) The decision to use hormone treatment in hormone-sensitive cancers should be carefully discussed with patients (Mayo Clinic, 2020b).

- (a) Local estrogen therapy for vaginal atrophy
      - i. Using low-dose estrogen can significantly decrease vulvo-vaginal dryness and associated pain (Falk & Dizon, 2020).
      - ii. Local estrogen use did not increase the risk of recurrence in women with hormone-sensitive breast cancer (Whicker et al., 2017).
      - iii. The safety of local estrogen for women on aromatase inhibitors is not yet established (Sulaica et al., 2016).
      - iv. Vaginal testosterone has proven efficacy in reducing vulvovaginal atrophy in women with breast cancer using aromatase inhibitors (Falk & Dizon, 2020).
    - (b) Systemic hormone replacement therapy has proven beneficial in ovarian and breast cancer survivors (Vermeulen et al., 2017).
  - (7) Other therapy agents are available, such as gels, creams, and suppositories (Barbera et al., 2017; Marchand & Bradford, 2017).
    - (a) Vaginal moisturizers can be used for daily comfort, and lubricants can be used during intercourse.
    - (b) Topical anesthetics may also be used to reduce pain during intercourse.
    - (c) Topical steroids, used to treat localized genital graft-versus-host disease, can help reduce symptoms (Jacobson et al., 2019).
  - (8) Vaginal dilators may be beneficial in the presence of vaginismus (involuntary muscle contraction) or vaginal stenosis, particularly among women who received radiation treatment for cervical cancer.
- d) Men
  - (1) Assessment should be conducted at each visit and include examining genital appearance, testing testosterone levels, and examining the prostate (Marchand & Bradford, 2017).
    - (a) The International Index of Erectile Function may be used to assess erectile dysfunction concerns quickly; however, it focuses on penile–vaginal intercourse and may not be appropriate to assess erectile dysfunction in men who have sex with men (Marchand & Bradford, 2017).
    - (b) The Patient-Reported Outcomes Measurement Information System (PROMIS) Sexual Interest and Satisfaction measures sexuality, sexual interest, satisfaction, and physical functionality in patients with prostate cancer (Agochukwu et al., 2019).
  - (2) Care coordination
    - (a) Coordinate interprofessional referrals, including urology and sex therapy.
    - (b) Begin penile rehabilitation early in the patient's treatment to improve erectile function (Yang et al., 2019).
    - (c) Psychosocial counseling is recommended to improve desire, arousal, orgasm, intimacy, and relationships (Barbera et al., 2017).
  - (3) Treatment options for erectile dysfunction
    - (a) Phosphodiesterase type 5 (PDE5) inhibitors, including sildenafil (Viagra®), tadalafil (Cialis®), and vardenafil (Levitra®), have demonstrated efficacy in supporting erectile function following nerve-sparing radical prostatectomy (Jo et al., 2018).
      - i. This drug class increases perfusion to the blood vessels of the corpus cavernosum of the penis by blocking the degradative action of cyclic granulocyte-macrophage inhibitor-specific PDE5 in smooth muscle cells.
      - ii. They are contraindicated with nitrates (Deng et al., 2017).
    - (b) Vacuum erection devices
      - i. Consists of a closed-ended, clear plastic cylinder and a vacuum that uses negative pressure to increase blood flow to the penis by distending the corporal sinusoids (Yang et al., 2019)
      - ii. Advantages
        - Easy to use, noninvasive, quick response with an average time to erection of two to three minutes; men have reported a reduction in penile shortening (Hecht & Hedges, 2016; Yang et al., 2019).

- Additionally, a fixed expense is associated with vacuum pumps (Hecht & Hedges, 2016).
  - iii. Disadvantages
    - Evidence-based guidelines are lacking, and the optimal level of negative pressure has not been appropriately established (Yang et al., 2019).
    - Men can experience pain and urethral constriction.
  - iv. Contraindicated with coagulation abnormalities and sickle cell disease
  - v. May be used in combination with PDE5 inhibitors (Falk & Dizon, 2020)
- (c) Prostaglandin E1 can be administered by suppository or intracavernosal injection to induce vasodilation and expansion of the corpora spongiosum to achieve an erection (Patel & Hsleh, 2016).
- i. It is typically used as second-line therapy in patients in whom PDE5 inhibitor therapy was unsuccessful or combined with other forms of penile rehabilitation (Patel & Hsleh, 2016).
  - ii. Intracavernosal injection is most effective when administered within three months of nerve-sparing radical prostatectomy.
  - iii. Suppositories may be used alone or with a vacuum erection device or PDE5 inhibitor. They have demonstrated increased efficacy when combined (Jo et al., 2018).
- (d) Penile prosthetic implants (Dadhich et al., 2017)
- i. Surgically implanted devices that may be noninflatable, semirigid, or inflatable, allowing for erection through manual manipulation or pump-facilitated inflation
  - ii. Advantages: Some studies suggest higher scores on measures of erectile function with implanted inflatable prosthetics than with medical management.
  - iii. Disadvantages: Invasive procedure; rare complications, including bladder injury, reservoir hernia, and reservoir erosion
  - iv. Minimally used, with less than 1% of patients reporting progression to prosthesis placement after cancer treatment
- (e) Other treatment modalities (Barbera et al., 2017)
- i. Venlafaxine, medroxyprogesterone acetate, cyproterone acetate, or gabapentin may be used to improve vasomotor symptoms.
  - ii. Some studies have suggested acupuncture may also be used to treat these symptoms.
- e) Assessment tools
- (1) Several models help communicate sexuality to patients. Historically, the most frequently used model is PLISSIT (permission, limited information, specific suggestion, intensive therapy) (Annon, 1976; M.R. Bennett, 2019). A more recent model specifically designed for the oncology population is BETTER (bring up, explain, tell, timing, educate, record) (Karakas & Aslan, 2019).
- (a) PLISSIT (M.R. Bennett, 2019)
- i. The first level involves giving the patients or clients permission to talk about sexual issues.
  - ii. The second level refers to the information given to patients in response to a question or observation.
  - iii. The third level involves making a specific suggestion to the patients or clients.
  - iv. The fourth level refers to the intensive therapy needed for severe or more long-standing sexual problems or referral to a specialist, such as a urologist or a gynecologist.
- (b) BETTER (Karakas & Aslan, 2019)
- i. The first level of intervention involves bringing up the topic.
  - ii. The second level involves explaining that sexuality is part of quality of life and that

patients can talk about this with the nurse.

- iii. Care providers should then tell patients that appropriate resources will be found to address their concerns.
- iv. Care providers should state that while the timing may not be appropriate now, patients can ask for information at any time.
- v. Patients should be educated about the sexual side effects of their treatment.
- vi. Finally, a note should be made in the patient's medical record stating that this topic has been discussed.

(c) Other assessment tools can be applied to assess sexual dysfunction, such as the 5 A's model, Changes in Sexual Functioning Questionnaire (CSFQ), and the Sexual Distress Scale-Revised (FSDS-R) (Duimering et al., 2020).

## 7. Patient and partner education

- a) Education and counseling should begin early to promote effective rehabilitation and limit sexual inactivity (Schover, 2016).
  - (1) Affected individuals should be encouraged to communicate openly about sex with their partners.
  - (2) Internet-based resources are recommended as self-help tools that individuals and their partners can use in the privacy of their homes.
  - (3) Patients and their partners should be encouraged to explore ways of expressing affection in the context of sexual dysfunction.
  - (4) Individuals or couples should be encouraged to view sexual activity as a chance to explore variety and fantasy rather than an action that needs to be performed correctly.
- b) Social support has a protective effect related to sexual dysfunction for young adults (Acquati et al., 2018); therefore, social connectivity should be emphasized and supported for young adults during and following cancer treatment.
- c) Access to support services can be challenging for gender and sexual minorities due to societal stigmas and biases, especially concerning services that have historically only served heterosexual patients (Kamen et al., 2018).

## B. Alterations in reproductive functioning

### 1. Overview

- a) Infertility, both temporary and permanent, is a possible side effect related to cancer type and any treatment received (Wettergren et al., 2020).
- b) Many young adult cancer survivors do not receive adequate information about treatment-related infertility and options for fertility preservation, which can lead to survivor regret (Chan et al., 2017; Fair et al., 2019).
- c) Attention to fertility concerns has been cited as an unmet need in 93% of adolescent and young adult survivors, and uncertainty about fertility status is common in young adult cancer survivors (Benedict et al., 2016; Wong et al., 2017).
- d) Attention to gender identity has also been identified as an unmet need in patients with cancer when addressing reproductive functioning, mainly due to provider knowledge regarding gender and sexual minorities (Kamen et al., 2018; Schabath et al., 2019).

### 2. Pathophysiology

- a) In women, chemotherapy causes damage to ovarian follicles, decreased ovarian volume, and decreased ovarian reserve.
- b) In men, gonadotropin and sperm production deficiencies (azoospermia) are common side effects of cancer treatment (Polackwich & Sabanegh, 2016).

### 3. Incidence

#### a) Women

- (1) Most female cancer survivors have reproductive alterations and distress (Wettergren et al., 2020).
- (2) Rates of chemotherapy-induced amenorrhea increase with age (Zavos & Valachis, 2016).
  - (a) Women younger than age 35: 26%
  - (b) Women aged 35–40 years: 39%
  - (c) Women older than age 40 years: 77%

#### b) Men

- (1) Infertility is dependent on the chemotherapy regimen, cumulative doses, and other therapies, such as radiation and surgical interventions (Vij & Gilligan, 2016).
- (2) Azoospermia rates range from 11%–100% (Ostrowski & Walsh, 2016).
- (3) Fertility-related distress in cancer survivors has not been well studied in men. Still, studies have shown that impaired infertility is directly related to decreased quality of life (Wettergren et al., 2020).

### 4. Risk factors

#### a) Disease-related risk factors

- (1) Women with ovarian cancer and hormone-sensitive breast cancer may have increased risk for infertility and genitourinary syndrome of menopause related to hypoestrogenism (Falk & Dizon, 2020).
  - (2) Men with testicular and Hodgkin lymphoma are more likely to have poor sperm quality prior to beginning treatment (Agarwal & Sharma, 2016).
- b) Treatment-related risk factors
- (1) Radiation therapy alone or in combination can significantly increase the risk of infertility (Clezki, 2016).
  - (2) High doses of alkylating agents pose the highest risk for infertility in pediatric cancer survivors and adult men and women (de Lambert et al., 2018).
    - (a) In women, procarbazine and the CMF (cyclophosphamide, methotrexate, and 5-fluorouracil) regimen are associated with increased risk of infertility (Overbeek et al., 2017).
    - (b) In men, the most spermatotoxic chemotherapy drugs include nitrogen mustard derivatives (e.g., busulfan, melphalan) and alkylating agents (e.g., cyclophosphamide, procarbazine) (Vij & Gilligan, 2016).
      - i. Cyclophosphamide, ifosfamide, and procarbazine are gonadotoxic and associated with azoospermia (de Lambert et al., 2018; Moss et al., 2016).
      - ii. Antimetabolites can cause a temporary reduction in sperm count but are not known to cause infertility (Vij & Gilligan, 2016).
  - (3) Age
    - (a) Older age increases the risk for infertility in men and women.
    - (b) Chemotherapy accelerates reproductive aging in childhood cancer survivors (Anderson & Wallace, 2016).
5. Clinical manifestations
- a) Women (Campbell & Woodard, 2020)
- (1) Women with high levels of concern about fertility are more likely to experience depression.
  - (2) Women are also concerned about the effects of cancer treatment.
  - (3) Women who receive fertility preservation counseling experience improved quality of life and have better coping skills and less long-term regret.
- b) Men
- (1) Oligozoospermia occurs in approximately 50%–70% of men with cancer before treatment begins (Giwerzman, 2017; Polackwich & Sabanegh, 2016).
  - (2) Azoospermia occurs in 9.7%–21% of men at diagnosis (Ostrowski & Walsh, 2016).
    - (a) Recovery of spermatogenesis is typically observed within two to five years after chemotherapy, after which 8% of men remain azoospermic, with prolonged azoospermia occurring in up to 65% of individuals receiving greater than 600 mg/m<sup>2</sup> of cisplatin (Giwerzman, 2017).
    - (b) Among male survivors of childhood cancer, approximately 20% present with azoospermia, with an incidence of 15% in individuals treated with chemotherapy alone versus 33% among those treated with chemotherapy plus radiation (Giwerzman, 2017).
6. Collaborative management
- a) An interprofessional approach is needed to manage reproductive dysfunction properly.
- (1) Referrals to gynecology, urology, or internal medicine may be needed to address reproductive needs and quality of life (Falk & Dizon, 2020).
  - (2) Additionally, patients expressing distress related to potential or actual infertility may benefit from a referral to a psychologist (Falk & Dizon, 2020).
  - (3) Sexual rehabilitation should be presented and offered to all patients with cancer.
- b) Women (Pereira & Schattman, 2017)
- (1) Oocyte and embryo cryopreservation techniques are established methods. Ovarian stimulation followed by cryopreservation is the most reliable technique for fertility preservation.
  - (2) Ovarian stimulation usually requires two weeks of gonadotropin injections.
  - (3) Ovarian stimulation with subsequent cryopreservation has proven to be efficacious and safe for patients with cancer.
  - (4) In recent years, ovarian cortex or immature oocyte cryopreservation has become an alternative for patients (de Lambert et al., 2018).
  - (5) Controversy exists about using gonadotropin-releasing hormone analogs to protect the ovaries from damage. This controversy is due to initial observations in which data might have been misinter-

- preted and studies provided contradicting results (Oktay & Bedoschi, 2016).
- (6) Ovarian suppression is not likely to benefit despite support for this strategy and apparent safety (Demeestere et al., 2016; Hickman et al., 2016; Kim et al., 2016).
  - (7) The return of menstrual periods does not necessarily indicate good ovarian function, and, in turn, lack of menstruation does not mean that ovarian function has ceased.
- c) Men
- (1) Sperm cryopreservation before treatment is highly effective, as sperm remain viable after freezing and can be used to fertilize ovum.
  - (2) Semen samples should be collected 48–72 hours apart (Agarwal & Sharma, 2016).
  - (3) Electroejaculation can be used in prepubertal males who are embarrassed or unable to produce a semen sample. This requires general anesthesia but can be done at the time of another surgical procedure, such as bone marrow aspiration (Romao & Lorenzo, 2017).
  - (4) Cryopreservation of testicular tissue is an experimental procedure that may offer hope to prepubertal boys (Wise, 2016).
7. Patient and family education (Hershberger et al., 2016)
- a) Decisions about fertility treatments must be made when patients are trying to cope with a cancer diagnosis; priorities may change over time, and some decisions are made without proper knowledge.
    - (1) It is essential to educate patients honestly and directly, as they may assume that modern reproductive technologies will result in a future pregnancy.
    - (2) A strong desire to be a biologic parent motivates some patients to attempt to preserve fertility.
  - b) Patients and caregivers need to be educated on possible barriers to fertility preservation (Flink et al., 2017).
    - (1) Urgency to initiate cancer treatment and limited time to complete fertility preservation
    - (2) Inadequate information on fertility preservation options from providers. The need for a referral to an oncofertility specialist may exist, which may not be available to patients.
    - (3) Cost associated with fertility preservation
    - (4) Sociodemographic factors (e.g., age, race, relationship status)
  - c) Parents of a child with cancer must make decisions about treatment for their child and may not be ready to discuss sperm banking or ovarian preservation with their child or healthcare providers, as their priority is to save their child's life (Wong et al., 2017).
  - d) Access to fertility services
    - (1) An interprofessional approach is optimal to address the complex ethical and psychological issues. Nurses who have longitudinal relationships with patients are vital to ensuring that information is provided to patients (Quinn et al., 2016).
    - (2) Barriers to fertility services
      - (a) Access to fertility services is related to a patient's developmental stage, age, literacy level, cultural beliefs, sexual orientation, gender identity, and assumptions made by clinicians (Ghazeeri & Khalife, 2020; Schabath et al., 2019). Demographic disparities and the availability of resources also impact access to fertility preservation (Flink et al., 2017).
      - (b) Age-appropriate information and services are an unmet need for adolescents and young adults with cancer, as is fertility-related follow-up after the completion of treatment (Bibby et al., 2017).
      - (c) Referrals for sperm banking remain low—29% of young men reported receiving counseling, and 11% attempted sperm banking (Grover et al., 2016).
      - (d) Only 34%–72% of women report receiving fertility preservation counseling and information (Campbell & Woodard, 2020).
      - (e) Patients who are not adequately educated on fertility preservation before beginning cancer treatment can make uninformed decisions that may permanently impact fertility and have lifelong consequences (Giles, 2017).
  - e) General education (Kelvin, 2020)
    - (1) Address the risk of infertility and discuss fertility preservation options with patients as part of informed consent before cancer therapy. Sperm and embryo cryopreservation are well established as the standard of care.

- (2) Encourage patients to participate in registries and clinical trials related to fertility preservation.
- (3) Provide information about the timeline for fertility preservation and how it may affect treatment and overall outcomes.
- (4) Advise patients of the potential toxicity to reproductive material or the loss of opportunity to preserve reproductive material after the start of chemotherapy.
- (5) Engage patients, partners, and caregivers (if applicable) in discussions of cryopreservation options.

## CHAPTER 21

# Cutaneous Toxicities and Alopecia

### A. Cutaneous toxicity

#### 1. Overview

- a) For years, the cutaneous side effects from conventional cytotoxic chemotherapy agents have been observed and described in detail.
- b) With the introduction of targeted therapies and immunotherapies, cutaneous toxicities have increased.
- c) Cutaneous toxicities can result in treatment interruptions and have financial implications and psychosocial impacts.
- d) As the number of agents and uses for targeted therapy and immunotherapy increase, so does the need to recognize and treat the dermatologic side effects of these agents (Lacouture et al., 2021).
- e) See Table 21-1 for cutaneous reactions and management of toxicities from chemotherapy, targeted therapy, and immunotherapy agents.

#### 2. Pathophysiology, incidence, risk factors, and clinical manifestations

##### a) Chemotherapy

- (1) Numerous cutaneous side effects have been reported from traditional chemotherapy drugs, including cytarabine, anthracyclines (e.g., doxorubicin), 5-fluorouracil (5-FU), capecitabine (5-FU prodrug), taxanes (e.g., docetaxel), and methotrexate.

(a) Reports include clinical and histologic findings that have significant overlap. Cutaneous adverse events from chemotherapy can affect the skin, hair, nails, and mucosa.

(b) Cutaneous side effects from chemotherapy occur due to disruptions in the cell cycle phases. The specific phase in which the disruption occurs will cause a specific type of cutaneous reaction (Reyes-Habito & Roh, 2014a).

- i. Alkylating agents, such as cyclophosphamide, cause dam-

age in all phases of the cell cycle and tend to cause hyperpigmentation.

- ii. Antimetabolites, such as gemcitabine, damage cells in the S phase and cause cutaneous effects, such as maculopapular rash, hand-foot syndrome, and hyperpigmentation.
- iii. Antitumor antibiotic agents, such as doxorubicin, cause damage in all phases of the cell cycle and lead to reactions, such as hand-foot syndrome and follicular rash.
- iv. Mitotic inhibitors, including taxanes, cause damage in the M phase of the cell cycle. Cutaneous reactions from these agents include hand-foot syndrome, nail changes, and erythema multiforme.
- v. Topoisomerase inhibitors, such as topotecan and etoposide, affect the cell cycle during the S or G<sub>2</sub> phase. Cutaneous reactions seen with these agents include hand-foot syndrome and paronychia (Reyes-Habito & Roh, 2014a).

- (2) Hand-foot syndrome (palmar-plantar erythroderma) occurs in 6%–62% of patients receiving single-agent therapy, increasing to as high as 89% in those receiving multiple agents.

(a) Development of hand-foot syndrome is usually seen within days to weeks after initiation of therapy.

(b) Presenting symptoms include numbness, paresthesia and erythema, or hyperpigmentation in patients with

**TABLE 21-1.** Cutaneous Reactions to Antineoplastic Agents

| Cutaneous Reaction                         | General Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Chemotherapy                                                                                                                                                                                                                                         | Targeted Therapy                                                                                                       | Immunotherapy                      |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| Acneiform eruptions or papulopustular rash | <p>EGFRI-mediated rashes generally follow a well-characterized clinical course. Within the first week of treatment, patients experience sensory disturbance with erythema and edema; from weeks 1–3, the papulopustular eruption manifests, followed by crusting at week 4. Despite successful treatment, erythema and dry skin may persist in the areas previously affected by skin rash through weeks 4–6.</p> <p>It generally presents as diffuse erythema over the face and body, progressing to follicular papules and pustules resembling acne.</p> <p>Causative chemotherapy agents should be discontinued. Causative EGFRIs may not need to be discontinued.</p> <p>The disorder is characterized by an eruption consisting of papules (small raised pimples) and pustules (small pus-filled blisters), typically appearing on the face, scalp, and upper chest and back. Unlike acne, this rash does not present with whiteheads or blackheads and can be symptomatic, with itchy or tender lesions.</p> <p>See text for grading and management of papulopustular rash.</p> | –                                                                                                                                                                                                                                                    | Brigatinib, dabrafenib, dacomitinib, erlotinib, everolimus, gefitinib, lapatinib, temsirolimus, trametinib, vandetanib | Cetuximab, durvalumab, panitumumab |
| Acral erythema                             | <p>Acral erythema consists of erythema, swelling, and pain of the digits. It usually occurs 1–14 days after treatment starts and lasts for 1–2 weeks.</p> <p>It generally presents as dysesthesia (altered sensation of the skin) with tingling in the hands and feet progressing to pain.</p> <p>After 4–5 days of intense edematous erythema and even fissures of the palms, soles, and digital joints, progression to desquamation and reepithelialization occurs. It resolves 5–7 days after therapy is discontinued. The etiology is not clear but may be related to drug concentration in eccrine glands of the palms and soles.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                           | Amsacrine, bleomycin, capecitabine, cyclophosphamide, cytarabine, etoposide, docetaxel, doxorubicin, 5-FU, floxuridine, gemcitabine, hydroxyurea, liposomal doxorubicin, mercaptopurine, methotrexate, mitotane, paclitaxel, teniposide, vinblastine | Axitinib, dasatinib, everolimus, sorafenib, sunitinib                                                                  | –                                  |

| Acral erythema<br>( <i>Cont.</i> ) | Applying cold compresses and elevating the hands and feet during drug administration may minimize the incidence and degree of toxicity.<br>Skin care and comfort measures are instituted as soon as symptoms are evident. Supportive care may include wound dressings, analgesia (pain relief), and cold compresses.                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                                           |                                            |
| Beau lines                         | Beau lines are transverse ridges across the nail plate. These findings are benign, dose related, and resolve with cessation of chemotherapy.                                                                                                                                                                                                                                                                                                                                                                                                                                   | Bleomycin, cisplatin, docetaxel (taxanes), doxorubicin, melphalan, vincristine; capecitabine, hydroxyurea                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Beau lines and nail changes are common with EGFRIs.       | –                                          |
| Dystrophy                          | Dystrophy is a transverse midline linear groove in the nail plate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Bleomycin, hydroxyurea                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Dystrophy and nail changes are common with EGFRIs.        | –                                          |
| Erythema multiforme                | The condition generally presents as a maculopapular erythematous lesion that may progress to vesicles and also can progress to Stevens-Johnson syndrome and toxic epidermal necrolysis.<br>Record description, presentation, and severity (use a grading scale). Consult with a physician regarding possible etiology. Consider discontinuing the offending chemotherapy agent. Causative EGFRIs may not need to be discontinued.<br>Examine areas of tissue breakdown, and attend to comfort measures with skin care and pain management strategies (see guidelines in text). | The condition is infrequently associated with chemotherapy. High-dose combination chemotherapy produces the highest risk. It is characterized by lesions over the extremities and often involving mucous membranes. Bleomycin, busulfan, cytarabine, etoposide, hydroxyurea, methotrexate, and procarbazine are associated with these lesions, which sometimes progress to generalized blistering.<br>Amifostine, cladribine, cyclophosphamide, daunorubicin, doxorubicin, docetaxel, 5-FU, ifosfamide, mechlorethamine, mitomycin C, mitotane, paclitaxel, vinblastine<br>Hormone therapy: tamoxifen | Alpelisib, apalutamide, duvelisib, gefitinib, vemurafenib | Bexarotene, durvalumab, enfortumab vedotin |

**TABLE 21-1.** Cutaneous Reactions to Antineoplastic Agents (*Continued*)

| Cutaneous Reaction                                | General Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Chemotherapy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Targeted Therapy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Immunotherapy                                                                                                                                              |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hair changes: alopecia, hirsutism, hypertrichosis | <p>Several chemotherapy drugs can cause hair changes and hair loss. Dose, route of administration, the combination of drugs, and other individual characteristics will influence the occurrence and degree of hair loss.</p> <p>Hair changes may occur 2–3 months after initiation of EGFR therapy, with hair thinning and developing a dry, brittle, or curly texture.</p> <p>Hirsutism is characterized by excess hair growth in women in anatomic sites where growth is typically a male characteristic (e.g., beard, mustache, hair on chest and abdomen).</p> <p>Hypertrichosis is characterized by hair density or length beyond the accepted limits of normal in a particular body region or a particular age or race.</p>                                                                                                                                                                                                            | <p>Hair changes: bexarotene, carboplatin, cisplatin, cyclophosphamide, dactinomycin, doxorubicin, etoposide, hexamethylmelamine, ifosfamide, paclitaxel, vincristine</p> <p>Alopecia: bleomycin, carboplatin, cisplatin, cyclophosphamide, cytarabine, dacarbazine, dactinomycin, daunorubicin, docetaxel, doxorubicin, epirubicin, eribulin, etoposide, 5-FU, hydroxyurea, ifosfamide, ixabepilone, methotrexate, paclitaxel</p>                                                                                                                 | <p>Alopecia: abemaciclib, alpelisib, axitinib, dabrafenib, dacomitinib, dasatinib, encorafenib, erdafitinib, eribulin, erlotinib, gefitinib, lapatinib, lenvatinib, nilotinib, pazopanib, pemigatinib, ribociclib, ripretinib, sorafenib, talazoparib tosylate, tazemetostat, vemurafenib, vismodegib</p> <p>Alopecia, hirsutism, and hypertrichosis: everolimus</p> <p>Hair color changes and alopecia: avapritinib, cabozantinib, pazopanib, sunitinib, tipiracil, trifluridine</p> <p>Hair color changes: imatinib, pexidartinib, selumetinib</p> | <p>Brentuximab, cetuximab, enfortumab vedotin, margetuximab-cmkb, mogamulizumab, panitumumab, pegylated IFN alfa-2b, sacituzumab</p> <p>govitecan-hziy</p> |
| Hyperpigmentation                                 | <p>Hyperpigmentation is the darkening of an area of skin or nails caused by increased melanin.</p> <p>Cutaneous hyperpigmentation associated with chemotherapy can present in localized or generalized patterns affecting the skin, teeth, or nails.</p> <p>Patients should avoid sun exposure or use effective sun barrier preparations to minimize the risk of hyperpigmentation. Sun exposure aggravates hyperpigmentation. It occurs most commonly in people of Mediterranean descent.</p> <p>Darkening may occur within 2–3 weeks of chemotherapy or immunotherapy and persist for months following the completion of therapy.</p> <p>Postinflammatory hyperpigmentation is seen following acneiform eruption or other causes of skin inflammation, such as eczema or an inflamed sebaceous cyst.</p> <p>No treatment or prevention methods exist, but these changes will usually resolve within months after cessation of therapy.</p> | <p>Bleomycin, busulfan, capecitabine, carboplatin, cisplatin, cyclophosphamide, dacarbazine, dactinomycin, daunorubicin, docetaxel, doxorubicin, etoposide, 5-FU, hydroxyurea, idarubicin, ifosfamide, melphalan, methotrexate, mitomycin C, mitoxantrone, nitrogen mustard, nitrosoureas, oxaliplatin, paclitaxel, prednisolone, 6-mercaptopurine, thiopeta, vincristine</p> <p>Flagellate streaks of hyperpigmentation caused by nails scratching the skin have been reported with parenteral and intrapleural administration of bleomycin.</p> | <p>Gilteritinib, imatinib, sunitinib</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | –                                                                                                                                                          |

| Nail changes                | –                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Cyclophosphamide, daunorubicin, docetaxel, doxorubicin, ifosfamide                                                                                                                                                   | Bevacizumab, dacomitinib, erdafitinib, gefitinib, neratinib, osimertinib, sorafenib, sunitinib, temsirolimus | Cetuximab, panitumumab |
| Nail shedding (onycholysis) | Loss of all or a portion of the nail                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Bleomycin, capecitabine, cisplatin, cyclophosphamide, docetaxel, doxorubicin, etoposide, hydroxyurea, ixabepilone, melphalan, mitoxantrone, topical 5-FU, vinblastine, vincristine, weekly paclitaxel administration | Dacomitinib, erdafitinib, everolimus, neratinib, pemigatinib                                                 | –                      |
| Painful fissures            | <p>Skin fissures and deep cracks in the skin can form due to significant xerosis and often occur in the fingertips, palms or knuckles, and soles. Fissures are a late side effect of EGFRi therapy, occurring around 30–60 days into therapy. They can be very painful and create a risk for infection.</p> <p>Cyanoacrylate glue (liquid bandage formulations) may help protect the fissures. Treat topically with propylene glycol 50% in water for 30 minutes under plastic occlusion every night, followed by applying hydrocolloid dressing, antiseptic baths, or topical application of silver nitrate.</p> <p>For painful fissures on toes, use protective footwear and a topical corticosteroid, thick moisturizer, or barrier cream (e.g., petroleum jelly, zinc oxide).</p> | –                                                                                                                                                                                                                    | EGFRi therapy can lead to painful fissures.                                                                  | Panitumumab            |

**TABLE 21-1.** Cutaneous Reactions to Antineoplastic Agents (*Continued*)

| Cutaneous Reaction                                     | General Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Chemotherapy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Targeted Therapy                                                                                                                                                                                                                                                                                                 | Immunotherapy                                |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|
| Palmar-plantar erythrodysesthesia (hand-foot syndrome) | <p>It first appears as mild redness on the palms and soles with tingling sensations in the hands, usually at the fingertips; symptoms progress to a more intense burning pain and tenderness.</p> <p>Palms and soles appear edematous, and patients may have difficulty walking or grasping objects.</p> <p>Ulceration may occur if therapy is not halted.</p> <p>Incidence and severity of symptoms are related to protracted exposure of cells to the drug. Symptoms usually develop 2–12 days after the administration of chemotherapy. Early recognition and cessation of drug administration are critical to symptom management.</p> <p>Symptoms may include flaking, swelling, small blisters, or small sores.</p> <p>Prevention and treatment include reducing exposure of hands and feet to friction and heat by having patients avoid hot water (e.g., washing dishes, long showers, hot baths), impact on their feet (e.g., jogging, aerobics, walking, jumping), use of tools that require them to squeeze their hand on a hard surface (e.g., garden tools, household tools, kitchen knives), and rubbing (e.g., applying lotion, massaging).</p> <p>Dose reduction may minimize the risk of recurrence.</p> | <p>Bleomycin, capecitabine, cisplatin, cyclophosphamide, cytarabine, daunorubicin, docetaxel, doxorubicin, etoposide, 5-FU (given in prolonged infusion), floxuridine, fludarabine, gemcitabine, hydroxyurea, idarubicin, ixabepilone, liposomal encapsulated doxorubicin, methotrexate, mitotane, thiotepa, vinorelbine</p> <p>Incidence is 50% (although reports vary) in patients receiving liposomal encapsulated doxorubicin. Incidence correlates with higher doses and an increased number of cycles.</p> <p>Combination therapy</p> <ul style="list-style-type: none"> <li>• Docetaxel and capecitabine (56%–63%)</li> <li>• Doxorubicin and continuous 5-FU (89%)</li> </ul> | <p>Hand-foot skin reaction is common with multikinase inhibitors and develops within the first 1–4 weeks of treatment.</p> <p>Axitinib, dacoritinib, erdafitinib, everolimus, gilteritinib, lapatinib, lenvatinib, pazopanib, pemigatinib, ripretinib, sorafenib, rucaparib, sunitinib, tivozanib, tucatinib</p> | <p>Enfortumab vedotin, margetuximab-cmkb</p> |

**TABLE 21-1.** Cutaneous Reactions to Antineoplastic Agents (*Continued*)

| Cutaneous Reaction | General Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Chemotherapy                                                                   | Targeted Therapy                                                                                                                                                                                                                                                                                                                                                   | Immunotherapy                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| Paronychia         | <p>Paronychia is characterized by tender, edematous, and often purulent nail fold inflammation. Fingernails and toenails may be affected, with the first digits the most commonly affected.</p> <p>It often is delayed, developing 4–8 weeks after the start of therapy and occurring in 10%–15% of patients.</p> <p>Encourage preventive measures, such as keeping hands dry and out of the water if possible, wearing gloves while cleaning (e.g., household, dishes), avoiding friction and pressure on the nail fold or manipulating the nail, and wearing comfortable shoes.</p> <p>Treatment includes topical steroids with antiseptic soaks to prevent infections.</p> | Bleomycin, cyclophosphamide, docetaxel, doxorubicin, hydroxyurea, methotrexate | Afatinib, dacomitinib, erlotinib, gefitinib, lapatinib, neratinib, pemigatinib, selumitinib                                                                                                                                                                                                                                                                        | Cetuximab, necitumumab, panitumumab |
| Photosensitivity   | <p>Photosensitivity presents as sunburn occurring after minimal sun exposure. It is an erythematous response to UV radiation; skin appears red with erythema, edema, and possibly vesicles.</p> <p>Patients are instructed to wear protective clothing and a hat when in the sun; avoid direct sunlight when possible, especially during peak hours between 10 am and 3 pm; and avoid tanning beds. They should wear a sunscreen with an SPF higher than 15.</p> <p>In addition to measures taken to avoid sun exposure, patients treated with EGFRIs are advised to wear sunscreen with an SPF of 30 or higher.</p>                                                          | Dacarbazine, 5-FU, high-dose methotrexate, vinblastine                         | <p>Patients treated with EGFRIs may develop photosensitivity characterized by erythema from UV-induced damage. Erythema may be painful and associated with desquamation. In severe cases, photosensitivity and erythema may be disabling or life threatening.</p> <p>Dabrafenib, dasatinib, imatinib, nilotinib, rucaparib, tivozanib, vandetanib, vemurafenib</p> | Cetuximab, panitumumab, tretinoin   |

| Cutaneous Reaction  | General Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Chemotherapy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Targeted Therapy                                                                                                                                                                                                                                                                                                                                                                                  | Immunotherapy                                                                                                                                                                                                                                        |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pruritus or itching | <p>Pruritus may be localized or generalized; symptoms may worsen with dehydration. Encourage patients to drink 8–10 glasses of fluid per day and minimize salt and alcohol intake.</p> <p>Recommended skin care includes medicated baths, anesthetic creams, and emollient creams. Mild soap designed for sensitive skin should be used, and perfumes, deodorants, cosmetics, and starch-based powders should be avoided. Instead of scratching, massaging, applying pressure, or rubbing with a soft cloth should be suggested.</p> <p>Wearing loose-fitting clothing and clothing made of cotton or other soft fabrics can alleviate pruritus. Use antibiotics if pruritus is secondary to infection. Use oral antihistamines, with increased doses at bedtime. Sedatives, tranquilizers, and antidepressants may be useful treatments. Aspirin seems to reduce itching in some patients but increases it for others. Aspirin combined with cimetidine may be effective for patients with Hodgkin lymphoma or polycythemia vera. Distraction, relaxation, positive imagery, or cutaneous stimulation are encouraged. A cool, humid environment may prevent skin from itching.</p> <p>Skin moisturizers and urea- or polidocanol-containing lotions are suitable to soothe pruritus. Systemic treatment with oral H<sub>1</sub>-antihistamines such as cetirizine, fexofenadine, or loratadine, and clemastine may provide relief of itching for patients with grade 2–3 pruritus.</p> | <p>Alkylating agents, antimetabolites, antibiotics, plant alkaloids, and nitrosoureas can cause pruritus. Agents most associated with hypersensitivities include cisplatin, cytarabine, daunorubicin, doxorubicin, L-asparaginase, and paclitaxel.</p> <p>L-asparaginase, carboplatin, cisplatin, cytarabine, daunorubicin, doxorubicin, etoposide, melphalan, pomalidomide, and teniposide can all cause a rash.</p> <p>Actinic keratoses: Topical 5-FU, cisplatin, cytarabine, dacarbazine, dactinomycin, docetaxel, doxorubicin, pentostatin, 6-thioguanine, vincristine</p> <p>Bendamustine, pralatrexate</p> | <p>Abemaciclib, alpelisib, afatinib, apalutamide, axitinib, bevacizumab, dacomitinib, dasatinib, encorafenib, entrectinib, erlotinib, gefitinib, glasdegib, imatinib, ivosidenib, lapatinib, neratinib, nilotinib, pexidartinib, osimertinib, ribociclib, rucaparib, selumetinib, sorafenib, sunitinib, tazemetostat, temsirolimus, tivozanib, trametinib, tucatinib, vandetanib, vemurafenib</p> | <p>Atezolizumab, avelumab, brentuximab, cemiplimab, cetuximab, enfortumab vedotin, IFN alfa-2a, IFN alfa-2b, ipilimumab, necitumumab, nivolumab, panitumumab, pegylated IFN alfa-2b, pembrolizumab, sacituzumab govitecan-hziy, tagraxofusp-erzs</p> |

| Skin depigmentation and vitiligo | Pigment changes occur due to inhibition of c-KIT, which is the protein that regulates melanocytes. Changes may be localized, patchy, or diffuse. They occur more often in darker skin. Effects can be reversed with dose reduction or discontinuation.                                                                                                                                                                                                                                                                                                                               | –                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Dasatinib, imatinib, nilotinib, pazopanib                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | –                                                                                                                                                                                                                                                                                                                             |
| Stevens-Johnson syndrome         | <p>Stevens-Johnson syndrome (also known as erythema multiforme major) is a rare, serious disorder in which the skin and mucous membranes react severely to a medication or infection. It often begins with flu-like symptoms, followed by a painful red or purplish rash that spreads and blisters, eventually causing the top layer of the skin to die and shed.</p> <p>Stevens-Johnson syndrome presents a medical emergency that usually requires hospitalization. Treatment focuses on eliminating the underlying cause, controlling symptoms, and minimizing complications.</p> | <p>Cases of Stevens-Johnson syndrome and toxic epidermal necrolysis, some fatal, have been reported when bendamustine was administered concomitantly with allopurinol and other medications known to cause these syndromes. The relationship with bendamustine cannot be determined.</p> <p>Stevens-Johnson syndrome has been reported with amifostine, L-asparaginase, bleomycin, capecitabine, chlorambucil, cladribine, cyclophosphamide, cytarabine, docetaxel, doxorubicin, etoposide, 5-FU, imatinib, methotrexate, paclitaxel, and procarbazine.</p> <p>Hormone therapy: letrozole</p> | <p>Alpelisib, bortezomib, cetuximab, duvelisib, gefitinib</p> <p>Sunitinib: If signs or symptoms are present, discontinue treatment and do not restart.</p> <p>Vemurafenib: Stevens-Johnson syndrome has been observed. Discontinue the drug permanently.</p>                                                                                                                                                                                                                                                                                                                                                       | <p>Atezolizumab, cetuximab, durvalumab, ipilimumab, lenalidomide, levamisole, mogamulizumab, rituximab, thalidomide</p>                                                                                                                                                                                                       |

**TABLE 21-1.** Cutaneous Reactions to Antineoplastic Agents (*Continued*)

| Cutaneous Reaction         | General Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Chemotherapy                                                                                                                                                                                                                                                                                                                                                                                                                                     | Targeted Therapy                                                                                                                | Immunotherapy                                                                                  |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|
| Telangiectasia             | <p>The disorder is characterized by local dilation of small vessels, resulting in red discoloration of the skin or mucous membranes.</p> <p>During the development of acneiform eruption or subsequent flares of the rash, scattered telangiectasia may appear on the face, on and behind the ears, and on the chest, back, and limbs, usually in the vicinity of a follicular pustule. Unlike other telangiectasias, the lesions tend to fade over months, usually leaving some hyperpigmentation.</p> <p>Telangiectasia caused by treatment with EGFRIs, unlike spontaneous telangiectasia, will gradually disappear over months. In select cases, electrocoagulation or pulsed dye laser therapy can be applied to accelerate disappearance.</p> <p>Radiation may cause telangiectasia, which is thought to be related to the destruction of the capillary bed. It generally is considered a permanent change in the vessel.</p> | Topical carmustine and mechlorethamine (nitrogen mustard) cause vessel fragility and destruction.                                                                                                                                                                                                                                                                                                                                                | Scattered telangiectasia can be seen with the development of any acneiform eruption caused by EGFRIs.                           | –                                                                                              |
| Toxic epidermal necrolysis | <p>Toxic epidermal necrolysis is most commonly drug induced. However, the disorder has other potential etiologies, including infection, malignancy, and vaccinations. Toxic epidermal necrolysis is idiosyncratic, and its occurrence is not easily predicted.</p> <p>Some authors believe that Stevens-Johnson syndrome is a manifestation of the same process involved in toxic epidermal necrolysis, with the latter involving more extensive necrotic epidermal detachment. Toxic epidermal necrolysis involves &gt; 30% of the body surface, whereas Stevens-Johnson syndrome involves &lt; 10%.</p> <p>It may be difficult to distinguish from grade 4 acute GVHD of the skin.</p>                                                                                                                                                                                                                                            | <p>Bendamustine: In combination with rituximab, one case of toxic epidermal necrolysis occurred. Toxic epidermal necrolysis has been reported with rituximab. Report and withhold bendamustine and rituximab.</p> <p>Toxic epidermal necrolysis has been reported with L-asparaginase, chlorambucil, cladribine, cytarabine, docetaxel, doxorubicin, gemcitabine, methotrexate, mithramycin, pemetrexed, procarbazine, and 6-mercaptopurine.</p> | <p>Duvelisib, gefitinib</p> <p>Vemurafenib: Toxic epidermal necrolysis has been observed. Discontinue the drug permanently.</p> | Aldesleukin (IL-2), atezolizumab, cetuximab, denileukin, durvalumab, ipilimumab, mogamulizumab |

| Cutaneous Reaction              | General Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Chemotherapy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Targeted Therapy                                                                                                                                                                                                                                       | Immunotherapy                                                                                                                                                                                                                                                     |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Transient erythema or urticaria | Urticaria is characterized as multiple swollen, raised areas on the skin that are intensely itchy and appear primarily on the chest, back, extremities, face, and scalp. It usually occurs within hours of chemotherapy and disappears within a few hours. It may be generalized or local at the site of chemotherapy or along the vein.                                                                                                                                                              | <p>Arsenic trioxide, L-asparaginase, carboplatin, cytarabine, daunorubicin, and prednisolone can cause urticaria.</p> <p>L-asparaginase can cause urticaria, fever, chills, and hypotension (skin testing is advised).</p> <p>Bleomycin can cause erythema over pressure points and hyperpigmentation.</p> <p>Chlorambucil, melphalan, methotrexate, and thiopeta can cause urticaria and angioedema.</p> <p>Cytarabine can cause transient erythema.</p> <p>Doxorubicin can cause an erythematous flare with pruritus at the IV site and along the vein.</p> <p>Oxaliplatin can cause delayed urticaria.</p> | <p>The offending agent may need to be discontinued if the reaction is severe or associated with systemic reactions such as a generalized rash.</p> <p>Dasatinib, ivosidenib, pexidartinib, rucaparib, sunitinib, tivozanib, tucatinib, vemurafenib</p> | <p>Aldesleukin can cause erythema and pruritus that may progress into a pruritic papular rash.</p> <p>IFN alfa-2a and IFN alfa-2b can cause dry, scaling, itchy skin or a pruritic maculopapular reaction.</p> <p>Enfortumab vedotin, ofatumumab, panitumumab</p> |
| Trichomegaly                    | <p>Increased hair growth of the eyelashes and eyebrows is rare but can occur.</p> <p>Trichomegaly is associated with patient discomfort and can lead to corneal abrasions and further ocular complications. Ocular changes may occur within 1–2 weeks of treatment.</p> <p>Trichomegaly can be treated with lash clipping every 2–4 weeks. Referral to an ophthalmologist is indicated for patients with irritation or persistent discomfort. Topical eflornithine cream has been well tolerated.</p> | Gemcitabine                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Erlotinib, gefitinib,                                                                                                                                                                                                                                  | Cetuximab, IFN alfa-2b, panitumumab                                                                                                                                                                                                                               |

**TABLE 21-1.** Cutaneous Reactions to Antineoplastic Agents (*Continued*)

| Cutaneous Reaction | General Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Chemotherapy | Targeted Therapy                                                                                                                                                                                                                                                        | Immunotherapy                                                                                             |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| Xerosis            | <p>Xerosis is abnormal dryness of the skin, mucous membranes, or conjunctiva.</p> <p>Treatment of mild or moderate xerosis consists of thick moisturizing creams without fragrances or potential irritants. Moisturizers should be occlusive, emollient creams that are generally packaged in a jar or tub rather than a lotion that can be pumped or poured. Specific creams can include urea, colloidal oatmeal, and petroleum-based creams.</p> <p>For scaly areas of xerosis, ammonium lactate or lactic acid creams can be used. Greasy creams may be used on the limbs for better control of xerosis but should be used with caution on the face, chest, and extremely hairy sites because of the risk for folliculitis secondary to occlusion.</p> <p>For more severe xerosis causing inflammation with or without eczema, topical steroid creams may be necessary. Topical retinoids and benzoyl peroxide gels are not recommended because of their drying effect.</p> | –            | <p>Afatinib, axitinib, cabozantinib, dacomitinib, dasatinib, erlotinib, everolimus, gefitinib, imatinib, lapatinib, nilotinib, osimertinib, pazopanib, regorafenib, sorafenib, sunitinib, temsirolimus, trametinib, trametinib, vandetanib, vemurafenib, vorinostat</p> | <p>Alemtuzumab, bexarotene, cetuximab, mogamulizumab, necitumumab, panitumumab, pegylated IFN alfa-2b</p> |

EGFRI—epidermal growth factor receptor inhibitor; 5-FU—5-fluorouracil; GVHD—graft-versus-host disease; IFN—interferon; IL—interleukin; IV—intravenous; SPF—sun protection factor; UV—ultraviolet

*Note.* Based on information from Agensys, 2021; Agios Pharmaceuticals, 2021; Amgen, 2021a, 2021b; Anforth et al., 2015; Ariad Pharmaceuticals, 2020; Array BioPharma, 2020, 2021; Astellas Pharma US, 2019; AstraZeneca Pharmaceuticals, 2020, 2021a, 2021b, 2021c, 2021d; AVEO Pharmaceuticals, 2021; Bayer HealthCare Pharmaceuticals, 2020, 2021; BeiGene USA, 2021; Blueprint Medicines, 2021; Bouché et al., 2005; Boucher et al., 2011; Caccavale & Ruocco, 2017; Camp-Sorrell, 2018; Celgene, 2020; Cephalon, 2016; Chon et al., 2012; Clovis Oncology, 2020; Daiichi Sankyo, 2020; Deciphera Pharmaceuticals, 2021; Degen et al., 2010; Eisai, 2021; Eli Lilly and Company, 2020, 2021; Epizyme, 2020; Fabbrocini et al., 2015; Genentech, 2019, 2020a, 2020b, 2021a, 2021b, 2021c; Genentech & Astellas Pharma US, 2016; GlaxoSmithKline, 2021; Hoffmann-La Roche, 2008; Hospira, 2021; Huang & Anadkat, 2011; ImClone, 2021; Immunomedics, 2021; Janssen Pharmaceuticals, 2020, 2021; Kamil et al., 2010; Kaur & Mahajan, 2015; Kheir et al., 2014; Kyowa Kirin, 2018; Lacouture et al., 2011, 2021; Ligand Pharmaceuticals, 2020; Lupu et al., 2016; MacroGenics, 2020; Merck, 2019, 2020; Morse, 2014; National Cancer Institute, 2021; Novartis Pharmaceuticals, 2020a, 2020b, 2021a, 2021b, 2021c, 2021d; Pfizer, 2020a, 2020b, 2020c, 2021a, 2021b; Potthoff et al., 2011; Prometheus Laboratories, 2019; Puma Biotechnology, 2021; Regeneron Pharmaceuticals, 2021; Reyes-Habito & Roh, 2014b; Rosen et al., 2014; Sanofi-Aventis U.S., 2021; Seattle Genetics, 2019, 2020; Segal & Van Cutsem, 2005; Shi et al., 2016; Sibaud, 2018; Stemline Therapeutics, 2018; Taiho Pharmaceutical, 2019; TG Therapeutics, 2021; Thebeau et al., 2017; Tischer et al., 2017; Tummino et al., 2007; Valentine et al., 2015; Verastem, 2019; Villée et al., 2010; White & Cox, 2006; Wu et al., 2011; Wyeth Pharmaceuticals, 2018.

- darker skin on the palms and soles of the feet.
- (c) Lesions related to hand-foot syndrome are painful and will turn into blisters that peel, leading to a decrease in daily activities.
  - (d) Patients also experience decreased quality of life and changes to their treatment schedule (Williams et al., 2020).
  - (e) The Oncology Nursing Society (ONS) Guidelines<sup>™</sup> for Cancer Treatment–Related Skin Toxicity recommend using cooling procedures for patients who received taxane-based therapy to prevent hand-foot syndrome. Cooling procedures include wearing frozen gloves and socks on the hands and feet during treatment (Williams et al., 2020).
- (3) The clinically descriptive term *toxic erythema of chemotherapy* has been introduced as an easily understood clinical name for numerous entities (Shi et al., 2016).
- (a) Clinical findings of toxic erythema of chemotherapy include areas of erythema that may be accompanied by edema, most often involving the hands, feet, and intertriginous zones, such as the axillae and inguinal folds. The elbows, knees, and ears are less frequently involved (Shi et al., 2016).
  - (b) Patches or plaques typically develop within two days to three weeks following drug administration.
    - i. Associated symptoms of pain, burning, paresthesia, and pruritus are frequently present.
    - ii. Areas of intense erythema can be accompanied by the development of a dusky discoloration, petechiae, or sterile bullae, which erosions can follow.
    - iii. Typically, spontaneous resolution and desquamation occur without specific therapy. If the chemotherapy agent is given again at the same or higher dose, recurrences are possible and may be more intense with higher doses.
    - iv. In some instances, delayed onset of 2–10 months can be seen, particularly in patients receiving lower-dose, continuous IV infusions (Shi et al., 2016).
  - (c) Treatment options for toxic erythema of chemotherapy have been of variable success and include bland emollients, analgesics, cool compresses, topical corticosteroids, and topical antibiotics for erosions. Nurses, oncologists, and dermatologists need to recognize the toxic erythema of chemotherapy and understand that the reaction is not allergic or infectious, thus avoiding unnecessary labeling of drug allergies or use of antimicrobials (Shi et al., 2016).
- b) Epidermal growth factor receptor inhibitors (EGFRIs)
- (1) EGFRIs include targeted agents (e.g., gefitinib, erlotinib, lapatinib, afatinib) and monoclonal antibodies (e.g., cetuximab, panitumumab).
  - (2) EGFRIs are associated with many cutaneous reactions due to the prevention of epidermal keratinocytes from controlling the intercellular signal transduction pathways, which regulate cell proliferation, apoptosis, angiogenesis, adhesion, and motility (Wallner et al., 2016). More than 80% of patients will have a cutaneous reaction from treatment with EGFRIs (Ding et al., 2020).
  - (3) Skin toxicities from EGFRIs include acneiform eruption; xerosis; paronychia; abnormal scalp, facial hair, and eyelash growth; maculopapular rash; and postinflammatory hyperpigmentation (see Figure 21-1). EGFR cutaneous reactions are labeled as PRIDE syndrome (papulopustules and/or paronychia, regulatory abnormalities of hair growth, itching, and dryness due to an EGFRi) (Lupu et al., 2016).
  - (4) Acneiform eruption is the most common reaction associated with EGFRIs and can occur in up to 90% of patients.
    - (a) The rash typically occurs in the first two weeks of therapy, peaking around four to six weeks, and resolves by three to four months after therapy (Williams et al., 2020).
    - (b) The presentation can be divided into four stages, beginning with sensory disturbance accompanied by edema and erythema.

**FIGURE 21-1.** Pustular/Papular Rash Presentations**Papular lesions on the chest****V-shaped papulopustular eruption on the back****Follicular pustules****Confluent pustules on the nose**

*Note.* From "Clinical Signs, Pathophysiology and Management of Skin Toxicity During Therapy With Epidermal Growth Factor Receptor Inhibitors," by S. Segaert and E. Van Cutsem, 2005, *Annals of Oncology*, 16(9), p. 1427 (<https://doi.org/10.1093/annonc/mdi279>). Copyright 2005 by European Society for Medical Oncology. Reprinted with permission.

- (c) Subsequently, the characteristic rash of papules and pustules appears and is predominantly but not exclusively folliculocentric in distribution.
- (d) This is followed by a postinflammatory phase of erythema and telangiectasias.
- (e) For patients with darker skin tone, a fourth phase of postinflammatory hyperpigmentation may be present and can be long lasting.
- (5) Refer to Figure 21-2 for treatment options.
- (6) Patients treated with radiation therapy have an increased risk of developing

severe radiation dermatitis. Prophylactic antibiotics have been shown to prevent the rash (Guggina et al., 2017).

c) Multikinase inhibitors

- (1) The multikinase inhibitors sorafenib and sunitinib cause cutaneous reactions in 74% and 81% of patients, respectively. The pathophysiology is unknown but thought to be related to vessel damage or extravasation of the drug (Reyes-Habito & Roh, 2014b).
- (2) Skin toxicities from multikinase inhibitors include hand-foot skin reaction, rash, pruritus, subungual splinter hemorrhage, yellow skin discoloration, hair depigmenta-

tion, pigment dilution, scrotal erythema, and nail splinter hemorrhage (Shi et al., 2016).

- (3) Hand-foot skin reaction, which differs from the classical hand-foot syndrome seen with nontargeted chemotherapy, presents in the first two to four weeks of treatment with the development of localized, painful, and symmetric erythematous plaques on the palms and soles (Ding et al., 2020).

(a) The incidence of hand-foot skin reaction is 9%–62% and dependent on the drug used for therapy (Williams et al., 2020).

(b) Symptoms of hand-foot skin reaction can include paresthesia, tingling, burning, and painful sensation in the palms and soles.

(c) Prior to treatment, prophylactic measures can be taken, including pretreatment pedicure, orthotic evaluation, reduced exposure of hands and

feet to heat, and avoidance of excessive friction.

(d) Celecoxib has been shown to prevent hand-foot skin reactions caused by capecitabine (Lacouture et al., 2021).

(e) ONS Guidelines for Cancer Treatment–Related Skin Toxicity recommend topical urea and topical steroids and usual skin care to prevent hand-foot skin reaction in patients treated with multikinase inhibitors (Williams et al., 2020).

(f) Treatment of hand-foot skin reaction usually requires dose interruption and reduction.

- (4) Symptoms can be reduced by using cooling or topical agents, such as keratolytics, topical corticosteroids, antiseptic solutions, and topical analgesics (Lacouture et al., 2021).

d) BRAF inhibitors (e.g., dabrafenib, vemurafenib) and multikinase inhibitors (e.g., selumetinib, trametinib)

**FIGURE 21-2.** Recommendations for Prevention and Management of Epidermal Growth Factor Receptor Inhibitor–Induced Rash

#### Multinational Association of Supportive Care in Cancer

##### Preventive/Prophylactic

- Systemic: minocycline 100 mg daily<sup>a</sup> or doxycycline 100 mg BID<sup>b</sup>
- Topical: hydrocortisone 1% cream with moisturizer and sunscreen BID

##### Treatment

- Topical
  - Alclometasone 0.05% cream
  - Fluocinonide 0.05% cream BID
  - Clindamycin 1%
- Systemic
  - Doxycycline 100 mg BID
  - Minocycline 100 mg daily
  - Isotretinoin at low doses of 20–30 mg/day

#### Not Recommended

Acitretin, oil-in-water topical trolamine emulsion, pimecrolimus 1% cream, sunscreen as a single agent, tazarotene 0.05% cream, tetracycline 500 mg BID, vitamin K<sub>1</sub> cream

#### National Comprehensive Cancer Network

##### Preventive/Prophylactic

- Systemic
  - Oral semisynthetic tetracycline agents (doxycycline or minocycline)
  - Doxycycline 100 mg BID in combination with the following topical agents
- Topical: hydrocortisone 1%, skin moisturizer, and sunscreen

##### Treatment

- Topical: Topical steroids and antibiotics, such as clindamycin and erythromycin, may be useful.
- Systemic
  - Oral antibiotics include doxycycline, minocycline, and oxytetracycline.
  - Topical low/moderate steroid
  - Isotretinoin at low doses of 20–30 mg/day

#### Oncology Nursing Society Guidelines™ for Cancer Treatment–Related Skin Toxicity

##### Preventive/Prophylactic

- Systemic<sup>c</sup>: doxycycline, tetracycline, or minocycline
- Topical: Topical steroids and antibiotics may be useful.

##### Treatment

- Systemic: Oral antibiotics include tetracycline, minocycline, and doxycycline.

<sup>a</sup>Minocycline is less photosensitizing.

<sup>b</sup>Doxycycline should be used in patients with renal impairment.

<sup>c</sup>The use of prophylactic antibiotics should be weighed against the possible side effects of antibiotic use. Patient clinical status and preference should also be considered.

BID—twice daily

Note. Based on information from Eaby-Sandy et al., 2012; Lacouture et al., 2011, 2020; Williams et al., 2020.

- (1) Dermatologic side effects are the most common adverse events seen with BRAF inhibitors. Pathophysiology is thought to be a hypersensitivity reaction (Shi et al., 2016).
  - (a) The most common dermatologic side effect is rash, which can be maculopapular, papulopustular, or folliculocentric and often appears on the face, upper torso, and arms.
  - (b) Other cutaneous reactions include photosensitivity, which usually occurs within 24 hours of sun exposure and can include painful blistering.
  - (c) It is important to provide patient education about proper sun protection, including broad-spectrum sunscreen and protective clothing (Russo et al., 2018).
  - (d) Squamoproliferative lesions are common and can present as skin papillomas, verrucous keratosis, and seborrheic keratosis.
  - (e) Vemurafenib or dabrafenib have been associated with keratoacanthomas or squamous cell carcinomas and melanocytic changes with all BRAF inhibitors. Regular dermatologic follow-up is recommended for these patients.
  - (f) Other dermatologic effects include hand-foot skin reaction and altered hair growth. MEK (mitogen-activated extracellular signal regulated kinase) inhibitors have similar cutaneous effects with EGFRIs, including xerosis, pruritus, and papulopustular eruption on the scalp, face, chest, and back (Shi et al., 2016).
- (2) Treatment
  - (a) Treatment for rash includes topical antibiotics, oral antibiotics, and topical corticosteroids.
  - (b) Treatments for squamoproliferative lesions include shave excision and cryotherapy (Shi et al., 2016).
- e) Immunotherapies
  - (1) Cytotoxic T-lymphocyte antigen 4 (CTLA-4) inhibitors, such as ipilimumab, are commonly associated with rash, usually occurring in the first three to four weeks.
    - (a) The rash is typically erythematous macules and papules that coalesce into thick plaques on the extremities and trunk.
    - (b) Vitiligo also can occur (Russo et al., 2018).
  - (2) The cutaneous adverse effects of programmed cell death protein 1 (PD-1) inhibitors, such as nivolumab and pembrolizumab, and programmed cell death-ligand 1 (PD-L1) inhibitors, such as atezolizumab, include vitiligo, rash, and pruritus, with rash and pruritus being the most common. Cutaneous complications from PD-1 inhibitors are less severe and occur later in therapy than those from CTLA-4 inhibitors.
    - (a) Cutaneous side effects are most often mild and easily managed with supportive care (Russo et al., 2018).
    - (b) Lichenoid rash presents with erythematous papules and plaques on the chest, back, abdomen, and extremities.
    - (c) The most common rash occurring from PD-1 inhibitor therapy is a nonspecific maculopapular rash, occurring most often on the trunk and extremities (see Figures 21-3, 21-4, and 21-5).
    - (d) PD-L1 inhibitors may have a slightly lower incidence of rash than CTLA-4 inhibitors (Sibaud, 2018).
  - (3) Cutaneous side effects occurring with anti-CTLA-4 and anti-PD-1 combination therapies are more frequent, severe, and longer lasting than those occur-

**FIGURE 21-3.** Immunotherapy-Mediated Rash: Metastatic Melanoma

Patient is a 67-year-old woman with metastatic melanoma status post 3 doses of pembrolizumab with diffuse rash to bilateral legs.

**FIGURE 21-4.** Immunotherapy-Mediated Rash: Merkel Cell Carcinoma

Patient is a 71-year-old man with Merkel cell carcinoma status post 22 doses of every-3-week pembrolizumab.

Note. Image courtesy of Johns Hopkins Hospital. Used with permission.

ring with single-agent therapy (Sibaud, 2018).

- (4) Treatment includes topical corticosteroids for low-grade eruptions and systemic corticosteroids for high-grade eruptions and antihistamines. Treatment interruption is rare (Russo et al., 2018).
- f) Combination radiation and targeted therapy
  - (1) Significant in-field toxicity can occur when radiation therapy and targeted agents are given concomitantly (Guggina et al., 2017).
  - (2) The best prevention for radiation dermatitis is to wash with soap and water. This can reduce the risk of radiation dermatitis by half (Lacouture, 2015).
  - (3) Topical nonsteroidal agents and moisturizers can significantly reduce discomfort, redness, and itching (Lacouture, 2015).
  - (4) Radiation recall dermatitis is an acute skin inflammatory reaction at the site of a previously treated radiation field that presents similarly to radiation dermatitis with erythema, edema, vesicles, or desquamation.
    - (a) It is most often caused by chemotherapy agents, especially conventional

chemotherapy agents, but can also occur with targeted agents (Laird et al., 2021).

- (b) Chemotherapy agents associated with radiation recall include arsenic trioxide, bleomycin, capecitabine, cyclophosphamide, cytarabine, dactinomycin, daunorubicin, docetaxel, doxorubicin (free and liposomal), etoposide, 5-FU, gemcitabine, hydroxyurea, idarubicin, lomustine, melphalan, methotrexate, paclitaxel, pemetrexed, tamoxifen, and vinblastine (Laird et al., 2021).

- (5) See Figures 21-6 through 21-9 for examples of specific cutaneous manifestations of EGFR- and chemotherapy-induced toxicities.

### 3. Assessment

- a) Accurate grading of dermatologic adverse events is necessary for drug toxicity determination, inte-

**FIGURE 21-5.** Immunotherapy-Mediated Rash: Full-Body Rash

Patient is a 59-year-old man with prostate cancer with biopsy-proven immune-mediated full-body rash after 4 doses of a PD-1 inhibitor, with oral mucositis requiring steroids and discontinuation of immunotherapy.

Note. Image courtesy of Johns Hopkins Hospital. Used with permission.

grant comparisons, and supportive grading scale. The *Common Terminology Criteria for Adverse Events* is widely accepted throughout the oncology community as the standard classification and severity grading scale for adverse events in cancer therapy clinical trials and other oncology settings (National Cancer Institute Cancer Therapy Evaluation Program, 2017; see Table 21-2). However, it was not explicitly designed for the newer agents and may result in underreporting and poor grading of specific adverse events (Wallner et al., 2016).

- b) The Multinational Association of Supportive Care in Cancer study group has proposed a new grading scale for EGFR-induced dermatologic adverse events. The organization believes that a class-specific grading scale is needed to help standardize assessment and improve reporting of these dermatologic adverse events (Lacouture, 2015).

#### 4. Collaborative management

##### a) General management

- (1) Prior to initiation of therapy, a full medical history should be taken, including a history of prior or active skin diseases.
  - (a) Partner with an interprofessional team and refer patients to a dermatologist if necessary.
  - (b) Provide patient education regarding reporting any adverse events (Thebeau et al., 2017).
  - (c) Multiple tools are available to assess the impact of cutaneous side effects

Van Cutsem, 2005, *Annals of Oncology*, 16(9), p. 1428 (<https://doi.org/10.1093/annonc/mdi279>). Copyright 2005 by European Society for Medical Oncology. Reprinted with permission.

**FIGURE 21-7.** Paronychia of the Nail

Note. From "Clinical Signs, Pathophysiology and Management of Skin Toxicity During Therapy With Epidermal Growth Factor Receptor Inhibitors," by S. Segal and E. Van Cutsem, 2005, *Annals of Oncology*, 16(9), p. 1428 (<https://doi.org/10.1093/annonc/mdi279>). Copyright 2005 by European Society for Medical Oncology. Reprinted with permission.

on overall quality of life, including the Skindex-16, Skindex-29, and Functional Assessment of Cancer Therapy (FACT)-RGFRI-18 (Tischer et al., 2017).

- (2) Skin reactions are associated with significant morbidity and can lead to dose reductions or premature discontinuation of chemotherapy.
  - (a) The adverse effect of cutaneous reactions on quality of life is only beginning to be understood.
  - (b) Patient-reported outcome questionnaires should be included in routine clinical care to improve the accuracy of reported adverse events (Tischer et al., 2017).
- (3) Treatment of rash is largely dependent on symptoms. Intervention should be recommended based on the severity of the symptoms, with the goal of alleviation or minimization (Thebeau et al., 2017).
- (4) Instruct patients to avoid sun exposure.
  - (a) Patients should apply sunscreen daily to exposed skin areas regardless of the season.
  - (b) Sunscreens with the following characteristics are recommended: hypoallergenic, high SPF (at least 30), para-aminobenzoic acid (PABA) free, ultraviolet A and B protection (broad spectrum), and containing zinc oxide or titanium dioxide.

- (c) Recommend that patients wear a hat and protective clothing for sun protection (Russo et al., 2018).
- b) Secondary infection
  - (1) Secondary bacterial, viral, or fungal infection occurs in 40% of patients taking EGFRIs.
  - (2) Providers should have a low threshold for sending cultures of any lesions with signs of infection, such as discharge.
  - (3) Although secondary infections can occur in any patient with cutaneous toxicity, they are most common with EGFRi rashes (Lacouture et al., 2021).
- c) Rash and response/survival
  - (1) Incidence and severity of papulopustular rashes are associated with a better prognosis, and therefore, are considered to predict tumor response to the EGFRi. Studies addressing EGFRi-induced rash suggest that its severity is a surrogate marker for the efficacy of therapy (Tischer et al., 2017).
  - (2) Data suggest a correlation of rash incidence and severity with clinical response and increased survival time, leading investigators to implement dose-to-rash strategies. An EGFRi dose is progressively escalated until a rash of a specified grade appears. A consistent relationship between rash and response has not been observed

- with all EGFRIs studied in clinical trials (Tischer et al., 2017).
- d) Psychosocial issues
  - (1) Skin toxicities from antineoplastic therapy can significantly impact physical, emotional, and social functions.
    - (a) Patients are at risk for low self-esteem, altered self-image, depression, anxiety, and vulnerability.
    - (b) These side effects may interfere with treatment adherence, but patients may accept them as part of their experience with cancer or as a sign of response to therapy (Williams et al., 2020).
  - (2) Cutaneous toxicity effects on quality of life (Charalambous & Charalambous, 2016)
    - (a) Loss of dignity
    - (b) Hopelessness
    - (c) Living in fear
    - (d) Isolation
    - (e) Feeling insecure
    - (f) Loss of independence
- 5. Patient and family education
  - a) Instruct patients about the potential treatment-related symptoms of dermatologic toxicities as part of supportive measures (Thebeau et al., 2017; Wallner et al., 2016).
  - b) Include information about the potential toxicities associated with the agent.
  - c) Provide information on preventive and management measures, such as avoiding topical products

**TABLE 21-2.** Common Terminology Criteria for Adverse Events Grading Relevant to Targeted Therapy–Associated Dermatologic Toxicity

| Adverse Event  | Grade                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                                    |                                                                                                                                                                           |                                                                                                                                                                                                                                      |       |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
|                | 1                                                                                                                                                                                                                                         | 2                                                                                                                                                                                                                                                                  | 3                                                                                                                                                                         | 4                                                                                                                                                                                                                                    | 5     |
| Alopecia       | Hair loss of < 50% of normal for that individual that is not obvious from a distance but only on close inspection; a different hairstyle may be required to cover the hair loss but it does not require a wig or hair-piece to camouflage | Hair loss of ≥ 50% of normal for that individual that is readily apparent to others; a wig or hair-piece is necessary if the patient desires to completely camouflage the hair loss; associated with psychosocial impact                                           | –                                                                                                                                                                         | –                                                                                                                                                                                                                                    | –     |
| Dry skin       | Covering < 10% BSA and no associated erythema or pruritus                                                                                                                                                                                 | Covering 10%–30% BSA and associated with erythema or pruritus; limiting instrumental ADL                                                                                                                                                                           | Covering > 30% BSA and associated with pruritus; limiting self-care ADL                                                                                                   | –                                                                                                                                                                                                                                    | –     |
| Paronychia     | Nail fold edema or erythema; disruption of the cuticle                                                                                                                                                                                    | Localized intervention indicated; oral intervention indicated (e.g., antibiotic, antifungal, antiviral); nail fold edema or erythema with pain; associated with discharge or nail plate separation; limiting instrumental ADL                                      | Operative intervention indicated; IV antibiotics indicated; limiting self-care ADL                                                                                        | –                                                                                                                                                                                                                                    | –     |
| Pruritus       | Mild or localized; topical intervention indicated                                                                                                                                                                                         | Widespread and intermittent; skin changes from scratching (e.g., edema, papulation, excoriations, lichenification, oozing/crusts); oral intervention indicated; limiting instrumental ADL                                                                          | Widespread and constant; limiting self-care ADL or sleep; systemic corticosteroid or immunosuppressive therapy indicated                                                  | –                                                                                                                                                                                                                                    | –     |
| Rash acneiform | Papules and/or pustules covering < 10% BSA, which may or may not be associated with symptoms of pruritus or tenderness                                                                                                                    | Papules and/or pustules covering 10%–30% BSA, which may or may not be associated with symptoms of pruritus or tenderness; associated with psychosocial impact; limiting instrumental ADL; papules and/or pustules covering > 30% BSA with or without mild symptoms | Papules and/or pustules covering > 30% BSA with moderate or severe symptoms; limiting self-care ADL; associated with local superinfection with oral antibiotics indicated | Life-threatening consequences; papules and/or pustules covering any % BSA, which may or may not be associated with symptoms of pruritus or tenderness and are associated with extensive superinfection with IV antibiotics indicated | Death |

with fragrance or alcohol and using mild soaps, cream-based moisturizers, and broad-spectrum sunscreen (Williams et al., 2020).

- d) Ensure that family and other support systems (e.g., friends, clergy, visiting nurses, home-care personnel) can encourage patients to help rebuild their self-esteem and self-belief. Discuss the potential for anxiety or depression.
- e) Perform follow-up phone calls to promote communication with patients regarding their treatment experience and provide an opportunity for nurses to educate and give supportive care.

## B. Alopecia

### 1. Overview

- a) Chemotherapy-induced alopecia is one of the most common and distressing side effects of chemotherapy.
- b) Hair loss has been identified as the most troubling aspect of chemotherapy by 58% of patients (Rubio-Gonzalez et al., 2018).
- c) The psychosocial distress associated with chemotherapy-induced alopecia can lead to treatment disruptions.
- d) A portion of these patients may choose not to receive chemotherapy because of an intense fear of this side effect (Ross & Fischer-Carlidge, 2017).
- e) In young adults aged 18–38 years, men and women reported equally negative experiences related to chemotherapy-induced alopecia (Chon et al., 2012).
- f) Chemotherapy-induced alopecia most commonly occurs on the scalp; however, it can occur any-

where on the body, including facial (e.g., beards, eyebrows, eyelashes), axillary, and pubic hair.

- g) Chemotherapy-induced alopecia negatively affects perceptions of body image, sexuality, and self-esteem (Lacouture et al., 2021).

### 2. Pathophysiology

- a) The pathobiology of the response of human hair follicles to chemotherapy remains largely unknown.
- b) Cells responsible for hair growth have high mitotic and metabolic rates, and specific cytotoxic agents disrupt the proliferative phase of hair growth.
- c) Approximately 90% of hair follicles on the scalp are in the anagen (growth) phase of the hair cycle at any given time (Rubio-Gonzalez et al., 2018).
- d) Telogen effluvium and anagen effluvium are the two major types of chemotherapy-induced alopecia.
  - (1) Telogen effluvium involves less than 50% of the scalp and results in hair thinning.
    - (a) Hair enters the telogen (resting) phase and results in shedding three to four months after drug administration.
    - (b) Antineoplastic drugs that can cause this type of alopecia are methotrexate, 5-FU, and retinoids (Paus et al., 2013).
  - (2) Anagen effluvium is the most common form of chemotherapy-induced alopecia.
    - (a) Because most hair follicles are in the anagen (growth) phase, chemother-

apy damages these rapidly growing cells, damaging the inner root sheath cells or the hair shaft integrity.

- (b) The hair shaft is no longer anchored and falls out easily or breaks off at the scalp. Hair falls out spontaneously or during washing or combing.
- (c) Chemotherapy agents such as cyclophosphamide, daunorubicin, doxorubicin, etoposide, ifosfamide, and paclitaxel are associated with this type of damage.
- (d) The hairs remain in the telogen phase after damage occurs until the chemotherapy is completed, at which time they can enter the anagen phase again, and hair regrowth resumes (Paus et al., 2013).

### 3. Incidence

- a) The average incidence of chemotherapy-induced alopecia is approximately 65% of patients and varies depending on the agents used (Williams et al., 2020). The overall risk is lower in patients receiving targeted therapies, with an incidence of 14.7% (Belum et al., 2015).
- b) The extent of alopecia depends on the mechanism of action of the drug, administration route, drug dose, serum half-life, duration (e.g., bolus vs. continuous infusion), the response of the patient, use of combination chemotherapy, and condition of the hair prior to treatment (Rubio-Gonzalez et al., 2018).

### 4. Risk factors

- a) Type of antineoplastic drugs administered
  - (1) The drugs that present the highest risk of alopecia are camptothecins, cyclophosphamide, daunorubicin, docetaxel, doxorubicin, epirubicin, etoposide, ifosfamide, paclitaxel, and vinorelbine (Lacouture et al., 2021; see Table 21-3).
  - (2) Combination chemotherapy is associated with a higher incidence of alopecia than single-agent therapy (Fabbrocini et al., 2015).
  - (3) Molecularly targeted agents, including EGFR antibodies, BRAF inhibitors, cyclin-dependent kinase inhibitors, and Hedgehog pathway inhibitors, have been associated with diffuse alopecia that is generally reversible (Rubio-Gonzalez et al., 2018).
  - (4) Multitargeted tyrosine kinase inhibitors (e.g., sorafenib, sunitinib) have been associated with alopecia, although the inci-

dence is lower than with chemotherapy (Lacouture, 2015).

- b) Certain noncytotoxic medications (e.g., propranolol hydrochloride, heparin sodium, lithium carbonate, prednisone, vitamin A, androgen preparations)
  - c) Certain medical conditions (e.g., hypothyroidism, aging)
  - d) Poor hair condition before cytotoxic treatment
  - e) Concomitant or previous radiation therapy to the head (local effect)
5. Clinical manifestations
- a) Scalp dryness, soreness, pruritus, and rash can occur before, during, or after hair loss.
  - b) Expected time frame and pattern (Lacouture et al., 2021)
    - (1) Chemotherapy-induced alopecia usually begins approximately one to three weeks after administration of the drug. Regrowth usually begins two to three months after completion of therapy.
    - (2) Pattern: Hair loss tends to occur first on the crown and sides of the head above the ears.
    - (3) Chemotherapy-induced alopecia generally is reversible.
    - (4) Regrown hair may demonstrate changes in color, structure, or texture, and in some patients, hair density may continue to be reduced after treatment.
    - (5) Persistent chemotherapy-induced alopecia can occur following chemotherapy and is defined as the absent or suboptimal hair growth continuing six months after the completion of chemotherapy. It can occur with high-dose busulfan and cyclophosphamide following hematopoietic stem cell transplantation, radiation, and taxane treatment (Silva et al., 2020).
6. Assessment (see Table 21-2)
7. Collaborative management: Alopecia is a constant reminder of disease and greatly affects the sense of self. Patients may experience privacy issues because alopecia often is associated with cancer.
- a) Currently, no approved pharmacologic treatment is available to prevent alopecia caused by cytotoxic therapy.
    - (1) Multiple agents have shown to be beneficial as adjunctive therapy, such as topical minoxidil, topical bimatoprost, and calcitriol (Rubio-Gonzalez et al., 2018).
    - (2) The ONS Guidelines for Cancer Treatment-Related Skin Toxicity recommend using topical minoxidil as a potential therapy to reduce or shorten

**TABLE 21-3.** Risk of Chemotherapy-Induced Alopecia for Antineoplastic Agents

| Classification          | High Risk                                                                                                                                                                                | Moderate Risk                                                                                                                                                      | Mild Risk                                                                                                                                                                                           |

This table may not include all antineoplastics that cause cutaneous toxicities.

Note. Based on information from Mir-Bonafé et al., 2019; Rugo et al., 2017.

chemotherapy-induced alopecia (Williams et al., 2020).

*b) Scalp cooling*

- (1) Scalp cooling is a strategy created to prevent or limit chemotherapy-induced alopecia. It is routinely used in more than 30 countries to prevent chemotherapy-induced alopecia, with reports of response in 50%–80% of patients.
- (2) Scalp cooling is the only intervention that significantly reduces the risk of chemotherapy-induced alopecia. Seven out of eight randomized clinical trials showed a significant advantage for patients who used scalp cooling (Lacouture et al., 2021).
  - (a) The process works by inducing vasoconstriction and decreased follicle metabolism. The decreased blood flow to the hair follicles limits the uptake of the chemotherapy agents. Decreased metabolism makes the follicles less susceptible to damage from the chemotherapy agent.
  - (b) Most patients studied had breast cancer (Ross & Fischer-Carlidge, 2017). A recent prospective cohort study conducted at five U.S. medical centers on women with breast

cancer found that scalp cooling was associated with less hair loss four weeks after the final dose of chemotherapy. The study also found that quality-of-life measures were better in the group that received scalp cooling (Rugo et al., 2017).

- (c) Contraindications exist for scalp cooling and include patients with known hematologic malignancies, lack of safety data, and patients with cold sensitivity, cold agglutinin disease, cryoglobulinemia, and cryofibrinogenemia. Patients may experience headaches, nausea, dizziness, excessive coldness, or feelings of claustrophobia (de Barros Silva et al., 2020).
- (d) Four systematic reviews looking at the percentage of successful hair preservation showed 10%–100% success rates, with the majority around 50% (Ross & Fischer-Carlidge, 2017). Another systematic review found that scalp cooling decreased the relative risk of alopecia by 43% (Rugo & Voigt, 2018).
- (e) The U.S. Food and Drug Administration approved the Digni-

Cap® Paxman® Scalp Cooling Systems in patients with solid tumors (Fischer-Carlidge et al., 2018). Scalp cooling typically begins 30 minutes prior to therapy for the skin temperature to be at its lowest point before the drug enters the hair follicles. Cooling continues throughout therapy and for some time after therapy, depending on the chemotherapy regimen (de Barros Silva et al., 2020).

i. Preparation for scalp cooling includes wetting the hair to improve conduction.

- Healthcare providers need to consider the differences in hair types of ethnicities that may impact proper preparation and efficacy (Araoye et al., 2020).
- The effectiveness of scalp cooling is impacted by cap-scalp contact.
- Areas without proper contact are not protected.
- Curly or kinky hair can become bulkier when wet, making it more challenging to get cap-scalp contact.

ii. Disparities in access to scalp cooling treatments are important to recognize.

- Healthcare providers need to identify potential barriers, such as patient awareness, financial limitations, and geographic access.
- The nearest scalp cooling center is often located more than 50 miles from most chemotherapy infusions, significantly limiting access.
- Financial barriers also restrict use. Medicaid and Medicare do not cover scalp cooling, and private insurance coverage is limited.
- High out-of-pocket costs can restrict use (Singer et al., 2020).

(3) The National Comprehensive Cancer Network (2021) Clinical Practice Guidelines in Oncology recommend scalp cooling treatments for the prevention (category

2A) of chemotherapy-induced alopecia in patients with breast cancer.

(4) The ONS Guidelines for Cancer Treatment-Related Skin Toxicity recommend scalp cooling to prevent chemotherapy-induced alopecia. For patients treated at facilities without access to a cooling system, an ice cap can be used as a prevention method; however, this method is less effective (Williams et al., 2020).

#### 8. Patient and family education

a) Ask patients to verbalize feelings related to hair loss. Increasing their knowledge may give them a sense of control as their appearance changes (Ishida et al., 2015).

b) Advise patients and caregivers about the following (Can et al., 2017):

(1) The cause of alopecia and the time frame of hair loss and regrowth

(2) Strategies to manage hair loss and regrowth

(a) Use baby shampoo with a neutral pH balance.

(b) Avoid using permanent waves, bleach, and coloring agents on hair, vigorous brushing, hot rollers, and excessive heat with hairdryers.

(c) Avoid excessive brushing or combing. Use a soft brush or a wide-tooth comb.

(d) Consider cutting hair in a short style or shaving the head if not participating in scalp cooling (Fabbrocini et al., 2015).

(e) Protect the scalp from the cold and sun with hats, scarves, wigs, and sunscreen. Consider cotton head coverings.

(f) Instruct patients that new hair that grows after completion of therapy may differ from the original hair in color or texture.

(3) Local resources for support (e.g., wig salons, scarf and turban catalogs, scalp cooling locations, support groups)

(a) Look Good Feel Better is a program offered by the Look Good Feel Better Foundation through community organizations, such as the American Cancer Society, that provides guidance and support regarding wigs and other head coverings, makeup, and skin care (Look Good Feel Better Foundation, n.d.).

- (b) Computerized imaging programs to simulate baldness and the look of various types and colors of wigs may be helpful and decrease distress related to hair loss (Chon et al., 2012).
- (c) The Rapunzel Project is a nonprofit organization that aims to increase awareness of scalp cooling therapy. They offer information and resources related to scalp cooling and a list of locations by state (Rapunzel Project, 2021).
- (4) A wig may be covered by insurance, which will help to defray costs. A prescription for a hair prosthesis may be required.
  - (a) Wigs can be synthetic or made of human hair, with the latter being more expensive. Representatives at salons or stores who specialize in wigs can discuss the pros and cons of each type of wig with patients. Synthetic wigs may be damaged by excessive heat during styling. Manufacturer care guidelines should be followed.
  - (b) Wig specialists may have an easier time matching a wig to a patient's usual style if the patient consults the stylist before hair loss begins or provides pictures. It may be helpful to preserve a portion of hair prior to complete hair loss to allow for color and texture matching.
  - (c) If a wig is purchased prior to hair loss, it should be adjustable to decrease the size as the hair loss occurs (Look Good Feel Better Foundation, n.d.).
  - (d) A variety of scarves and turbans are available and assist with protecting the scalp and preventing heat loss.

## CHAPTER 22

# Endocrine Toxicities

### A. Overview

1. Diverse modalities are currently being used to treat cancer, including cytotoxic chemotherapies, targeted therapies, cellular therapies, and immunotherapies (Rivera et al., 2020).
2. Antineoplastic therapies can cause many adverse events, endocrine toxicities, and endocrinopathies.
3. Endocrinopathies are a dysfunction in the endocrine system that can be transient or permanent (Ravi & Gang, 2019).
4. Aside from steroids administered as part of a chemotherapy regimen, many chemotherapies, targeted therapies, hormones, and immunotherapy agents have been shown to cause hyperglycemia.
5. Targeted therapies cause endocrine disorders and endocrinopathies primarily related to the thyroid.
6. Endocrinopathies are associated with immunotherapy.
  - a) Pancreas, adrenal, thyroid, and pituitary glands are the endocrine organs most commonly affected by immune checkpoint inhibitors (Sznol et al., 2017; Wright et al., 2021).
  - b) Adverse effects include hyperthyroidism, hypothyroidism, hypophysitis, panhypopituitarism, hyperglycemia (diabetes), myxedema, and adrenal insufficiency.
  - c) Most of these are associated with repeated administration of immunotherapy agents.
7. These side effects have a diverse and nonspecific nature.
  - a) They may often go unnoticed and, therefore, underreported, underdiagnosed, and undertreated.
  - b) It is important to remain vigilant and ensure that patients are evaluated for these endocrine disorders prior to, during, and following treatment.
8. Although endocrinopathies may not be considered the most common adverse side effects of antineoplastics, they have been associated with the following:
  - a) Mammalian target of rapamycin inhibitors

- b) Recombinant human interferon alpha
- c) Cytokine interleukin (IL)-2
- d) Tyrosine kinase inhibitors (TKIs)
- e) Glucocorticoids
- f) Checkpoint inhibitors: These therapies upregulate and engage the immune system to destroy tumor cells (González-Rodríguez & Rodríguez-Abreu, 2016; Shariff et al., 2019; see Table 22-1).
  - (1) Cytotoxic T-lymphocyte antigen 4 (CTLA-4)
  - (2) Programmed cell death protein 1 (PD-1)
  - (3) Programmed cell death-ligand 1 (PD-L1)

### B. Drug-specific endocrinopathies

1. Mammalian target of rapamycin inhibitors
  - a) Hyperglycemia is associated with the mammalian target of rapamycin inhibitors (Dy & Adjei, 2013; Hwangbo & Lee, 2017; Kezic et al., 2018; Shariff et al., 2019).
  - b) This category of drugs includes rapamycin, sirolimus, everolimus, and temsirolimus.
  - c) Pathophysiology
    - (1) Decrease in glucose-stimulated insulin secretion from beta cells
    - (2) Increase in apoptosis of beta cells and reduction in mass
    - (3) Increase in peripheral insulin resistance and glucose intolerance
    - (4) Promotion of gluconeogenesis in the liver and hepatic glucose production
  - d) Incidence
    - (1) Hyperglycemia has been found to occur in 12% of patients treated with everolimus and 11% of those treated with temsirolimus.
    - (2) Overall incidence of hyperglycemia is 5.25%–50%.
    - (3) Diabetes due to treatment with everolimus may occur in up to 32% of patients (Kezic et al., 2018).

**TABLE 22-1.** Endocrine Toxicities of Antineoplastics

| Classification                 | Drug                                                 | Side Effects                                                                                                                                                      | Nursing Considerations                                                                                                                                                                                                                                                                                                           |
|--------------------------------|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Chemotherapy Agents</b>     |                                                      |                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                  |
| Antimetabolites                | Decitabine (Dacogen®)                                | Hyperglycemia observed in clinical trials: 6%–33%                                                                                                                 | Monitor blood glucose, and educate patients and families on the signs and symptoms of hyperglycemia. (MCI Pharma, 2006)                                                                                                                                                                                                          |
| Antitumor antibiotics          | Valrubicin (Valstar®)                                | Hyperglycemia observed in clinical trials: 1%                                                                                                                     | Monitor blood glucose, and educate patients and families on the signs and symptoms of hyperglycemia. (Endo Pharmaceuticals, 2016)                                                                                                                                                                                                |
| Miscellaneous                  | Asparaginase <i>Erwinia chrysanthemi</i> (Erwinaze®) | Glucose intolerance: 5%<br>Hyperglycemia secondary to inhibition of insulin or insulin receptor synthesis: 4%–17%<br>Potentially irreversible glucose intolerance | Monitor blood glucose at baseline and periodically during treatment, and educate patients and families on the signs and symptoms of hyperglycemia. (Porton Biopharma, 2016)                                                                                                                                                      |
|                                | Mitotane (Lysodren®)                                 | Acute adrenal insufficiency                                                                                                                                       | In the presence of acute adrenal injury, hold the drug and administer hydrocortisone; monitor for worsening signs of shock.<br>Inform healthcare providers of planned surgeries.<br>In the presence of adrenal insufficiency, if indicated, initiate steroid replacement therapy with monitoring. (Bristol-Meyers Squibb, 2019b) |
|                                | Omacetaxine (Synribo®)                               | Hyperglycemia (grade 3–4): (11%)<br>Hyperosmolar hyperglycemic                                                                                                    | Avoid use in patients with poorly controlled diabetes mellitus unless good glycemic control is achieved.<br>Monitor blood glucose levels frequently, and educate patients and families on the signs and symptoms of hyperglycemia. (Teva Pharmaceuticals, 2021)                                                                  |
|                                | Pegaspargase (Oncaspar®)                             | Irreversible glucose intolerance<br>Hyperglycemia: 5% (grade 3–4 up to 24%)                                                                                       | Monitor blood glucose levels frequently, and educate patients and families on the signs and symptoms of hyperglycemia. (Sigma-Tau Pharmaceuticals, 2011)                                                                                                                                                                         |
|                                | Vorinostat (Zolinza®)                                | Hyperglycemia: 8.1%                                                                                                                                               | Monitor blood glucose, and educate patients and families on the signs and symptoms of hyperglycemia.<br>Monitor serum glucose every 2 weeks during the first 2 months of treatment and monthly thereafter. (Merck, 2021)                                                                                                         |

*Note.* The table is not all inclusive of every agent that causes endocrine toxicities. Review package inserts for dosing and prescribing information.

- e) Risk factors may be similar to those for cancer and include obesity, decreased physical activity, and older age.
  - f) Manifestations: Hyperglycemia usually occurs within the first six weeks of treatment and resolves between doses.
  - g) Assessment: Patients should have fasting blood glucose and hemoglobin A1c levels checked prior to initiating treatment, every two weeks for one month, and then monthly during treatment.
  - h) Prevention and treatment
    - (1) Lifestyle modifications should be made (e.g., caloric restriction, exercise), and antidiabetic medication should be initiated if indicated (American Diabetes Association, 2021).
    - (2) Concurrent use of metformin (biguanides) with rapalogs may help prevent the development of diabetes (Kezic et al., 2018).
    - (3) For patients with a history of hyperglycemia or diabetes, optimize blood glucose control prior to treatment.
    - (4) For blood glucose levels of 250–500 mg/dl, hold the drug temporarily and restart at a decreased dose.
    - (5) For blood glucose greater than 500 mg/dl, discontinue the drug.
  - i) Patient and family education: Educate patients and families to report the signs and symptoms of hyperglycemia (e.g., increased thirst, increased urination, blurred vision).
2. Human interferon alpha
    - a) Hyperthyroidism or hypothyroidism and biphasic thyroiditis are associated with recombinant human interferon alpha used in the treatment of hairy cell leukemia, resected high-risk melanoma, renal cell carcinoma, Kaposi sarcoma, and lymphoma (Bhattacharya et al., 2020; Hauschild et al., 2008; Weber et al., 2015).
    - b) Pathophysiology: The mechanism by which thyroid dysfunction occurs is not fully understood. It is believed to occur due to the expression of the MHC-1 antigen, which causes activation of cytotoxic T cells and results in cellular destruction (Bhattacharya et al., 2020).
    - c) Incidence: Thyroid disorders occur in 2.4%–31% of patients receiving treatment for solid tumors (Bhattacharya et al., 2020).
    - d) Risk factors
      - (1) Presence of thyroid antibodies
      - (2) Preexisting thyroid disease, leading to increased severity of hypothyroidism
    - e) Manifestations
      - (1) Symptoms of hyperthyroidism

- (a) Palpitations
    - (b) Weight loss
    - (c) Diarrhea
    - (d) Cold intolerance
  - (2) Symptoms of hypothyroidism
    - (a) Constipation
    - (b) Heat intolerance
    - (c) Weight gain, which usually occurs 3–12 weeks after initiation of therapy
  - f) Assessment
    - (1) Assess thyroid function (i.e., thyroid-stimulating hormone [TSH] and free thyroxine [ $T_4$ ] and antibodies (i.e., thyroid peroxidase antibodies and thyroglobulin) at induction and maintenance.
    - (2) If thyroid antibodies are present, recheck thyroid function every two months.
    - (3) If not antibody positive, check every six months.
  - g) Prevention and treatment
    - (1) Levothyroxine (1.6 mcg/kg) is used to treat hypothyroidism.
    - (2) Beta-blockers or corticosteroids may also be used.
    - (3) Symptoms may resolve when therapy is discontinued.
    - (4) If thyroid functions do not normalize, therapy should be discontinued.
  - h) Patient and family education
    - (1) Instruct patients and families to report symptoms of hypo- or hyperthyroidism.
    - (2) If thyroid hormone replacement has been initiated, instruct patients to take medication on an empty stomach in the morning.
3. Cytokine IL-2
- a) Thyroiditis is associated with cytokine IL-2 used to treat advanced renal cell carcinoma and melanoma (Bhattacharya et al., 2020; Weber et al., 2015).
  - b) This category of drugs includes aldesleukin.
  - c) Pathophysiology
    - (1) IL-2 increases IL-1, interferon gamma, tumor necrosis factor-alpha, and infiltration of lymphocytes into the thyroid gland.
    - (2) This induces the presence of autoantigens and human leukocyte antigen class II on thyrocytes, resulting in autoimmune destruction.
  - d) Incidence: Approximately 35% of patients may experience hypothyroidism, and 7% may experience hyperthyroidism (Bhattacharya et al., 2020).
  - e) Risk factors: Hypothyroidism is related to the duration of therapy and the presence of thyroid antibodies prior to treatment.
  - f) Manifestations
    - (1) Hyperthyroidism
      - (a) Palpitations
      - (b) Weight loss
      - (c) Diarrhea
      - (d) Cold intolerance
    - (2) Hypothyroidism
      - (a) Weight gain
      - (b) Constipation
      - (c) Heat intolerance
      - (d) Constipation
  - g) Assessment: Routine testing of thyroid hormones (TSH and free  $T_4$ ) should be performed prior to and every two to three months during treatment.
  - h) Prevention and treatment
    - (1) If hypothyroidism is detected before initiation of treatment, hormone replacement therapy should be initiated and treatment delayed for at least two weeks.
    - (2) Hormone replacement therapy should be continued for one year or until levels return to normal. Symptoms resolve upon withholding the drug, usually in 6–10 months.
  - i) Patient and family education
    - (1) Instruct patients and families to report symptoms of hypo- or hyperthyroidism.
    - (2) If thyroid hormone replacement has been initiated, instruct patients to take medication on an empty stomach in the morning.
4. TKIs
- a) This category of drugs includes axitinib, erlotinib, dasatinib, nilotinib, lenvatinib, pazopanib, vandetanib, sorafenib, sunitinib, motesanib, gefitinib, and regorafenib.
  - b) Hyperglycemia and improved blood glucose levels have been associated with TKIs used in treating renal cell carcinoma, hepatocellular carcinoma, pancreatic neuroendocrine tumors, gastrointestinal stromal tumor, medullary thyroid cancer, adenosquamous cell carcinoma of the lung, and small cell cancer (Shariff et al., 2019).
    - (1) Pathophysiology
      - (a) Improved blood glucose is associated with protection from beta cell apoptosis.
      - (b) Hyperglycemia is attributed to the blocking of TKI activity, resulting in insulin resistance.
    - (2) Incidence: Hyperglycemia occurs in 5%–45% of patients treated with TKIs.
    - (3) Assessment: Patients should have fasting blood glucose and hemoglobin A1c levels checked prior to initiating treatment, every two weeks for one month, and then monthly during treatment.

- (4) Lifestyle modifications should be made (e.g., caloric restriction, exercise), and antidiabetic medication should be initiated if indicated (American Diabetes Association, 2021).
  - (5) Patient and family education: Educate patients and families to report signs and symptoms of hyperglycemia (e.g., increased thirst, increased urination, blurred vision) and hypoglycemia (e.g., lightheadedness, dizziness, weakness, palpitations).
- c) Hypothyroidism has been shown to occur with TKIs and increases with time and the number of treatments (Bhattacharya et al., 2020).
- (1) Pathophysiology: TKIs impair the vascularization of the thyroid, induce ischemia, and block vascular growth factor signaling pathways.
  - (2) Incidence: Approximately 14%–70% of patients receiving sunitinib may experience hypothyroidism. Incidence with sorafenib is less frequent (6.3%–27%). Hypothyroidism may occur at 4–92 weeks.
  - (3) Manifestations: Weight gain, constipation, heat intolerance, dry skin, and fatigue can occur.
  - (4) Assessment
    - (a) Routine testing of thyroid hormones (TSH and free  $T_4$ ) should be performed prior to treatment and monthly for the first six months (every two to three months or at the time of clinical symptoms).
    - (b) For patients with preexisting thyroid disease, TSH testing should be performed monthly for the first three months and then every three months for the duration of therapy.
  - (5) Prevention and treatment
    - (a) If hypothyroidism is detected prior to treatment, hormone replacement therapy should be initiated.
    - (b) Hormone replacement therapy should be continued until treatment is completed. At that time, a trial withdrawal can be considered. If symptoms resolve upon withholding of the drug, the medication can be discontinued.
  - (6) Patient and family education
    - (a) Instruct patients and families to report symptoms of hypo- or hyperthyroidism.
    - (b) If thyroid hormone replacement has been initiated, instruct patients to take medication on an empty stomach in the morning.
5. Glucocorticoids
- a) Glucocorticoids are used in cancer treatment as curative agents (in combination with other chemotherapy agents) for chronic lymphocytic leukemia, Hodgkin lymphoma, multiple myeloma, and acute lymphoblastic leukemia. They are also used as antiemetics and anti-inflammatories (Pufall, 2015).
  - b) Glucocorticoids are known to cause the following (Hwangbo & Lee, 2017; Oyer et al., 2006; Shariff et al., 2019; Simmons et al., 2012; Trencce, 2003; van Raalte et al., 2009; Vigneri et al., 2009):
    - (1) Decreased beta cell mass
    - (2) Increased glucose intolerance
    - (3) Decreased insulin effectiveness
    - (4) Increased hepatic glucose output
    - (5) Hyperinsulinemia
    - (6) Decreased beta cell effectiveness and beta cell failure
  - c) This category of drugs includes hydrocortisone, methylprednisolone, prednisone, prednisolone, and dexamethasone.
  - d) Pathophysiology
    - (1) Glucocorticoids inhibit glucose transport and phosphorylation, decreasing available intracellular energy.
    - (2) They impede mitotic cell division.
    - (3) Glucocorticoids inhibit protein synthesis, resulting in apoptotic cell death (Coleman, 1992; Laane et al., 2009; Shariff et al., 2019).
    - (4) Glucocorticoids enhance the effect of glucagon and epinephrine and increase gluconeogenesis.
  - e) Incidence: Approximately 60%–80% of patients treated with corticosteroids will experience hyperglycemia (Shariff et al., 2019).
  - f) Risk factors (Handy et al., 2013; Hwangbo & Lee, 2017)
    - (1) Preexisting diabetes mellitus (prolonged or undiagnosed)
    - (2) Family history of diabetes mellitus
    - (3) Down syndrome
    - (4) Increased age
    - (5) Increased body mass index
    - (6) Central nervous system disease
    - (7) Concurrent administration of tacrolimus, cyclosporine, or L-asparaginase
    - (8) Female sex
    - (9) Ethnicity

g) Manifestations (Cleveland Clinic, 2020; Handy et al., 2013)

(1) Early

- (a) Hyperglycemia (blood glucose greater than 180 mg/dl)
- (b) Dry mouth
- (c) Irritability
- (d) Drowsiness
- (e) Blurred vision
- (f) Polyphagia (increased hunger)
- (g) Dry and itchy skin
- (h) Polydipsia (increased thirst)
- (i) Polyuria (increased urination)
- (j) Fatigue
- (k) Weight loss

(2) Late

- (a) Confusion and disorientation
- (b) Dehydration
- (c) Nausea and vomiting
- (d) Shortness of breath
- (e) Tremor
- (f) Tachycardia
- (g) Elevated systolic blood pressure
- (h) Anxiety
- (i) Seizures
- (j) Coma

h) Assessment

- (1) Monitor blood glucose, both fasting and two hours postprandial (after lunch) (Hwangbo & Lee, 2017).
- (2) Assess for diabetic ketoacidosis. Check electrolytes and urine ketones, calculate the anion gap, and check arterial venous blood gas (Mouri & Badireddy, 2021).
- (3) Check hemoglobin A1c every three to six months (American Diabetes Association, 2021; Mouri & Badireddy, 2021).
- (4) Monitor for glucocorticoid-induced osteoporosis and osteonecrosis (Oray et al., 2016).

i) Prevention and treatment (see Figure 22-1)

j) Patient and family education: The degree of hyperglycemia often is related to the potency and duration of action of the steroid administered.

- (1) For example, hydrocortisone has a short duration of action (2–10 hours) compared to dexamethasone (72 hours).
- (2) Repeated exposure to steroids can result in sustained hyperglycemia, requiring long-term use of antidiabetic medications.

C. Immune checkpoint inhibitor–related endocrinopathies (Bhattacharya et al., 2020; Spain et al., 2016; Vaddepalay et al., 2020; Villadolid & Amin, 2015; Wright et al., 2021)

1. CTLA-4 is a checkpoint protein expressed on the surface of activated T cells that bind to B7 molecules and inhibit T-cell–mediated immune responses.

- a) Ipilimumab is an example of a CTLA-4 inhibitor.
- b) CTLA-4 inhibitors are used to treat renal cell carcinoma, melanoma, hepatocellular cancer, colorectal cancer, metastatic non-small cell lung cancer, and pleural mesothelioma.

2. PD-1 is an immune checkpoint expressed on the surface of activated T cells. Blockade of the PD-1 pathway results in T-cell antitumor activity, leading to the killing of cancer cells.

- a) PD-1 inhibitors include pembrolizumab, nivolumab, cemiplimab, and dostarlimab.
- b) PD-1 inhibitors are used in the treatment of renal cell carcinoma, melanoma, Hodgkin lymphoma, non-small cell lung cancer, small cell lung cancer, B-cell lymphoma, hepatocellular carcinoma, squamous cell carcinoma of the head and neck, urothelial carcinoma, colorectal cancer, Merkel cell carcinoma, cervical cancer, gastric/esophagogastric junction/esophageal cancer, cutaneous squamous cell cancer, endometrial cancer, and triple-negative breast cancer.

3. PD-L1 is expressed on T cells and interacts with B7 molecules, resulting in T-cell inactivation.

- a) PD-L1 inhibitors include atezolizumab, avelumab, and durvalumab.
- b) PD-L1 inhibitors are used to treat urothelial carcinoma, melanoma, hepatocellular carcinoma, non-small cell lung cancer, small cell lung cancer, metastatic Merkel cell carcinoma, and metastatic triple-negative breast cancer.

4. The adverse side effects of CTLA-4, PD-1, and PD-L1 inhibitors are similar. Side effects from CTLA-4 inhibitors are usually dose related; however, there does not appear to be a dose–toxicity relationship between PD-1 and PD-L1 inhibitors.

- a) Hypothyroidism (Dy & Adjei, 2013; González-Rodríguez & Rodríguez-Abreu, 2016; Hattersley et al., 2021; Khan et al., 2017; Spain et al., 2016; Villadolid & Amin, 2015; Wright et al., 2021)

(1) Pathophysiology: The pathophysiology has not been fully elucidated.

- (2) Incidence: Hypothyroidism occurs in 7%–8% of patients treated with PD-1 inhibitors and 3.9% treated with CTLA-4 inhibitors. Incidence is 13.2% with combination PD-1 and CTLA-4 (Barroso-Sousa et al., 2018; Hattersley et al., 2021).

- (3) Risk factors: Adverse events are more common in women and patients with pre-existing antithyroid antibodies.

**FIGURE 22-1.** Glucocorticoid-Induced Hyperglycemia

| Glucocorticoids                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Mechanism                                                                                                                                                                                                                  | Risk Factors                                                                                                                                                                                                                                                                                                             | Characteristics                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Treatments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

- (4) Manifestations
    - (a) Symptoms of hypothyroidism include fatigue, dry skin, cold sensitivity, constipation, depression, and weight gain.
    - (b) Manifestation (increased TSH and decreased free  $T_4$ ) can occur at any time but is usually six weeks after initiation of immune checkpoint inhibitors.
  - (5) Assessment: TSH and free  $T_4$  should be measured prior to treatment, at each treatment, four to six weeks after the final cycle, and every three months after that.
  - (6) Prevention and treatment: levothyroxine replacement at 1.6 mcg/kg daily
  - (7) Patient and family education
    - (a) Instruct patients and families to report symptoms of hypothyroidism.
    - (b) If thyroid hormone replacement has been initiated, instruct patients to take medication on an empty stomach in the morning.
- b) Hyperthyroidism (Barroso-Sousa et al., 2018; Hattersley et al., 2021; Spain et al., 2016)
- (1) Pathophysiology: Currently, no histopathologic findings exist. To date, a mechanism has not been established.
  - (2) Incidence: Hyperthyroidism occurs in 2.9%–8% of patients treated with immune checkpoint inhibitors (Hattersley et al., 2021).
  - (3) Risk factors
    - (a) Transient thyroiditis proceeding hypothyroidism
    - (b) TSH receptor antibody development
    - (c) Graves disease
  - (4) Manifestations: Symptoms usually occur 4–10 weeks after initiation of treatment and consist of weight changes, tachycardia, tremors, fatigue, diarrhea, and anxiety.
  - (5) Assessment
    - (a) Thyroid function testing should be performed prior to treatment, before each cycle for the first five cycles, four to six weeks after the final cycle, and every three months after that.
    - (b) If thyrotoxicosis is suspected, obtain TSH, free  $T_4$ , thyroid autoantibodies, cortisol, and glucose.
    - (c) With hyperthyroidism, a thyroid uptake scan may be clinically indicated to distinguish between Graves hyperthyroidism and thyroiditis.
- (6) Prevention and treatment
    - (a) Beta-blockers can be used to treat tremors, tachycardia, and other signs and symptoms of sympathetic activation.
    - (b) Methimazole may be used to treat Graves disease.
    - (c) For thyroiditis, the treatment is steroids. Steroids are not recommended if patients have low cardiovascular risk.
    - (d) If hypothyroidism results following prolonged hyperthyroidism, the treatment is levothyroxine 0.8–1.6 mcg/kg.
  - (7) Patient and family education
    - (a) Instruct patients and families to report symptoms, including palpitations, diarrhea, and tremors.
    - (b) If thyroid hormone replacement has been initiated, instruct patients to take medication on an empty stomach in the morning.
    - (c) Patients should be encouraged to carry an immunotherapy wallet card, indicating their diagnosis and immunotherapy (see Figure 10-3).
- c) Hypophysitis (González-Rodríguez & Rodríguez-Abreu, 2016; Sznol et al., 2017; Vazquez, 2017; Villadolid & Amin, 2015; Weber et al., 2015; Wright et al., 2021)
- (1) Pathophysiology: Hypophysitis may be caused by T-cell-mediated pituitary destruction due to CTLA-4 blockade.
  - (2) Incidence: The prevalence of hypophysitis is reported in up to 10% of patients treated with CTLA-4 inhibitors and 0.5%–1% of those treated with PD-1 and PD-L1 inhibitors.
  - (3) Risk factors: Male sex and older age
  - (4) Manifestations
    - (a) The most frequent complaints associated with hypophysitis are fatigue, headache, nausea, vomiting, and visual field defects, with magnetic resonance imaging showing swelling of the pituitary.
    - (b) Other manifestations include arthralgias, behavioral changes, and loss of libido.
    - (c) The usual time to the manifestation of symptoms is 9–12 weeks with ipilimumab and 26 weeks with PD-1 or PD-L1 inhibitors. These symptoms are likely permanent.

- (5) Assessment: A detailed history and physical examination should be performed prior to treatment. Each patient should have laboratory work completed consisting of the following:
    - (a) TSH
    - (b) Free T<sub>4</sub>
    - (c) Pituitary function tests (e.g., luteinizing hormone, follicle-stimulating hormone, growth hormone)
    - (d) Prolactin
    - (e) Adrenocorticotrophic hormone
    - (f) Cortisol
    - (g) Testosterone (in men)
    - (h) Estradiol (in women)
  - (6) Prevention: No preventive measures are reported.
  - (7) Treatment
    - (a) Corticosteroids should be used with caution for symptom control (Petrelli et al., 2020).
    - (b) For grade 3–4 adverse events, withhold treatment.
    - (c) If patients are asymptomatic, treatment measures include magnetic resonance imaging, hormone replacement, and cortisol replacement one week prior to the initiation of levothyroxine.
    - (d) If patients are symptomatic, recommendations include prednisolone (1–2 mg/kg), magnetic resonance imaging, and IV fluids for hypotension (if indicated). Steroids should be tapered over two to four weeks, followed by hormone replacement.
  - (8) Patient and family education
    - (a) Instruct patients and families to report any changes.
    - (b) Patients should be encouraged to carry an immunotherapy wallet card, indicating their diagnosis and immunotherapy (see Figure 10-3).
- d) Hyperglycemia (Hwangbo & Lee, 2017; Leiter et al., 2021)
- (1) Pathophysiology: PD-1, which is expressed on beta cells of islets (in the pancreas), is inhibited. Immune checkpoint inhibitors cause adipose tissue inflammation and lipodystrophy associated with insulin resistance.
  - (2) Incidence: Hyperglycemia occurred in 45%–49% of patients, with 3%–6% experiencing grade 3–4.
  - (3) Risk factors
    - (a) Underlying positive glutamic acid decarboxylase
    - (b) Human leukocyte antigen antibodies
    - (c) Low C-peptide (reference range: normal fasting C-peptide 1.1–4.4 ng/ml) (Kotwal et al., 2019)
    - (d) Asian or Hispanic ethnicity
    - (e) Obesity (body mass index greater than or equal to 30 kg/m<sup>2</sup>)
    - (f) Preexisting hyperglycemia
  - (4) Manifestations: Elevated blood glucose, which manifests in 0.4–107 weeks (median: 9.7 weeks) (Leiter et al., 2021)
  - (5) Assessment
    - (a) Check fasting blood glucose and hemoglobin A1c prior to initiation of treatment.
    - (b) Closely monitor blood glucose during treatment.
  - (6) Prevention and treatment
    - (a) Blood glucose should be adequately controlled using antidiabetic medications (oral agents or insulin) and adequate hydration.
    - (b) In the case of a sudden onset of severely elevated blood glucose, admission to a unit with a higher level of care (close monitoring) and administration of an insulin drip may be required.
  - (7) Patient and family education
    - (a) Depending on the severity of the blood glucose elevation, patients may need to learn how to perform self-monitoring of blood glucose and insulin injections.
    - (b) It may benefit patients and their families to attend a diabetes self-management education course.
    - (c) All patients should be educated on the signs and symptoms of hyperglycemia and instructed to report any symptoms related to diabetic ketoacidosis.
    - (d) Patients should be encouraged to carry an immunotherapy wallet card, indicating their diagnosis and immunotherapy.
- e) Diabetes (Alhousseini & Samantray, 2017; Barroso-Sousa et al., 2018; Fessas et al., 2020; Godwin et al., 2017; Kotwal et al., 2019; Nogueira et al., 2019; Paschou et al., 2021; Wright et al., 2021)
- (1) Pathophysiology: The pathophysiology includes destruction of pancreatic beta cells by autoreactive T cells.

- (2) Incidence: The incidence of type 1 diabetes was 0.4%–2% and associated with PD-1 and PD-L1 inhibitors (Barroso-Sousa et al., 2018; Higham et al., 2020; Kotwal et al., 2019; Nogueira et al., 2019; Paschou et al., 2021; Shariff et al., 2019; Wright et al., 2021).
- (3) Risk factors
  - (a) Previous history of prediabetes or diabetes
  - (b) Positive antibodies (e.g., glutamic acid decarboxylase, insulin autoantibodies, insulin antibodies)
  - (c) Asian ethnicity
  - (d) Obesity
  - (e) Older than age 60 years
  - (f) Human leukocyte antigen (HLA): Patients with HLA-DR3-DQ2 or HLA-DR4-DQ8 haplotypes appear to be at higher risk of developing immune checkpoint inhibitor-related type 1 diabetes (Barroso-Sousa et al., 2018).
- (4) Manifestations
  - (a) Elevation of blood glucose in people without a history of diabetes.
  - (b) Worsening of hyperglycemia in patients with a history of type 2 diabetes
  - (c) Onset: 1–228 weeks (median 7–17 weeks) after the first dose of an immune checkpoint inhibitor (Wright, et al., 2021)
- (5) Assessment: Blood glucose should be monitored every treatment cycle. For patients with new-onset hyperglycemia, a chemistry panel, urine ketones, serum ketones (beta-hydroxybutyrate), hemoglobin A1c, and C-peptide should be obtained.
- (6) Prevention and treatment
  - (a) Blood glucose and hemoglobin A1c should be monitored prior to treatment with immune checkpoint inhibitors. Blood glucose should be monitored with each treatment, and A1c should be obtained every three months (if patients have not received prior blood transfusions).
  - (b) Blood glucose should be adequately controlled using antidiabetic medications (oral agents or insulin) and adequate hydration.
  - (c) In the case of a sudden onset of severely elevated blood glucose, admission to a unit with a higher level of care (close monitoring) and administration of an insulin drip may be required.
  - (d) Referral to endocrinology is recommended.
- (7) Patient and family education
  - (a) Depending on the severity of the blood glucose elevations, patients may need to learn how to perform self-monitoring of blood glucose and insulin injections.
  - (b) It may also benefit patients and their families to attend a diabetes self-management education course.
  - (c) All patients should be educated on the signs and symptoms of hyperglycemia and instructed to report any symptoms related to diabetic ketoacidosis.
  - (d) Patients should be encouraged to carry an immunotherapy wallet card, indicating their diagnosis and immunotherapy (see Figure 10-3).
- f) Adrenal insufficiency (Barroso-Sousa et al., 2018; Dy & Adjei, 2013; Hattersley et al., 2021; Postow, 2022; Villadolid & Amin, 2015; Weber et al., 2015)
  - (1) Pathophysiology: Destruction of the adrenal cortex occurs, but the pathophysiology has not been fully elucidated.
  - (2) Incidence: Adrenal insufficiency occurs in less than 1% of patients and is more common among those treated with combination therapy (5%–7%) (Barroso-Sousa et al., 2018; Hattersley et al., 2021).
  - (3) Risk factors: Adrenal insufficiency was associated with the male sex.
  - (4) Manifestations: Symptoms usually occur within 10 weeks of initiation of treatment but can occur between 1–36 weeks.
    - (a) Dehydration
    - (b) Hypotension
    - (c) Electrolyte imbalances (e.g., hyperkalemia, hyponatremia)
    - (d) Abdominal pain and nausea
    - (e) Fever
    - (f) Hypoglycemia
    - (g) Fatigue
    - (h) Weakness
  - (5) Assessment
    - (a) Routine testing is not advised for patients treated with PD-1 or PD-L1 inhibitors. If symptoms occur, check thyroid hormones, serum glucose,

- electrolytes, adrenocorticotrophic hormone, and morning cortisol levels.
- (b) Perform magnetic resonance imaging of the pituitary gland within one month of diagnosis of adrenal insufficiency.
  - (c) Obtain an endocrinology consult.
- (6) Prevention and treatment
- (a) Hormone replacement therapy should be given if needed.
  - (b) Withhold treatment if evidence of an adrenal crisis.
  - (c) If severe symptoms of adrenal insufficiency are detected, patients should be hospitalized immediately and IV steroids initiated.
- (7) Patient and family education: Instruct patients and families to report signs and symptoms of the following:
- (a) Dehydration (e.g., dizziness, thirst, dry mouth, muscle fatigue)
  - (b) Hypotension (e.g., dizziness, lightheadedness, unsteadiness)
  - (c) Hyperkalemia (e.g., tachycardia, muscle weakness, muscle cramps, fatigue, chest pain)
  - (d) Hyponatremia (e.g., fatigue, nausea and vomiting, headache, confusion, muscle spasms)
- (8) If steroids are initiated, patients should learn the sick day rule for how to adjust steroids when ill (National Institutes of Health Clinical Center, 2016). Sick day rules for patients with adrenal insufficiency due to steroids outline the adjustment of the steroid dose when patients have an elevated temperature or vomiting and diarrhea.
- (9) Patients should wear medical alert necklaces or bracelets indicating that they have adrenal insufficiency.
- (10) Patients should be encouraged to carry an immunotherapy wallet card, indicating their diagnosis and immunotherapy.

## CHAPTER 23

# Fatigue

### A. Overview

1. “Cancer-related fatigue is a distressing, persistent, subjective sense of physical, emotional, and/or cognitive tiredness or exhaustion related to cancer or cancer treatment that is not proportional to recent activity and interferes with usual functioning” (National Comprehensive Cancer Network [NCCN], 2022, p. FT-1).
2. Multiple factors contribute to this complex syndrome in patients with cancer, making it challenging to identify a clear underlying cause (Bower, 2019; Gerber, 2017).
3. Cancer-related fatigue (CRF) is underreported, underdiagnosed, and undertreated. Healthcare professionals may not fully appreciate the degree of distress and functional loss that fatigue produces (Ripamonti et al., 2018; Thong et al., 2020). Fatigue is the most common, distressing, and disabling side effect of cancer treatment. It is also experienced by cancer survivors and those at the end of life (Charalambous et al., 2019; de Raaf, de Klerk, & van der Rijt, 2013).
4. It can produce profound decrements in physical, social, cognitive, and vocational functioning (Schmidt et al., 2020; Tan, Yip, et al., 2021), sleep disturbances (Charalambous et al., 2019), anxiety and depression (Brownstein et al., 2021; Ebede et al., 2017; Thompson & Bobonis Babilonia, 2017), and emotional and spiritual distress for patients and their family members (Bootsma et al., 2020; Miller et al., 2022; Schellekens et al., 2021).
5. NCCN guidelines recommend that all patients with cancer be screened for fatigue at their initial visit and at regular intervals across the cancer continuum. Fatigue in adults and children should be treated promptly (NCCN, 2022).

B. Pathophysiology: Exact mechanisms are unknown. Clinical studies have focused on understanding the factors contributing to CRF, including the tumor itself, treatments, late and long-term effects, and comorbid conditions (Ma et al., 2020).

1. Underlying mechanisms of CRF are believed to involve several physiologic and biochemical systems (Bower, 2019; Yang et al., 2019; see Figure 23-1).
  - a) Evidence suggests gene polymorphisms, hypothalamic-pituitary-adrenal disruption, altered circadian rhythmicity, diminished heart rate variability, immune dysfunction, serotonin dysregulation, mitochondrial dysfunction, 5-hydroxytryptophan dysregulation, and proinflammatory cytokine activity are mechanisms that directly or indirectly contribute to CRF.
  - b) Studies also suggest that fatigue may be related to impairments in neuromuscular metabolism and function, distressing symptoms such as pain and dyspnea, psychological and coping responses, and imbalanced neuroendocrine-immune stress responses (Brownstein et al., 2021; Chartogne et al., 2021; Feng et al., 2019; Hughes et al., 2020; Lacourt, Vichaya, Chiu, et al., 2018; Lacourt, Vichaya, Escalante, et al., 2018; Poort et al., 2017).
2. Direct effects of chemotherapies, hormone therapies, radiation therapies, molecularly targeted agents, immunotherapies, and combined-modality therapies have been implicated as contributors to the intensity of CRF (Abdel-Rahman et al., 2016; Li & Gu, 2017; Ma et al., 2020; Wagland et al., 2016). The burden of traveling to and from a clinic for treatments and office visits and the requirements for self-management during treatment can also amplify CRF.
3. The CRF disease process and comorbid conditions (e.g., metabolic disorders) can contribute to causing or exacerbating fatigue.
  - a) Endocrine dysfunction (e.g., hypothyroidism, adrenal insufficiency, testicular hypogonadism/androgen deficiency [low testosterone levels in males])
  - b) Cardiopulmonary dysfunction (e.g., cardiomyopathy, bronchiolitis, pneumonitis)
  - c) Dehydration and electrolyte imbalances
  - d) Infection

**FIGURE 23-1.** Etiology of Cancer-Related Fatigue

CNS—central nervous system

Note. Image courtesy Sandra A. Mitchell and Ann M. Berger. Used with permission.

- e) Insulin sensitivity: Insulin resistance causes abnormal glucose uptake by muscle and increases body fat, contributing to CRF (Yang et al., 2019).
  - f) Uncontrolled concurrent symptoms (e.g., pain, nausea and vomiting, dyspnea, anxiety)
  - g) Side effects of medications that act on the central nervous system (e.g., narcotics, anxiolytics, antiemetics)
  - h) Sleep disturbances (Charalambous et al., 2019; NCCN, 2022)
    - (1) Obstructive sleep apnea
    - (2) Restless legs syndrome/periodic limb movements
    - (3) Narcolepsy
    - (4) Insomnia (e.g., difficulty falling asleep, staying asleep, early morning awakening)
    - (5) Hypersomnia
  - i) Disease recurrence
  - j) Anemia: A relationship exists between low hemoglobin and fatigue. A decrease in red blood cells increases hypoxia-related compromise in organ function, contributing to fatigue (Kink et al., 2020).
  - k) Nutritional deficiencies: Reduced caloric intake and imbalances in serum levels of sodium, potassium, calcium, and magnesium may contribute to fatigue and affect quality of life (Inglis et al., 2019; NCCN, 2022).
  - l) Sarcopenia, physical deconditioning, and inactivity: Direct effects of the tumor or side effects of the treatment regimen often contribute to fatigue through sarcopenia (loss of muscle mass), reduced physical activity, cardiopulmonary deconditioning, and reduced muscle strength (Li, Chou, & Shun, 2021; Neefjes et al., 2017).
  - m) Psychological distress
  - n) Depression: Depression may occur concurrently with or independently of fatigue and can have a different pattern of expression over time (Bower, 2019; Müller et al., 2021).
  - o) Phenotypes/genotypes: Single nucleotide polymorphisms, especially in the regulatory regions of relevant genes, are thought to contribute to the development of CRF (Cameron et al., 2021; Wang et al., 2017).
- C. Incidence: Fatigue is one of the most reported symptoms experienced by patients receiving treatment for cancer, and it often persists beyond the conclusion of active treatment. Across the cancer care continuum, depending on how fatigue is defined and measured, prevalence estimates are 25%–99% (Christen et al., 2020; Ma et al., 2020; Thong et al., 2020).
- D. Assessment: Oncology nurses are responsible for ensuring that screening for CRF occurs and is documented at regular intervals across the cancer control continuum (Ebede et al., 2017; Pearson et al., 2016). A detailed evaluation of the characteristics, consequences, and potential contributing factors to fatigue should be performed, and fatigue should be managed with evidence-based interventions (NCCN, 2022).
1. Brief measures to screen for fatigue are rapid and sensitive and can be applied efficiently in the clinic to identify individuals who would benefit from additional systematic evaluation (Danjoux et al., 2007; Goedendorp et al., 2016; Kirsh et al., 2001; Temel et al., 2006).
  2. Increased availability of item banks, computerized adaptive testing, and collection and integration of patient-reported outcomes into the electronic health record may advance the precision, efficiency, interpretation, and actionability of screening measures for CRF (Lai et al., 2005, 2011; Wagner et al., 2015). Recent methodologies are exploring ways to combine self-report and performance-based assessments (Cuesta-Vargas et al., 2019), create interpretive crosswalks among various self-report measures of fatigue (Friedrich et al., 2019), and explore the role of sensors as digital biomarkers of fatigue (Sada et al., 2021).
  3. Multiple CRF screening and evaluation measures are available (Al Maqbali et al., 2019; Seyidova-Khoshknabi et al., 2011).
    - a) Single-item, single-dimension measures are easy to administer. These include a 0–10 scale, a visual analog scale, or Likert scales.
      - (1) On a 0–10 scale (0=no fatigue; 10=worst fatigue imaginable), mild fatigue is reflected by a score of 1–3, moderate by a score of 4–6, and severe by a score of 7–10 (NCCN, 2022).
      - (2) Fatigue measurement in children is simplified. Young children (aged younger than 6 years) may be asked if they are tired or not tired. Valid and reliable instruments are available to measure fatigue in children and adolescents (Christen et al., 2020; Tomlinson et al., 2013).
      - (3) If fatigue is absent or mild (score 0–3), patients and family members should receive anticipatory guidance about fatigue and available strategies for fatigue prevention and management (e.g., exercise, relaxation, stress management).
      - (4) When fatigue is rated as moderate to severe (4–10), a focused history and physical examination should be conducted as part of the primary evaluation phase.
    - b) More than 20 self-report measures, including single-item measures, multi-item unidimen-

sional scales, and multidimensional inventories, have been developed to evaluate fatigue in children, adolescents, and adults during and following cancer treatment (Al Maqbali et al., 2019; Christen et al., 2020; Seyidova-Khoshknabi et al., 2011; Tomlinson et al., 2013).

- (1) Consideration of the measurement properties and strengths and limitations of these instruments, including psychometric properties, sensitivity to change, and the availability of normative values to aid interpretation, combined with practical issues, such as respondent burden and availability of the measure in multiple languages, should guide decisions about the feasibility and usability of a measure for specific clinical or research purposes.
  - (2) Based on its sound psychometric properties, flexibility, and precision, the PROMIS (Patient-Reported Outcome Measurement Information System) instrument is recommended for fatigue measurement (Barsevick et al., 2013; Shaw et al., 2018). PROMIS measures are available for children (and parent proxies) and adults as short forms developed using item-response theory and as item banks for computerized adaptive testing.
4. NCCN (2022) guidelines recommend CRF assessment as a two-tiered approach. Patients should be screened for fatigue. Fatigue should be assessed quantitatively on a 0–10 scale if present. Patients who score 4 or higher should be further evaluated with a history and physical examination.
- a) A detailed history includes the presence, intensity, and pervasiveness of fatigue, its course over time, the factors that exacerbate or relieve fatigue, the effectiveness of the self-management interventions the patient has tried for fatigue, and the impact of fatigue on functioning and level of distress.
  - b) A complete review of systems should be performed.
  - c) Etiologic, potentiating, or predisposing factors that may contribute to CRF and which may be treatable should be evaluated. These factors include hypothyroidism, hypogonadism, adrenal insufficiency, cardiomyopathy, pulmonary dysfunction, anemia, neutropenia, cachexia, sleep disturbance, fluid and electrolyte imbalances, emotional distress, and uncontrolled concurrent symptoms (Alesi & del Fabbro, 2014; Berger et al., 2013; Bower, 2019; Koornstra et al., 2014; Kumar et al., 2018; Ma et al., 2020; Neeffes et al., 2013; Penson et al., 2021; Thong et al., 2020; Wang & Woodruff, 2014).

d) Evaluation should also include whether disease progression or recurrence could be among the causes of fatigue.

e) The medication profile should be reviewed to identify specific classes of medications that have fatigue as a potential side effect (e.g., over-the-counter medications). Polypharmacy is common in patients with cancer and has been associated with fatigue (Turner et al., 2016). Many drugs (e.g., antihistamines, beta-blockers) alone or in combination may significantly compound fatigue (Savard et al., 2015; Wang et al., 2014; Zlott & Byrne, 2010; see Table 23-1).

f) Other components of a comprehensive fatigue evaluation

- (1) Nutritional and metabolic evaluation: Improving dietary intake with appropriate caloric intake can often improve fatigue symptoms. Fluids and electrolytes should be assessed. Specifically, imbalances in sodium, potassium, calcium, and magnesium can be reversed with appropriate supplementation, which may improve fatigue (David et al., 2021; Inglis et al., 2019; NCCN, 2022).

- (2) Evaluation for symptoms such as nausea and vomiting, taste changes, bowel changes (e.g., obstruction, constipation, diarrhea), shortness of breath, pain, and sleep disturbances, individually or in symptom clusters, which may amplify fatigue (Charalambous et al., 2019; Kwekkeboom, 2016)

- (3) Physical activity level

#### E. Collaborative management

1. Treatable causes of fatigue should be screened for and managed, including concurrent distressing symptoms, physical deconditioning, endocrinopathies, emotional distress, and sedation secondary to specific medication classes.
  2. Across tumor types and at different places on the cancer continuum, the accumulated evidence strongly supports exercise as an intervention to manage CRF (Batalik et al., 2021; Capozzi et al., 2016, 2021; De Lazzari et al., 2021; Dun et al., 2020; Jiang et al., 2020; Kelley & Kelley, 2017; Nadler et al., 2019; NCCN, 2022; Song, Wang, Wang, Hong, et al., 2021; Vannorsdall et al., 2021; Wagoner et al., 2021).
- a) All patients with cancer should be encouraged to maintain an optimum level of physical activity during and following cancer treatment. Exercise improves aerobic capacity, prevents muscle loss and deconditioning, and may favorably affect sleep quality, psychological stress, mood, and

**TABLE 23-1.** Drug Classifications and Pharmacologic Agents Associated With Fatigue

| Drug Classification               | Examples                                                                                          | Potential Adverse Effects                     |
|-----------------------------------|---------------------------------------------------------------------------------------------------|-----------------------------------------------|
| Anticholinergics                  | Oxybutynin, tolterodine, trospium chloride                                                        | Fatigue, sedation                             |
| Anticonvulsants                   | Carbamazepine, gabapentin, pregabalin                                                             | Sedation, daytime sleepiness                  |
| Antidepressants                   | Paroxetine, sertraline                                                                            | Sedation, daytime sleepiness                  |
| Antiemetics                       | Haloperidol, metoclopramide, prochlorperazine, scopolamine                                        | Sedation, daytime sleepiness                  |
| Antihistamines                    | Diphenhydramine, hydroxyzine                                                                      | Sedation, daytime sleepiness                  |
| Anxiolytics, sedatives, hypnotics | Alprazolam, chloral hydrate, chlordiazepoxide, clonazepam, diazepam, doxepin, lorazepam, zolpidem | Sedation, daytime sleepiness                  |
| Barbiturates                      | Phenobarbital, secobarbital                                                                       | Sedation, daytime sleepiness                  |
| Beta-blockers                     | Atenolol, carvedilol, metoprolol                                                                  | Bradycardia                                   |
| Cannabinoids                      | Dronabinol, nabilone                                                                              | Sedation, daytime sleepiness                  |
| Corticosteroids                   | Dexamethasone, prednisone                                                                         | Sleep disturbances, proximal muscle weakness  |
| Hormone anticancer treatments     | Androgen deprivation therapy, aromatase inhibitors, selective estrogen receptor modulators        | Sarcopenia, fatigue, muscle weakness          |
| Opioid analgesics                 | Codeine, fentanyl, hydrocodone, hydromorphone, methadone, morphine, oxycodone                     | Sedation, daytime sleepiness                  |
| Skeletal muscle relaxants         | Baclofen                                                                                          | Sedation, daytime sleepiness, muscle weakness |

Note. Based on information from Savard et al., 2015; Wang et al., 2014; Zlott & Byrne, 2010.

- quality of life (Christensen et al., 2018; Nadler et al., 2019; Zyzniowska-Banaszak et al., 2021).
- b) Exercise may also favorably affect inflammation, the hypothalamic-pituitary-adrenal axis, circadian rhythm dysregulation, serotonin dysregulation, and alterations in adenosine triphosphate and muscle metabolism (Serdà i Ferrer et al., 2018).
  - c) Exercise intensity, frequency, and activity need further study to determine the most beneficial program for each individual and stage of disease (Sheill et al., 2018). Referral for structured rehabilitation may be helpful and is an effective intervention for CRF (Mitchell et al., 2014; NCCN, 2022).
  - d) National guidelines recommend that patients aim for at least 150 minutes of moderate-intensity physical activity (e.g., brisk walking, bicycling, swimming, deep water walking/running) each week and include strength training (all major muscle groups, 10 repetitions, 1–3 sets per exercise) twice weekly (Centers for Disease Control and Prevention, 2022).
  - e) Other types of physical activity can also be incorporated, including yoga, Pilates, tai chi, or organized sports.
  - f) Referrals to community-based exercise programs, comprehensive rehabilitation programs, or an exercise professional (e.g., physical therapist, exercise trainer, physiatrist) should be provided (Stout et al., 2019, 2021).
  - g) Although exercise programs are generally safe and well-tolerated across many types of cancer and stage along the continuum, these programs must be undertaken with caution and only after medical clearance, especially for patients with bone metastasis, immunosuppression, fever, thrombocytopenia, anemia, or peripheral neuropathy. Those at risk for falls or experiencing treatment complications should also proceed with caution (Schmitz et al., 2019, 2021). Models of care to support clinicians in providing physical activity recommendations to all patients during and following cancer treatment are beginning to emerge (Butts et al., 2021).
  - h) Medical clearance should be obtained prior to initiating an exercise program for patients with osteoporosis, bone metastases, neuropathy, neurologic disorders, weakness, cardiopulmonary dysfunction, arrhythmia, chest pain, shortness of breath, peripheral edema, or history of coronary

- artery disease. Compromised immunity requires clearance before using public gyms or pools. Patients with tunneled or peripherally inserted central venous catheters must avoid swimming.
- i) Programs should be initiated slowly to assess tolerance and can be modified or advanced as patient condition changes (NCCN, 2022). Walking, cycling, swimming, and resistance training have been evaluated and are appropriate modalities for patients. Programs that are too vigorous may increase fatigue.
  - j) Mobile health tools, such as activity monitors, smartphone applications, and social media websites, may strengthen motivation and adherence (Ester et al., 2021).
  - k) Relative contraindications to exercise include nonhealed surgical wounds, extreme fatigue, severe anemia, ataxia, and acute arm or shoulder problems (e.g., lymphedema [avoid upper body exercises]).
  - l) Patients should stop an exercise program and contact a member of the healthcare team if they experience dizziness, blurred vision, fainting, sudden onset of nausea or vomiting, unusual or sudden shortness of breath, irregular heart-beat, palpitations, chest pain, leg/calf pain, bone or joint pain, muscle cramping, or sudden onset of muscle weakness. During and in the period immediately following the conclusion of treatment, patients should be encouraged to exercise with a partner, caregiver, or exercise professional for safety reasons.
3. A meta-analysis of randomized controlled trials found yoga to be effective in reducing fatigue, particularly in breast cancer survivors (Dong et al., 2019; Hall et al., 2021; Lin et al., 2018; Liu et al., 2021; O'Neill et al., 2020; Song, Wang, Wang, Li, et al., 2021). However, systematic reviews have concluded that due to a high risk of bias in studies, the effectiveness of yoga on fatigue outcomes has not been sufficiently established as effective in reducing fatigue across a wide range of patient populations or at all points in the cancer continuum (Carlson et al., 2017).
  4. Tai chi and qigong have shown beneficial effects on fatigue outcomes in randomized clinical trials; however, study results should be interpreted cautiously due to heterogeneous study quality and high risk of bias (Hilfiker et al., 2018; Liu et al., 2021; Xiang et al., 2017; Yang et al., 2021; Zeng et al., 2014).
  5. Structured rehabilitation improves fatigue outcomes, particularly in cancer survivors (Hunter et al., 2017; Wirtz & Baumann, 2018). The rehabilitation interventions tested were generally multicomponent interventions that included exercise, psychoeducational support, mind-body therapies, and physical modalities (e.g., manual lymph drainage).
  6. Consistent evidence supports psychoeducational interventions to improve fatigue outcomes (Bennett et al., 2016; Hilfiker et al., 2018; Howell et al., 2017; Pearson et al., 2018; Poort et al., 2017; Ream et al., 2020; Sadeghi et al., 2016; Seiler et al., 2017; Tuominen et al., 2019).
    - a) Effective psychoeducational interventions include anticipatory guidance about patterns of fatigue, counseling and supportive psychotherapy, cognitive behavioral therapy (CBT), care coordination, and recommendations for energy conservation and self-management (e.g., exercise, lifestyle changes to improve sleep quality). The additions of coaching, praise, and encouragement augment feelings of control and promote self-efficacy.
    - b) CBT approaches (with or without hypnosis) for fatigue, depression, and pain are generally promising for the relief of CRF in patients with various cancers during and following treatment (Arring et al., 2019; Carlson et al., 2017; Cramer et al., 2015; David et al., 2021; Kwekkeboom, 2016; Kwekkeboom et al., 2018; Müller et al., 2021).
    - c) Energy conservation can balance rest and activity so that valued activities can be maintained (NCCN, 2022). This is a learned process for patients and is dictated by the disease experience.
      - (1) Instruct patients to delegate activities, pace themselves, take extra rest periods, plan high-energy activities at peak energy, and conserve energy for valued activities (NCCN, 2022).
      - (2) Recommend energy-saving devices (e.g., raised toilet seats, grabber tools, seated walkers, wheelchairs).
  7. Interventions designed to improve the management of concurrent symptoms (e.g., pain, depression, shortness of breath) have demonstrated an impact on fatigue outcomes. Evidence suggests that routine symptom monitoring alone, or in conjunction with an advanced practice registered nurse intervention and symptom-focused palliative and supportive care interventions, are efficacious approaches to manage CRF (de Raaf, de Klerk, Timman, et al., 2013; Kao et al., 2014; Klafke et al., 2019; Lizán et al., 2021; Yen-nurajalingam et al., 2011).
  8. CBT for insomnia to optimize sleep quality has decreased CRF (Dun et al., 2021; NCCN, 2022).
    - a) This intervention can be delivered individually, in a group setting, or via the internet (Büttner-Teleagă et al., 2021).
    - b) CBT for insomnia may take several weeks of steady practice to become fully effective and

usually requires four to eight 30-minute sessions with a behavioral sleep therapist, such as a nurse, psychologist, or other professional.

c) Components of CBT for insomnia

- (1) Stimulus control: Go to bed only when sleepy, use bed/bedroom for sleep and sexual activities only, and maintain a consistent presleep routine and time to lie down and get up.
  - (2) Sleep consolidation: Limit the amount of time in bed, including naps.
  - (3) Sleep hygiene: Avoid caffeine late in the day and provide a comfortable sleep environment to promote a good night's sleep.
  - (4) Intervention components also include relaxation training and strategies to reduce cognitive emotional arousal (e.g., reserving at least an hour to relax before bed, establishing a presleep routine).
9. Meditation, mindfulness-based stress reduction, and cognitive behavioral stress management, including internet-based interventions, can improve fatigue severity and fatigue-related daytime interference during and following cancer treatment (David et al., 2021; Haller et al., 2017; He et al., 2020; NCCN, 2022; Schell et al., 2019; Toivonen et al., 2017; Wyatt et al., 2021; Xie et al., 2020; Zhang et al., 2019).
  10. Progressive muscle relaxation with or without imagery, relaxation breathing, coping skills training, and distraction delivered in a series of sessions have demonstrated effectiveness in improving fatigue outcomes (Carlson et al., 2017; Hilfiker et al., 2018).
  11. Bright-light therapy has been shown in several controlled trials to prevent deterioration in CRF during treatment (Hung et al., 2021; Xiao et al., 2022) and in cancer survivors after treatment (Johnson et al., 2018). The underlying mechanism of action remains an area of active research and may include protecting recipients from circadian rhythm desynchronization (Johnson et al., 2020) and improving depression (Kronish et al., 2020). Trials of this promising therapy are ongoing and employing more rigorous and reproducible study designs.
  12. Evidence for the effectiveness of acupuncture, acupressure, self-acupuncture, and electroacupuncture in reducing CRF has been summarized in nearly a dozen meta-analyses and systematic reviews (Arring et al., 2019; Han et al., 2021; Hsieh et al., 2021; Jang et al., 2020; Tan, Wang, et al., 2021; Wu et al., 2019; Zhang et al., 2018). Although most of these reviews concluded that acupuncture and acupressure interventions are beneficial, acceptable, and well-tolerated, the authors drew somewhat conflicting conclusions about whether these interventions were ready for translation into practice. All have urged additional studies using rigorous trial designs.
  13. Complementary and integrative therapies, including polarity therapy (energy therapy), moxibustion (heat therapy), healing touch, Reiki, reflexology, and massage, may improve CRF (Ben-Arye et al., 2018; Carlson et al., 2017; David et al., 2021; Hilfiker et al., 2018; Mao et al., 2016; Wang et al., 2021; Wyatt et al., 2021). Continued study of these potentially promising interventions with longer follow-up and active control conditions is warranted. Complementary and integrative medicine strategies are well-tolerated and may be particularly useful when other methods are contraindicated or infeasible. They can also be considered to augment different treatment approaches for fatigue, such as yoga, relaxation, or CBT.
  14. Because the exact pathophysiology of CRF is obscure and multifactorial, pharmacotherapy is empiric or geared toward reversing possible contributing factors, such as anemia, poor nutrition, or depression (Belloni et al., 2021; Chow et al., 2021; Inglis et al., 2019; Klasson et al., 2021; Sun et al., 2021).
    - a) Although data from several systematic reviews suggest that patients receiving recombinant human erythropoietin to correct anemia less than 10 g/dl may experience increased vigor and diminished fatigue, only limited evidence suggests erythropoiesis-stimulating agents improve fatigue when anemia is less severe (Bohlius et al., 2019). Importantly, erythropoiesis-stimulating agents to manage fatigue cannot be recommended because of safety issues (Aapro et al., 2018; Schoen et al., 2020). National clinical practice guidelines should weigh risks and benefits and guide the management of patients receiving these agents (Bohlius et al., 2019; Gawade et al., 2017; NCCN, 2021).
    - b) Antidepressants have been recommended to treat fatigue, particularly when depression is suggested as a causal factor. Although drugs such as paroxetine, bupropion, and venlafaxine may help alleviate depression, studies have not consistently demonstrated a clinically significant benefit to their use compared to placebo in nondepressed patients with fatigue, and they are not explicitly recommended to lessen fatigue (Chow et al., 2021; Klasson et al., 2021; Mitchell et al., 2014; Mücke et al., 2016; NCCN, 2022; Sun et al., 2021). Small trials have shown a trend toward a possible benefit for antidepressant agents in treating fatigue in women experiencing hot flashes and patients receiving interferon alpha.

- c) Several systematic reviews produced preliminary evidence suggesting that psychostimulants (e.g., methylphenidate, dexamethylphenidate, modafinil) may help treat fatigue (Belloni et al., 2021; Qu et al., 2016; Sun et al., 2021). However, given the mixed evidence for efficacy and concern about the potential for side effects (e.g., headache, insomnia, agitation, anorexia, nausea, vomiting, dry mouth), the use of these agents outside the context of a clinical trial has been discouraged (Barton, 2014; Ruddy et al., 2014).
- d) Corticosteroids (e.g., prednisone, dexamethasone) have short-term efficacy in ameliorating CRF. Given the potentially detrimental side effects of muscle wasting and infection with long-term use, it is difficult to draw definitive conclusions about their risk–benefit profile (Klasson et al., 2021).
- e) Megestrol acetate is widely used for appetite improvement, and its safety and efficacy have been confirmed in treating cancer cachexia. However, a meta-analysis of the four trials that compared progestational steroids with placebo found no difference in the two arms for reducing CRF (NCCN, 2022; Payne et al., 2012).
- f) Although male hypogonadism is thought to be a contributor to fatigue (Vigano et al., 2010), a blinded, placebo-controlled trial of testosterone replacement in a small sample of men with advanced cancer did not improve fatigue end points (Del Fabbro et al., 2013).
- g) Thyrotropin-release hormone improved fatigue outcomes in a small, randomized, placebo-controlled crossover pilot study in eight patients with cancer and significant fatigue (Kamath et al., 2012).
- h) Targeted anticytokine therapy (e.g., etanercept, infliximab) may have favorable effects on CRF (Monk et al., 2006; Tookman et al., 2008); however, small sample sizes and the use of nonrandomized study designs that limit the strength of the conclusions that can be drawn about the efficacy of these therapies in treating CRF.
- i) Wisconsin, Asian, and fermented red ginseng extract have effectively improved fatigue outcomes in patients during and following cancer treatment (Arring et al., 2018, 2019; Inglis et al., 2019). The optimal dose and duration of these treatments are unknown (Lemke, 2021). Possible drug–drug interactions must also be considered (Choi & Song, 2019).
- j) Several nutritional and herbal supplements (e.g., guarana, essiac, valerian, vitamin supplements, zinc, levocarnitine, coenzyme Q10,

mistletoe extract, melatonin) and combined modality interventions that incorporate several complementary therapies (e.g., megestrol acetate, omega-3 fatty acid supplementation) have been evaluated with mixed evidence for efficacy (Inglis et al., 2019; Marx et al., 2017; NCCN, 2022; Sun et al., 2021). Interpretation of the study outcomes in these trials is limited by small sample sizes and the predominant use of single-arm, open-label study designs (Klasson et al., 2021).

#### F. Principles of patient and family education and care planning

1. Management of fatigue originates with the primary oncology team assessing fatigue as a symptom related to treatment and disease status. Begin with an initial screening and expand to a more focused evaluation for moderate and higher levels of fatigue (NCCN, 2022).
2. Inform patients and family members that fatigue is a significant symptom of the disease and the treatment process. Patterns are variable and do not necessarily indicate treatment failure or disease progression. Discuss multifactorial causes of fatigue, including psychosocial stressors, concurrent symptoms, sleep disturbances, muscle weakness and deconditioning, sedating side effects of medications, and proinflammatory cytokine release. Clarify effective interventions to manage fatigue and create an individualized and multicomponent treatment plan (Lacourt et al., 2020; Martin et al., 2021).
3. Daily self-monitoring of fatigue levels in a log or diary can be helpful (NCCN, 2022). Encourage patients to differentiate facets of the fatigue experience (e.g., fatigue, tiredness, weakness, cognitive slowing) and document the use and effectiveness of self-management interventions (e.g., exercise, sleep, progressive muscle relaxation, meditation).
4. Offer anticipatory guidance about possible patterns of when fatigue may develop or worsen, including at the time of white blood cell nadir, when radiation therapy concludes, and in association with demanding physical activity, impairments in sleep quality, psychological stress, and concurrent symptoms.
5. Develop and tailor an individualized plan for fatigue management that considers factors that may influence specific fatigue management interventions (Charles et al., 2021).
6. Inform patients and family that interventions such as energy conservation, exercise, relaxation and stress management, psychosocial support, and measures to optimize sleep quality and reduce concurrent symptoms can be effective in limiting the severity of fatigue during treatment.

7. Teach energy conservation strategies and other fatigue self-management techniques. Provide coaching to enhance self-efficacy for fatigue management and discern ways to integrate these techniques into daily life.
8. Provide information concerning the importance of a balanced diet with adequate intake of fluid, calories, protein, carbohydrates, fat, vitamins, and minerals (NCCN, 2022).
9. Instruct patients about implementing a balanced exercise program (e.g., walking, stretching, strength training). Encourage patients to continue normal activities and to remain as active as possible during treatment. Following treatment, the exercise program should be advanced as tolerated, gradually building up the length and intensity of physical activity to meet national guidelines of at least 150 minutes of moderate-intensity physical activity each week. Offer referrals to exercise professionals and community-based exercise programs.
10. Offer information and referrals to counseling or a support group (in person or online). Supportive expressive therapies, counseling, and journal writing may serve as emotional outlets and avenues for support and encouragement (NCCN, 2022). Oncology nurses frequently provide this one-on-one education and support for the patient.
11. Care planning
  - a) Causes of CRF are often overlapping and may evolve across the cancer continuum from diagnosis to treatment to survivorship or end of life. Therefore, intervention approaches are symptom oriented and individualized (Chartogne et al., 2021).
  - b) The care plan should be regularly revised based on goals, preferences, response, and tolerance.
  - c) A multimodal approach that includes exercise, psychoeducational interventions, management of concurrent symptoms, and efforts to improve sleep quality, combined with judicious use of complementary therapies, such as relaxation, massage, acupuncture, or bright light therapy, offers the greatest likelihood of success and is consistent with evidence-based guidelines from the Oncology Nursing Society (Mitchell et al., 2014), International Late Effects of Childhood Cancer Guideline Harmonization Group (Christen et al., 2020), American Society of Clinical Oncology (Bower et al., 2014), and NCCN (2022).
  - d) Consideration may be given to a trial of antidepressants, psychostimulants, wakefulness-promoting agents, corticosteroids, or ginseng in specific clinical circumstances.

## CHAPTER 24

# Neurologic Toxicities

### A. Overview

1. *Neurotoxicity* refers to an injury to the brain and spinal cord (central nervous system [CNS]) or the peripheral nervous system (nervous system outside of the brain and spinal cord) caused by exposure to natural or manufactured toxic substances.
2. Cancer therapies can induce a range of toxic side effects (see Table 24-1) on nervous tissue, resulting in significant morbidity and mortality, which may persist beyond the treatment period.
3. Neurologic toxicity from cancer therapies is a common problem for patients and second only to myelosuppression as a root cause of dose modification or discontinuation (Dietrich, 2020).
4. Besides this potential to limit the overall efficacy of the cancer treatment, neurologic sequelae have become some of the most important challenges in patient survivorship (Wick et al., 2016).
5. Neurotoxicity presents most frequently as fatigue and peripheral neuropathies (see Table 24-2), although many clinical symptoms have been reported.
6. Acute toxicities (e.g., seizure), encephalopathy, and cerebrovascular events (e.g., thromboembolic stroke, hemorrhage) require immediate intervention.
7. Therefore, oncology nurses must regularly assess for and recognize early neurotoxicity to allow for rapid diagnosis, treatment, and dose adjustment to mitigate the risk of irreversible neurologic impairment.

### B. Radiation-induced CNS toxicity

1. Neurotoxicity is often the result of the synergistic effects of concurrent chemotherapy and radiation.
2. General neurotoxicities
  - a) Overview
    - (1) Direct or ancillary exposure of nervous tissue to radiation therapy carries a risk of neurologic injury.
    - (2) General neurotoxicities result from permeating injury to brain tissue with accompanying nonspecific symptoms,

such as headache, fatigue, and nausea (Rahman et al., 2020; Tanguturi & Alexander, 2018).

#### b) Pathophysiology

- (1) Radiation delivered to the entire brain (i.e., whole-brain radiation therapy), partial brain radiation therapy, or targeted radiation therapy (e.g., stereotactic radiosurgery, Gamma Knife®) causes irreversible injury to brain tissue that frequently results in the death of healthy brain tissue as well as tumor tissue (Ai et al., 2020).
- (2) Swelling of the brain and meninges following radiation can further potentiate injury, and this edema often is the root cause of acute neurotoxicity. Delayed neurotoxicities are frequently attributed to demyelination or vasculopathy (Stubblefield, 2017b).

#### c) Incidence

- (1) Radiation therapy is often synergistic with chemotherapy but carries an independent risk of neurotoxicity.
- (2) Incidence and severity vary according to multiple factors, including radiation dose and type, treatment sites, and body mass index.

#### d) Clinical manifestations

- (1) Neurologic sequelae often are described temporally to the administration of radiation therapy as acute (during or immediately after treatment), early-delayed (weeks to months following treatment), and late-delayed (months to years following treatment) (Rahman et al., 2020; Schiller et al., 2017).
- (2) Acute through early-delayed symptoms are generally reversible and include headache, fatigue, nausea, irritability, somnolence, and encephalopathy. They may be associ-

**TABLE 24-1.** Central Neurotoxicity in Chemotherapy, Immunotherapy, and Targeted Therapies

| Adverse Effect                                                                           | Signs and Symptoms                                                                                                                                                       | Reported Agents                                                                                                                                                                                                                                                                                                                                                                                                     | Potential Treatment                                                                                                                                                                                |

Note. Based on information from AstraZeneca Pharmaceuticals, 2021; Bayer HealthCare Pharmaceuticals, 2021; Bristol-Myers Squibb, 2021b, 2021c; Cintrón-García & Guddati, 2020; Dietrich, 2020; EMD Serono, 2021; Genentech, 2021; Haugh et al., 2020; Juno Therapeutics, 2021; Kite Pharma, 2021a, 2021b; Merck, 2021; Novartis Pharmaceuticals, 2021; Pfizer, 2021a, 2021b; Pinner & Tierney, 2020; Regeneron Pharmaceuticals, 2021; Stone & DeAngelis, 2016; Wick et al., 2016; Y-mAbs Therapeutics, 2020; Zukas & Schiff, 2018.

ated with fever, vomiting, drowsiness, and exacerbation of focal deficits (Rahman et al., 2020; Smart, 2017; Tanguturi & Alexander, 2018).

- (3) Delayed neurotoxicity from radiation therapy is usually progressive and irreversible. Sequelae can include leukoencephalopathy, necrosis, cystic degeneration, hydrocephalus, cerebrovascular events such as infarct or hemorrhage, radiation-induced tumors, parenchymal calcifications, brain atrophy, and cognitive impairment (Rahman et al., 2020; Turnquist et al., 2020).

e) Assessment

- (1) Diagnosis is typically by patient self-report of symptoms.
- (2) Careful neurologic assessment may reveal focal deficits or altered mental status and encephalopathy.
- (3) Leukoencephalopathy, cystic degeneration, hydrocephalus, cerebrovascular events, second tumors, and parenchymal calcifications are usually seen radiographically; however, a surgical biopsy may be required to achieve the final diagnosis.

f) Collaborative management

- (1) Limited literature shows promising evidence for using lithium as a prophylactic measure to prevent radiation-induced cell death (Turnquist et al., 2020).

- (2) Treatment for acute toxicity includes careful planning and directed pharmacologic intervention (e.g., steroids for swelling, antiemetics for nausea and vomiting).

- (3) For delayed toxicities, preliminary evidence in animal studies supports using renin-angiotensin system blockers to decrease the inflammatory process and subsequent cell injury induced by radiation therapy (Turnquist et al., 2020).

- (4) Other late toxicities often require surgical intervention, such as hydrocephalus, cerebrovascular events, and the development of radiation-induced tumors.

- (5) For other types (e.g., brain atrophy, cognitive impairment, parenchymal calcifications), no treatment options may be available.

3. SMART syndrome (stroke-like migraine attacks after radiation therapy)

- a) Overview: SMART syndrome is a delayed neurotoxic effect occurring anywhere from 1 to 37 years following radiation treatment to the brain (Dominguez & Malani, 2021; Singh et al., 2017).

b) Pathophysiology

- (1) The etiology is uncertain, but conflicting evidence suggests SMART syndrome is caused by neuronal dysfunction or cerebral vascular pathology (Singh et al., 2017).

<sup>a</sup>To date, peripheral neuropathy has not been reported with chimeric antigen receptor T cells.

<sup>b</sup>This table may not be inclusive of all agents associated with neurotoxicity.

<sup>c</sup>Coasting refers to worsening of neuropathy signs or symptoms after drug discontinuation.

*Note.* Based on information from AstraZeneca Pharmaceuticals, 2021; Bristol-Myers Squibb, 2021a, 2021b, 2021c; Dietrich, 2020; EMD Serono, 2021; Genentech, 2021; Haugh et al., 2020; Ibrahim & Ehrlich, 2020; Karyopharm Therapeutics, 2020; Merck, 2021; Pellacani & Eleftheriou, 2020; Pfizer, 2021a, 2021b; Regeneron Pharmaceuticals, 2021; Stone & DeAngelis, 2016; Taillibert et al., 2016; Takeda Oncology, 2021; Truven Health Analytics, 2017; Wick et al., 2016; Zajackowska et al., 2019.

- (2) Some evidence suggests that the activation of the trigeminovascular system could play a significant role in SMART syndrome (Dominguez & Malani, 2021; Singh et al., 2017)
- c) Incidence: SMART syndrome is rare, but the condition is likely underreported.
- d) Clinical manifestations: Symptoms can include headache, focal neurologic deficits, drowsiness, altered mental status, and seizures (Dominguez & Malani, 2021; Lim et al., 2016; Singh et al., 2017; Stone & DeAngelis, 2016).

#### e) Assessment

- (1) Radiographic imaging, such as magnetic resonance imaging (MRI) with gadolinium, may help rule out other differential diagnoses (e.g., second mass, radiation necrosis), but findings are otherwise non-specific and nondiagnostic (Dominguez & Malani, 2021).
- (2) Diagnosis is achieved by the patient report of symptoms, treatment history, careful neurologic examination, and the elimination of organic causes (Dominguez &

Malani, 2021; Lim et al., 2016; Singh et al., 2017; Stone & DeAngelis, 2016).

f) Collaborative management

- (1) Antimigraine therapies (e.g., valproic acid) have been used with some success to prevent the onset of SMART syndrome (Stone & DeAngelis, 2016).
- (2) Recent literature also supports using antiseizure medications, calcium channel blockers, and steroids to control vaso-reaction responses (de Oliveira Franco et al., 2021; Dominguez & Malani, 2021; Jia et al., 2018; Patel et al., 2020).

4. Leukoencephalopathy

a) Overview

- (1) Leukoencephalopathy includes the toxicity of treatment caused by injury to white matter, specifically when the myelin sheaths that cover nerve fibers degenerate (Kanda et al., 2018).
- (2) It is a late effect characterized by white matter changes on MRI with or without variable neurocognitive changes.

b) Pathophysiology: The exact pathophysiology of leukoencephalopathy is unknown but globally attributed to injury of the brain parenchyma and small blood vessel damage (Kanda et al., 2018).

c) Incidence

- (1) The incidence of leukoencephalopathy varies widely (5.4%–92%) according to radiation dose and type, when imaging was obtained, and how the diagnosis was achieved (Cummings et al., 2016).
- (2) Subclinical cases (e.g., mild or no symptoms) may not be recognized or are unreported.

d) Clinical manifestations

- (1) Patients may report no symptoms or a range of minor symptoms (mild cognitive impairment) to a progressive cognitive decline, including dementia, altered consciousness, ataxia, focal deficits, balance issues, and seizure (Bargiotas et al., 2019; Taillibert et al., 2016).
- (2) Gait abnormalities and urinary incontinence are noteworthy to correlate with higher severity (Bompaire et al., 2018).
- (3) Recent evidence also suggests a direct correlation between visual and postural or balance deficits (Bargiotas et al., 2019).
- (4) Although acute white matter injury in the immediate aftermath of treatment can lead to headache, fever, vomiting, drowsiness, and encephalopathy, symptoms are

more commonly experienced one month to a year following radiation.

e) Assessment

- (1) Diagnosis is achieved radiographically with MRI, which typically shows deep and periventricular white matter abnormalities characterized by T2WI or FLAIR hyperintensities in the absence of focal lesions (Cummings et al., 2016; Kanda et al., 2018).
- (2) Additional findings may include cortical atrophy and dilated ventricles, as well as necrosis and demyelination, if tissue is obtained for biopsy (Kanda et al., 2018).

f) Collaborative management

- (1) No specific treatment exists for leukoencephalopathy.
- (2) The focus is on palliative support for clinical manifestations.

5. Radiation necrosis

a) Overview: For cancers requiring radiation therapy to the head, radiation necrosis is a form of delayed cell injury and death of healthy brain tissue that results in the formation of single or multiple nodules (Winter et al., 2019).

b) Pathophysiology

- (1) Radiation exposure provokes damage to the vascular endothelium in the noncancerous neural tissue surrounding the original tumor or surgical bed.
- (2) The initiation of inflammation response leads to cell apoptosis and small artery thrombosis, arterial occlusion, and eventually tissue death (Ali et al., 2019).

c) Incidence

- (1) Incidence varies widely (5%–26%) according to how radiation necrosis is defined and ultimately diagnosed, the type of radiation, and the presence of concurrent systemic agents (Vellayappan et al., 2018).
- (2) Importantly, emerging evidence suggests that the incidence of radiation necrosis has increased as concomitant immunotherapy (e.g., ipilimumab), select targeted agents (e.g., BRAF inhibitors), and steroid therapy have become more accepted treatment modalities (Colaco et al., 2016; Kim et al., 2017; Patel et al., 2016; Winter et al., 2019).

d) Clinical manifestations

- (1) Patients typically present months to years after radiation treatment with new onset of neurologic symptoms resulting from a mass effect of the necrotic tissue plug.
- (2) Symptoms include headache, focal neurologic deficits, seizures, and cognitive impairment (Vellayappan et al., 2018).

## e) Assessment

- (1) Diagnostics can include MRI, MR perfusion, MR spectroscopy, positron-emission tomography-computed tomography, and diffusion-weighted images (Kanda et al., 2018; Vellayappan et al., 2018).
- (2) These scans often show an enhancing mass radiographically indistinguishable from tumor recurrence or progression.
- (3) Biopsy or surgical resection is often required to determine whether the mass represents true tumor progression/recurrence or radiation necrosis (Ali et al., 2019; Vellayappan et al., 2018; Winter et al., 2020).

## f) Collaborative management

- (1) No approved treatment exists, although numerous off-label treatment modalities for radiation necrosis have been reported in the literature, including anticoagulation with heparin or warfarin, hyperbaric oxygen, focused interstitial laser therapy, and bevacizumab (Co et al., 2020; Vellayappan et al., 2018; Winter et al., 2020).
- (2) Of these, bevacizumab is the most supported in the literature. Therapies for the second effects of brain swelling include systemic steroids (Tanguturi & Alexander, 2018; Vellayappan et al., 2018).
- (3) Left untreated, radiation necrosis typically self-resolves.

## 6. Pseudoprogression

## a) Overview

- (1) Pseudoprogression occurs when a CNS-based tumor increases in size radiographically during or immediately (first few weeks to six months) following active treatment with radiation therapy alone or with a combination of radiation and immunotherapy (Yekula et al., 2020).
- (2) Although the appearance of pseudoprogression on MRI can be similar to radiation necrosis, time is the primary distinction; pseudoprogression occurs in the immediate aftermath of treatment, whereas radiation necrosis presents months to years following treatment.

## b) Pathophysiology: The mechanism by which pseudoprogression occurs is poorly understood but is thought to be a secondary effect of blood-brain barrier breakdown, which causes edema and increases the uptake of contrast material (Yekula et al., 2020).

## c) Incidence

- (1) The incidence of pseudoprogression varies widely based on how it is defined and

which diagnostics are used (e.g., Response Assessment in Neuro-Oncology and Response Evaluation Criteria in Solid Tumors), with reports specifying the overall incidence across all categories of solid tumors ranging from less than 10% to as high as 30% in patients with high-grade gliomas (Park et al., 2020; Thust et al., 2018).

- (2) More recently, pseudoprogression has also been reported with the use of targeted therapies and immunotherapies (e.g., immune checkpoint inhibitors) (Thust et al., 2018).

## d) Clinical manifestations: Typically, pseudoprogression is a treatment-related effect. It can only be seen radiographically, and patients often do not report symptoms.

## e) Assessment

- (1) The enhancing lesion is seen on MRI and often followed serially until resolution.
- (2) Emerging evidence shows that perfusion MRI with radiomics and advanced techniques, such as perfusion-weighted imaging, MR spectroscopy, and amino acid positron-emission tomography, can help distinguish pseudoprogression in patients (Elshafeey et al., 2019; Galdiks et al., 2017; Rahman et al., 2020; Thust et al., 2018).

## f) Collaborative management

- (1) No approved treatment exists for pseudoprogression, and in the absence of symptoms, patients typically only require surveillance with serial imaging until the condition self-resolves.
- (2) However, for patients reporting persistent symptoms, a biopsy is recommended, and supportive therapies mirror those for radiation necrosis (Tanguturi & Alexander, 2018).

## C. Radiation-induced peripheral nervous system toxicity: radiation fibrosis syndrome

1. Overview: Radiation fibrosis syndrome describes specific and late toxicity of radiation therapy that causes progressive fibrotic sclerosis to the musculoskeletal, soft, neural, and cardiopulmonary tissues within the irradiation field (Stubblefield, 2017b). Specific forms of radiation fibrosis are lumbosacral plexopathy and brachial plexopathy.

## a) Lumbosacral plexopathy is a rare but serious form of radiation fibrosis affecting the lumbar or sacral plexuses following radiation therapy for pelvic-area cancers (e.g., cervical).

- b) Brachial plexopathy occurs in patients who have had radiation therapy directed at the chest, axillary region, thorax, or neck (e.g., radiation therapy for breast cancer), injuring the network of nerves (brachial plexus) that innervate the sensorimotor function of the shoulder, arm, and hand.
  2. Pathophysiology
    - a) The pathologic mechanism is not fully delineated but involves capillary network/vascular disruption, vascular endothelial damage, and microvascular injury with subsequent tissue sclerosis, fibrosis, atrophy, and disruption of the extracellular matrix (Purkayastha et al., 2019).
    - b) Ultimately, radiation treatment can trigger the inflammatory process, leading to granulation tissue formation and the activation of the coagulation system (Clark, 2018).
  3. Incidence
    - a) Radiation fibrosis syndrome is a late (months to years following radiation therapy) and rare effect, with incidence varying according to the cancer, specific radiation therapy, and radiation dose (Clark, 2018; Purkayastha et al., 2019).
    - b) Its occurrence is probably underestimated because it is not commonly evaluated by radiation oncologists and symptoms often are overlooked or attributed to other causes.
  4. Clinical manifestations
    - a) Skin changes may be seen in the radiation field. Symptoms vary according to site.
    - b) In head and neck cancers, radiation fibrosis can cause the inability to fully open the mouth, swallowing difficulties, and associated speech pathologies (Stubblefield, 2017a).
    - c) Skin changes at the radiation site can include slower healing, changes in pigmentation, and photosensitivity (Clark, 2018).
    - d) In lung cancer, postradiation pulmonary fibrosis manifests as difficulty breathing, dry cough, fatigue, and inspirational pain, resulting in decreased oxygen levels (Purkayastha et al., 2019).
    - e) Symptoms of lumbosacral plexopathy typically include lower leg pain; reduced sensation; different degrees of weakness, paresis, or paralysis; and urinary or fecal incontinence in severe cases.
    - f) Numbness, weakness, pain, or abnormal sensations (e.g., tingling, burning) are often reported along the wrist, hand, arm, or shoulder in brachial plexopathy (Purkayastha et al., 2019; Stubblefield, 2017a).
  5. Assessment
    - a) Diagnosis is based on the report of symptoms in the context of time, location, and dose of radiation therapy.
    - b) Histopathologic evaluation of fibrotic masses, if present, can provide a definitive diagnosis.
  6. Collaborative management
    - a) Fibrosis is a permanent effect of radiation therapy. No cure exists; therefore, pretreatment prevention of radiation toxicities through external beam radiation therapy techniques (e.g., intensity modulated, image guided) is recommended (Purkayastha et al., 2019).
    - b) Traditional treatment consists of education, physical therapy, occupational therapy, orthotics, and medication to increase function, decrease sensory abnormalities, and protect from further injury (Stubblefield, 2017a).
    - c) Other recommended therapies include nonsteroidal anti-inflammatory drugs and muscle relaxants for muscle pain and spasms and nerve-stabilizing drugs for neuropathic symptoms (Purkayastha et al., 2019).
    - d) Emerging evidence supports angiotensin-converting enzyme inhibitors for patients with lung radiation fibrosis syndrome and tyrosine kinase inhibitors and corticosteroids for those with skin fibrosis (Purkayastha et al., 2019).
- D. Chemotherapy-induced CNS toxicity
  1. Fatigue
    - a) Overview
      - (1) Fatigue, the feeling of extreme tiredness, is the most common CNS complication of cancer therapies and is not agent specific (Wick et al., 2016).
      - (2) Cancer-related fatigue (CRF) is an adverse effect of traditional chemotherapy agents, radiation therapy, targeted agents, and immunotherapies, including chimeric antigen receptor (CAR) T cells (Wick et al., 2016; Zhu et al., 2016; see Chapter 23).
    - b) Pathophysiology
      - (1) CRF occurs as either a direct effect of the cancer therapy itself (e.g., anemia, hormone changes) or an indirect effect through reactions with the immune system, specifically the release of cytokines (Cohen et al., 2019).
      - (2) Literature further suggests interdependent relationships and shared mechanisms with the greater disease process, as well as a patient's innate stress and coping responses (e.g., depression, anxiety) (Lacourt & Heijnen, 2017; Poort et al., 2020).
    - c) Incidence
      - (1) The incidence of CRF varies widely according to cancer diagnosis, disease

phase, and treatment modality, with patients with advanced cancer and those receiving anticancer therapies having the highest prevalence rates at greater than 60% (Al Maqbali et al., 2021).

- (2) Symptoms of CRF persist throughout cancer therapy and can last for up to two years post-treatment (Cohen et al., 2019).

d) Clinical manifestations

- (1) Patients with CRF commonly describe themselves as weak, tired, exhausted, slow, having no energy, feeling worn out, or unable to perform activities.
- (2) Severity of symptoms can vary throughout the course of treatment.

e) Assessment: CRF is a self-perceived symptom identified by patients. It may be assessed clinically using a validated patient-reported outcome measure, such as unidimensional or multidimensional tools (Mohandas et al., 2017).

f) Collaborative management

- (1) Acute fatigue management focuses on identifying associated target factors, such as anemia, depression, alterations in mood, or sleep disturbances.
- (2) Cognitive deficits, such as attention and memory issues, are strongly associated with fatigue severity, especially in breast cancer survivors (Cohen et al., 2019).
- (3) Effective strategies for reducing CRF include exercise, good nutrition, friend and family support, adequate rest, and purposeful relaxation (Mohandas et al., 2017; O'Regan et al., 2019).

## 2. Acute or chronic encephalopathy

a) Overview

- (1) *Encephalopathy* is a general term referring to a syndrome of overall brain dysfunction that commonly manifests as confusion and altered mental status. Encephalopathy may be acute or chronic.
- (2) The permeating symptom of all forms of encephalopathy is varying levels of altered mental status.
- (3) The exact pathologic mechanisms vary according to the agent and subtype of encephalopathy. Progressive multifocal leukoencephalopathy, for example, results from opportunistic infection in the setting of an immunocompromised host.
- (4) Toxic leukoencephalopathy is an encephalopathy specifically of white matter resulting from exposure to antineoplastic therapies or other toxic agents. In addition to treatment temporality (acute vs. chronic), specific types of toxic leukoencephalopathy are further distinguished by stability (e.g., reversible vs. permanent).

tion to treatment temporality (acute vs. chronic), specific types of toxic leukoencephalopathy are further distinguished by stability (e.g., reversible vs. permanent).

b) Acute encephalopathy

- (1) Acute encephalopathy emerges within a few hours or days after chemotherapy administration, often resolves spontaneously with complete recovery after discontinuation of the agent, and rarely confers long-term sequelae such as epilepsy (Fischer & Schmutzhard, 2017).
- (2) Acute encephalopathy is commonly associated with alkylating agents, antimetabolites, antihormonal agents, topoisomerase inhibitors, DNA-intercalating agents, antiangiogenic agents, and immunomodulatory agents (Dietrich, 2020). Specific agents such as methotrexate, ifosfamide, and cytarabine are highly associated with acute encephalopathy.
- (3) Acute encephalopathy can develop as a constellation of symptoms, including focal neurologic deficits, neurobehavioral problems, seizures, or alterations in consciousness.
- (4) Acute encephalopathy typically self-resolves with discontinuation of the agent.

c) Posterior reversible encephalopathy syndrome (PRES)

(1) Pathophysiology

(a) PRES is an acute leukoencephalopathy that occurs with multiple anticancer agents, particularly certain tyrosine kinase inhibitors (e.g., imatinib), as well as immunosuppressants (e.g., cyclosporine, tacrolimus) used for patients undergoing allogeneic stem cell transplant (Ridgeway et al., 2020). It also can occur in patients who have received CAR T cells.

(b) Other classes of chemotherapy agents have been associated with PRES, including platinum analogs (e.g., cisplatin, carboplatin), folate antagonists (e.g., methotrexate), antimetabolites (e.g., gemcitabine, 5-fluorouracil), vinca alkaloids (e.g., vincristine), and targeted agents (e.g., bevacizumab, ramucirumab, rituximab) (Cacho-Díaz et al., 2019; Dietrich, 2020; Janjua et al., 2017; Kaur et al., 2020; Singer et al., 2015).

- (2) Clinical manifestations
  - (a) Somnolence and lethargy are the first reported symptoms by patients (Janjua et al., 2017).
  - (b) The most common symptoms cited in the literature include headache, seizure, altered mental status (e.g., confusion), and visual changes ranging from blurred vision to cortical blindness (Janjua et al., 2017).
  - (c) Other symptoms associated with PRES include nausea, vomiting, and focal neurologic deficits.
  - (d) Hypertension is the most common condition associated with PRES, presenting in 6%–72% of cases (Janjua et al., 2017).
  - (e) It is thought that hypertension, impaired autoregulation, and hyperperfusion collectively play a part in the onset of PRES (Janjua et al., 2017).
  - (f) Status epilepticus, one of the most severe and life-threatening complications, can develop in 3%–13% of cases (Fischer & Schmutzhard, 2017).
- (3) Assessment: Radiographically, PRES is characterized by vasogenic edema throughout the brain.
- (4) Collaborative management
  - (a) Treatment is primarily supportive to reduce the severity of symptoms (e.g., analgesic for headache) and manage blood pressure.
  - (b) Magnesium levels should be monitored to prevent hypomagnesemia in patients with PRES (Fischer & Schmutzhard, 2017).
  - (c) Intensive care monitoring and treatment are indicated in 40% of cases for more severe complications, such as status epilepticus, intracranial hypertension, intracerebral hemorrhage, and cerebral ischemia (Fischer & Schmutzhard, 2017).
  - (d) Discontinuation of the drug is necessary to reduce the risk of progression to irreversible cytotoxic edema.
  - (e) Symptoms of PRES improve or dissipate entirely with drug discontinuation and supportive therapy in 84% of patients (Fischer & Schmutzhard, 2017).
  - (f) The mortality rate is 8%–19% (Kaur et al., 2020).
  - (g) Early recognition of symptoms is essential to prevent the development of serious complications.
- d) Encephalitis: Encephalitis, or autoimmune encephalitis, is an immune-related event in which severe brain inflammation occurs that can cause serious adverse effects.
  - (1) Pathophysiology
    - (a) Immune checkpoints, such as programmed cell death protein 1, programmed cell death-ligand 1, and cytotoxic T-lymphocyte antigen 4, are integral for preventing autoimmunity and are widely distributed throughout healthy tissues, including the CNS (Haugh et al., 2020).
    - (b) Immune checkpoint inhibitors block these pathways and can produce autoimmune toxicities in the CNS.
    - (c) A proliferation of lymphocytes, including T lymphocytes, has been demonstrated in the cerebrospinal fluid of individuals with autoimmune encephalitis from immune checkpoint inhibitors (Kopecký et al., 2018; Sanchis-Borja et al., 2020).
  - (2) Incidence: The incidence of immune checkpoint inhibitor-induced encephalitis is less than 1% (Xu et al., 2019); however, it is increasingly being reported in the literature as immune checkpoint inhibitors become part of the standard of care for many cancer types.
  - (3) Clinical manifestations
    - (a) Immune checkpoint inhibitor-induced encephalitis is associated with significant morbidity and a 13% mortality rate. It has been seen in the settings of melanoma, non-small cell lung cancer, and urinary malignancies (Marini et al., 2021).
    - (b) Immune checkpoint inhibitor-induced encephalitis can be difficult to recognize and should be considered when symptoms of CNS toxicity are present, such as mental status changes, mild fatigue, headache, fever, weakness, seizure, or neurologic deficits (Haugh et al., 2020).
    - (c) Immune checkpoint inhibitors, such as ipilimumab, nivolumab, pembrolizumab, cemiplimab, atezolizumab, avelumab, and durvalumab, have been associated with severe encephalitis (Marini et al., 2021).

- (d) In the case of melanoma, where immune checkpoint inhibitors are commonly used, autoimmune toxicity can cause CNS demyelination (Zukas & Schiff, 2018).
  - (e) Patients who have an autoimmune disorder, such as multiple sclerosis, can be at higher risk of relapse or worsening symptoms when receiving immune checkpoint inhibitors as part of cancer treatment and should be closely monitored (Haugh et al., 2020; Zukas & Schiff, 2018).
- (4) Assessment
- (a) Diagnosis is achieved with neurologic examination and the presence of abnormalities on MRI and in cerebrospinal fluid.
  - (b) On brain MRI, the most common abnormality is hyperintensity involving the medial temporal lobes (Haugh et al., 2020; Marini et al., 2021).
  - (c) Analysis of cerebrospinal fluid obtained from lumbar puncture demonstrates inflammatory alterations in 93% of patients and elevated protein and leukocytes (Marini et al., 2021).
  - (d) In metastatic cancer, immune checkpoint inhibitor-induced encephalitis is more challenging to diagnose due to other CNS effects of disease progression (Haugh et al., 2020).
- (5) Collaborative management
- (a) Early identification of the causative agent and appropriate management of symptoms are key to preventing adverse outcomes (Haugh et al., 2020).
  - (b) Current treatment consists of discontinuation of the drug, inpatient monitoring, and high-dose IV steroids (Marini et al., 2021).
  - (c) IV immunoglobulin or rituximab have also been used for severe or progressive symptoms of autoimmune encephalitis (Haugh et al., 2020).
  - (d) Literature suggests more data are needed to determine best practice recommendations for managing immune checkpoint inhibitor-induced encephalitis.
- e) Chronic encephalopathy
- (1) Chronic encephalopathy is typically observed more than six months post-treatment and even several years beyond treatment (Taillibert et al., 2016).
  - (2) It is generally irreversible and occasionally progressive. No cure or effective treatment exists for chronic encephalopathy.
  - (3) Clinical manifestations
    - (a) Patients usually report mild to moderate neurocognitive deficits, such as memory impairment or inability to focus. More severe symptoms, such as ataxia, urinary incontinence, and spasticity, correlate with more significant neurotoxicity.
    - (b) Chronic encephalopathy is frequently described as “chemobrain” or “chemo fog,” in which patients experience problems with memory function and multitasking. Chemobrain may reduce the ability to perform socially and professionally, decreasing quality of life (Dietrich, 2020).
    - (c) Some patients report no symptoms.
- f) Progressive multifocal leukoencephalopathy (PML)
- (1) Pathophysiology
    - (a) PML is a neuroinfectious disease-causing demyelinating injury to the CNS that can manifest during treatment or months to years following treatment with immunomodulatory therapy.
    - (b) PML is caused by reactivation of latent John Cunningham virus, a human polyomavirus that is normally innocuous and present in 50%–70% of healthy adults (Bohra et al., 2017).
    - (c) Treatment-related immunosuppression with brentuximab, rituximab, alemtuzumab, obinutuzumab, and ofatumumab therapy leads to lytic infection of CNS white matter with resultant demyelination (Bohra et al., 2017).
  - (2) Incidence
    - (a) The incidence of PML in the setting of hematologic malignancies is rare (0.07%).
    - (b) PML may be underreported given the challenges of achieving diagnosis (Bohra et al., 2017).
    - (c) However, with the increasing use of immunomodulatory therapies in

oncology, clinicians should be familiar with PML as a differential diagnosis.

(3) Clinical manifestation

(a) Patients should be monitored closely for CNS symptoms that could indicate encephalopathy.

(b) Symptoms can include hemiparesis, visual impairment, altered mental status, ataxia, dysmetria, dysarthria, headache, vertigo, seizures, sensory deficits, parkinsonism, aphasia, and neglect syndromes (Bohra et al., 2017).

(4) Assessment

(a) Diagnosis can be difficult, as the list of differential diagnoses is extensive (e.g., brain metastases, aseptic meningitis) but is typically achieved based on the report of symptoms, neurologic examination, and treatment context and timing.

(b) Because of the structural changes within white matter, PML can often be identified radiographically via MRI. A brain biopsy is required for a definitive diagnosis of PML.

(5) Collaborative management

(a) PML is untreatable, progressive, and nearly always fatal (90% fatality rate) (Bohra et al., 2017).

(b) The use of medications such as mefloquine (a drug used to treat malaria) and mirtazapine (inhibitor of serotonin 5-HT<sub>2A</sub> receptor) to treat PML remains investigational (Bohra et al., 2017).

### 3. Focal deficits

#### a) Overview

(1) Focal neurologic deficits are limited failures of neurologic function that affect a specific part of the body.

(2) Vision, speech, and hearing impairments during or immediately following cancer treatment are considered focal neurologic toxicities. Isolated sensory and motor losses are other examples.

#### b) Pathophysiology

(1) All focal nerve deficits originate from injury to the nerve, either as a direct result of chemotherapy or as a secondary effect (e.g., swelling).

(2) The exact pathogenesis of cranial nerve involvement is uncertain. Focal defi-

cits may also be a direct consequence of malignancy.

c) Incidence: Transient focal deficits are relatively common over the cancer trajectory and are sometimes difficult to attribute exclusively to cancer or its treatment.

#### d) Clinical manifestations

(1) Each cranial nerve operates a distinct neurologic function and can help localize neurotoxic injury (see Table 24-3).

(2) For example, double vision and oromandibular dystonia have been reported with capecitabine use and correlated with neurotoxic palsy of cranial nerve VI (Cengiz et al., 2018; Dasgupta et al., 2010).

(3) Literature suggests vision loss and visual-motor integration skill impairment with certain drugs (e.g., carmustine, fludarabine) (Pinner & Tierney, 2020).

(4) Ipilimumab, an immune checkpoint inhibitor, is known to cause optic neuritis and focal deficits in some patients (Zukas & Schiff, 2018).

(5) Carboplatin is known to cause ototoxicity in patients with neuroblastoma (Pinner & Tierney, 2020).

(6) Platinum-based agents can cause irreversible hearing impairment and tinnitus in 20%–40% of patients (Dietrich, 2020).

e) Assessment: Diagnosis is achieved with a careful neurologic examination.

f) Collaborative management: Treatment typically involves supportive therapy or, in severe cases, discontinuation of the agent.

### 4. Cerebellar syndrome

a) Overview: Neurotoxic injury to the cerebellum may result in cerebellar syndrome, characterized by ataxia, dysmetria, dizziness, nystagmus, and gait imbalance.

#### b) Pathophysiology

(1) Cerebellar syndrome has been reported as an acute to subacute event with traditional chemotherapy agents, including capecitabine, cytarabine (high dose), 5-fluorouracil, oxaliplatin, procarbazine, and vincristine.

(2) It is generally dose related and self-limiting, but 20%–30% of patients may experience permanent dysfunction secondary to loss of Purkinje cells in the cerebellum (Dietrich, 2020).

(3) Exact pathologic mechanisms vary according to the agent, but symptoms arise from loss or delay of nerve conduction through the cerebellum, which is

responsible for coordinating muscle activity and movement.

c) Incidence

- (1) Overall, the incidence of cerebellar syndrome is low, with variation by the agent.
- (2) Literature shows that high-dose cytarabine is the agent most associated with cerebellar syndrome, occurring in 10%–20% of patients receiving high-dose therapy (Dietrich, 2020).

d) Risk factors

- (1) CNS effects directly correlate with the degree to which a drug passes the blood–

brain barrier (Cintrón-García & Guddati, 2020).

- (2) Prior brain irradiation combined with other therapies can also lead to a greater risk of CNS toxicity (Cintrón-García & Guddati, 2020).
- (3) Several risk factors have been associated with the development of CNS toxicity, including concurrent or prior brain irradiation, older age, renal dysfunction, hepatic dysfunction, presence of comorbidities (e.g., hypertension, cardiovascular disease), and previous history of neurologic dysfunction (Dietrich, 2020).

**TABLE 24-3.** Focal Deficits Involving the Cranial Nerves

| Signs and Symptoms                                                                                               | Cranial Nerve | Name             | Origination    | Function                                                                                                                                                                           |
|------------------------------------------------------------------------------------------------------------------|---------------|------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Loss of smell (anosmia)                                                                                          | I             | Olfactory        | Olfactory bulb | Special sensory: smell                                                                                                                                                             |
| Visual disturbances; vision loss                                                                                 | II            | Optic            | Thalamus       | Special sensory: vision                                                                                                                                                            |
| Loss of pupillary light reflex; papilledema; ptosis; double vision (diplopia); blurry vision                     | III           | Oculomotor       | Midbrain       | Motor: eyeball movement; controls eyelid<br>Parasympathetic: pupil constrictor                                                                                                     |
| Diplopia; nystagmus                                                                                              | IV            | Trochlear        | Midbrain       | Motor: eyeball movement                                                                                                                                                            |
| Loss of sensations (see function column); difficulty chewing, abnormal jaw-jerk reflex                           | V             | Trigeminal       | Pons           | Motor: chewing muscles<br>Sensory: touch, pain, temperature, vibration for face, mouth, anterior two-thirds of tongue                                                              |
| Strabismus; nystagmus; diplopia                                                                                  | VI            | Abducens         | Pons           | Motor: eyeball movement                                                                                                                                                            |
| Facial paresis or plegia; loss of taste                                                                          | VII           | Facial           | Pons           | Motor: face muscles<br>Sensory: sense near ears<br>Special sensory: taste in anterior two-thirds of tongue                                                                         |
| Hearing loss; balance issues                                                                                     | VIII          | Auditory         | Pons/medulla   | Special sensory: hearing and balance                                                                                                                                               |
| Absent gag; impaired or absent swallow; loss of taste; loss of pharyngeal movement                               | IX            | Glossopharyngeal | Pons/medulla   | Motor: pharyngeal movement<br>Sensory: middle ear; pharynx, posterior one-third of tongue<br>Parasympathetic: parotid gland                                                        |
| Absent gag; impaired or absent swallow; loss of velar movement; loss of voice or hoarseness, dyspnea, dysarthria | X             | Vagus            | Medulla        | Motor: pharyngeal and laryngeal muscles<br>Sensory: pharynx and blood pressure<br>Special sensory: taste from epiglottis/pharynx<br>Parasympathetic: heart, lungs, digestive tract |
| Droopy shoulder, movement of neck                                                                                | XI            | Spinal accessory | Medulla        | Motor: neck and shoulder muscles                                                                                                                                                   |
| Loss of tongue movement; tongue fasciculation, tongue atrophy                                                    | XII           | Hypoglossal      | Medulla        | Motor: tongue muscles                                                                                                                                                              |

## e) Clinical manifestations

- (1) Early signs include nystagmus, speech difficulties (e.g., dysarthria), uncoordinated movements, abnormal gait, and trouble writing (e.g., dysmetria). Somnolence, encephalopathy, and nausea can also occur (Dietrich, 2020).
- (2) Symptoms typically resolve with drug discontinuation, but up to 30% of patients suffer permanent cerebellar injury (Dietrich, 2020).
- (3) Cerebellar atrophy is a late effect that can develop several months after using cytarabine (Dietrich, 2020).

## f) Assessment

- (1) Diagnosis is achieved by reporting symptoms with careful neurologic examination before each infusion of agents known to cause cerebellar syndrome.
- (2) This includes assessment of patient coordination (e.g., finger-to-nose and finger-to-finger test, rapid alternating hand movements, ability to write), speech pattern, gait and balance, and presence of abnormal eye movements (e.g., nystagmus).
- (3) When signs and symptoms are present, the causative medication should be held, and the prescriber should be notified immediately.

## g) Collaborative management

- (1) Symptoms typically resolve over time or with discontinuation of therapy.
- (2) Depending on the extent of injury, some sequelae may be permanent.
- (3) Early recognition of treatment-induced adverse neurologic effects is essential to avoid more severe or permanent neural injury to the brain (Dietrich, 2020).

## 5. Adverse cerebrovascular events

## a) Overview

- (1) Cerebrovascular events are a constellation of clinical syndromes that disrupt the blood supply to the brain with a resultant neurologic symptom or symptom complex.
- (2) Cerebrovascular events are classified according to etiology, location, and duration of symptoms.
- (3) Common cerebrovascular events manifesting in the setting of chemotherapy include thromboembolism, intracranial hemorrhage, and ischemic stroke.

(a) Cerebral thromboembolism is a blood clot that occludes the small and large cerebral arteries.

(b) Intracranial hemorrhage is bleeding inside the cranial vault, resulting in accumulation of blood and, frequently, increased intracranial pressure.

(c) Ischemic stroke is the sudden loss of blood circulation to an area of the brain, resulting in a corresponding loss of neurologic function. It occurs in the setting of thrombotic or embolic occlusion of a cerebral artery (American Stroke Association, n.d.).

## b) Pathophysiology

- (1) Cancer stimulates the coagulation system, predisposing patients to a baseline hypercoagulable or prothrombotic state.
- (2) Many cancer therapies further potentiate this risk of thrombosis through procoagulant release, endothelial damage, or stimulation of tissue factors. Ischemic stroke, a direct effect of arterial occlusion by thromboembolism, is associated with chemotherapies (e.g., pegaspargase, cisplatin), immunotherapies (e.g., thalidomide), antiangiogenesis monoclonal antibodies (e.g., bevacizumab, ramucirumab), targeted therapies (e.g., lenvatinib, osimertinib), and hormone therapies (e.g., tamoxifen) (Nasser et al., 2020).
- (3) In contrast, intracranial hemorrhage, including intratumoral hemorrhage, in patients with cancer is typically a secondary effect of disseminated intravascular coagulation, thrombocytopenia due to bone marrow suppression, or vitamin K deficiency.
- (4) An increased risk of thromboembolic events exists in the setting of bevacizumab, and a 24% incidence of stroke or transient ischemic attack has been reported in patients undergoing hematopoietic stem cell transplantation (Ridge-way et al., 2020).

## c) Incidence

- (1) Incidence varies according to the type of cancer, event, and agent.
- (2) Hematologic cancers show the highest association with cerebrovascular events, followed by brain tumors (Cordelli et al., 2017).
- (3) The highest incidence of intracranial hemorrhage is noted with acute myeloid leukemia (Cordelli et al., 2017).
- (4) Risk of hemorrhage or ischemic stroke is higher with bevacizumab when given

alone or in combination with chemotherapy (Nasser et al., 2020).

- (5) In some instances, the risk of stroke is higher when chemotherapy drugs are given in combination with other drugs, although the exact pathophysiology is unknown (Stone & DeAngelis, 2016).
- (6) For example, the risk of stroke is higher when cisplatin is used in combination with other chemotherapy drugs (Stone & DeAngelis, 2016).
- (7) L-Asparaginase increases the risk of venous sinus thrombosis, leading to potentially serious cardiovascular events, such as stroke, intracranial hemorrhage, and seizures (Cintrón-García & Guddati, 2020; Stone & DeAngelis, 2016).

*d) Clinical manifestations*

- (1) The cardinal clinical feature of many cerebrovascular events is painful headaches.
- (2) Additional symptoms include nausea, vomiting, altered mental status, seizure, or focal neurologic symptoms.
- (3) Depending on when a patient is seen and the underlying cause, the deficit may be stable, progressive, or completely resolved.
- (4) Methotrexate-induced neurotoxicity can specifically present as stroke-like manifestations, including symptoms such as hemiparesis, dysphasia, and seizures (Dietrich, 2020).

*e) Assessment:* Diagnosis is made radiographically via computed tomography or MRI (American Stroke Association, n.d.).

*f) Collaborative management*

- (1) Patients with thromboembolism and ischemic stroke typically are given multimodal therapy, such as anticoagulation, thrombolysis, and platelet inhibition.
- (2) Hemorrhage may require neurosurgical intervention to decompress the brain, initiate invasive pressure monitoring, or evacuate a clot. Supportive treatment includes pain medication, steroids, and antiseizure medication.

## 6. Aseptic meningitis

*a) Overview*

- (1) Aseptic meningitis is irritation and inflammation of the meninges in the absence of infection.
- (2) It is the most commonly reported toxicity of intrathecal chemotherapy, especially methotrexate and cytarabine.
- (3) Other agents that induce aseptic meningitis include cetuximab, ipilimumab, IV

immunoglobulin, high-dose cytarabine, and rituximab.

*b) Pathophysiology*

- (1) The pathologic mechanism of aseptic meningitis is indeterminate and likely varies by the agent.
- (2) For example, aseptic meningitis following cetuximab administration is thought to stem from an allergic hypersensitivity reaction or serum immunoglobulin crossing the blood–brain barrier, causing meningeal inflammation (Maritaz et al., 2016).

*c) Incidence*

- (1) Incidence of aseptic meningitis varies widely according to agent and dose, but it is usually observed after intrathecal drug administration.
- (2) For example, meningitis following intrathecal methotrexate administration is reported in 10%–60% of patients (Dietrich, 2020).
- (3) However, the incidence of meningitis following cetuximab administration is much lower, with fewer than a dozen reports in the literature (Maritaz et al., 2016).

*d) Clinical manifestations:* Symptoms include low-grade fever, headache, stiff neck, back and neck pain, nausea, vomiting, lethargy, photophobia, and increased cell presence (e.g., white blood cells, protein) in the cerebrospinal fluid (Dietrich, 2020; Taillibert et al., 2016).

*e) Assessment*

- (1) The diagnosis is usually presumptive based on symptoms, temporality, and chemotherapy route.
- (2) Cerebrospinal fluid obtained from lumbar puncture generally shows mild pleocytosis and protein elevation (Dietrich, 2020).

*f) Collaborative management*

- (1) Prophylactic dosing with dexamethasone prior to intrathecal chemotherapy may help reduce the risk of aseptic meningitis.
- (2) Symptoms can be managed with supportive therapy, which includes analgesics, antiemetics, steroids if not already given prophylactically, and IV fluids.
- (3) Otherwise, spontaneous recovery is seen within days without any neurologic sequelae when the agent is discontinued.
- (4) Aseptic meningitis is considered a stand-alone event and does not indicate similar reactions with subsequent administration of the same drug (Dietrich, 2020).

## 7. Myelopathy

a) Overview: Myelopathy is a rare complication of swelling and spinal cord compression during or following intrathecal chemotherapy administration, such as methotrexate and cytarabine (Tariq et al., 2018).

## b) Pathophysiology

- (1) The etiology of myelopathy following intrathecal chemotherapy remains unclear.
- (2) Symptoms develop over hours or days following the intrathecal infusion of methotrexate (Tariq et al., 2018).
- (3) Ultimately, spinal cord dysfunction results from swelling and cord compression.

c) Incidence: Myelopathy as a complication of intrathecal chemotherapy is rare in adults (approximately 3%), with most cases occurring in the pediatric population (Cordelli et al., 2017).

d) Clinical manifestations: Symptoms include low back pain or leg pain followed by sensory loss or motor deficits in the lower extremities (e.g., paraplegia), flaccid paresis (e.g., loose and floppy limbs), and bowel or bladder incontinence or retention (Cordelli et al., 2017).

e) Assessment: MRI is the most sensitive radiologic technique in diagnosing myelopathy, but MRI abnormalities are nonspecific and include T2 hyperintensity and contrast enhancement. Elevation in cerebrospinal fluid protein levels is also evident on lumbar puncture (Cordelli et al., 2017).

## f) Collaborative management

- (1) No approved treatment exists for chemotherapy-induced myelopathy. Recent literature supports the use of high doses of S-adenosylmethionine, folinate, methionine, and cyanocobalamin (vitamin B<sub>12</sub>) to reverse toxicity and improve clinical symptoms (Tariq et al., 2018).
- (2) Symptoms and swelling are generally reversible, but in some instances, symptoms are rapidly progressive, and recovery is only partial (Cordelli et al., 2017).
- (3) Deficits can be permanent in some cases (Tariq et al., 2018).

## 8. Seizures

## a) Definition

- (1) A seizure is the manifestation of an abnormal, hypersynchronous electrical discharge of a population of cortical neurons.
- (2) This discharge may produce symptoms or objective signs (e.g., clinical seizure) or may be subclinical, materializing only on an electroencephalogram.

## b) Pathophysiology

- (1) The underlying etiology of seizures in patients with cancer can be complex, involving anatomic and metabolic disruptions caused by brain tumors, tumor- or medication-related stroke or opportunistic infection, chemotherapy, or neuro-radiation therapy. Seizures may be caused directly by agents themselves (e.g., busulfan [used commonly during stem cell transplantation]) or may result from hyponatremia as a secondary effect of hormone or electrolyte imbalances (Taillibert et al., 2016).
- (2) For example, syndrome of inappropriate antidiuretic hormone secretion is a known effect of vinca alkaloids and cisplatin that can result in hyponatremia, leading to severe confusion, coma, and seizures (Bénit & Vecht, 2016).
- (3) Cisplatin-induced renal injury can result in salt wasting, hyponatremia, and seizures (Bénit & Vecht, 2016).
- (4) Targeted therapies that inhibit epidermal growth factor receptor pathways, such as the monoclonal antibodies cetuximab and panitumumab and the tyrosine kinase inhibitors gefitinib and erlotinib, also cause secondary electrolyte depletion, which increases the risk of seizure (Wick et al., 2016).
- (5) Seizures also result from interferon and interleukin-2, which cause cytokine release in CAR T-cell therapy (Latchford & Tierney, 2020).

## c) Incidence

- (1) Incidence varies according to the cancer, location, and agent.
- (2) Busulfan, an agent used during conditioning for stem cell transplantation, carries a 10% risk of seizures in the absence of prophylactic anticonvulsants (Ridgeway et al., 2020).
- (3) The seizure risk decreases to 0%–5.5% with prophylaxis (Latchford & Tierney, 2020).
- (4) For patients with primary brain tumors, more than 65% with gliomas and 33% with meningiomas will have epilepsy (Bénit & Vecht, 2016).
- (5) For patients with systemic cancer, the incidence of seizures is higher. Approximately 60% of patients with brain metastases will develop epilepsy (Bénit & Vecht, 2016).

d) Clinical manifestations: Signs and symptoms of a seizure can include temporary confusion, staring

spells, involuntary jerking or violent movements of the arms and legs, and altered mental status, including loss of consciousness.

e) Assessment

- (1) A thorough neurologic examination is performed to explore differential diagnoses.
- (2) A diagnosis is typically achieved via electroencephalogram, although a witnessed tonic-clonic seizure can be enough to initiate treatment.

f) Collaborative management

- (1) Patients with brain tumors have reported seizures as a significant cause of distress, which is often associated with the perception of poor quality of life (Grant, 2017).
- (2) Proper management of these symptoms is key, and typical treatment includes antiepileptics.
- (3) In the case of high-dose busulfan, prophylaxis with antiepileptics prior to therapy is standard practice, as the risk of seizure is significantly high (Ridgeway et al., 2020).
- (4) Literature suggests that up to 66% of brain tumors have seizure foci that can be surgically resected, resulting in the elimination of seizures in 65%–85% of cases (Chen et al., 2018).

## 9. Headache

a) Overview: Headache is pain with or without pressure in the head.

b) Pathophysiology

- (1) Headache is one of the most common complications in cancer treatment.
  - (a) Headache can be caused directly by the mass effect of intracranial malignancy, malignant infiltration of the meninges or pituitary gland, or as a direct effect of anticancer therapies, such as radiation therapies, chemotherapies (e.g., 5-fluorouracil, procarbazine), targeted therapies (e.g., imatinib, rituximab, infliximab), and immunotherapies (e.g., CAR T cells, ipilimumab) (Ridgeway et al., 2020; Stone & DeAngelis, 2016).
  - (b) As a result, attributing a single causative agent is challenging, but the temporality of headache emergence to treatment can be instructive.
  - (c) Mechanisms of action are varied based on the agent. For example, a headache during rituximab infusion or after CAR T-cell infusion likely results from the release of inflamma-

tory cytokines (Ridgeway et al., 2020; Wick et al., 2016).

- (2) Headache can also be a secondary effect of treatment. Examples include postprocedural complications of cancer diagnostics, such as a lumbar puncture or brain biopsy; stress, fatigue, anxiety, or sleep disturbances resulting from cancer or its treatment; cancer- or treatment-associated anemia; and hypercalcemia and dehydration from vomiting and diarrhea.

c) Incidence: Incidence varies widely according to the causative agent.

d) Clinical manifestation: Patients may report pain, tightness, or pressure in the head or upper neck.

e) Assessment: Diagnosis is based on patient self-report.

f) Collaborative management: Treatment typically involves administering analgesics and, if warranted, intervention to correct the proximate cause, such as a blood patch for post-lumbar puncture headache or correction of anemia or hypercalcemia.

## E. Peripheral neuropathy (PN): general neurotoxicities

1. Overview: PN is damage to nerve cells, nerve fibers (axons), and nerve coverings (myelin) due to exposure to a neurotoxic chemotherapy agent that inhibits or decelerates nerve signals. The three major categories of PN are sensory, motor, and autonomic (Clark, 2018).

a) Sensory neuropathy

(1) Sensory neuropathy is known as glove-and-stocking neuropathy. It results from damage to sensory nerves causing problems with sensation in distal portions of the limb (e.g., the ability to feel pain or light touch) (Zajackowska et al., 2019).

(2) This type of neuropathy is often progressive and can decrease overall proprioception, leading to ambulatory difficulties (Clark, 2018).

b) Motor neuropathy is less common than sensory neuropathy and leads to injury to motor nerves, affecting movement (Clark, 2018).

c) Autonomic neuropathy is the impairment of the nonsensory, involuntary nervous system that controls and regulates smooth muscles, cardiac muscles, and glands (e.g., nerves innervating the heart, bladder, and salivary glands).

## 2. Pathophysiology

a) Antineoplastics differentially impair specific structures within the neuron according to their mechanism of action.

*b)* In general, the predominant pathophysiologic mechanism of PN across all chemotherapy agents is induction of mitochondrial abnormalities and inhibition of mitochondrial function (Brewer et al., 2016).

*c)* PN can be broadly attributed to the resultant demyelination and disruption in axonal transport and resulting degeneration (Clark, 2018).

### 3. Incidence

*a)* Incidence and severity of PN vary by the specific type (sensory, motor, or autonomic), agent, agent combinations, and dosages. PN is likely under-reported.

*b)* In aggregate, PN occurs in 30%–70% of patients receiving neurotoxic chemotherapy, most notably platinum agents, vinca alkaloids, taxanes, proteasome inhibitors, antimicrotubules, anti-angiogenesis agents, and immunotherapy agents (e.g., immune checkpoint inhibitors) (Clark, 2018; Marini et al., 2021; Staff et al., 2017; Zajączkowska et al., 2019).

### 4. Clinical manifestations

#### *a)* Sensory

(1) Sensory neuropathies may be subtle and not consistently present during physical examination.

(2) Symptoms may be positive, in which sensations are present in the absence of external stimuli and perceived as tingling, burning, pins and needles, or pain typically described as stabbing or shooting.

(3) Sensory disturbances can also manifest as negative phenomena (e.g., numbness, loss of sensation, impaired proprioception), in which sensations are completely absent with external stimulation; for example, patients report the inability to feel a pinprick.

#### *b)* Motor

(1) Motor neuropathies may manifest as weakness, muscle fatigue, or atrophy.

(2) Patients also may report abnormally frequent and painful muscle cramps or fasciculation, causing problems with ambulation due to gait and balance issues and manual dexterity (Zajączkowska et al., 2019).

(3) Motor neuropathy may co-occur with sensory neuropathy (i.e., sensorimotor neuropathy).

*c)* Autonomic: Autonomic neuropathy is seen most commonly with vinca alkaloids and can be associated with orthostatic hypotension, erectile dysfunction, and bowel and bladder dysfunction,

including paralytic ileus, constipation, and urinary retention.

### 5. Assessment

*a)* Results from the physical examination may be normal or show a sensory loss.

*b)* Loss of the Achilles tendon reflex is usually the first clinical sign of PN (Tzatha & DeAngelis, 2016).

*c)* Nerve conduction studies and an electromyogram can assist with diagnostic evaluation but can be costly (Ibrahim & Ehrlich, 2020).

*d)* Newer web-based self-assessment tools have been developed and have shown to be an effective approach to identifying and grading PN (Ibrahim & Ehrlich, 2020).

### 6. Collaborative management

*a)* PN is managed by empirical dose modifications or discontinuation of treatment at the discretion of the treating provider.

*b)* Treatment of urinary retention may include intermittent catheterization until recovery of function.

*c)* Pharmacologic agents occupy a key role in managing PN symptoms.

(1) Adjuvant therapies, often used with opioid analgesics, are the cornerstone of treatment.

(2) These therapies include anticonvulsants (e.g., gabapentin, pregabalin), antidepressants (e.g., tricyclics, serotonin-norepinephrine reuptake inhibitors), and ion channel blockers (e.g., lidocaine) (National Comprehensive Cancer Network [NCCN], 2022a; Oncology Nursing Society, 2019).

(3) Additional evidence suggests that the use of venlafaxine and duloxetine may benefit sensory and motor neuropathies (Farshchian et al., 2018; Ridgeway et al., 2020).

## F. Common antineoplastics conferring increased neurotoxicity

### 1. Chemotherapy

#### *a)* Vinca alkaloids

(1) Vinca alkaloids (e.g., vinblastine, vincristine, vinorelbine) inhibit cell proliferation and promote cytotoxicity by direct binding to beta-tubulin, a critical component of microtubules (Pellacani & Eleftheriou, 2020).

(2) Microtubules perform the essential function of aligning chromosomes during metaphase (the third phase of mitosis) (Ibrahim & Ehrlich, 2020).

- (3) The binding of agents to the microtubules ultimately results in inhibition of mitotic spindle function and arrests cancer cells in metaphase, rendering them unable to divide (Pellacani & Eleftheriou, 2020).
  - (4) However, throughout the nervous system, microtubules also help direct axonal transport of neuronal signals.
  - (5) PNs of vinca alkaloids that target microtubules result from interruption of the axonal transport and nerve degeneration, most commonly resulting in axonal sensorimotor neuropathy characterized by paresthesias and weakness (Ibrahim & Ehrlich, 2020).
  - (6) Vincristine can increase neural excitability by affecting calcium homeostasis and the dorsal root ganglia membrane (Ibrahim & Ehrlich, 2020).
  - (7) Pain in the hands and feet is often the first sign of neurotoxicity (Zajackowska et al., 2019).
  - (8) Rarely, vincristine also may cause focal neuropathies of the cranial nerves, resulting in hoarseness, diplopia, jaw pain, and facial palsies.
  - (9) Autonomic neuropathies rarely occur but can include urinary retention, orthostatic hypotension, and hypertension.
  - (10) Another rare but notable effect of vincristine specifically is its ability to cause an asymptomatic carrier of Charcot-Marie-Tooth disease to develop severe weakness and other symptoms (Kissoon et al., 2019; Zajackowska et al., 2019).
- b) Platinum-based agents*
- (1) Cisplatin and oxaliplatin are two widely used neurotoxic agents.
    - (a) PN seen with cisplatin is dose dependent and usually manifests at cumulative doses of 500–600 mg/m<sup>2</sup> (Zajackowska et al., 2019).
    - (b) Symptom severity is also dose dependent and can include numbness, tingling, and pain in the extremities.
    - (c) Additional neurotoxicity may present as myelotoxicity, nephrotoxicity, ototoxicity (e.g., tinnitus, hearing loss), and encephalopathy caused by seizures and focal neurologic deficits (Dietrich, 2020; Pellacani & Eleftheriou, 2020).
  - (2) Oxaliplatin induces a PN as two clinically distinct syndromes.
    - (a) Acute transient paresthesia in the distal extremities usually occurs within the early phase of drug administration, during or just following infusion in approximately 65%–98% of those treated (Zajackowska et al., 2019).
    - (b) A unique effect of oxaliplatin treatment is cold-triggered hand and foot paresthesias, which usually occur within a week after the first infusion and may reappear with subsequent infusions (Pellacani & Eleftheriou, 2020; Zajackowska et al., 2019).
    - (c) Other symptoms include pharyngolaryngeal dysesthesias, jaw spasms, and muscle cramps in the extremities (Pellacani & Eleftheriou, 2020; Zajackowska et al., 2019).
    - (d) Chronic cumulative sensory neuropathy can be observed in 50%–70% of those treated with oxaliplatin because of the damage caused to the sensory nerve axons (Pellacani & Eleftheriou, 2020; Zajackowska et al., 2019).
    - (e) These neuropathies cause more persistent clinical impairments, including eye and jaw pain, ptosis, visual impairment, voice changes, sensory ataxia, and muscle cramps that may persist for several months (Pellacani & Eleftheriou, 2020; Zajackowska et al., 2019).
    - (f) A frequent side effect of oxaliplatin is ocular toxicity, occurring acutely during infusion or as a late effect. Symptoms include tearing, dry eyes, conjunctivitis, blurred vision, photosensitivity, altered color vision, and eye pain triggered by cold (Cidon & Alonso, 2016; Pellacani & Eleftheriou, 2020).
- c) Taxanes*
- (1) Cabazitaxel, docetaxel, nab-paclitaxel, and paclitaxel are associated with sensory neuropathies involving the feet and occasionally the hands, with painful paresthesias, numbness, dysesthesias, dexterity deficits in toes and fingers, and altered proprioception (Ibrahim & Ehrlich, 2020; Zajackowska et al., 2019).
  - (2) Symptoms are dose dependent and usually start after the first dose and improve

after treatment discontinuation; however, symptoms may persist (Zajackowska et al., 2019).

- (3) Symptoms associated with changes in autonomic function are rarer but must be carefully evaluated in patients receiving taxanes; cardiac and vascular dysfunction reported as arrhythmias and orthostatic hypotension can occur in patients receiving paclitaxel (Dietrich, 2020).

d) Antitumor antibiotics

- (1) Of note, antitumor antibiotics (e.g., bleomycin, doxorubicin) produce highly selective neurotoxic effects (to dorsal root ganglia) and peripheral neurotoxicity.
- (2) CNS toxicity is primarily described in terms of cognitive impairment (Kesler & Blayney, 2016; Pellacani & Eleftheriou, 2020).

2. Immunotherapy

a) Thalidomide and its synthetic analogs

- (1) Neurotoxic effects from thalidomide are dose dependent (Zajackowska et al., 2019).
- (2) The most common toxicity seen with thalidomide and thalidomide analogs is somnolence (thalidomide was first marketed as a sedative).
- (3) At typical doses, approximately 50% of patients taking thalidomide develop PN (10% with severe symptoms), including distal paresthesias or dysesthesias with or without sensory loss (Ibrahim & Ehrlich, 2020; Stone & DeAngelis, 2016; Zajackowska et al., 2019).
- (4) This loss primarily occurs due to thalidomide's antiangiogenic effects, which promote peripheral vasculature loss (Ibrahim & Ehrlich, 2020).
- (5) Anti-inflammatory effects are also typical of thalidomide and even more pronounced with second-generation immunomodulatory agents, such as lenalidomide and pomalidomide (Ibrahim & Ehrlich, 2020).
- (6) Autonomic neuropathies include constipation and, rarely, impotence and bradycardia (Pellacani & Eleftheriou, 2020; Stone & DeAngelis, 2016).

b) CAR T cells

- (1) CAR T cells are manufactured using T cells drawn from the patient's blood. The T cells are then genetically modified to express a CAR specific to an antigen expressed by the patient's cancer cells.

- (2) The binding of CAR T cells to cancer antigens in the body results in T-cell proliferation and expansion and further immune activation, including elevations in cytokines, ultimately resulting in cancer cell death (Latchford & Tierney, 2020).

- (3) Neurotoxicity from CAR T cells is primarily a secondary result of cytokine-associated toxicity, also known as cytokine release syndrome.

- (4) Specific to CAR T-cell therapy, cytokine release syndrome-related neuropathies are referred to as immune effector cell-associated neurotoxicity syndrome (ICANS) (Dietrich, 2020; Harrison et al., 2020; Ridgeway et al., 2020).

- (5) ICANS symptoms are generally grouped in early and late phases.

(a) The early-phase symptoms are typical of cytokine release syndrome, usually occur within five days, and are characterized by fever and hypotension (Ridgeway et al., 2020).

(b) The late phase occurs after that and describes the general resolution of the early-phase symptoms (Ridgeway et al., 2020).

(c) This phase can typically last up to 14 days after the CAR T-cell infusion (Brudno & Kochenderfer, 2019).

- (6) Other more severe symptoms caused by ICANS are generally a result of capillary leak and primarily present as encephalopathic-type symptoms.

- (7) These symptoms result from a distinct syndrome of ICANS known as CAR T-cell-related-encephalopathy syndrome. They include headache, mental status changes, confusion, delirium, focal deficits, word-finding difficulty or aphasia, hallucinations, tremor, dysmetria, altered gait, and seizures (Brudno & Kochenderfer, 2019; Harrison et al., 2020; Kotch et al., 2019; Ridgeway et al., 2020).

- (8) Clinical management is dependent on the severity and type of presenting symptoms and can include supportive care and steroids (Ridgeway et al., 2020).

- (9) Newer evidence also suggests that tocilizumab may effectively treat cytokine release syndrome-related symptoms (Harrison et al., 2020).

c) Immune checkpoint inhibitors

- (1) Recent literature supports that immune checkpoint inhibitors also contribute

to PN complications (Chen et al., 2019; Marini et al., 2021; Möhn et al., 2019; Psimaras et al., 2019).

- (2) Most often, these complications result from specific neuropathies, including motor-sensory axonal neuropathy, demyelinating polyneuropathy, and axonal sensorimotor polyneuropathy (Chen et al., 2019; Marini et al., 2021; Möhn et al., 2019; Psimaras et al., 2019).
- (3) Another common side effect of immune checkpoint inhibitor therapy includes Guillain-Barré syndrome (Möhn et al., 2019). Patients with immune checkpoint inhibitor-induced Guillain-Barré syndrome often present with an elevated cerebrospinal fluid cell count (B. Hu et al., 2017).

#### G. Risk factors and prophylaxis

##### 1. Risk factors

- a) The clinical sequelae of neurotoxicity from antineoplastic therapies are complex functions of dose, mode of administration, exposure time, and the unique genetic susceptibilities of patients.
- b) Risk factors for the development of PN include preexisting neuropathies due to diabetes, alcohol use disorder, folate/vitamin B<sub>12</sub> deficiency, moderate obesity, hereditary sensorimotor neuropathy (e.g., Charcot-Marie-Tooth disease), or neuropathies caused by the malignancy (L.-Y. Hu et al., 2019; Ibrahim & Ehrlich, 2020; Molassiotis et al., 2019; Timmins et al., 2021).

##### 2. Prophylaxis

- a) Only a few prophylactic agents have been supported in the literature to reduce specific neurotoxic effects.
- b) Treatments such as amifostine, glutathione, infusions of calcium, magnesium, and venlafaxine have shown limited but promising results (L.-Y. Hu et al., 2019; Ibrahim & Ehrlich, 2020; Taillibert et al., 2016).
- c) Erythropoietin and lithium are newer agents of interest in recent literature but need further investigation in humans (L.-Y. Hu et al., 2019; Ibrahim & Ehrlich, 2020).
- d) Conflicting evidence supports vitamin E supplementation as an effective neuroprotective agent (L.-Y. Hu et al., 2019; Ibrahim & Ehrlich, 2020; Taillibert et al., 2016).
- e) For specific neurotoxic effects, the following have demonstrated efficacy:
  - (1) Aseptic meningitis: Prophylactic dosing with dexamethasone prior to intrathecal

chemotherapy may help reduce the risk of aseptic meningitis (Dietrich, 2020).

- (2) Seizures: For agents with known seizure risk (e.g., busulfan), prophylaxis with anti-convulsants is highly effective in reducing the development of seizures (Akiyama et al., 2018).
- (3) Autonomic neuropathy affecting gastrointestinal motility: Prevention of functional bowel disorders, such as paralytic ileus, often requires concomitant bowel prophylaxis with high fiber intake, fluid balance, and the use of opioid-sparing analgesia, stool softeners, and laxatives (Taillibert et al., 2016).
- (4) General PN: Increased physical activity and exercise have been shown to consistently mitigate the general effects of PN during treatment with antineoplastics (Duregon et al., 2018; Timmins et al., 2021). Newer evidence has shown promise for using the mitochondrial protectant pifithrin- $\mu$  in the prevention of neuropathic pain often caused by cisplatin and paclitaxel therapies (Ma et al., 2018).

#### H. Cognitive impairment

##### 1. Overview

- a) Cognitive function is a multidimensional concept that encompasses several domains regulated by the brain (e.g., attention and concentration, executive function, information processing speed, language, psychomotor ability, visuospatial skill, learning, memory) (Jansen et al., 2019; see Figure 24-1).
- b) Cognitive impairment is a decline in function in one or multiple domains of cognitive function. It may represent a single, highly specific deficit or a cluster of related deficits (Jansen et al., 2019).

##### 2. Pathophysiology

- a) Altered brain functioning and cognitive impairment: Evidence of altered brain functioning and cognitive impairment has been found prior to treatment for non-CNS cancers, indicating that cancer and tumor burden may contribute to cognitive concerns (Mayo, Lustberg, et al., 2021).
- b) Multimodal therapy: Although cancer therapies (e.g., surgery, radiation therapy, chemotherapy, targeted therapy, hematopoietic stem cell transplant, endocrine therapy, immunotherapy) have been associated with cognitive changes, the use of multimodal therapy makes it difficult to determine the underlying mechanism for cognitive impairment. Likewise, the mechanisms of cancer treatment-related cognitive changes are

thought to be multifactorial and are still not fully understood.

(1) Structural and functional damage to the brain

(a) The effects of direct tumor involvement in the brain, surgical removal of CNS tumors, or brain metastases are specific to the area of the tumor location, type of cancer, size, and rate of growth (Chang et al., 2019; Ouyang & Kanekar, 2021; Phillips et al., 2021).

(b) Structural and functional damage may also occur in patients with non-CNS cancers who receive chemotherapy, as evidenced by declines in gray matter volume (most often in the prefrontal lobe and hippocampus) and widespread decreases in white matter integrity and brain activity (Amidi & Wu, 2019).

(2) Direct injury to neurons or other brain structures, including oligodendrocytes, astrocytes, glial cells, and white matter tracts

(a) Neurotoxic effects of chemotherapy may disrupt neural stem and progenitor cells within the CNS, which appear to be more sensitive than cancer cells to various chemotherapy agents (Gibson & Monje, 2019; Nguyen & Ehrlich, 2020).

(b) Specific chemotherapy drugs shown to target neural progenitor cells in experimental studies include, but are not limited to, carmustine, cisplatin, cyclophosphamide, cytarabine, docetaxel, doxorubicin, 5-fluorouracil, ixabepilone, methotrexate, paclitaxel, tamoxifen, temozolomide, thiotepa, vinblastine, and vincristine (Mounier et al., 2020; Nguyen & Ehrlich, 2020).

c) Disruption of the blood–brain barrier: Although most chemotherapy drugs are unable to cross the blood–brain barrier, antineoplastic agents cause peripheral damage to blood vessels, resulting in a disruption of blood–brain barrier integrity and adversely affecting the brain and cognitive func-

**FIGURE 24-1.** Anatomic Correlates of Cognitive Function

tioning (Fernandez et al., 2020; Mounier et al., 2020).

d) DNA damage: Several chemotherapy agents can cause DNA damage (e.g., alkylating agents), impair DNA synthesis (e.g., antimetabolites), or otherwise block DNA production (e.g., taxanes). They also may cause direct inflammatory effects, oxidative stress, and increased free radical formation, which can cause neuronal death (Nguyen & Ehrlich, 2020).

e) Cytokine dysregulation

- (1) Although many chemotherapy agents cannot cross the blood–brain barrier, they can stimulate a release of proinflammatory cytokines (e.g., interleukin-1, interleukin-6, tumor necrosis factor- $\alpha$ ) in response to cell injury.
- (2) Cytokines are proteins that have a role in neural function and repair and the metabolism of neurotransmitters.
- (3) Increased levels of cytokines may activate a stress cascade, leading to an elevation in circulating tumor necrosis factor- $\alpha$ . This can cross the blood–brain barrier and cause excessive levels of cytokines in the CNS, leading to cognitive changes (Castel et al., 2017; Shi et al., 2019).
- (4) Evidence for increased cytokine levels exists for most treatment modalities (e.g., chemotherapy, immunotherapy, radiation therapy), which can lead to declines in memory and global cognition (Williams et al., 2018).

f) Oxidative stress or inflammatory responses

- (1) Radiation therapy and chemotherapy can cause oxidative damage (Mayo, Lustberg, et al., 2021).
- (2) Various chemotherapy drugs (e.g., carboplatin, carmustine, cyclophosphamide, cytarabine, doxorubicin, methotrexate, oxaliplatin) have been shown to initiate oxidative stress that can trigger cell membrane damage and produce large amounts of free radicals (Bagnall-Moreau et al., 2019; Branca et al., 2018; Mounier et al., 2020).

g) Anemia

- (1) Primary or metastatic cancer involvement of the bone marrow or bones and cancer treatments (e.g., radiation therapy, chemotherapy) can cause anemia.
- (2) Insufficient brain oxygenation is associated with cognitive problems in multiple domains, such as attention and concentration, executive functioning, motor

function, and memory (Lezak et al., 2012; Mounier et al., 2020).

h) Hormone-mediated effects

- (1) Estrogen and androgen are neuroprotective, and receptors for these hormones are widely distributed throughout the brain (Lobo, 2019; Ryan et al., 2020; Wu & Amidi, 2017).
- (2) Although hormone agents work by different mechanisms, selective estrogen receptor modulators act as estrogen agonists or estrogen antagonists, which block estrogen receptors; aromatase inhibitors decrease estrogen synthesis in the peripheral tissues; and androgen deprivation therapy reduces testosterone levels. Their use can affect cognitive functioning (Hong et al., 2020; Ryan et al., 2020; Underwood et al., 2018; Wu & Amidi, 2017).
- (3) Greater menopausal symptoms, cognitive complaints, and slower information processing speed have been found in postmenopausal women with cancer than in healthy women (Vega et al., 2018).
- (4) Chemotherapy often induces menopause with a more accelerated decline in estrogen levels, but the significance as applied to cognitive functioning is still unclear (Lobo, 2019).
- (5) Similarly, although age-related decreases in testosterone may be associated with cognitive decline, the evidence for cognitive impairment from androgen deprivation therapies is inconsistent (Morgans et al., 2021).

i) Leukoencephalopathy

- (1) Structural alterations in cerebral white matter can occur with cranial irradiation (Phillips et al., 2021).
- (2) White matter changes have also been reported with various chemotherapy, immunotherapy, and targeted agents, such as alemtuzumab, bevacizumab, carmustine, cisplatin, cytarabine, 5-fluorouracil, fludarabine, ifosfamide, infliximab, interferon- $\alpha$ , interleukin-2, lenalidomide, levamisole, melphalan, methotrexate, rituximab, sorafenib, sunitinib, temozolomide, and thiotepa (Fernandez-Robles et al., 2016; Filley et al., 2017; Ouyang & Kanekar, 2021; Westin et al., 2018).

j) Accelerated aging

- (1) Various processes have been determined to contribute to aging (e.g., telomere attrition, cellular senescence, free radical gen-

- eration, stem cell exhaustion, increased DNA damage, epigenetic alterations) that may be associated with declines in cognitive functioning (Carroll et al., 2019; Cupit-Link et al., 2017; Wang et al., 2021).
- (2) Studies have found associations between some predictors of biologic aging (e.g., telomere attrition, increased DNA damage) and cognitive impairment (Carroll et al., 2019).
  - (3) Specific treatments that may induce accelerated aging may include, but are not limited to, chemotherapy (e.g., cisplatin, cyclophosphamide, daunorubicin, docetaxel, doxorubicin, etoposide, 5-fluorouracil, hydroxyurea, irinotecan, methotrexate, mitomycin C, paclitaxel, temozolomide, vinblastine, vincristine, vinorelbine), hormone therapy (e.g., tamoxifen), targeted therapy (e.g., dasatinib, sunitinib, vemurafenib), and radiation therapy (Cupit-Link et al., 2017).
    - (a) The incidence of treatment-related cognitive changes is difficult to determine because many factors influence cognition. However, an estimated 30%–40% of people with non-CNS cancers have cognitive impairment prior to treatment, and up to 75% have cognitive changes during or after cancer treatment (Mayo, Lustberg, et al., 2021).
    - (b) The incidence of cognitive impairment is even greater for patients undergoing hematopoietic stem cell transplantation (50%). It is as high as 40% six years after treatment (Mayo, Wozniczka, et al., 2021; Nakamura et al., 2021).
    - (c) Cognitive problems, especially difficulties with attention, concentration, memory, ability to multitask, and maintain work productivity, can persist for months or several years and are a major concern to cancer survivors, especially when reentering the workplace (Klaver et al., 2020; Von Ah et al., 2018).
    - (d) Studies have confirmed that cognitive issues continue to negatively impact survivors in the workplace for at least one if not many years after treatment (Cheng et al., 2018; Dorland et al., 2018; Klaver et al., 2020; Lange et al., 2019; Von Ah et al., 2018).
3. Risk factors: Predisposing factors that influence cognitive function are inconsistent, but the following have been suggested:
    - a) Individual risk factors
      - (1) Age: Cognitive decline occurs with aging. Although younger patients with cancer report more cognitive problems, older patients perform even worse on objective tests (Gutenkunst et al., 2021). Of note, normative data for neuropsychological tests are based on age.
      - (2) Comorbidities: Patients with greater comorbidity levels, especially illnesses such as diabetes and cardiovascular disease, have been reported to have cognitive impairment prior to initiating cancer treatments (Allen et al., 2018).
      - (3) Genetics and epigenetics
        - (a) As is the case with other treatment side effects, not all patients are equally affected by the same regimen.
        - (b) The most commonly studied genetic variants implicated in cancer treatment-related cognition include apolipoprotein E epsilon 4 variant, brain-derived neurotrophic factor, and catechol-o-methyltransferase (Buskbjerg et al., 2019; Correa et al., 2019; Demby et al., 2020; Fernandez et al., 2020; Lange et al., 2019; Li et al., 2020; Speidell et al., 2019; Tan et al., 2019; Toh et al., 2018).
        - (c) Genetic polymorphisms have become an area of increasing interest in how they might influence the individual risk of cognitive changes during a cancer diagnosis and treatment (Bender et al., 2018; Merriman et al., 2019).
    - (4) Psychological factors: Stress, anxiety, depression, and other factors can affect performance on neuropsychological testing (Lezak et al., 2012).
      - (a) Higher anxiety and depressive symptoms prior to treatment may be predictive of cognitive decline in attention, executive functioning, and memory, as measured by objective neuropsychological tests. They may also be associated with persistent cognitive problems over time (Janelins et al., 2018; Merriman et al., 2019).
      - (b) It has also been suggested that patient perception of cognitive impairment may indicate emotional distress

- (e.g., anxiety, depression, stress) and is often correlated with subjective measures of cognitive functioning (Boscher et al., 2020; Gutenkunst et al., 2021).
- (c) Unsurprisingly, higher depressive symptoms have been associated with more significant cognitive issues for survivors in the workplace (Dorland et al., 2018).
- (5) Fatigue and sleep disturbances
- (a) Fatigue can negatively affect cognitive function and is related to greater cognitive complaints during treatment and for cancer survivors (Gutenkunst et al., 2021).
- (b) Similarly, sleep disturbances (e.g., insomnia) are negatively correlated with subjective cognitive impairment (Boscher et al., 2020; Lange et al., 2019; Liou et al., 2019).
- b) Risk factors related to cancer treatments
- (1) Regimens: Because most patients receive multimodal therapy, it is difficult to determine if specific drugs or regimens promote a greater incidence of cognitive changes.
- (2) Dose intensity and cumulative effects
- (a) Cognitive changes in patients who receive cranial irradiation are related to the total dose received (Chang et al., 2019; Ouyang & Kanekar, 2021).
- (b) Exposure to higher doses of chemotherapy (or higher concentrations due to impaired clearance) and the additive or synergistic effects of multiagent regimens also may increase risk (Mounier et al., 2020).
- (c) In addition, cumulative chemotherapy cycles have been reported as a predictor of cognitive decline (Gutenkunst et al., 2021).
- (d) Similarly, decreases in cognition have been shown in women on endocrine therapy (Underwood et al., 2019).
- (3) Concomitant medications, such as analgesics, antidepressants, antiepileptics, anxiolytics, antipsychotics, immunosuppressants, and steroids, also may contribute to cognitive deficits (Jansen, 2017).
4. Clinical manifestations
- a) Although cognitive changes may be subtle, patients report difficulties with their ability to concentrate, think clearly, retain or learn new information, be efficient, organize and prioritize, manage responsibility, interact socially, and cope with problems.
- b) Cognitive problems can persist for months up to several years and are a major concern for cancer survivors, especially when reentering the workplace (Klaver et al., 2020; Von Ah et al., 2018).
5. Assessment
- a) Patients who report cognitive problems should be screened for potentially reversible factors that may contribute to cognitive impairment (Allen et al., 2018; NCCN, 2022b).
- b) Many neuropsychological tests are available to measure cognitive function but are generally used only in studies and require referral to a neuropsychologist.
- c) Imaging studies (e.g., MRI, electroencephalogram, positron-emission tomography) have been used to study electrophysiologic outcomes, synaptic activity, and structural and functional brain changes related to cognitive impairment; however, these are generally not considered feasible for routine cognitive evaluation (Deprez et al., 2018; Xu et al., 2020). NCCN (2022b) guidelines recommend imaging only to rule out structural abnormalities in high-risk patients or individuals with focal neurologic deficits.
- d) Assess patients for cognitive complaints, such as the inability to focus on tasks or follow instructions and difficulties with concentration, memory, and word-finding, including onset, duration, and intensity. One should also consider eliciting caregiver input regarding cognitive function.
- e) Assess for any focal neurologic deficits and refer to a physician for further workup (neuroimaging).
- f) Assess social history (e.g., living situation, lifestyle factors including alcohol or drug use, work history) and potential influencing factors (e.g., anxiety, depression, emotional distress, pain, sleep disturbances, fatigue). Manage any contributing symptoms.
- g) Review cancer and treatment history (e.g., tumor type, staging, treatments, disease trajectory).
- h) Review coexisting medical conditions (e.g., cardiovascular disease, diabetes, neurologic conditions, psychiatric illness) and menopausal status.
- i) Review current medications (e.g., analgesics, antidepressants, antiemetics, antiepileptics, antipsychotics, immunosuppressants, steroids); evaluate for new medications, supplements, or potential medication interactions; and adjust regimens as needed.
- j) Monitor laboratory results to determine if patients have anemia, metabolic abnormalities, new-onset endocrinopathy (e.g.,

thyroid-stimulating hormone), vitamin deficiencies (e.g., B<sub>12</sub>), or liver or renal dysfunction. Take appropriate action as indicated.

k) Consider referral for neuropsychological testing, if indicated.

#### 6. Collaborative management

a) Currently, the only evidence-based recommendation for preventing or treating cognitive impairment is cognitive training (Jansen et al., 2019; Mayo, Lustberg, et al., 2021). Although the mechanisms of cancer treatment-related cognitive changes are still unclear, several pharmacologic and nonpharmacologic interventions have been studied. Many focus on preventing cognitive impairment by targeting the potential mechanisms discussed earlier. Further research is needed to determine potential interventions for patients experiencing cognitive impairments.

#### b) Nonpharmacologic interventions

(1) Cognitive rehabilitation, which encompasses cognitive training and cognitive behavioral interventions, is the technique most likely to improve cognitive functioning.

(a) Cognitive training involves interventions to improve, maintain, or restore attention, concentration, and memory through repeated and structured practice of tasks.

(b) Cognitive behavioral interventions focus on adaptive strategies to compensate for cognitive impairment.

(c) Systematic reviews have suggested that although cognitive rehabilitation has demonstrated beneficial outcomes in several cognitive domains (e.g., memory, executive function, progressing speed), further studies are needed to ascertain the optimal delivery method, feasibility, and specific recommendations (Fernandes et al., 2019; Von Ah & Crouch, 2020).

(2) Exercise (e.g., aerobic, resistance training, yoga) was shown as potentially preventive for cognitive impairment in animal studies (Park et al., 2018).

(a) Overall, increasing evidence supports exercise as an intervention for cognitive impairment, and it is recommended in NCCN guidelines (Campbell et al., 2020; NCCN, 2022b).

(b) Future studies are needed to determine the specific types of exercise

(as well as frequency and duration) that are beneficial to preventing and improving cognitive functioning.

#### (3) Complementary interventions

(a) Complementary interventions (e.g., acupuncture, guided imagery, meditation, mindfulness, natural restorative environment, neurofeedback, nutrition) have also been studied to minimize cognitive impairment.

(b) For example, acupuncture has been used for other chemotherapy-related toxicities (e.g., PN, nausea, pain).

(c) Preliminary study results indicated that acupuncture may improve objective and subjective cognitive functioning (Tong et al., 2018; Zeng et al., 2018; Zhang et al., 2020).

(d) Evidence for other alternative therapies is even more limited.

#### c) Pharmacologic interventions

(1) Pharmacologic interventions, such as psychostimulants (e.g., methylphenidate, dexamethylphenidate, modafinil), cholinesterase inhibitors (e.g., donepezil), N-methyl-D-aspartate (NMDA) receptor antagonists (e.g., memantine), complementary medicines (e.g., ginkgo biloba, vitamin E), and erythropoiesis-stimulating agents (e.g., erythropoietin) have been evaluated; however, limited data are available to recommend their use (Jansen et al., 2019; Karschnia et al., 2019; Mayo, Lustberg, et al., 2021; Miladi et al., 2019).

(2) In fact, erythropoiesis-stimulating agents are not recommended for practice because of U.S. Food and Drug Administration warnings regarding risks associated with their use (Jansen et al., 2019).

(3) However, NCCN guidelines propose that trial use of psychostimulants may be considered for select individuals (NCCN, 2022b).

### I. Patient and family education

1. Teach patients and caregivers the general signs and symptoms of neurotoxicity and provide written information describing the immediate and delayed effects of specific treatment agents. Provide information on how, when, and to whom signs and symptoms should be reported.

2. Teach patients and caregivers to recognize signs and symptoms that may indicate life-threatening toxicities.

ties (e.g., cerebrovascular events) and instruct them to immediately seek medical attention (Banach et al., 2016).

3. When neurotoxic effects manifest, orient patients and caregivers to the relevant safety issues and precautions.

a) Seizures

- (1) Patients with a known seizure event or who are prophylactically treated for seizures should be instructed not to drive, operate heavy machinery, swim, take baths (showers only), or use heated appliances while alone (e.g., stoves, curling irons, barbecue grills).
- (2) A medical alert bracelet or similar disclosure tool should be worn or carried at all times.
- (3) Caregivers should ensure patients are in the safest position possible if a seizure does occur.
- (4) This would include lowering patients to the floor, moving objects out of the way, and not touching patients who are seizing (American Cancer Society [ACS], 2020c).

b) Sensory neuropathy

- (1) Patients with loss of sensation in their extremities are at risk for thermal or ischemic injuries.
- (2) Teach patients and caregivers to pay particular attention to hands and feet, including regular inspection of the feet, and emphasize the importance of wearing properly fitted shoes covering the entire foot (ACS, 2021).
- (3) Additionally, cold pain is a frequent symptom of neuropathic pain, manifesting as a pain response to a normally innocuous cold stimulus (cold allodynia) or heightened sensitivity to a painful cold stimulus (cold hyperalgesia).
- (4) When these symptoms are present, patients should be taught to avoid exposure to cold environments and objects and to wear gloves in low temperatures (ACS, 2021; Banach et al., 2016).

c) Motor neuropathy

- (1) Patient counseling should focus on strategies to avoid falls and injury, especially when navigating changing surfaces, such as going from a bare floor to a carpet.
- (2) Patients should consider walking shoes, which provide traction and support, and should generally opt for shoes that tie versus those that slip on (e.g., flip-flops, sandals, slippers).

- (3) Removing throw rugs, clearing walkways of clutter, and using skid strips on slippery surfaces (e.g., shower and tub floors) can help reduce the risk of falls.

- (4) When possible, patients should be offered physical or occupational therapy to preserve function and limit further injury, especially if their condition becomes chronic (ACS, 2021).

d) Autonomic neuropathy: Teach strategies to manage symptoms of autonomic dysfunction (e.g., postural hypotension, constipation, urinary retention), such as dangling the legs prior to standing, increasing oral intake, and adding dietary fiber or a formalized bowel regimen.

4. Cognitive impairment: Inform patients that cognitive changes are a possible side effect of treatment and that studies elucidating this phenomenon, its mechanisms, and subsequent interventions are ongoing (ACS, 2020a).

a) Acknowledge, validate, and record patient reports of cognitive changes.

b) Encourage patients and family members to report cognitive problems.

c) Acknowledge that although studies have been done for various interventions, limited evidence is available to make treatment recommendations.

d) Encourage routine physical activity.

e) Recommend optimizing management of anxiety, depression, fatigue, sleep disturbances, and other contributing symptoms (NCCN, 2022b).

f) If patients show signs of confusion or delirium, they or their caregivers should call their provider immediately (ACS, 2020b).

g) General management strategies have been suggested (ACS, 2021; NCCN, 2022b).

(1) Healthy lifestyle practices

(a) Ensure adequate sleep and rest.

(b) Eat a well-balanced diet.

(c) Engage in physical exercise.

(2) Intellectual activities (e.g., reading, learning new skills, solving puzzles, working out math problems)

(3) Social activities (e.g., support groups)

(4) Practical management

(a) Use technology (e.g., smartphones, voice recorders).

(b) Keep a daily planner or calendar.

(c) Keep things in the same place.

(d) Develop lists, write reminders, and use notes.

(e) Reduce distractions and focus on one task at a time.

(f) Develop a routine schedule.

(5) Work strategies (Klaver et al., 2020)

- (a) Accept limitations.
- (b) Split assignments into manageable subtasks.
- (c) Decrease work hours and purposively take breaks.

## CHAPTER 25

# Ocular Toxicities

### A. Overview

1. Patients may develop ocular toxicities due to cancer treatments, with the onset, presentation, and incidence varying by drug and dose.
2. Nurses should be familiar with the signs and symptoms, assessment, and management of these potential complications. Patients receiving novel therapies, such as targeted therapies and immune checkpoint inhibitors, should complete ophthalmologic examinations at baseline (Bindiganavile et al., 2021; Corbelli et al., 2019; Dolgin, 2020; Fortes et al., 2021; Fu et al., 2017; Kunkler et al., 2019; Liu et al., 2020; Montazeri & Bellmunt, 2020; National Cancer Institute Cancer Therapy Evaluation Program, 2017; Park et al., 2021; Schoenfeld et al., 2020; Shah & Shah, 2019; Shahzad et al., 2021; Vishnevskia-Dai et al., 2021; Young et al., 2021).
3. Patient and family education includes recognition, mechanisms for reporting, mitigation (if possible), and management strategies (Bitton et al., 2019; Davis & Francis, 2017; Fu et al., 2017; Young et al., 2021).

### B. Pathophysiology

1. The etiology of ocular toxicity is not fully understood and may include the following (see Table 25-1):
  - a) Damage to the eye or eye structures related directly to treatment, such as distribution of cytotoxic drugs in tears, direct vascular injury during intracarotid administration, direct nerve injury from chemotherapy or radiation therapy, solubility characteristics of the drug and its ability to gain access through barriers such as the blood–ocular barrier, and inflammatory toxicities related to immunotherapies (Bhatti & Salama, 2018; DeAngelis, 2017; Liu et al., 2020; Park et al., 2021; Puzanov et al., 2017)
  - b) A secondary process related to treatment, such as eye irritation caused by loss of eyelashes in the presence of neutropenia (Schoenfeld et al., 2020)
  - c) A secondary process related to concurrent diseases, such as diabetes or Graves disease leading to diplopia or ptosis (DeAngelis, 2017)
  - d) Metastases to the eyes or central nervous system resulting in increased intracranial pressure
  - e) Factors unrelated to cytotoxic therapy, such as head trauma or drug toxicity from narcotics or anticonvulsants leading to diplopia (DeAngelis, 2017)
  - f) Checkpoint inhibitors: Checkpoint inhibitors are immunologic agents that block inhibitory receptors of immune system elements, such as cytotoxic T-lymphocyte antigen 4, programmed cell death protein 1, and its ligand, leading to the activation of specific antitumor T-cell responses (Bitton et al., 2019; Emens et al., 2019; Liu et al., 2020; Park et al., 2021; Shahzad et al., 2021; Young et al., 2021).
    - (1) The mechanisms of immune-related adverse events have been hypothesized to involve a breakdown of peripheral tolerance and induction of organ-specific inflammatory processes due to their non-specific immune activation. By disrupting checkpoints to preexisting antitumor immune responses, the therapies permit the immune system to fight cancer (Bitton et al., 2019; Park et al., 2021; Young et al., 2021).
    - (2) Ophthalmic immune-related adverse events include iritis, uveitis, conjunctivitis, dry eyes, and blurred vision. These can be treated with topical nonsteroidal or steroid therapy (Bhatti & Salama, 2018; Bitton et al., 2019; Brahmer et al., 2018; Durrechou et al., 2020; Emens et al., 2019; Fortes et al., 2021; Park et al., 2021; Puzanov et al., 2017; Schoenfeld et al., 2020; Shahzad et al., 2021; Young et al., 2021).
  - g) Epidermal growth factor receptor (EGFR) inhibitors: EGFR is a normal part of epidermal cells. It is widely distributed on the eye surface in the conjunctival and corneal epithelium, as well as in the eyelid skin, lash follicles, tear glands, and seba-

**TABLE 25-1.** Ocular Toxicities and Their Treatments

| Toxicity                                        | Definition and Symptoms                                                                                                                                                                                       | Treatment                                                                                                                                                                                                       |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Blepharitis                                     | Inflammation of the eyelids, mainly at the margin<br>Redness and flaking of the skin on the eyelids and crusting that worsens on waking                                                                       | Use warm compress, eyelid hygiene, and corticosteroids or anti-inflammatory medications.                                                                                                                        |
| Blurred vision                                  | Decreased clarity or sharpness in vision                                                                                                                                                                      | Refer to an ophthalmologist.<br>Discontinue agent.                                                                                                                                                              |
| Central serous retinopathy                      | Localized serous retinal detachment observable only on fundoscopy<br>Manifests as slightly blurry vision and the perception of objects smaller than they are (micropsia)                                      | —                                                                                                                                                                                                               |
| Conjunctivitis                                  | Inflammation and redness of the conjunctiva                                                                                                                                                                   | Hold agent.<br>Use corticosteroids or anti-inflammatory medications and artificial tears.                                                                                                                       |
| Corneal edema                                   | Swelling of the cornea                                                                                                                                                                                        | Refer to an ophthalmologist.                                                                                                                                                                                    |
| Corneal epithelial defect                       | Significant eye pain, sensitivity to light                                                                                                                                                                    | Refer to an ophthalmologist.                                                                                                                                                                                    |
| Cystoid macular edema                           | Chronic inflammation of the macular area only observable on fundoscopy and confirmed by fluorescein angiography                                                                                               | Refer to an ophthalmologist.<br>Hold agent.                                                                                                                                                                     |
| Diplopia                                        | Double vision                                                                                                                                                                                                 | Refer to an ophthalmologist and neurologist.                                                                                                                                                                    |
| Dysfunctional tear syndrome (tear film changes) | Fluctuating or mild decrease in vision, transient eye pain, burning or foreign body sensation in the eye, eye fatigue                                                                                         | Mild symptoms: Apply supplemental tears 4–6 times daily.<br>Severe symptoms or no relief: Refer to an ophthalmologist. Treatment may consist of punctal plugs or anti-inflammatory medications.                 |
| Epiphora                                        | Excessive tear production, usually caused by eye irritation                                                                                                                                                   | Refer to an ophthalmologist.<br>Use topical lubricants.                                                                                                                                                         |
| Hemianopia                                      | Visual field defect that respects the vertical midline in both eyes<br>Can be homonymous or bitemporal                                                                                                        | —                                                                                                                                                                                                               |
| Iridocyclitis                                   | Sensitivity to light, sustained eye pain, decrease in vision                                                                                                                                                  | Refer to an ophthalmologist.<br>Treatment involves the use of anti-inflammatory medications.                                                                                                                    |
| Keratitis and keratopathy                       | Inflammation of the cornea, usually referring to the corneal surface (epithelium)<br>Manifests as pain, photophobia, and increased lacrimation<br>More evident in slit-lamp examination with the aid of a dye | Refer to an ophthalmologist.<br>Use topical lubricants.                                                                                                                                                         |
| Lacrimal duct stenosis                          | Narrowing of the tear duct                                                                                                                                                                                    | Refer to an ophthalmologist.<br>Hold agent.                                                                                                                                                                     |
| Maculopathy                                     | Disease or damage to the central part of the retina or macula                                                                                                                                                 | Refer to an ophthalmologist.<br>Discontinue agent.                                                                                                                                                              |
| Meibomitis (meibomian gland dysfunction)        | Fluctuations in vision (varying degrees), burning sensation in the eye, some mucous discharge, eye redness (may occur only on awakening)                                                                      | Clean eyelid and apply warm compresses to the eyelid for at least 4 minutes twice daily. Use artificial lubricants.<br>If lid scrubs and warm compresses are ineffective, consider topical or oral antibiotics. |
| Optic neuritis                                  | Inflammation of the optic nerve                                                                                                                                                                               | Refer to an ophthalmologist and neurologist.<br>Discontinue agent.                                                                                                                                              |

**TABLE 25-1.** Ocular Toxicities and Their Treatments (*Continued*)

| Toxicity                                         | Definition and Symptoms                                                                                                                                                                                                           | Treatment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Papilledema                                      | Optic disc swelling caused by increased intracranial pressure                                                                                                                                                                     | Use corticosteroids or anti-inflammatory medications.<br>Discontinue agent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Periorbital edema                                | Inflammation and increased fluid accumulation of the interstitial tissues from the eyelid into the orbital septum<br>Manifests as a hard swelling of the eyelid                                                                   | Apply warm compress.<br>Refer to an ophthalmologist.<br>Discontinue agent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Periorbital rash                                 | Discoloration of the tissue around the eye                                                                                                                                                                                        | Use corticosteroids or anti-inflammatory medications, warm compress, and eyelid hygiene.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Photopsia and photophobia                        | Ocular pain and sensitivity to light                                                                                                                                                                                              | Use topical lubricants.<br>Avoid light exposure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Ptosis                                           | Drooping or falling of the upper eyelid over the eye<br>Also known as drooping eyes                                                                                                                                               | Refer to an ophthalmologist and neurologist.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Retinal vein occlusion                           | Blockage of the small veins that carry blood away from the retina                                                                                                                                                                 | Refer to an ophthalmologist.<br>Discontinue agent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Retinopathy                                      | Damage to the retina caused by abnormal blood flow                                                                                                                                                                                | Refer to an ophthalmologist and neurologist.<br>Discontinue agent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Squamous blepharitis (i.e., eyelid skin changes) | Hyperemia, papulopustular rash, crusting<br>Sore and irritated eyelids, with discomfort described as severe<br>Mild redness to significant edema and soreness of the eyelid margin<br>Small pustules at the base of the eyelashes | Acute reactions: Apply warm compresses with a moist washcloth; ensure regular cleaning of the eyelid; use an artificial lubricant.<br>Apply fluorometholone (0.1%) ointment to the eyelid (both skin and lid margin) for 1 week. Do not use for > 2 weeks. An ophthalmologist must examine the patient within 4 weeks.<br>Chronic reactions: Apply tacrolimus 0.03% ointment or pimecrolimus cream twice daily to the skin of the eyelid only. If treatment is minimally effective or not effective at all, try tacrolimus 0.1%. This treatment should not be used for > 6 months. |
| Trichomegaly                                     | Pathologically long eyelashes that can get misdirected and cause ocular surface abrasions                                                                                                                                         | Refer to an ophthalmologist.<br>Trim long or misdirected eyelashes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Uveitis                                          | Inflammation of the uveal tract; can be anterior (involving the anterior chamber and iris) or posterior (involving the vitreous and choroid)                                                                                      | Refer to an ophthalmologist.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

*Note.* Based on information from Bhatti & Salama, 2018; Bindiganavile et al., 2021; Bitton et al., 2019; Brahmer et al., 2018; Chelala et al., 2019; Corbelli et al., 2019; Davis & Francis, 2017; Dolgin, 2020; Durrechou et al., 2020; Emens et al., 2019; Fortes et al., 2021; Fu et al., 2017; Kunkler et al., 2019; Liu et al., 2020; Montazeri & Bellmunt, 2020; Moshirfar et al., 2021; Munir & Aylward, 2017; National Cancer Institute Cancer Therapy Evaluation Program, 2017; Park et al., 2021; Puzanov et al., 2017; Schoenfeld et al., 2020; Shah & Shah, 2019; Shahzad et al., 2021.

ceous and sweat glands (Liu et al., 2020; Moshirfar et al., 2021; Puzanov et al., 2017; Shah & Shah, 2019). The EGFR pathway regulates proliferation and ocular tissue differentiation. Inhibiting EGFR can cause damage to the epidermal cells found in the ocular region, which includes the eye and surrounding skin (Bhatti & Salama, 2018; Fortes et al., 2021; Fu et al., 2017; Moshirfar et al., 2021).

- (1) Examples of EGFR inhibitor-induced effects are tear film dysfunction and unusual hyperpigmentation or hypopig-

mentation. EGFR inhibitors have led to dry eyes, inflammation of the lid margin (blepharitis), dysfunction of the sebaceous glands of the eyelid (meibomitis), corneal erosion, and inversion or eversion of the eyelid margin (Liu et al., 2020; Moshirfar et al., 2021; Shah & Shah, 2019).

- (2) EGFR also has a crucial role in regulating the hair growth cycle.
  - (a) An EGFR inhibitor can hinder this cycle, leading to loss of eyelashes and

eyebrows or an accelerated growth and curling of the eyelashes, leading to tortuous eyelashes or eyelash trichomegaly (Moshirfar et al., 2021).

- (b) Most ocular side effects are not vision threatening but should be followed by an ophthalmologist to quickly treat the discomfort and prevent ocular injury (Bhatti & Salama, 2018; Bitton et al., 2019; Durrechou et al., 2020; Fortes et al., 2021; Moshirfar et al., 2021; National Cancer Institute Cancer Therapy Evaluation Program, 2017; Puzanov et al., 2017; Schoenfeld et al., 2020; Shah & Shah, 2019; Shahzad et al., 2021).
  - h) B-cell maturation antigen–targeted therapies may have a specter of toxicities.
    - (1) Belantamab mafodotin, recently approved by the U.S. Food and Drug Administration to treat multiple myeloma, may produce dry eyes and blurring but can progress to keratopathy (Dolgin, 2020).
    - (2) An ophthalmic examination should be performed at baseline, prior to each dose, and promptly for worsening symptoms.
    - (3) Belantamab mafodotin should be held until improvement. Based on severity, it can be resumed or permanently discontinued (Markham, 2020).
  - i) Antibody-drug conjugates that combine a monoclonal antibody and a cytotoxic drug attachment can be directed to a specific antigen on tumors. Tisotumab vedotin, approved by the U.S. Food and Drug Administration to treat cervical cancer and graft-versus-host disease, has a black box warning specific to ocular toxicities with mitigation strategies (Seagen, 2021).
  - j) A growing number of actionable gene alterations increase the list of targeted treatments. Erdafitinib received U.S. Food and Drug Administration approval as a pan-fibroblast growth factor receptor inhibitor in 2020. Grade 3 or higher ocular toxicities caused permanent discontinuation (Montazeri & Bellmunt, 2020).
2. A broad spectrum of disorders have been documented, including the inflammatory conditions uveitis, conjunctivitis, keratitis, blepharitis, and iritis and the development of retinal opacities, cataract formation, lid and lacrimation disorders, optic neuritis, and other neurologic injuries (Bindigana-vile et al., 2021; Brahmer et al., 2018; Davis & Francis, 2017; Fortes et al., 2021; Kunkler et al., 2019; Puzanov et al., 2017). For site-specific disorders, see Table 25-2.

**TABLE 25-2.** Specific Ocular Toxicities by Anatomic Site

| Site                                 | Ocular Toxicity                                                                                     |
|--------------------------------------|-----------------------------------------------------------------------------------------------------|
| Central nervous system               | Cortical blindness, internuclear ophthalmoplegia, blepharospasm                                     |
| Conjunctiva                          | Conjunctivitis                                                                                      |
| Cornea                               | Keratopathy, keratitis                                                                              |
| Cranial nerves III, IV, V, VI        | Ptosis, paresis with or without diplopia, corneal hypesthesia                                       |
| Extraocular muscles                  | Fibrosis                                                                                            |
| Lacrimal drainage                    | Tear duct fibrosis, punctal occlusion                                                               |
| Lacrimal gland                       | Keratoconjunctivitis sicca                                                                          |
| Lens                                 | Cataract                                                                                            |
| Lids                                 | Cicatricial ectropion, ankyloblepharon, increased lid necrosis after cryotherapy, hyperpigmentation |
| Optic nerve                          | Disc edema, optic neuritis, optic atrophy                                                           |
| Orbit                                | Arteriovenous shunts, cavernous sinus syndrome, edema, exophthalmos, pallor, pain                   |
| Pupil                                | Pinpoint pupils, internal ophthalmoplegia                                                           |
| Retina                               | Toxic retinopathy                                                                                   |
| Sclera                               | Discoloration                                                                                       |
| Trabecular meshwork and ciliary body | Increased intraocular pressure                                                                      |
| Uvea                                 | Uveitis                                                                                             |
| Vitreous                             | Opacification                                                                                       |

*Note.* Based on information from Bhatti & Salama, 2018; Bindigana-vile et al., 2021; Bitton et al., 2019; Brahmer et al., 2018; Davis & Francis, 2017; Durrechou et al., 2020; Fortes et al., 2021; Fu et al., 2017; Kunkler et al., 2019; Liu et al., 2020; National Cancer Institute Cancer Therapy Evaluation Program, 2017; Park et al., 2021; Puzanov et al., 2017; Schoenfeld et al., 2020; Shahzad et al., 2021; Young et al., 2021.

3. With frequent use of combination therapy, it may be challenging to determine the specific drug causing complications.
4. Patients may experience toxicity-related visual impairment during and up to two weeks after chemotherapy (Kende et al., 1979). Neurologic damage to the eye has occurred up to 43 days following chemotherapy (Warrell & Berman, 1986).
5. The toxic effect of certain drugs may be cumulative and dose dependent.

6. Ocular changes may go unnoticed until irreversible damage occurs (Shahzad et al., 2021).
7. Ocular signs and symptoms, such as dry eyes and keratoconjunctivitis sicca, may precede the development of peripheral neuropathies and thus may be an important marker of neurologic status (Bhatti & Salama, 2018).
8. The presence of ocular signs or symptoms may predict the development of graft-versus-host disease in patients who have received an allogeneic hematopoietic stem cell transplant (Munir & Aylward, 2017).
9. Ocular changes may be incorrectly attributed to the aging process and underreported (Brahmer et al., 2018; Davis & Francis, 2017; Kunkler et al., 2019; Schoenfeld et al., 2020).

#### C. Incidence

1. Incidence varies according to drug classification, dose, and route of administration (see Table 25-3).
2. Ophthalmologic effects of chemotherapy occur less frequently and tend to be less severe than other chemotherapy-related side effects. Most ocular side effects tend to improve or even resolve completely upon discontinuation of the drug. Early detection often minimizes sequelae (Bitton et al., 2019; Kunkler et al., 2019; Schoenfeld et al., 2020).
3. Ophthalmic immune-related adverse events have been reported in 1%–3% of patients (Bhatti & Salama, 2018; Bitton et al., 2019; Durrechou et al., 2020; Shahzad et al., 2021). Ocular toxicities occur in 4%–64% of patients using EGFR tyrosine kinase inhibitors; most are grade 2 or lower (Chelala et al., 2019; Fortes et al., 2021; Fu et al., 2017; Liu et al., 2020; Montazeri & Bellmunt, 2020; Shah & Shah, 2019).

D. Risk factors: Causal relationships between agents and ocular toxicities are difficult to establish. Risk factors are equally difficult to establish.

E. Clinical manifestations: These may be noted as class-specific ocular adverse effects and should be anticipated or at least evaluated and reviewed. Most ophthalmic effects can be treated with specific ocular therapy without discontinuation of cancer treatment. Ophthalmologists are integral members of the treatment team, as they maintain a high level of suspicion regarding class effects (Fortes et al., 2021).

#### F. Assessment

1. Ask patients about a history of any eye disturbances and changes to their vision at each visit.
2. In addition, assess the following (Bickley, 2017; Brahmer et al., 2018; Davis & Francis, 2017; Durrechou et al., 2020; Fu et al., 2017; Kunkler et al., 2019; Liu

et al., 2020; Montazeri & Bellmunt, 2020; Moshirfar et al., 2021; National Cancer Institute Cancer Therapy Evaluation Program, 2017; Puzanov et al., 2017; Schoenfeld et al., 2020; Shah & Shah, 2019; Shahzad et al., 2021; Vishnevskia-Dai et al., 2021):

##### a) Visual acuity

- (1) Use a Snellen eye chart if possible.
  - (a) Position the patient 20 feet from the chart.
  - (b) Have the patient wear glasses or contacts for the examination if the corrective lenses are typically used other than for reading.
  - (c) Ask the patient to cover one eye with a card and to read the smallest line possible.
  - (d) Have the patient repeat with the other eye.

- (2) Acuity can be assessed using a near-vision card held at arm's length; patients who wear glasses or contact lenses should remove them. Record any visual disturbances.

##### b) Visual fields

- (1) Sit or stand in front of the patient and have the patient look with both eyes into your eyes.
- (2) While the patient gazes into your eyes, place your hands two feet apart, lateral to the patient's ears.
- (3) Instruct the patient to point to your fingers as soon as they are seen.
- (4) Slowly move your fingers along an imaginary bowl and toward the line of gaze until the patient identifies them.
- (5) Repeat this pattern in upper and lower temporal quadrants.

##### c) Position of eyes, eyebrows, and eyelids

- (1) While standing or sitting in front of the patient, observe the eyes for position and alignment with each other.
- (2) Inspect the eyebrows, noting their quantity and distribution and any flaking of the underlying skin.
- (3) Survey the eyelids, observing and palpating for signs of erythema and edema.
- (4) Assess for signs of exudates, crusting, and presence of ptosis.
- (5) Observe the condition of lashes.

##### d) Lacrimation: Note dryness, foreign body sensation, excessive tearing, or swelling of the lacrimal sac.

##### e) Conjunctiva and sclera

- (1) Ask the patient to look up as you depress both lower lids with your thumbs, exposing the sclera and conjunctiva.

**TABLE 25-3.** Ocular Toxicities of Antineoplastic Agents

| Classification             | Drug                                                                                | Side Effects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Nursing Considerations                                                                                                                                                                                                                                                                                      |

| <b>Chemotherapy Agents (Cont.)</b>  |                           |                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                          |
| Antimetabolites<br>( <i>Cont.</i> ) | Cytarabine                | IV: keratitis and conjunctivitis most common; blurred vision with evidence of bilateral conjunctival hyperemia, ocular pain, photophobia, and foreign body sensation at high doses; case reports of corneal toxicity with low dose of cytarabine<br>Intrathecal: optic neuropathy leading to severe visual loss (potentiated by cranial radiation therapy)                       | Hydrocortisone or dexamethasone eye drops may prevent keratitis. It is recommended to start eye drops the evening before therapy begins. (Bobba & Klein, 2012; Hopen et al., 1981; Lochhead et al., 2003)                                                                                                                                                                |
|                                     | 5-Fluorouracil (Adrucil®) | Conjunctivitis, excessive lacrimation; tear duct fibrosis; blepharitis<br>Other ocular toxicities: keratoconjunctivitis, cicatricial ectropion, ankyloblepharon, blepharospasm, punctal occlusion, oculomotor disturbances, blurred vision, photophobia, nystagmus, increased lid necrosis after cryotherapy, ocular pain, circumorbital edemas, dry eyes, and excessive tearing | Loprinzi et al. (1994) studied ice packs to decrease ocular irritation; effectiveness was also reinforced in a North Central Cancer Treatment Group clinical trial (ice applied for 30 minutes, starting 5 minutes before infusion).<br>The use of dexamethasone eye drops decreased ocular toxicities. (Haidak et al., 1978; Kunkler et al., 2019; Singh & Singh, 2012) |
|                                     | Fludarabine               | Decreased visual acuity (most common presenting sign before the development of progressive encephalopathy); rare cases of diplopia, photophobia, and optic neuritis                                                                                                                                                                                                              | Effects are dose dependent. (Bobba & Klein, 2012; Singh & Singh, 2012)                                                                                                                                                                                                                                                                                                   |
|                                     | Gemcitabine (Gemzar®)     | Retinopathy                                                                                                                                                                                                                                                                                                                                                                      | (Eli Lilly and Company, 2019)                                                                                                                                                                                                                                                                                                                                            |
|                                     | Methotrexate              | IV: blepharitis, conjunctival hyperemia, increased lacrimation, periorbital edema, photophobia, optic pain<br>Intrathecal: With concurrent radiation, case reports of bilateral ophthalmoplegia with exotropia; optic nerve atrophy<br>Intra-arterial: retinal changes in the ipsilateral eye                                                                                    | Up to 25% of patients may develop ocular toxicity. Toxicity is more common with higher doses.<br>The drug is found in tears. (Bobba & Klein, 2012; Singh & Singh, 2012)                                                                                                                                                                                                  |
|                                     | Pemetrexed (Alimta®)      | Conjunctivitis: generally associated with hyperemia, irritation, and serous secretions                                                                                                                                                                                                                                                                                           | Treatment usually involves artificial tears, withdrawal of the agent, and a short course of topical steroids. Treatment is usually curative. (Kunkler et al., 2019)                                                                                                                                                                                                      |
|                                     | Pentostatin (Nipent™)     | Conjunctivitis, photophobia, diplopia; abnormal vision, amblyopia, conjunctivitis, dry eyes, problems with lacrimation, photophobia, retinopathy, watery eyes                                                                                                                                                                                                                    | (Singh & Singh, 2012)                                                                                                                                                                                                                                                                                                                                                    |
| Antitumor antibiotics               | Doxorubicin (Adriamycin®) | Conjunctivitis, increased lacrimation (in up to 25% of patients receiving doxorubicin)                                                                                                                                                                                                                                                                                           | Serious ocular side effects are rare. (Bobba & Klein, 2012; Kunkler et al., 2019; Singh & Singh, 2012)                                                                                                                                                                                                                                                                   |

| Taxanes                                | Docetaxel (Taxotere <sup>®</sup> )                                                 | Epiphora, canalicular stenosis, nasolacrimal duct obstruction, conjunctivitis, punctal stenosis, optic neuropathy                                                                                                                                                                                                                                                                                                                                | The drug is secreted in tears. Successful treatment is achieved with bicanalicular silicone intubation. Optic neuropathy is treated with steroids.<br>(Ahmadi & Esmaeli, 2001; Kunkler et al., 2019; Moloney et al., 2014; Singh & Singh, 2012)                                                                                                                                                                              |
|                                        | Paclitaxel (Taxol <sup>®</sup> )                                                   | Scintillating scotomas or shooting lights in 20% of cases, which resolved spontaneously; transient scintillating scotoma, visual impairment, photopsia, possible ischemic optic neuropathy, bilateral cystoid macular edema, retinal capillary leakage, intracellular fluid accumulation, glaucoma, dry eyes, keratitis                                                                                                                          | Scotomas usually occur toward the end of the 3-hour infusion. Photopsia usually appears during the last 30 minutes of the infusion and resolves within 3 hours. Toxicities are treated by discontinuing the agent and using topical carbonic anhydrase agents and injection of anti-vascular endothelial growth factor antibodies.<br>(Bobba & Klein, 2012; Kunkler et al., 2019; Rao & Choudhry, 2016; Singh & Singh, 2012) |

| Aromatase inhibitors               | Anastrozole (Arimidex®), exemestane (Aromasin®), letrozole (Femara®) | Visual disturbances, retinal hemorrhages, hemiretinal artery occlusion, vitreoretinal traction, corneal epithelial cysts, dry eyes, impact on retinal and optic nerve function                                                                                          | (Chatziralli et al., 2016)                                                                                                                                                                                                                                                                                                                                                                                                       |
|                                    | Tamoxifen (Nolvadex®)                                                | Cataracts and decreased color vision; increased risk with doses > 20 mg daily; retinal toxicity (small refractile or crystalline dot-like yellowish deposits in the area surrounding the macula, in the nerve, and in plexiform layers); corneal opacities; retinopathy | A baseline ophthalmic examination is recommended within the first year. Visual acuity and macular edema may improve with tamoxifen withdrawal, but retinal deposits often do not.<br>Small doses (20–40 mg daily) can cause ocular side effects. The incidence rises with increasing total cumulative dose and duration of treatment.<br>(Bommireddy & Carrim, 2016; Gorin et al., 1998; Singh & Singh, 2012; Tsai et al., 2003) |
| <b>Immunotherapy Agents</b>        |                                                                      |                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Cytokines: interferons             | Interferon alpha, beta, and gamma                                    | Retinopathy, primarily retinal hemorrhages; cotton wool spots; disc edema<br>Vision changes, nonspecific conjunctivitis, and ocular pain are the most frequently reported ocular side effects.                                                                          | Risk is increased in patients with hypertension or diabetes and those receiving higher doses. Effects may occur as soon as 15 minutes after initial exposure or take many months to be apparent. Less than 1% of patients receiving interferon develop ocular toxicities.<br>(Bindiganavile et al., 2021; Kunkler et al., 2019; Willson, 2004)                                                                                   |

| <b>Miscellaneous Agents (Cont.)</b>                                       |                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Miscellaneous<br>(Cont.)                                                  | Ethambutol hydrochloride | Decreased visual acuity, color blindness, visual defect, possible irreversible blindness, optic neuritis                                                                                                                                                                                                                                                                                                                                                                                                                       | Ocular toxicity can happen at any dose but is increased at doses > 50 mg/kg; visual acuity changes can be unilateral or bilateral. Testing for visual acuity should be performed before treatment begins and periodically during treatment unless dose is > 15 mg/kg daily, in which monthly testing is needed. (STI Pharma, 2017)                                                                                                                                                                                                                                                                                                      |
|                                                                           | Mannitol (Osmitrol®)     | Blurred vision                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Because of fluid and electrolyte shifts, side effects can be prevented with close monitoring and test dose to evaluate the degree of renal failure when indicated. (Baxter Healthcare, 2011)                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                                                                           | Tacrolimus (Prograf®)    | Optic neuropathy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | (Ascaso et al., 2012)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Targeted Therapy Agents</b>                                            |                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Monoclonal antibody: chimeric (epidermal growth factor receptor targeted) | Cetuximab (Erbix®)       | Blurred vision, eye pain, visual field cuts; blepharitis; eyelid dermatitis, conjunctivitis, poliosis (whitening of the eyelashes), corneal erosions, punctate keratitis<br>Relatively common: loss of eyelashes or eyebrows (madarosis) and cicatricial ectropion, loss of color of the skin around the eye with weekly infusions; trichomegaly<br>Very rare: bilateral ocular discomfort with itchiness around both eyelids, foreign body sensation, tearing associated with exfoliated skin, oil secretions, crusty scaling | Ocular side effects occurred in < 20% of patients and resolved after treatment was discontinued.<br>Blepharitis was treated with oxytetracycline cream 3 times daily for 20 days.<br>Madarosis and cicatricial ectropion resolved after discontinuation of cetuximab.<br>Ocular discomfort cleared with topical antibiotics and holding therapy. Many researchers recommend an ophthalmologist referral for patients experiencing trichomegaly if eye irritations occur, and eyelashes may be carefully and safely trimmed. (Fortes et al., 2021; Kunkler et al., 2019; Liu et al., 2020; Liu & Kurzrock, 2015; Moshirfar et al., 2021) |
| Small molecule inhibitors                                                 | Afatinib (Gilotrif®)     | Conjunctivitis, keratitis, blepharitis, corneal thinning and erosion, dry eyes, trichomegaly, uveitis                                                                                                                                                                                                                                                                                                                                                                                                                          | Ocular toxicity occurred in 13%–20% of patients; none were greater than grade 3. (Fortes et al., 2021; Fu et al., 2017; Kunkler et al., 2019; Shah & Shah, 2019)                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                                                                           | Axitinib (Inlyta®)       | Retinal artery occlusion, retinal vein occlusion/thrombosis                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | (Fortes et al., 2021)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Small molecule inhibitors ( <i>Cont.</i> ) | Imatinib mesylate (Gleevec <sup>®</sup> ) | Periorbital edema; dry eyes; visual disorders such as blurred vision, reduced visual acuity, and visual disturbances; epiphora, optic neuritis, cystoid macular edema                                                   | Periorbital edema develops in 70% of patients and usually occurs 5–8 weeks after treatment starts. It can occur 24 hours after treatment starts or up to 1 year after, depending on dose. It is usually mild and does not require therapy. (Davis, 2016; Fortes et al., 2021; Fu et al., 2017; Liu & Kurzrock, 2015; Singh & Singh, 2012) |
|                                            | Nilotinib (Tasigna <sup>®</sup> )         | Hemorrhage, periorbital edema, pruritis, conjunctivitis, dry eyes<br>Rarely causes diplopia, photophobia, blepharitis                                                                                                   | Hold drug; refer to an ophthalmologist. (Bindiganavile et al., 2021)                                                                                                                                                                                                                                                                      |
|                                            | Pazopanib (Votrient <sup>®</sup> )        | Eyelash discoloration, eye edema                                                                                                                                                                                        | (Fortes et al., 2021)                                                                                                                                                                                                                                                                                                                     |
|                                            | Sunitinib (Sutent <sup>®</sup> )          | Periorbital edema; neurosensory retinal detachment; increased lacrimation; eyelid edema                                                                                                                                 | Effects resolve after epidermal growth factor receptor inhibitor treatment is discontinued. (Davis, 2016; Fortes et al., 2021)                                                                                                                                                                                                            |
|                                            | Trametinib (Mekinist <sup>®</sup> )       | Gradual or immediate loss of vision, including blind spots; temporarily or permanently blurred vision; dimness of vision; double vision; halo vision around lights; colorful spots or floaters; changes in color vision | Ocular toxic effects were seen in 15% of patients. (Bindiganavile et al., 2021; Davis, 2016; Fortes et al., 2021; Purbrick et al., 2017; Vishnevskia-Dai et al., 2021)                                                                                                                                                                    |
|                                            | Vandetanib (Caprelsa <sup>®</sup> )       | Conjunctivitis, corneal structure change, glaucoma, vortex keratopathies, cataract, dry eyes, blurred vision, visual impairment, halo vision, photopsia, accommodation disorders                                        | Cornea verticillata (brownish lines within the corneal epithelium) may develop. Complete regression of the cornea verticillata occurs after the drug is discontinued, but it may take several months to resolve. (Bindiganavile et al., 2021; Davis, 2016; Fortes et al., 2021)                                                           |
|                                            | Vemurafenib (Zelboraf <sup>®</sup> )      | Uveitis, iritis, retinal vein occlusion, blurry vision, photophobia, vision disorder                                                                                                                                    | Treatment may need to be held; refer to an ophthalmologist. (Fortes et al., 2021; Liu et al., 2020; Vishnevskia-Dai et al., 2021)                                                                                                                                                                                                         |

*Note.* This table may not include all antineoplastics that cause ocular toxicities. Review package inserts for dosing and prescribing information.

- (2) Inspect for color, vascular pattern, discharge, and any nodules or swelling.
- f) Cornea, lens, iris, and pupils
  - (1) Observe the cornea and lens for a smooth appearance, clarity, and any opacities in the lens.
  - (2) Test corneal reflex by gently touching a cotton swab to the corneal surface.
  - (3) Observe iris and pupils.
  - (4) Margins should be clearly identified.
  - (5) Observe the pupils for size, shape, and symmetry.
  - (6) If the pupils are larger than 5 mm or smaller than 3 mm, measure the pupils with a pupil guide (a card or penlight with black circles of varying sizes).
  - (7) Test the pupils for light reaction, observing for direct reaction (pupillary constriction in the same eye) and consensual reaction (pupillary constriction in the opposite eye).
  - (8) Note pain and photophobia.
- g) Extraocular muscles (cranial nerves)
  - (1) Observe for light reflex (shining a light in the patient's eyes and inspecting the reflections in the corneas) and extraocular movement by having the patient follow finger movements in six planes and convergence.
  - (2) Note any unilateral movement, lack of movement, nystagmus, lid lag, or other abnormal movements.

#### G. Collaborative management

1. Refer to an ophthalmologist for further evaluation and treatment (Dolgin, 2020; Fortes et al., 2021; Kunkler et al., 2019; Shah & Shah, 2019; Vishnevskia-Dai et al., 2021; Young et al., 2021).
2. Symptoms that necessitate a referral (Bhatti & Salama, 2018; Brahmer et al., 2018; Davis & Francis, 2017; Fu et al., 2017; Kunkler et al., 2019; Montazeri & Bellmunt, 2020; Munir & Aylward, 2017; National Cancer Institute Cancer Therapy Evaluation Program, 2017; Puzanov et al., 2017)
  - a) Persistent ocular pain, significant loss of vision, or decreased acuity of vision
  - b) Severe redness of the eye or light sensitivity
  - c) Trichomegaly
  - d) Failure to respond to treatment within one week of initiation for squamous blepharitis, meibomitis, or dysfunctional tear syndrome
3. Instruct patients to use pharmacologic management as appropriate (e.g., antibiotics, steroids, artificial tears).
4. To prevent further damage, discontinue the causative agent and promote symptom management.
5. Surgical interventions may be necessary (e.g., cataract surgery, dilation for punctal stenosis, enucleation).

#### H. Patient and family education

1. Teach patients self-examination techniques, emphasizing the importance of close monitoring and prompt reporting of any structural changes in eyelids or eyelashes or changes in vision.
2. Emphasize the importance of careful hygiene and handwashing techniques to minimize cross-contamination.
3. Demonstrate the proper use of eye drops and lubricants.
4. Encourage patients to schedule regular eye examinations (Brahmer et al., 2018; Davis & Francis, 2017; Durrechou et al., 2020; Fortes et al., 2021; Puzanov et al., 2017; Schoenfeld et al., 2020; Young et al., 2021).

## SECTION VI

# Post-Treatment

Chapter 26. Post-Treatment and Survivorship Care

## CHAPTER 26

# Post-Treatment and Survivorship Care

### A. Overview

1. Fitzhugh Mullan coined the term *cancer survivorship*.
  - a) In 1985, he famously wrote about his experience with cancer and acknowledged that survivorship “begins at the point of diagnosis” (Mullan, 1985, p. 270).
  - b) Subsequently, major federal, public, and private cancer organizations have defined survivorship as beginning with diagnosis and continuing for the rest of life.
  - c) An important concept to understand is that survivorship includes people living with cancer.
2. Over the past 35 years, the number of cancer survivors in the United States has increased from 3 million to more than 16.9 million (American Cancer Society, 2019).
  - a) The number is expected to increase to 22.1 million (a 34% increase) by 2030 (American Cancer Society, 2019).
  - b) The past 20 years have seen a continuous decline in mortality in the most prevalent cancers—lung, breast, prostate, and colorectal (Siegel et al., 2022).
  - c) A decrease in tobacco use, earlier cancer diagnoses, and advances in cancer treatment have led to an improvement in five-year relative survival rates for all cancers from 49% in the 1970s to 66% for those diagnosed between 2014 and 2018 (Noone et al., 2018; U.S. Cancer Statistics, 2021).
  - d) In 2019, approximately 64% of survivors were aged 65 years or older (Miller et al., 2019).
  - e) The exponential growth in older survivors has been called the “silver tsunami.” An estimated 73% of cancer survivors will be aged 65 years or older by 2040 (Bluethmann et al., 2016).
  - f) In 2021, approximately 64% of survivors were diagnosed five or more years ago, 15% were diagnosed 20 or more years ago, and 5% were diagnosed 30 or more years ago (U.S. Cancer Statistics, 2021).
3. Childhood cancer survivors constitute 0.5%–3% of the cancer survivor population (Denlinger et al., 2014).
  - a) Approximately 85% of children and adolescents survive a cancer diagnosis (Siegel et al., 2022). However, long-term childhood cancer survivors are at risk for long-term effects from disease and treatment.
  - b) Research suggests that approximately 60%–90% of survivors of childhood cancers have one or more treatment- or disease-related long-term effect (Phillips et al., 2015).
  - c) The Children’s Oncology Group published long-term follow-up guidelines for screening and management of late effects for survivors of childhood cancer ([www.survivorshipguidelines.org](http://www.survivorshipguidelines.org)).
  - d) The organized research effort to prospectively follow childhood cancer survivors has provided data for long-term care recommendations. Data-driven recommendations for adults are often cancer type and treatment specific.
4. Adult cancer survivors
  - a) Currently, 64% of cancer survivors are aged 65 years or older, and almost half (47%) are aged 70 or older (Cancer.Net, 2019; Miller et al., 2019).
  - b) In the United States, the five-year relative survival rate is worse for Black people (62%) than for White or other races (66%), with Black women faring the worst (61.6%) (U.S. Cancer Statistics Working Group, 2021).
5. Long-term and late effects
  - a) In addition to the physical long-term and late effects of cancer and its treatment, cancer survivors may face psychological, financial, emotional, spiritual, and social challenges.
  - b) The number and types of continuing, long-term, and late effects experienced by survivors are influenced by the type and dose of treatments received.
6. Nursing
  - a) Nurses have multiple roles in the continuing care of cancer survivors.

- b) These roles include monitoring, assessing, and treating survivors for the effects of treatment that emerge after completion of therapy.
- c) Nurses have a vital role in teaching survivors about the advantages of a healthy lifestyle and other interventions to minimize the potential effects of cancer diagnosis and treatment.

## B. Cancer survivorship care

1. The goals of survivorship care were outlined in a seminal report by the Institute of Medicine (now the National Academy of Medicine) (Hewitt et al., 2006).
  - a) Surveillance for cancer spread, recurrence, and second cancers and assessment of medical and psychosocial late effects
  - b) Prevention of recurrent and new cancers and other late effects
  - c) Intervention for consequences of cancer and its treatment
  - d) Coordination between primary and specialty care
2. The essential elements of survivorship care to achieve these goals were defined by interprofessional clinical and research experts in 2011 (Livestrong, 2011). Accrediting organizations such as the American College of Surgeons Commission on Cancer (ACoS CoC, 2022) adapted these elements as services for optimal cancer care.
  - a) Services include screening for recurrence and new cancers, symptom management, health promotion education, care coordination, and a survivorship care plan (SCP), including a treatment summary (ACoS CoC, 2022).
  - b) Other recommended services include comprehensive medical and psychosocial assessment and care, a transition visit, nutrition services, rehabilitation, physical activity programs, psychiatric services, financial support, patient navigation, and family and caregiver support (ACoS CoC, 2022).
3. ACoS CoC (2022) requires accredited healthcare organizations to offer at least three survivorship care services and hire and support a cancer survivorship program coordinator. SCPs are recommended but no longer required.
4. Regular follow-up care for all cancer survivors is recommended.
  - a) The National Comprehensive Cancer Network (NCCN) provides evidence-based guidelines for disease-specific follow-up care.
  - b) Betty R. Ferrell developed a quality-of-life model for the physical, psychosocial, emotional, and spiritual well-being of cancer survivors. It can be used as a framework for the holistic assessment of cancer survivors (Ferrell & Hassey Dow, 1997).

- c) A holistic assessment can help target the type of survivorship care needed and facilitate person-centered care (Young et al., 2015).
- d) Early follow-up care should occur frequently and emphasize the management of continuing physical, psychological, financial, emotional, spiritual, and social effects of the disease, its treatment, and surveillance for and detection of disease recurrence.
- e) Long-term follow-up care focuses on anticipating and identifying late effects of the disease or treatment, assessing quality of life, and providing continued surveillance for disease recurrence.

## 5. Nursing

- a) Interprofessional cancer care teams, primary care providers, and other specialist providers often participate in post-treatment care, making coordination of care a crucial component of survivorship care (Salz & Baxi, 2016).
- b) Nurses often play the coordinator role.
- c) In addition, registered nurses and advanced practice nurses are identified as members of the cancer care team prepared to coordinate survivorship programs and deliver survivorship care, including SCPs, to survivors after treatment completion (ACoS CoC, 2022).
- d) Advanced practice nurses, known providers of cost-effective, quality patient care, deliver survivorship care following National Academy of Medicine goals (Thom et al., 2019).

## 6. Cancer SCPs

- a) Delivery and discussion of SCPs to all patients completing primary treatment are recommended by survivorship advocates and accrediting organizations (ACoS CoC, 2022). Despite the promise of SCPs, research trials have not yet demonstrated efficacy (Salz & Baxi, 2016).
- b) SCPs include general patient information, a treatment summary, a plan for cancer surveillance, recommendations for other cancer screening, suggested health behaviors, education about possible late effects specific to the cancer type, and treatment and support resources.
- c) Many organizations have developed templates for SCPs (American Society of Clinical Oncology, n.d.; Livestrong, n.d.; see Table 26-1).

## 7. Models of survivorship care

- a) Although different models for delivering survivorship care have been implemented, the superiority of one model has not yet been demonstrated, and models vary widely by institution.
- b) Models may include specialist-led, nurse-led, community-based, primary provider-led, or interprofessional or shared care (Powel & Seibert, 2017).

### C. Long-term and late effects of cancer treatment

1. Long-term effects occur during treatment and continue beyond the acute period of recovery from treatment. Late effects occur a significant time after the end of treatment.
2. Perhaps the most common long-term effect is fear of recurrence (Sharpe et al., 2018, Smith et al., 2020).
  - a) The fear can manifest in specific situations, such as waiting for cancer surveillance test results, or it may be a more global fear.
  - b) When the stress of living with uncertainty is global, it can contribute to a cluster of symptoms, such as sleep disturbance, fatigue, and cognitive changes (Guimond et al., 2020).
  - c) Financial toxicity, prolonged changes in social and professional roles, and disruption of life's meaning can contribute to the stress of living with uncertainty.
  - d) Guidelines on assessing and treating these symptoms can be found in the other chapters of this book and on the NCCN ([www.nccn.org](http://www.nccn.org)) and Oncology Nursing Society ([www.ons.org](http://www.ons.org)) websites.
3. The most serious and life-threatening late effects of cancer treatment are cardiovascular disease (CVD) and second primary cancers.
4. Nonmalignant late effects
  - a) Incidence
    - (1) Approximately 40%–70% of survivors will develop a health problem related to cancer or its treatment (Demoor-Goldschmidt &

de Vathaire, 2019). Age of diagnosis and treatment, comorbidities, and exposures increase the risk of developing a long-term or late effect from cancer treatment.

- (2) Female childhood cancer survivors are more likely than male survivors to have one or more chronic health condition (Oeffinger et al., 2006).
  - (3) The cumulative incidence of a chronic health condition in childhood cancer survivors is more than 70% within 30 years of the cancer diagnosis. More than 40% of these conditions will be severe, disabling, or fatal (Oeffinger et al., 2006). Hospitalization rates of childhood cancer survivors are 1.6 times the rate of the general U.S. population, indicating that while cure may be attainable for many children with cancer, the long-term health effects and costs associated with treatment-related long-term toxicities are notable (Kurt et al., 2012).
- b) Potential long-term and late effects (see Table 26-2)
- (1) Auditory
  - (2) Bladder
  - (3) Cardiovascular
    - (a) The most common long-term and late effects of the heart are cardiomyopathies, subclinical left ventricular dysfunction, coronary artery

**TABLE 26-2.** Potential Long-Term and Late Effects and Associated Treatments

| Function or System    | Associated Treatments                                                                                                                                                                                                                       | Potential Late Effects                                                                                                                                                        |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Auditory              | Platinum agents, head radiation therapy                                                                                                                                                                                                     | Hearing loss, tinnitus                                                                                                                                                        |
| Bladder               | Cyclophosphamide, pelvic and lumbar–sacral radiation, spinal surgery, cystectomy, prostatectomy                                                                                                                                             | Bladder fibrosis, incontinence, neurogenic bladder                                                                                                                            |
| Cardiovascular        | Anthracyclines, cyclophosphamide, cisplatin, 5-fluorouracil, taxanes, trastuzumab, radiation therapy                                                                                                                                        | Cardiomyopathy, ischemia, pericardial disease, arrhythmias, congestive heart failure, coronary artery disease, valvular heart disease                                         |
| Cognitive             | Intrathecal or high-dose methotrexate; high-dose cytarabine; adjuvant chemotherapy for breast cancer; systemic chemotherapy treatment for lung cancer, ovarian cancer, and lymphoma; cranial radiation; neurosurgery                        | Alterations in attention, concentration, memory, and mental processing speed; visual and auditory impairment; dementia                                                        |
| Endocrine             | Immunotherapy, corticosteroids, hormone therapy, head/neck and abdominal/pelvic radiation therapy, hematopoietic stem cell transplantation                                                                                                  | Hypothyroidism, hypopituitarism, hyperparathyroidism, adrenal dysfunction                                                                                                     |
| Gastrointestinal      | Head/neck, abdominal, and pelvic radiation therapy; head/neck, colorectal, and pelvic/spinal surgery; hematopoietic stem cell transplantation with chronic graft-versus-host disease                                                        | Diarrhea, constipation, incontinence, gastrointestinal tract strictures/fibrosis/vasculitis, obstruction, impaired swallowing, impaired absorption of nutrients, fistulas     |
| Hepatic               | Antimetabolites, abdominal radiation therapy, hematopoietic stem cell transplantation                                                                                                                                                       | Hepatitis B and C, hepatic dysfunction, cirrhosis, cholelithiasis                                                                                                             |
| Lymphatic             | Radiation therapy, melanoma excision, pelvic lymph node dissection, axillary lymph node dissection                                                                                                                                          | Lymphedema                                                                                                                                                                    |
| Multisystem           | Any treatment                                                                                                                                                                                                                               | Fatigue, sleep disturbance, chronic pain                                                                                                                                      |
| Neurologic—central    | High-dose intravenous and intrathecal methotrexate; high-dose cytarabine; head, brain, and neck radiation therapy; neurosurgery                                                                                                             | Motor and sensory deficits, leukoencephalopathy, stroke, seizures                                                                                                             |
| Neurologic—peripheral | Brachial or lumbosacral plexus radiation therapy, spinal surgery, vincristine, vinblastine, platinum agents, taxanes, bortezomib, thalidomide                                                                                               | Brachial plexopathy, peripheral neuropathy                                                                                                                                    |
| Ocular                | Corticosteroids, busulfan, tamoxifen, head and total body irradiation, neurosurgery, hematopoietic stem cell transplantation with graft-versus-host disease                                                                                 | Cataracts, glaucoma, retinopathy, ocular nerve palsy, xerophthalmia                                                                                                           |
| Oral                  | Head and total body irradiation, hematopoietic stem cell transplantation with graft-versus-host disease                                                                                                                                     | Xerostomia, tooth decay                                                                                                                                                       |
| Psychosocial          | Any cancer treatment                                                                                                                                                                                                                        | Fear of recurrence, adjustment disorder, depression, anxiety, post-traumatic stress disorder, altered body image, financial toxicity and health insurance coverage challenges |
| Renal                 | Cisplatin, methotrexate, nitrosoureas, nephrectomy, abdominal and total body irradiation                                                                                                                                                    | Renal dysfunction, hypertension, chronic kidney disease                                                                                                                       |
| Respiratory           | Alkylating agents, bleomycin, busulfan, and nitrosoureas; head/neck, chest, and total body irradiation/radiation therapy; head/neck surgery and pulmonary lobectomy; hematopoietic stem cell transplantation with graft-versus-host disease | Dyspnea, restrictive lung disease, pulmonary fibrosis, pneumonitis, idiopathic pneumonia syndrome, bronchiolitis obliterans                                                   |

(Continued on next page)

**TABLE 26-2.** Potential Long-Term and Late Effects and Associated Treatments

| Function or System  | Associated Treatments                                                                                                                                             | Potential Late Effects                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Sexual/reproductive | Alkylating agents, abdominal/pelvic radiation and surgery, androgen-suppressing treatments                                                                        | Infertility; higher risk of miscarriage, preterm labor, and low birth-weight infants; erectile dysfunction; painful sex; diminished libido |
| Skeletal            | Alkylating agents, anthracyclines, taxanes, corticosteroids, hormone therapies, aromatase inhibitors, pelvic radiation therapy, orchiectomy, androgen deprivation | Osteopenia, osteoporosis, avascular necrosis                                                                                               |

Note. Based on information from Andersen et al., 2014; Bower et al., 2014; Given & Vachon, 2019; Hershman et al., 2014; Koelwyn et al., 2012; Lenihan & Cardinale, 2012; Marchese et al., 2011; National Comprehensive Cancer Network, 2021a, 2021b; Travis et al., 2012; Treanor & Donnelly, 2014; Valdivieso et al., 2012.

From "Late Effects of Cancer Treatment," by K.M. Slusser, in C.H. Yarbro, D. Wujcik, and B.H. Gobel (Eds.), *Cancer Nursing: Principles and Practice* (8th ed., p. 2031), 2018, Jones and Bartlett Learning. Copyright 2018 by Jones and Bartlett Learning. Adapted with permission.

disease, valvular heart disease, pericardial disease, and arrhythmias (see Chapter 16).

- (b) More than 50% of children treated for childhood cancers are at an increased risk for CVD 5–10 years following chemotherapy (Henning & Harbison, 2017).
- (c) Cardiotoxicity from commonly used anticancer drugs (e.g., anthracyclines, monoclonal antibodies, tyrosine inhibitors) may not occur or become clinically evident until 10–20 years after chemotherapy treatment (Henning & Harbison, 2017).
- (d) The risk of developing anthracycline-associated cardiotoxicity increases with the lifetime cumulative dose of doxorubicin at 400–550 mg/m<sup>2</sup>, with many survivors receiving lower doses (McGowan et al., 2017). All survivors treated with an anthracycline should be considered at risk for cardiac dysfunction.
- (e) Cisplatin can be detected in the blood 20 years after treatment (Fung et al., 2019). It is associated with an increased risk of obesity, dyslipidemia, and hypertension, contributing to CVD (Okwuosa et al., 2017).
- (f) Chest irradiation, particularly to the left side or mantle, increases the risk of coronary artery disease, congestive heart failure, peripheral vascular disease, and arrhythmias (NCCN, 2021b).
- (4) Endocrine: hypothyroidism, growth hormone deficiency, gonadal failure, panhy-

popituitarism, adrenal insufficiency or dysfunction, diabetes mellitus, hypopituitarism, hyperparathyroidism (Gebauer et al., 2019; Treanor & Donnelly, 2014)

- (5) Gastrointestinal: impaired swallowing; gastrointestinal tract strictures, fibrosis, or vasculitis; obstruction; impaired absorption of nutrients; fistulas; incontinence; diarrhea; constipation (Slusser, 2018)
- (6) Hepatic: liver dysfunction, cirrhosis, hepatitis B and C (Treanor & Donnelly, 2014)
- (7) Lymphatic: cancer-related lymphedema (National Cancer Institute, 2019)
- (8) Neurologic: cognitive impairment, leukoencephalopathy, visual and auditory impairment, brain atrophy, brain necrosis, dementia, brachial plexopathy, peripheral neuropathy (Treanor & Donnelly, 2014; see Chapter 24)
- (9) Ocular
  - (a) Cataracts occur most often after alkylating agents, tamoxifen, and glucocorticoid steroids (Bommireddy & Carrim, 2016; Prenskey et al., 2018).
  - (b) Ocular inflammation (e.g., uveitis, episcleritis) has been associated with checkpoint inhibitors and other immunotherapy agents (Kunkler et al., 2019; NCCN, 2021a; see Chapter 25).
- (10) Oral: xerostomia, dental caries, infection and gum disease, after radiation to head and neck, chemotherapy, chronic graft-versus-host disease (Barrett & Cassidy, 2019; Cancer.Net, 2020)
- (11) Pulmonary: pulmonary fibrosis, dyspnea, radiation pneumonitis, idiopathic pneumonia syndrome, bronchiolitis obliter-

ans, generally impaired pulmonary function (Treanor & Donnelly, 2014)

- (12) Psychosocial effects (McFarland & Holland, 2016)
    - (a) Psychosocial issues: social withdrawal, relationship issues, body image changes, sexuality issues
    - (b) Mental health disorders: adjustment, delirium, depression, anxiety, post-traumatic stress
    - (c) Financial and vocational issues: employment, access to health care, insurance, educational assistance
  - (13) Renal: nephropathy, chronic kidney disease (Treanor & Donnelly, 2014)
  - (14) Skeletal: osteopenia, osteoporosis, osteonecrosis (Treanor & Donnelly, 2014)
  - (15) Sexual and reproductive: gonadal failure; treatment-induced menopause; infertility; higher risk of miscarriage, preterm labor, and low birth-weight infants; sexual dysfunction, including loss of libido, erectile dysfunction, and pain (Treanor & Donnelly, 2014; see Chapter 20)
5. Malignant late effects
- a) A second primary cancer is a new cancer distinct from the original malignancy that does not represent metastatic disease from the first primary tumor (Wood et al., 2012).
  - b) Incidence of second cancers
    - (1) Approximately 15%–20% of cancers are second cancers (Demoor-Goldschmidt & de Vathaire, 2019; Donin, 2016).
    - (2) Cancer survivors have an increased risk of developing another malignancy, given the longer duration of cancer survivorship. The lifetime risk is as high as 33% in some populations and includes a greater risk for mortality. More than 8% of survivors diagnosed with one of the 10 most prevalent cancers were found to have a second cancer, the most common of which being lung cancer (Donin et al., 2016).
    - (3) The 30-year cumulative incidence of second cancers among survivors of childhood malignancies is 3.9% after chemotherapy, 9% after chemotherapy and radiation, and 10.8% after radiation when excluding nonmelanoma skin cancer (Turcotte et al., 2019).
  - c) Pathophysiology
    - (1) Chemotherapy and radiation therapy cause DNA damage, the mechanism that leads to apoptosis. However, if nonlethal DNA damage occurs, DNA repair is criti-

cal to prevent the development of a second cancer (Cowell & Austin, 2012).

- (2) Alkylating chemotherapy agents transfer an alkyl group to DNA, causing DNA mismatch and inhibition of DNA replication and transcription.
    - (a) A DNA mismatch repair mechanism is responsible for repairing this cell damage; otherwise, apoptosis occurs.
    - (b) If cells survive with a dysfunctional DNA mismatch repair or genomic instability, this may lead to malignancy (Allan & Travis, 2005; Cowell & Austin, 2012; Tward et al., 2007).
  - (3) Topoisomerase II inhibitors
    - (a) Topoisomerase II inhibitors cause double-stranded DNA breaks, which leads to apoptosis.
    - (b) If the cell survives, these DNA breaks may cause chromosomal translocations of the histone-lysine N-methyltransferase 2A (*KMT2A*) gene, formerly known as the myeloid lymphoid leukemia/mixed-lineage leukemia (*MLL*) gene, or other crucial transforming genes that can lead to leukemia (Allan & Travis, 2005; Cowell & Austin, 2012; Tward et al., 2007).
  - (4) Radiation therapy
    - (a) Radiation therapy deposits energy in or near DNA, resulting in genetic or epigenetic changes that cause apoptosis.
    - (b) If radiation induces variations in the DNA and the cells do not die, the variants are passed on to cellular progeny and may lead to malignant transformation (Gebauer et al., 2019; Travis et al., 2014).
  - (5) Chemotherapy and radiation therapy interact with other factors, such as tobacco exposure, genetic makeup, hormone status, and immune function, and contribute to the development of second cancers (Allan & Travis, 2005; Travis et al., 2014).
- d) Types of second primary cancers
- (1) The two major types of second cancers are acute myeloid neoplasms and solid neoplasms.
  - (2) The relative risk of treatment-related leukemia is generally most significant during the first five years after therapy (Wood et al., 2012).
  - (3) Solid tumors occur at least 5–10 years after treatment. The risk differs across

the age spectrum by type of malignancy, latency period, associated risk factors, and modifying influences (Ng et al., 2010).

- (4) Treatment-related acute myeloid leukemia/myelodysplastic syndrome generally presents within five years of chemotherapy and is most associated with alkylating agents or topoisomerase inhibitors.
- (5) Two types of treatment-related leukemia exist (Fung et al., 2019).
  - (a) Alkylating agent-induced acute myeloid leukemia (Fung et al., 2019)
    - i. Risk is associated with alkylating agents, such as cyclophosphamide, cisplatin, melphalan, chlorambucil, and nitrosoureas.
    - ii. The disease usually occurs five to eight years after treatment.
    - iii. Development is associated with myelodysplastic syndrome and deletion or loss of chromosome 5 or 7.
  - (b) Topoisomerase II inhibitor-induced acute leukemia (Fung et al., 2019)
    - i. Risk is associated with topoisomerase II inhibitors, such as etoposide, teniposide, mitoxantrone, and anthracyclines.
    - ii. The disease usually occurs two to three years after treatment.
    - iii. Occurrence is often not associated with preceding myelodysplastic syndrome.
    - iv. Development is associated with chromosomal translocations 11q23 or 21q22, and sometimes t(15;17).
- e) Treatment-related risk factors of second primary cancers
  - (1) Chemotherapy
    - (a) Chemotherapy is associated with a risk of second cancers, primarily treatment-related leukemia and, to a lesser extent, solid tumors (Cowell & Austin, 2012; Demoor-Goldschmidt & de Vathaire, 2019; Morton et al., 2019; Ng & Travis, 2008; Travis et al., 2010).
    - (b) Alkylating agents are associated with the greatest incidence of second cancers. Risk increases with higher cumulative doses (Turcotte et al., 2019).

(c) A higher cumulative dose increases the risk of treatment-related leukemia (Leone et al., 2011; Travis et al., 2010; Turcotte et al., 2019).

(d) Agents with known carcinogenic potential are noted in Chapter 6.

(2) Radiation therapy

(a) Radiation-induced second cancers tend to occur within or at the margins of the radiation field, and the risk increases with the dose of radiation and the extent of the radiation field (Demoor-Goldschmidt & de Vathaire, 2019; Wood et al., 2012).

(b) Radiation-induced second cancers can occur in the bone (e.g., sarcoma), breast, lung, cervical, prostate, skin, stomach, esophageal, thyroid, blood (e.g., myelodysplastic syndrome, leukemia), and lymph systems (e.g., Hodgkin lymphoma). They are often observed 5–10 years after treatment, and the risk persists for decades (Demoor-Goldschmidt & de Vathaire, 2019; Travis et al., 2014; Wood et al., 2012).

(c) Radiation-associated solid tumors are the most common second cancers (Ng et al., 2010).

(d) Cranial irradiation at 18–24 Gy (Gray) doses increases the risk for central nervous system malignancy by 17-fold after five years in acute lymphoblastic leukemia survivors (Erb & Vogel, 2013).

(e) The risk of a second cancer diagnosis was similar after intensity-modulated radiation versus three-dimensional conformal radiation therapy. In contrast, proton beam radiation therapy was associated with lower risk of a second cancer.

(f) The risk of second cancers is similar with involved-field radiation therapy compared to three-dimensional conformal radiation therapy. It is possibly lower in proton beam radiation therapy (Xiang et al., 2020).

(3) Combination chemotherapy and radiation

(a) Many cancers are treated with combination and, at times, concurrent therapy.

(b) Combination therapy increases the risk of late effects, including second cancers. Few high-quality stud-

- ies have reported the association of combination radiation and chemotherapy, including alkylating agents, with increased risk of second cancers (Morton et al., 2013; Oeffinger et al., 2006).
- (c) Exposure to one of five specific combinations is associated with a risk of having a severe health condition that is at least 10 times the expected risk of the general population (Oeffinger et al., 2006).
    - i. Chest irradiation plus bleomycin
    - ii. Chest irradiation plus an anthracycline
    - iii. Chest irradiation plus abdominal or pelvic irradiation
    - iv. An anthracycline plus an alkylating agent
    - v. Abdominal or pelvic irradiation plus an alkylating agent
  - (4) Immunotherapy
    - (a) Data on late effects of immunotherapy are emerging as agents are approved and individuals receive standard-of-care treatment with long-term follow-up.
    - (b) A unique attribute of immunotherapy treatment is the potential for long-term immunogenicity surveillance that can protect against future recurrence but may also have adverse sequelae for healthy cells.
    - (c) Most late effects (e.g., pneumonitis, pericarditis, enterocolitis) are reported in the context of case studies and are related to checkpoint inhibitors (Blevins Primeau, 2018).
    - (d) A cohort study reported a 43% rate of chronic immune-related adverse events from anti-programmed cell death protein 1 therapy in patients treated for melanoma. The most frequent events were mild and included endocrinopathies, arthritis, xerostomia, neurotoxicity, and ocular changes (Patrinely et al., 2021).
    - (e) Immunotherapy agents targeting the BRAF protein are used to treat melanoma and are being studied for use in other cancers. A meta-analysis showed a significantly higher risk of squamous cell carcinomas of the skin after receiving single-agent BRAF inhibitors for melanoma (Peng et al., 2017).
  - f) Survivor-related risk factors of second primary cancers
    - (1) Age
      - (a) Younger age at cancer diagnosis increases the risk of developing a second cancer (Friedman et al., 2010). The risk of developing subsequent cancer in childhood cancer survivors is increased three- to sixfold (Reulen et al., 2011).
      - (b) Developing organs in younger patients may be especially vulnerable to the effects of medication and radiation (Ng et al., 2010).
      - (c) Older patients who experience adverse effects from a disease or its treatment may be unable to compensate for lost function, leading to less physical activity.
    - (2) Sex: Overall, women have a slightly higher risk of second cancers than men (Friedman et al., 2010; Miller et al., 2019; Turcotte et al., 2019).
    - (3) Genetic predisposition
      - (a) Survivors with genetic phenotypes that contributed to the development of their original cancer are at increased risk for second cancers.
      - (b) Common syndromes identified with increased risk are hereditary breast and ovarian cancer and hereditary nonpolyposis colorectal cancer (Lynch syndrome) (Wood et al., 2012).
      - (c) Immunodeficiency increases the risk of second cancers. Immune dysregulation may be associated with primary cancers, such as leukemia and lymphoma, or with immunosuppressive treatment (Brewer et al., 2014; Inamoto et al., 2015; Ng, 2014; Visentin et al., 2017).
      - (d) Infections such as human papillomavirus may increase the risk of second cancers in survivors of cervical and head and neck cancers. Human papillomavirus and hepatitis B and C increase the risk in hematopoietic stem cell transplantation (HSCT) recipients (Diaz et al., 2016; Inamoto et al., 2015; Ng & Travis, 2008).
    - (4) Exposures

- (a) Tobacco and alcohol exposure increase the risk of developing a second cancer in all cancer survivors (Wood et al., 2012). Approximately 4% of newly diagnosed cancer cases in 2020 were associated with alcohol consumption (Rumgay et al., 2021).
  - (b) Sun overexposure and tanning bed exposure increase the risk of developing skin cancer (U.S. Food and Drug Administration, 2015). Cancer survivors who have received chemotherapy, immunotherapy, and radiation are more likely to develop skin cancer (Huang et al., 2019; Teeppen et al., 2019).
- (5) Diet and exercise: Caloric excess, a diet low in fruits and vegetables, obesity, and physical inactivity increase the risk of second cancers involving the upper aerodigestive tract, colon, breast, and female reproductive organs (Rock et al., 2020; Wood et al., 2012).
- g) Risk of late effects for patients with select primary cancers and survivor populations: Select cancers are highlighted based on available long-term data.
- (1) Breast cancer
    - (a) Breast cancer survivors are at risk for cardiotoxicity from anthracyclines or trastuzumab, chemotherapy-induced premature menopause, osteoporosis, chemotherapy-induced cognitive impairment, sexual dysfunction, and taxane-related neuropathy (Azim et al., 2011; Ganz & Hahn, 2008).
    - (b) Breast cancer survivors younger than age 40 years at the time of diagnosis and carriers of a genetic predisposition (e.g., *BRCA2*, *TP53*) are at increased risk for second cancers (Azim et al., 2011; Erb & Vogel, 2013). This increased risk may also be attributed to treatment modality and reproductive, environmental, or other genetic factors (Molina-Montes et al., 2015).
      - i. Chemotherapy
        - The incidence of myelodysplastic syndrome and acute myeloid leukemia is higher in breast cancer survivors who have received alkylating agents, antimetabolites, platinum-based agents, and topoisomerase inhibitors. A longer duration of exposure to these agents increases the risk (Shenolikar et al., 2018).
      - Cumulative incidence is 0.5% at 8–10 years after anthracycline and cyclophosphamide chemotherapy (Erb & Vogel, 2013).
      - Other possible cancers include sarcoma, melanoma, and cancers of the salivary gland, esophagus, stomach, colon, breast, uterine corpus, ovary, and thyroid (Curtis et al., 2006; VanderWalde & Hurria, 2011).
    - ii. Hormone therapy: Risk of endometrial cancer after tamoxifen is 35% (Erb & Vogel, 2013).
    - iii. Radiation therapy
      - Radiation to the breast increases the risk of lung cancer, esophageal cancer, and sarcoma in all survivors. It also increases the risk of contralateral breast cancer in patients aged younger than 45 years (Azim et al., 2011; Ng et al., 2010; Travis et al., 2014).
      - The risk for sarcoma is SIR (standard incidence ratio) 3–6, with a latency period of 5–10 years (Erb & Vogel, 2013).
- (2) Cervical cancer
  - (a) Cervical cancer survivors have an increased risk for human papillomavirus-related (i.e., pharynx, genital sites, and rectum/anus) and smoking-related cancers (i.e., pharynx, trachea, bronchus, lung, pancreas, and urinary bladder) (Chaturvedi et al., 2007).
  - (b) An increased risk for second cancers exists for 40 or more years in women who have received pelvic irradiation to the colon, rectum/anus, urinary bladder, ovary, or genitals (Curtis et al., 2006; Travis et al., 2014).
  - (c) The 40-year cumulative risk of any second cancer is 22% among women diagnosed with cervical can-

cer before age 50 years and 16% for those diagnosed after age 50 years (Chaturvedi et al., 2007).

(3) Hodgkin lymphoma

(a) The leading causes of death in Hodgkin lymphoma survivors are second cancers and CVD (Matasar et al., 2015; Ng & van Leeuwen, 2016).

(b) Survivors treated with radiation therapy are at greater risk for second cancers and CVD than those treated with chemotherapy alone (Ng et al., 2011).

(c) Second primary cancers: Hodgkin lymphoma survivors are at risk for leukemia and solid tumors, particularly lung and breast cancer (Ng & van Leeuwen, 2016).

i. Solid tumors account for 75%–80% of all second cancers following treatment for Hodgkin lymphoma, and the risk is significantly increased with radiation (Ng et al., 2010).

ii. Radiation therapy, compared to chemotherapy for Hodgkin lymphoma, was associated with a higher risk for second and third malignancies during the first five years of follow-up (van Eggermond et al., 2014).

- The cumulative incidence of any second cancer following radiation is 11% for males and 26% for females, with the difference due to breast cancer. Other common solid tumors include thyroid and bone (Travis et al., 2014).

- The cumulative risk of second cancers following treatment with 40–45 Gy of extended-field or mantle radiation therapy is approximately 30% at 30 years (Hodgson, 2011).

- Modern radiation therapy for Hodgkin lymphoma uses involved-field radiation therapy, which treats only the lymph node regions initially involved. Prescribed radiation doses are 20–30 Gy. This reduces the volume of healthy

tissue exposed to radiation and significantly decreases the risk of second cancers (Hodgson, 2011; Koh et al., 2007).

iii. Breast cancer (Oeffinger et al., 2013)

- The risk of breast cancer in Hodgkin lymphoma survivors is significantly increased, particularly for women treated with chest irradiation before age 30 years.

- The latency period is 8–10 years following treatment.

- The risk of breast cancer appears to decrease in patients who reduce lifetime exposure to endogenous estrogens, such as those who experience ovarian failure or premature menopause.

iv. Lung cancer: The risk of lung cancer is associated with radiation therapy, alkylating agents, and smoking (Oeffinger et al., 2013).

(d) CVD: Hodgkin lymphoma survivors have a three- to fivefold increased risk of CVD, which generally manifests 10 years after therapy and persists for more than 25 years (Ng et al., 2011).

i. Coronary artery disease is the most common cardiovascular toxicity among Hodgkin lymphoma survivors and accounts for approximately 40%–50% of adverse cardiac events (Hodgson, 2011).

ii. Valvular disease is less common. It typically has a late onset (more than 10 years after radiation therapy) and is related to higher doses (greater than 30 Gy) or young age at treatment (Hodgson, 2011).

iii. Acute pericarditis is uncommon but may occur following radiation therapy with a large cardiac volume (Hodgson, 2011).

iv. Hodgkin lymphoma survivors treated with mantle radiation therapy at doses of 35–45 Gy are estimated to have a two- to

- fourfold increased risk of cardiac morbidity.
- v. The cumulative risk of significant heart disease among survivors of adult Hodgkin lymphoma is approximately 5%–10% at 15 years, 16% at 20 years, and 34% at 30 years (Hodgson, 2011).
  - (e) Hodgkin lymphoma survivors have an increased risk of treatment-related pulmonary toxicity, including radiation pneumonitis and bleomycin toxicity (Ng et al., 2011).
- (4) Lung cancer: Possible second cancers from alkylating agents are leukemia with SIR of 1.47 for non-small cell lung cancer and 6.57 for small cell lung cancer (Erb & Vogel, 2013).
- (5) Non-Hodgkin lymphoma
- (a) The relative risk of second cancers in non-Hodgkin lymphoma survivors is 1.8 times greater than the risk of the general population (Pirani et al., 2011).
  - (b) Survivors are at increased risk for acute myeloid leukemia, sarcomas, melanoma, Hodgkin lymphoma, and cancers of the bladder, head and neck, lung, gastrointestinal system, kidney, and thyroid (Tward et al., 2007).
    - i. Chemotherapy increases the risk of acute myeloid leukemia, lung cancer, and bladder cancer.
    - ii. Radiation therapy increases the risk of sarcomas, breast cancer, and mesothelioma.
- (6) Prostate cancer
- (a) Androgen deprivation therapy causes intended hypogonadism and possible osteoporosis (Shapiro et al., 2019).
  - (b) Possible second cancers from chemotherapy are melanoma, small intestine, soft tissue, bladder, thyroid, and thymus cancer (American Cancer Society, 2020; Curtis et al., 2006; Ng et al., 2010).
  - (c) After radiation to the pelvis, there is an increased risk of bladder cancer, colorectal cancer, and leukemia. The rate of second cancers from radiation for prostate cancer was 0.1%–3.8% for bladder cancer, 0.3%–4.2% for colon cancer, and 0.3%–1.2% for rectal cancer (Wallis et al., 2016). The colorectal cancer risk is similar to having a first-degree relative with colorectal cancer.
- (7) Testicular cancer
- (a) Testicular cancer is highly curable for men aged 18–39 years, with 95% living for 10 years or longer (Fung et al., 2019).
  - (b) The most common and concerning late effect for testicular cancer survivors is infertility. Regardless of planned therapy, sperm banking should be offered.
  - (c) Hypogonadism can occur, especially after chemotherapy, commonly cisplatin, etoposide, and bleomycin. Hypogonadism decreases sexual function, energy, muscle strength, and mood and is associated with metabolic syndrome (Fung et al., 2019).
  - (d) An increased risk of cardiotoxicity exists, including myocardial infarction, coronary artery disease, hyperlipidemia, and metabolic syndrome (Ng et al., 2011; Travis et al., 2010).
  - (e) Late pulmonary inflammation and fibrosis from bleomycin are rare and more likely to occur with a history of lung surgery, a greater than or equal to 20 pack-year history of tobacco smoking, and a cumulative cisplatin dose of more than 850 mg. One study suggests the *HFE* gene may affect the rate of bleomycin-induced pulmonary toxicity (Fung et al., 2019).
  - (f) Nephrotoxicity can occur in decreased glomerular filtration rate from cisplatin (Fung et al., 2019; Travis et al., 2010).
  - (g) Raynaud phenomenon is vascular damage caused by bleomycin. Symptoms occur in 18%–39% of survivors 4–12 months after bleomycin administration (Fung et al., 2019).
  - (h) A significant risk of leukemia and solid tumors exists. The risk of second cancers increases with younger age at treatment. The median time to occurrence is 20 years (van den Belt-Dusebout et al., 2007).
    - i. Chemotherapy increases the risk of radiation-associated

- second cancers (van den Belt-Dusebout et al., 2007).
  - ii. Risk of cisplatin- or etoposide-induced leukemia (0.5%–2%) is dose dependent (Fung et al., 2019; Travis et al., 2010).
  - iii. Risk of cisplatin-induced solid cancers shows a 1.4-to-2.4-fold increase (Fung et al., 2019). The most frequent types of solid cancers are thyroid, kidney, and gastrointestinal (Fung et al., 2019).
  - iv. Among 10-year testicular cancer survivors, a statistically significant increased risk exists of malignant melanoma and cancers of the lung (relative risk [RR] = 1.5, 95% confidence interval [CI] [1.2, 1.7]); thyroid, esophagus, pleura, and stomach (RR = 4, 95% CI [3.2, 4.8]); and pancreas, colon, rectum, kidney, bladder, and connective tissue (RR = 4, 95% CI [2.3, 6.3]) (Travis et al., 2005, 2012).
  - v. Radiation to the abdomen and pelvis increases leukemia risk threefold, with a mean latency of five years. Infradiaphragmatic radiation therapy fields were higher (RR = 2.7) than unexposed sites and remained elevated for 35 years (Fung et al., 2019).
  - vi. Gastric radiation doses greater than or equal to 50 Gy cause a 5.9-fold risk of gastric cancer (Fung et al., 2019).
- (8) Pediatric malignancies
  - (a) The risk of second cancers among childhood cancer survivors is associated with radiation therapy, chemotherapy, and genetic predisposition (Henderson et al., 2012; Travis et al., 2014). The risk of second cancers varies based on survivor age at exposure and the years since treatment (Hawkins et al., 2020).
  - (b) Second cancers often occur 10 or more years after treatment. Specific groups of pediatric cancer survivors have a 10-fold increase in developing second cancers based on treatment received, behaviors such as smoking tobacco and drinking alcohol, and the presence of rare genetic variants (Hawkins et al., 2020).
  - (c) The 30-year cumulative incidence of all second cancers in survivors of childhood cancer from 1970 to 1986 was 20.5% (95% CI [19.1, 21.8]) and was higher for patients who had received radiation therapy than for those who had not (25% vs. 10%) (Friedman et al., 2010; National Cancer Institute, 2022; Travis et al., 2014).
    - i. Second cancers with a 30-year cumulative incidence were nonmelanoma skin cancer (9.1%), other malignancies (7.9%), and meningioma (3.1%), with higher incidence for survivors who received radiation than those who did not (10% vs. 5%) (Friedman et al., 2010; Hawkins et al., 2020; National Cancer Institute, 2022; Travis et al., 2014).
    - ii. Among survivors of childhood cancer treated in the 1990s, the risk of second cancers at 15 years from cancer diagnosis was lower than those treated in the 1970s due to decreased use of radiation (Turcotte et al., 2017).
  - (d) Chemotherapy increases the risk of hematologic and solid second cancers, depending on chemotherapy type and cumulative dose (Hawkins et al., 2020).
    - i. Pediatric survivors exposed to chemotherapy only have a 2.8-fold increase in risk of second cancers compared to the general population.
    - ii. Exposure to alkylating agents increases the risk for gastrointestinal, thyroid, lung, breast, and bladder cancers; melanomas; and sarcomas. Cyclophosphamide increases sarcoma risk in a dose-dependent manner. Equivalent doses greater than 18,000 mg/m<sup>2</sup> increase breast cancer risk threefold (SIR: 3; 95% CI [1.2, 7.7]). Pro-

carbazine and cisplatin have been associated with 3.2-fold (95% CI [1.1, 9.4]) and 7.6-fold (95% CI [2.3, 25.5]) increased risk of gastrointestinal second cancers.

- iii. The risk for breast cancer treated with more than 250 mg/m<sup>2</sup> of anthracycline and no chest radiation was increased by nearly fourfold compared to the general population (SIR: 3.8; 95% CI [1.7, 8.3]).

(9) HSCT recipients are at risk for post-transplant lymphoproliferative disorders, treatment-related acute leukemia/myelodysplastic syndrome, and second solid tumors.

(a) In autologous HSCT recipients for lymphoma, the cumulative incidence of second acute leukemia/myelodysplastic syndrome was 3.09% at five years and 4.52% at 10 years (Tarella et al., 2011).

- i. The cumulative incidence of solid tumors was 2.54% at five years and 6.79% at 10 years.
- ii. The risk of solid tumors was associated with advanced age and radiation therapy.

(b) Allogeneic HSCT recipients were twice as likely to develop a solid tumor when compared to the general population.

- i. Risk was related to age younger than 30 years at transplantation and exposure to radiation therapy (Bhatia, 2014).
- ii. Allogeneic HSCT recipients with chronic graft-versus-host disease have a greater chance of developing skin and oral cancers (Gündüz et al., 2017; Rambhia et al., 2018).

(c) The risk of a post-transplant malignancy increases with younger age at the time of transplant, especially for those younger than 17 years (Serrano et al., 2017).

- i. Approximately 7% of pediatric HSCT recipients develop a second cancer by 20 years after transplant.
- ii. Lymphoproliferative disorders usually occur within two years.

iii. Therapy-related acute myeloid leukemia/myelodysplastic syndrome usually occurs three to seven years after transplant.

iv. Treatment-related leukemia mainly occurs in autologous recipients and is related to previous chemotherapy with alkylating agents or topoisomerase II inhibitors.

v. A wide range of solid second cancers have been described as occurring 10 or more years after HSCT and are primarily treatment related (Bomken & Skinner, 2015).

(d) Relative risk of thyroid carcinoma in HSCT recipients is 3.26 overall, with a significantly increased risk associated with age younger than 10 years, radiation therapy, female sex, and chronic graft-versus-host disease (Cohen et al., 2007).

## 6. Screening and early detection of late effects

### a) Cancer (NCCN, 2021b)

- (1) Survivors should follow adult cancer screening recommendations. This is especially important for childhood cancer survivors who have an additional risk for premature development of adult cancers (Children's Oncology Group, 2018; NCCN, 2021b).
- (2) Irradiated skin and soft tissues should be thoroughly and regularly evaluated for skin cancer throughout the life of survivors who have received chemotherapy, immunotherapy, or radiation therapy and undergo regular skin assessment.
- (3) Women younger than 30 years old who received greater than or equal to 10 Gy radiation to the chest should have a mammogram and magnetic resonance imaging at age 30 or eight years after exposure to radiation, whichever comes last (NCCN, 2021a). They should perform breast self-examination monthly beginning at puberty, and a clinical breast examination should be performed annually.

### b) Noncancer

- (1) Regular dental cleaning should be performed.
- (2) Routine vision examination should be performed.
- (3) Bone mineral density tests are indicated for survivors who are advanced in age,

- have limited or no gonadal function (e.g., hypogonadism, menopause), take chronic glucocorticosteroids, smoke tobacco, drink excessive alcohol, are frail, have an increased risk of falls, have an adult history of nontraumatic fractures, or a parental history of hip fracture (Shapiro et al., 2019).
7. Preventive health (NCCN, 2021b)
    - a) Healthcare providers have the opportunity to counsel cancer survivors about behaviors that promote health, including nutrition, exercise, avoidance of tobacco, and limited consumption of alcohol.
    - b) Health promotion behaviors decrease the risk for some second cancers and reduce comorbidity (Travis et al., 2013).
    - c) Regular physical exercise and a healthy diet appear to lower the risk of cancer recurrence and increase overall survival in multiple cancer survivor groups, including breast, colorectal, prostate, and ovarian cancer (Rutledge & Demark-Wahnefried, 2016).
      - (1) Eating a diet high in fruits, vegetables, and whole grains and low in red and processed meats protects against cancer progression, risk of recurrence, and overall mortality for various cancers. Nutritional counseling from a registered dietitian can be beneficial.
      - (2) Regular physical exercise appears to be associated with a lower risk for recurrence and improved survival following treatment for breast, prostate, ovarian, and colorectal cancers.
      - (3) Regular exercise also minimizes the long-term symptoms associated with cancer treatment.
      - (4) Physical activity programs and rehabilitation can assist survivors in establishing exercise habits, gaining strength, and adapting to physical limitations from treatment.
    - d) Cancer survivors who are overweight or obese may benefit from intentional weight loss following treatment. Cancer survivors who are underweight may benefit from appropriate weight gain.
    - e) Cancer survivors should obtain nutrients from foods instead of supplements or vitamins.
    - f) Cancer survivors should be offered routine vaccinations and encouraged to visit with a primary care provider regularly.
  8. Patient and family education
    - a) Provide information about the treatment and potential late effects of the disease and its treatment.
    - b) Explain the risks of second cancers, the typical time to onset, cancer screening recommendations, and the importance of follow-up visits.
    - c) Promote healthy lifestyle practices (NCCN, 2021b).
      - (1) Nutrition (Rock et al., 2020)
        - (a) A diet high in fruits, vegetables, and whole grains is associated with a lower risk of death than one that contains a high intake of processed and red meats, refined grains, sugar, and high-fat dairy products.
        - (b) It is recommended to ingest 1,000–1,200 mg of calcium and 800–1,000 IU of vitamin D daily (Shapiro et al., 2019).
        - (c) Avoid vitamin supplements and obtain nutrients from food.
      - (2) Regular physical exercise
      - (3) Tobacco avoidance and smoking cessation
      - (4) Alcohol limitation
      - (5) Sun protection practices
      - (6) Stress modification
      - (7) Sleep quality
      - (8) Offer relevant educational and support resources.
  9. Professional education
    - a) Continue learning about cancer survivorship care and possible long-term and late effects of established and emerging treatments.
    - b) Contribute to the interprofessional discussion about methods to effectively deliver survivorship care.
    - c) Consider using an SCP to communicate potential long-term and late effects of treatment and recommend follow-up to patients, caregivers, and primary care providers who may be unfamiliar with cancer and its treatments. A discussion of the SCP with primary care providers may be required (Iyer et al., 2017).

| Coordinates time of administration with pharmacy and others, as needed                                                                                                                                                                                                                                                                                                                                                                                                             |      |                    |  |  |
| Verifies documentation of consent for treatment (if applicable)                                                                                                                                                                                                                                                                                                                                                                                                                    |      |                    |  |  |
| Verifies that criteria to treat (e.g., laboratory data) are within acceptable parameters and reports results to provider as needed                                                                                                                                                                                                                                                                                                                                                 |      |                    |  |  |
| Completes physical assessment to ensure that no existing toxicities would preclude administration of the antineoplastic therapy (e.g., peripheral neuropathy, immuno-oncology toxicities)                                                                                                                                                                                                                                                                                          |      |                    |  |  |
| Completes review of response to previous therapy                                                                                                                                                                                                                                                                                                                                                                                                                                   |      |                    |  |  |
| Performs independent double check of original orders with a second RN for accuracy of the following <ul style="list-style-type: none"> <li>• Date of treatment</li> <li>• Agents</li> <li>• Dose calculation methodology (e.g., body surface area, area under the curve, mg/kg)</li> <li>• Drug dose</li> <li>• Schedule/sequence</li> <li>• Route</li> </ul>                                                                                                                      |      |                    |  |  |
| Verifies patient understanding of treatment goals, administration procedures, potential side effects, and when and how to contact the healthcare team                                                                                                                                                                                                                                                                                                                              |      |                    |  |  |
| Verifies that premedication, prehydration, and other preparations are completed and documented                                                                                                                                                                                                                                                                                                                                                                                     |      |                    |  |  |
| Verifies drug appearance and expiration date and/or time                                                                                                                                                                                                                                                                                                                                                                                                                           |      |                    |  |  |
| ADMINISTRATION                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |      |                    |  |  |
| Applies personal protective equipment, closed-system drug-transfer device (when the dosage form allows), and uses safe handling precautions                                                                                                                                                                                                                                                                                                                                        |      |                    |  |  |
| Applies filter and/or special tubing, if required by manufacturer                                                                                                                                                                                                                                                                                                                                                                                                                  |      |                    |  |  |
| Compares original order to dispensed drug label at the bedside or chairside with a second RN                                                                                                                                                                                                                                                                                                                                                                                       |      |                    |  |  |
| Verifies two patient identifiers (cannot use a room or chair number)                                                                                                                                                                                                                                                                                                                                                                                                               |      |                    |  |  |
| Verifies the presence of vascular access appropriate to the treatment plan (location, type)                                                                                                                                                                                                                                                                                                                                                                                        |      |                    |  |  |
| Assesses patency of vascular access device and ensures blood return is present                                                                                                                                                                                                                                                                                                                                                                                                     |      |                    |  |  |
| Demonstrates safe administration: <ul style="list-style-type: none"> <li>• <b>For IV push or IV minibag of vesicant medications:</b> Administers through side arm hub closest to patient, through a free-flowing IV; checks patency every 2–5 ml (every 2–3 ml for pediatric patients)</li> <li>• <b>For infusions:</b> Verifies appropriate rate of administration and infusion pump settings with a second RN; verifies blood return/patency per institutional policy</li> </ul> |      |                    |  |  |
| Demonstrates appropriate monitoring/observation for specific acute drug effects                                                                                                                                                                                                                                                                                                                                                                                                    |      |                    |  |  |
| Verbalizes appropriate action in the event of infiltration or extravasation                                                                                                                                                                                                                                                                                                                                                                                                        |      |                    |  |  |
| Verbalizes appropriate action in the event of hypersensitivity or anaphylactic reaction                                                                                                                                                                                                                                                                                                                                                                                            |      |                    |  |  |

| <b>CHEMOTHERAPY REGIMEN</b><br><i>21-day cycle for 4 cycles</i> <ul style="list-style-type: none"> <li>• <b>DOXOrubicin</b> 60 mg/m<sup>2</sup> IV push on Day 1 <ul style="list-style-type: none"> <li>– See <i>Safety Parameters and Special Instructions</i> for information on slow IV Push administration.</li> </ul> </li> <li>• <b>Cyclophosphamide</b> 600 mg/m<sup>2</sup> IV over 30 minutes on Day 1 <ul style="list-style-type: none"> <li>– Oral hydration is strongly encouraged with cyclophosphamide; poorly hydrated patients may need supplemental IV hydration. Patients should attain combined oral and IV hydration of 2000 – 3000 mL/day on day of chemotherapy. See <i>Other Supportive Therapy</i> for example of IV hydration.</li> </ul> </li> </ul> <p><b>This course is 4 cycles of AC (DOXOrubicin and cyclophosphamide) Every 21 Days. DOCEtaxel Every 21 Days and Trastuzumab course is initiated following completion of this course. Please see Order Template BRS27b for DOCEtaxel Every 21 Days and Trastuzumab course.</b></p> <b>SUPPORTIVE CARE</b><br><b>Antiemetic Therapy</b><br>Scheduled prophylactic antiemetic therapy should be given for prevention of acute and delayed nausea and vomiting based on the emetic risk of the chemotherapy regimen. This may include antiemetic therapy given on the days following chemotherapy. For more information on emetic prophylaxis, refer to the NCCN Guidelines for Antiemesis and Appendix D to the NCCN Chemotherapy Order Templates.<br><b>PRN for breakthrough:</b> All patients should be provided with at least one medication for breakthrough emesis. Please consult the NCCN Guidelines for Antiemesis for appropriate antiemetic therapy.<br><b>Other Supportive Therapy</b> <ul style="list-style-type: none"> <li>• For cyclophosphamide: <i>Example of recommended hydration:</i> Sodium chloride 0.9% infused IV at a rate of 1.5 – 3 mL/kg/hour for a total of 500 mL on day of chemotherapy.</li> </ul> <b>MONITORING AND HOLD PARAMETERS</b> <ul style="list-style-type: none"> <li>• CBC with differential should be monitored as clinically indicated for potential dose modification.</li> <li>• For DOXOrubicin: <ul style="list-style-type: none"> <li>– This agent is an anthracycline. Cumulative anthracycline dosage should be monitored.</li> <li>– Ejection fraction should be monitored prior to initiation of treatment and as clinically indicated.</li> <li>– Liver function should be monitored prior to each cycle and as clinically indicated for potential dose modification or discontinuation.</li> </ul> </li> <li>• For cyclophosphamide: Renal function should be monitored as clinically indicated for potential dose modification or discontinuation.</li> </ul> <b>SAFETY PARAMETERS AND SPECIAL INSTRUCTIONS</b> <ul style="list-style-type: none"> <li>• For DOXOrubicin: <ul style="list-style-type: none"> <li>– <b>This agent is a vesicant OR an irritant with vesicant properties.</b></li> <li>– This agent is administered IV push. The preferred IV push method for a vesicant is administration through the side port of a freely flowing IV.</li> <li>– Secondary malignancies have been associated with this drug. Review drug package insert for additional information.</li> <li>– Central venous access is recommended for administration of this agent.</li> </ul> </li> <li>• For cyclophosphamide: Secondary malignancies have been associated with this drug. Review drug package insert for additional information.</li> </ul> |                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                            |

NCCN Chemotherapy Order Templates (NCCN Templates®) are peer-reviewed statements of the consensus of its authors derived from the NCCN Clinical Practice Guidelines in Oncology (NCCN Guidelines®) regarding their views of currently accepted approaches to treatment. An NCCN Template does not constitute an order. Any clinician seeking to treat a patient using the NCCN Template® is expected to use independent medical judgment in the context of individual clinical circumstances of a specific patient's care or treatment. NCCN disclaims all warranties, express or implied including, without limitation, the implied warranties of merchantability and fitness for a particular purpose. NCCN does not warrant the accuracy, currency, or completeness of the NCCN Templates or make any representation regarding the use or the results of the use of the NCCN Templates in treatment. (2016). 2016 updated American Society of Clinical Oncology/Oncology Nursing Society chemotherapy administration safety standards, including standards for pediatric oncology. *Journal of Oncology Practice*, 12(12), 1262–1271. <https://doi.org/10.1200/JOP.2016.017905>.

## APPENDIX E. Consent for Antineoplastic Drug Treatment

Patient Name: \_\_\_\_\_ Date: \_\_\_\_\_

Diagnosis: \_\_\_\_\_

Treatment Medications: \_\_\_\_\_

**Possible side effects may include any of the following or a combination of the following:**

- |                                        |                                       |                                     |
|----------------------------------------|---------------------------------------|-------------------------------------|
| • Allergic and allergic-like reactions | • Kidney damage                       | • Nausea or vomiting                |
| • Anemia                               | • Light and temperature sensitivity   | • Numbness or tingling              |
| • Cognitive impairments                | • Liver damage                        | • Risk of infection                 |
| • Constipation                         | • Loss of appetite                    | • Secondary cancer                  |
| • Diarrhea                             | • Low platelet count causing bleeding | • Skin and nail darkening           |
| • Dizziness                            | • Low white blood cell count          | • Skin rash                         |
| • Fatigue                              | • Lung damage                         | • Skin ulceration at injection site |
| • Forgetfulness                        | • Menopausal symptoms                 | • Sterility                         |
| • Hair loss                            | • Menstrual irregularities            | • Thyroid changes                   |
| • Hearing loss                         | • Mouth sores                         | • Weight gain or loss               |
| • Heart damage                         | • Muscle aching or weakness           |                                     |

**Unexpected side effects may occur in addition to those noted above. Cancer treatments can cause long-term toxicities. In rare instances, cancer treatment can cause life-threatening complications and death.**

Many anticancer drugs can be harmful to an unborn child. I understand that it is important to tell the doctor if I think I may be pregnant. It is important for both men and women who are being treated with these drugs and who are sexually active and fertile and who have a fertile partner to use a reliable form of birth control (birth control pills, a reliable barrier method, or a hormonal implant as recommended by a physician). I have discussed possible ways of preserving my fertility with my doctor, if applicable.

\_\_\_\_ (Patient Initials) A healthcare professional has provided and reviewed with me written information on the drugs I will receive. I HAVE HAD THE CHANCE TO ASK ANY QUESTIONS ABOUT THE DRUGS I WILL RECEIVE AND AM SATISFIED WITH THE INFORMATION PROVIDED.

My healthcare team has explained my treatment plan in detail. My doctor has discussed with me other methods of treating this disease and the risks and benefits of treatment. There is no guarantee that this treatment will give me the same results that other patients have received. If I change my mind and decide to stop treatment at any time, my doctor will continue to provide for my care in the future.

**I have read the above information. I understand the possible risks and benefits of the recommended treatment plan. I agree to accept the treatment and authorize Dr. \_\_\_\_\_ and his/her healthcare team to carry out the treatment plan.**

Patient Signature: \_\_\_\_\_ Date: \_\_\_\_\_

I have explained the expected response, side effects, and possibility of risks of the listed drugs to the above named patient.

| 1. Wash hands and don personal protective equipment before opening drug delivery bag.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |     |    |          |
| 2. Visually inspect the contents of the delivery bag for leaks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |     |    |          |
| 3. For IV infusions <ul style="list-style-type: none"> <li>• Ensure tubing is primed with a non-HD solution. Back-priming is acceptable when using secondary tubing for administration. For HDs with high risk of reaction that have the tubing primed with HDs, pharmacy must prime tubing within a containment primary engineering controls (C-PEC) and deliver with a CSTD on the end of the tubing.</li> <li>• Work below eye level.</li> <li>• Utilize CSTD when the dosage form allows.</li> <li>• Utilize plastic backed absorbent pad under work area. Remove cap from IV tubing/CSTD and connect to patient's IV device with CSTD.</li> <li>• Tighten locking connections.</li> <li>• Remove outer gloves prior to programming pump.</li> <li>• Doff personal protective equipment and wash hands with soap and water.</li> <li>• When HD administration is complete, don personal protective equipment and discontinue IV bag with tubing intact (do not unspike bag, or reuse tubing).</li> <li>• Utilize gauze pads and a closed cap (for end of tubing to prevent dripping) when disconnecting from patient's IV device.</li> <li>• Remove outer gloves and discard.</li> <li>• Discard HD and HD administration set in HD waste container without touching surfaces. Tip: hold HD supplies in one hand and use clean inner glove to open doors, if traveling to a waste container.</li> </ul> |     |    |          |
| 4. For IV push medications <ul style="list-style-type: none"> <li>• Utilize CSTD when the dosage form allows.</li> <li>• Utilize plastic backed absorbent pad under work area. Remove cap from IV tubing and connect to patient's IV device.</li> <li>• Tighten locking connection.</li> <li>• When complete, remove outer gloves.</li> <li>• Do not recap needle.</li> <li>• Discard HD and HD storage container in HD waste container without touching surfaces. Tip: hold HD supplies in one hand and use clean inner glove to open doors, if traveling to a waste container.</li> <li>• Discard syringe-needle unit in puncture-proof container.</li> <li>• Doff personal protective equipment and wash hands with soap and water.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |     |    |          |

**APPENDIX G. Hazardous Drug Administration Safe Handling Checklist (Continued)**

| ADMINISTRATION (Cont.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Yes | No | Initials |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|----|----------|
| 5. For intramuscular/subcutaneous injections <ul style="list-style-type: none"> <li>Utilize CSTD when dosage form allows.</li> <li>Attach needle to syringe.</li> <li>Utilize plastic backed absorbent pad under work area.</li> <li>Tighten locking connection.</li> <li>When complete, do not recap needle.</li> <li>Discard HD and HD storage container in HD waste container without touching surfaces. Tip: hold HD supplies in one hand and use clean inner glove to open doors, if traveling to a waste container.</li> <li>Discard syringe-needle unit in puncture-proof container.</li> <li>Doff personal protective equipment and wash hands with soap and water.</li> </ul> |     |    |          |
| 6. For oral drugs (tablets/capsules) <ul style="list-style-type: none"> <li>If using bar code technology, scan medication prior to removing medication from packaging.</li> <li>Don gloves.</li> <li>Open unit-dose package and place into medicine cup (avoid touching drug or inside of package).</li> <li>Avoid touching tablets/capsules.</li> <li>Doff gloves and wash hands with soap and water.</li> </ul>                                                                                                                                                                                                                                                                      |     |    |          |
| 7. For oral drugs in liquid form <ul style="list-style-type: none"> <li>Obtain drug in final form in appropriate oral syringe or appropriate container.</li> <li>Don double gloves, gown, and mask with face protection.</li> <li>Use plastic-backed absorbent pad during administration.</li> <li>Discard syringe in hazardous waste container after administration.</li> <li>Doff personal protective equipment and wash hands with soap and water.</li> </ul>                                                                                                                                                                                                                       |     |    |          |
| POST ADMINISTRATION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |     |    |          |
| 1. Don personal protective equipment.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |     |    |          |
| 2. Seal hazardous drug–contaminated supplies in sealable plastic bag for transport to hazardous waste container.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |     |    |          |
| 3. Remove outer gloves before touching equipment.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |     |    |          |
| 4. Place sealed plastic bag in hazardous waste container.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |     |    |          |
| 5. Close lid on waste container.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |     |    |          |
| 6. Clean equipment per manufacturer guidelines.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |     |    |          |
| 7. Remove and discard gown, and inner gloves.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |     |    |          |
| 8. Wash hands thoroughly with soap and water.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |     |    |          |
| 9. If a mask and face shield was used, don clean gloves to remove and then repeat hand washing after glove removal.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |     |    |          |
| 10. If the patient is on airborne precautions and full personal protective equipment with a powered air purifying respirator (PAPR)/cartridge mask or N95 is used, a new pair of gloves should be worn to remove the PAPR/cartridge mask or N95 and it should be placed on a plastic-backed pad, gloves removed, and hands washed. A final pair of gloves should be used to clean the equipment per manufacturer's guidelines and then remove gloves and wash hands again.                                                                                                                                                                                                             |     |    |          |

## APPENDIX H. Extravasation

Photo 1. Erythema of site of port extravasation of doxorubicin (February 14)

Photo 2. Beginning of skin necrosis (February 28)

Photo 3. Area of extravasation following debridement (March 18)

Photo 4. Granulation of outer areas of debrided area (June 5)

Photo 5. Ten months following extravasation, healing of area and formation of scars (December 10)

Photo 6. Severe tissue necrosis secondary to vesicant extravasation

 genitourinary toxicity of, 622t  
 pulmonary toxicity of, 567t–568t
- anti-CD20 antibody, 258t, 294
- anti-CD38 antibody, 255t
- anticholinergics  
 for diarrhea, 456t  
 fatigue from, 707t
- anticipatory CINV, 428–429, 432
- anticonvulsants, fatigue from, 707t
- antidepressants, and cancer-related fatigue, 707t, 709
- anti-EGFR antibodies, 257t, 259t
- antiemetics  
 fatigue from, 707t  
 for nausea/vomiting, 431–432, 477t
- antigen recognition, by immune system, 208
- antihistamines, fatigue from, 707t
- antimetabolites, 75t–82t, 97. *See also specific agents*  
 cardiotoxicity of, 500t–502t  
 cutaneous toxicities of, 657  
 endocrine toxicities from, 686t  
 genitourinary toxicity of, 618t–619t  
 hepatotoxicity of, 586t–588t  
 ocular toxicity of, 758t–759t  
 pulmonary toxicity of, 547t–548t  
 sexual dysfunction from, 645
- antimotility agents, for diarrhea, 455t
- anti-RANK antibody, 256t
- antitumor antibiotics, 83t–87t, 97, 294. *See also specific agents*  
 cardiotoxicity of, 502t  
 cutaneous toxicities of, 657  
 endocrine toxicities from, 686t  
 extravasation of, 364t  
 genitourinary toxicity of, 619t  
 hepatotoxicity of, 588t–589t  
 ocular toxicity of, 759t–760t  
 pulmonary toxicity of, 548t  
 sexual dysfunction from, 645
- anti-VEGFR2 antibody, 259t–260t
- anxiolytics, fatigue from, 707t
- apalutamide, 102t–103t
- apoptosis, inhibition of, 44
- aprepitant, for CINV, 439t
- aromatase inhibitors, 103t–104t, 109. *See also specific agents*
- arsenic trioxide, 88t, 97
- cardiotoxicity of, 504t
- genitourinary toxicity of, 619t
- hepatotoxicity of, 589t
- pulmonary toxicity of, 549t
- asciminib, 113, 117t–118t
- ASCO/ONS *Chemotherapy Administration Safety Standards*, 3
- aseptic meningitis, 718t, 733
- asparaginase, 88t, 97  
 endocrine toxicities from, 686t  
 hepatotoxicity of, 589t
- atezolizumab, 232t–233t  
 cardiotoxicity of, 518t  
 endocrine toxicities from, 689t  
 hepatotoxicity of, 600t  
 infusion reaction from, 372t  
 pulmonary toxicity of, 557t
- atrial fibrillation, 493, 528
- atropine, for diarrhea, 454–455, 455t, 456t
- atypical antipsychotics, for CINV, 432, 436t
- AUC dosing calculation, 304
- autologous cellular immunotherapy, 247t  
 cardiotoxicity of, 526t
- autonomy, 16, 17t
- avapritinib, 118t
- avelumab, 234t  
 cardiotoxicity of, 518t  
 endocrine toxicities from, 689t  
 hepatotoxicity of, 600t  
 infusion reaction from, 372t  
 pulmonary toxicity of, 558t
- axicabtagene ciloleucel, 235t–236t, 277  
 cardiotoxicity of, 519t  
 pulmonary toxicity of, 568t
- axitinib, 119t, 198  
 cardiotoxicity of, 505t  
 endocrine toxicities from, 686t  
 hepatotoxicity of, 592t  
 ocular toxicity from, 764t
- azacitidine, 75t  
 cardiotoxicity of, 496t  
 genitourinary toxicity of, 618t
- ## B

zoledronic acid, genitourinary toxicity of, 623, 623*t*

Zubrod score. *See* ECOG Performance Status Scale

Oncology nursing is a unique specialty that requires continuous learning to stay current on cancer pathophysiology, cutting-edge drugs, and the evidence-based management of cancer and its treatment-related toxicities. The Oncology Nursing Society's *Chemotherapy and Immunotherapy Guidelines and Recommendations for Practice* (second edition) provides nurses with the tools to understand how medications are used in cancer treatment, the effect of medication-related toxicities, and evidence-based recommendations to manage and treat these toxicities. This edition features many new cancer therapies approved since the 2019 publication. Extensive drug tables provide nurses with categorical drug information based on treatment type and tips for managing patients receiving these treatments.

New evidence relating to cancer nursing care is incorporated into this edition, such as hypersensitivity response, safe handling of hazardous drugs, and more. Expanded content on genomics corresponds with the progress made toward personalized oncology. Health equity is approached with information discussing financial distress, cultural disparities, and health literacy. The latest guidelines and recommendations for treatment, symptom management, and survivorship are also included.

A QR code is provided with the purchase of this book, allowing access to periodic drug updates.
