Peripheral Sensation Management: Prevention or minimization of injury or discomfort in the patient with altered sensation

Circulatory Care: Arterial [or] Venous Insufficiency: Promotion of arterial [or] venous circulation

NURSING PRIORITY NO. 1 To determine significance/degree of potential for compromise:

- Assess for individual risk factors: (1) trauma to extremity that causes internal tissue damage such as crush injuries, high-velocity and penetrating trauma, and fractures (especially long-bone fractures) with hemorrhage; (2) fluid accumulation into confined space (including IV infiltration, postoperative hematoma, circumferential burns); (3) long-term pressure on tissues, such as could occur from individual being trapped under collapsed structure; (4) external pressure on tissues (e.g., tight dressings, military anti-shock trousers, splints, casts, or restraints); and (5) presence of conditions affecting peripheral circulation, such as atherosclerosis, cardiovascular or cerebrovascular disease; diabetes, sickle cell disease, DVT, and coagulation disorders or use of anticoagulants *that potentiate risk of circulation disruption, insufficiency, and occlusion.*^{1-3,6,10}
- Monitor for tissue bleeding and spread of hematoma *that can compress blood vessels and raise compartment pressures.*^{1,2}
- Note position and location of casts, braces, traction apparatus, and use of restraints *to ascertain potential for pressure on tissues.*
-  Review recent and current drug regimen, noting use of anticoagulants and vasoactive agents.

NURSING PRIORITY NO. 2 To assess for early signs of peripheral vascular impairment:

- Conduct a comprehensive upper or lower extremity assessment in at-risk client, including color, sensation, and functional ability. *Many individuals in this risk category are seen in the community healthcare setting for conditions not recognized as being related to peripheral vascular issues. However, early detection of circulatory issues may prevent the onset or severity of functional impairments associated with arterial or venous disorders of the extremities.*⁶
-  Perform frequent neurovascular assessment in person immobilized for any reason (e.g., surgery, prolonged bedrest, diabetic neuropathy, fractures) or individuals with suspected neurovascular problems, noting differences in affected limb as compared with unaffected limb. Use the 6 Ps of assessment:⁴
Pain: Using 0 to 10 (or a similar pain scale), assess for presence, location, severity, and duration of pain. *Pain may be intermittent (e.g., intermittent claudication) or more constant (e.g., compartment syndrome or*

arterial occlusion). Pain may range from muscle tension/tenderness and burning to severe pain. Pain may be present with active or passive movement, or at rest.^{2,5,6,8}

Pulses: Monitor presence (or absence) and quality of peripheral pulses (distal to injury or impairment) via palpation and/or Doppler. *Intact pulse usually indicates adequate circulation. However, occasionally a pulse may be palpated even though circulation is blocked by a soft clot; also, perfusion through larger arteries may continue after increased compartment pressure has collapsed the arteriole and venule circulation in the muscle.*^{1,2,5,8}

Pallor: Evaluate skin temperature, capillary refill, and color changes to assess perfusion. *Pallor with cool, shiny, taut skin and slow venous refill is indicative of circulatory impairment. Cold, pale, bluish color with purpura indicates arterial insufficiency.*^{5,6}

Paresthesia: Assess sensation (e.g., test peroneal nerve by pinch or pinprick in the dorsal web between first and second toe, and assess ability to dorsiflex toes in presence of leg fracture). *Changes in sensation cover a wide continuum and may include feeling of tingling, numbness, “pins and needles,” burning, or diminished or absent sensation. Changes that might not be apparent to client could include loss of protective sensation in feet as determined by screening with tuning fork or percussion hammer. Sensation may be normal early in the presence of compartment syndrome because superficial circulation is not yet compromised.*^{2,6,8,12}

Paralysis: Evaluate for range of motion. *Movement may be limited or absent because of tissue edema and nerve compression or because of nerve impingement such as would occur with spinal nerve compression.*^{2,8}

Pressure: Evaluate by palpating the extremity. *Swelling or tightness may indicate obstruction, such as might occur with DVT, or compartment syndrome.*¹¹

-  Assist with diagnostic studies (e.g., blood studies, Doppler, ultrasound, angiography, segmental arterial pressures, intracompartmental pressures, ankle-brachial index [ABI], transcutaneous oximetry) as indicated. *Numerous diagnostic tests may be needed if diagnosis is in doubt and in view of the multitude of medical and surgical conditions associated with peripheral vascular dysfunction.*¹³

NURSING PRIORITY NO. 3 To minimize edema formation/elevated tissue pressure.^{1,3,5}

- Apply cold packs around injury/fracture site as indicated *to limit tissue swelling and hematoma formation.*
- Remove jewelry and constrictive clothing or other items from affected limb *to limit injury caused by swelling in injured tissues.*
- Elevate injured extremity(ies) unless contraindicated by confirmed presence of compartment syndrome *where elevation can actually impede arterial flow, decreasing perfusion.*⁸
-  Monitor for development of infiltration of IV fluids *to prevent excessive accumulation of fluids in tissues.*⁸
- Position extremity(ies) in proper alignment *to prevent nerve impingement and elevation of tissue pressures.*^{8,9}
- Monitor skin and tissues around protective and corrective devices (e.g., dressings, splint, cast, traction devices) for proper application and function *to provide support and protection without causing undue pressure on tissues.*
-  Assist with or perform procedures (e.g., splitting cast, repositioning of restraints, continuous motion apparatus) *to release pressure and prevent permanent tissue damage or nerve injury.*
-  Observe position and location of supporting ring of traction splints or sling and readjust as indicated *to reduce pressure on tissues and risk of nerve impingement and improve blood flow.*
-  Avoid or limit use of restraints. Use padding and frequently evaluate extremity circulation, movement, and sensation when restraints are required.

NURSING PRIORITY NO. 4 To maximize circulation.^{1-3,5,6}

-  Position all extremities in proper alignment and keep injured extremity in neutral position *to maximize circulation.*
- Provide or assist with range-of-motion exercises. Encourage client to routinely exercise digits and joints distal to injury *to enhance circulation.*

-   Administer IV fluids and blood products as needed to *maintain circulating volume and reduce potential for ischemic tissue injury associated with loss of perfusion.*
-  Monitor hemoglobin/hematocrit and coagulation studies if either clotting or bleeding into tissues is known or suspected or client is receiving anticoagulant therapy.^{8,9}

NURSING PRIORITY NO. 5 Prevent/limit potential for complications:^{1-3,5-7}

-  Assist with treatment of underlying conditions to *reduce risks of complications.*
- Investigate sudden changes (e.g., changes in skin temperature or color, reports of pain that are extreme for type of injury, increased pain at rest or on passive movement of extremity, development of burning or tingling sensations, tense muscles, change in pulse quality distal to injury) *that are suggestive of compartment syndrome, requiring prompt intervention.*^{1,2}
- Place limb in neutral position, avoiding elevation to *enhance circulation in compartment syndrome.*
-  Report symptoms to physician at once to *provide for timely evaluation and intervention.*
- Assist with and encourage early ambulation to *help prevent DVT formation.*⁹
-   Apply antiembolic hose or sequential compression devices as indicated.⁹
-   Prepare for surgical intervention or other therapies (e.g., fibulectomy, fasciotomy, revascularization surgery, hyperbaric oxygen therapy) as indicated to *relieve increasing pressures and restore circulation.*¹³

NURSING PRIORITY NO. 6 To promote wellness (Teaching/Discharge Considerations):^{1-3,5,6,9}

-  Encourage good nutrition with adequate calories and micronutrients to *promote healing and reduce sluggishness of circulation.*
- Review proper body alignment of limbs (e.g., elevated or neutral position) as appropriate for individual situation.
-  Instruct client and family in neurovascular findings to be reported to healthcare provider when indicated (e.g., client with new fractures in cast at home, client at risk for DVT) to *limit preventable complications through early intervention.*
- Promote benefits of walking and smoking cessation to *improve circulation.*
- Discuss necessity of avoiding constrictive clothing, sharp angulation of legs, crossing ankles or legs, and thermal or mechanical trauma, *especially if client has history of peripheral vascular insufficiency or is at risk for DVT.*^{8,9}
- Demonstrate proper application and removal of antiembolic hose or sequential compression devices, as indicated.
- Review safe use of heat or cold therapy, especially if client has poor sensation in extremities to *avoid thermal injury.*
- Instruct client/SO(s) to check shoes and socks for proper fit and/or wrinkles to *reduce potential for foot problems associated with neuropathies.*
- Recommend continuation of prescribed exercise program to *maintain extremity circulation and strength.*
-  Review proper use and monitoring of drug regimen and safety concerns associated with anticoagulant use to *ensure maximum benefit and avoid complications and bleeding problems.*
-  Recommend regular follow-up with healthcare provider to *monitor status of condition, treatment efficacy, and to provide for timely intervention, when needed.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Specific risk factors, nature of injury to limb.
- Assessment findings, including comparison of affected and unaffected limb, characteristics of pain in involved area.
- Doppler or compartment pressure results.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modification of plan of care.

Discharge Planning

- Long-term needs, referrals, and who is responsible for actions to be taken.
- Specific referrals made.

imbalanced Nutrition: less than body requirements

Taxonomy II: Nutrition—Class 1 Ingestion (00002) [Diagnostic Division: Food/Fluid], Approved 1975; Revised 2000; 2017

DEFINITION: Intake of nutrients insufficient to meet metabolic needs.

RELATED FACTORS

Insufficient dietary intake

DEFINING CHARACTERISTICS

Subjective

Insufficient interest in food; food aversion; alteration in taste sensation; perceived inability to ingest food
Satiety immediately upon ingesting food
Abdominal pain or cramping; sore buccal cavity
Insufficient information; misinformation; misconception

Objective

Body weight 20% or more below ideal weight range; insufficient muscle tone; [decreased subcutaneous fat or muscle mass]

Weight loss with adequate food intake

Food intake less than recommended daily allowances (RDA)

Hyperactive bowel sounds; diarrhea; steatorrhea

Weakness of muscles required for mastication or swallowing; insufficient muscle tone

Pale mucous membranes; capillary fragility

Excessive hair loss [or increased growth of hair on body (lanugo)]; [cessation of menses]

[Abnormal laboratory studies (e.g., decreased albumin, total proteins; iron deficiency; electrolyte imbalances)]

At Risk Population: Biological factors

Economically disadvantaged

Associated Condition: Inability to absorb nutrients; inability to ingest/digest food

Psychological disorder

Sample Clinical Applications: Cancer, AIDS, anorexia or bulimia nervosa, burns, facial trauma, brain injury, coma, stroke, Parkinson's disease, cleft lip/palate, anemia, dementia, Alzheimer's disease, major depression, schizophrenia

DESIRED OUTCOMES/EVALUATION CRITERIA**Sample NOC linkages:**

Nutritional Status: Extent to which nutrients are ingested and absorbed to meet metabolic needs

Knowledge: Healthy Diet: Extent of understanding conveyed about a balanced nutritious diet

Weight Gain Behavior: Personal actions to gain weight following voluntary or involuntary significant weight loss

Client Will (Include Specific Time Frame)

- Demonstrate progressive weight gain toward goal.
- Display normalization of laboratory values and be free of signs of malnutrition as reflected in Defining Characteristics.
- Verbalize understanding of causative factors when known and necessary interventions.
- Demonstrate behaviors and lifestyle changes to regain or maintain appropriate weight.

ACTIONS/INTERVENTIONS**Sample NIC linkages:**

Nutrition Management: Providing and promoting a balanced intake of nutrients

Weight-Gain Assistance: Facilitating gain of body weight

Eating Disorders Management: Prevention and treatment of severe diet restrictions and overexercising or bingeing and purging of foods and fluids

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- ∞ Identify client at risk for malnutrition (e.g., institutionalized elderly; client with chronic illness; child or adult living in poverty/low-income area; client with facial injuries or deformities; restrictive weight-loss program or surgical intervention; prolonged time of restricted intake, prior nutritional deficiencies; hypermetabolic states [e.g., hyperthyroidism, burns]; malabsorption syndromes).^{2,9,10}

- Obtain dietary history *to determine chronic problems and ongoing needs, such as:*
Increased caloric requirements with difficulty ingesting sufficient calories (e.g., cancer, burns).
 - ∞ Maturation or developmental issues (e.g., premature baby with sucking difficulties, child with lack of emotional stimulation, frail elderly living alone, hospitalized, or in nursing home). Note: A recent study confirms that almost 90% of elderly persons transitioning from acute care to a subacute facility are either malnourished or at risk of malnutrition.²
 - Swallowing difficulties (e.g., stroke, Parkinson's disease, cerebral palsy, dementia [especially Alzheimer's disease]; other neuromuscular disorders).²
 - Poor dentition (damaged or missing teeth, ill-fitting dentures, gum disease).
 - Decreased absorption (e.g., lactose intolerance, Crohn's disease).
 - Diminished desire or refusal to eat (e.g., anorexia nervosa, cirrhosis, pancreatitis, alcoholism, bipolar disorder, depression, chronic fatigue).^{2,6}
 - Treatment-related issues (e.g., chemotherapy, radiation, stomatitis, facial surgery, wired jaw).
 - Personal or situational factors (e.g., inability to procure or prepare food, social isolation, grief, loss).⁸
- ∞ Assess pediatric concerns (e.g., changes in nutritional needs related to growth phase; congenital anomalies, including tracheoesophageal fistula, cleft lip/palate; metabolic or malabsorption problems, such as diabetes, phenylketonuria, cerebral palsy; chronic infections).⁴
- Determine lifestyle factors that may affect weight. *Socioeconomic resources, amount of money available for purchasing food, proximity of grocery store, and available storage space for food are all factors that may impact food choices and intake.*
- 🌐 Evaluate impact of cultural, ethnic, and religious influences. *The nutritional balance of a diet is recognized by most cultures, with distinct theories of nutritional practices for health promotion and disease prevention. Foods are used for prevention or treatment of disease (e.g., client may believe in use of "hot" or "cold" foods to treat certain conditions or use low-fat, low-sodium foods to prevent heart disease). Certain foods may be thought to cause a disease condition (e.g., upset stomach caused from eating too many cold foods). Special diets or food preparation may be cultural or religious based (e.g., kosher preparation for Jewish client or eating no meat or meat by-products for vegetarian).¹*
- Explore specific eating habits, the meaning of food to client (e.g., never eats breakfast, snacks throughout entire day, fasts for weight control, no time to eat properly), and individual food preferences and intolerances/aversions. *Identifies eating practices that may need to be corrected and provides insight into dietary interventions that may appeal to client.*
- Obtain history or review diary of daily portion (or calorie) intake and patterns and times of eating *to reveal recent changes in client's weight or appetite and to identify strengths and weaknesses in client's dietary habits.*²
- Assess client's knowledge of nutritional needs and ways client is meeting these needs. *Identifies teaching needs and/or helps guide choice of interventions.*²
- Note availability and use of financial resources and support systems. *These factors affect or determine ability to acquire, prepare, and store food. Lack of support or socialization may impact client's desire to eat.*
- 🩺 Assess medication regimen, noting possible drug side effects or interactions, allergies, use of laxatives, and diuretics. *These factors may be affecting appetite, food intake, or absorption.*^{2,8}
- ∞ Note client's ability to feed self or presence of interfering factors. *Difficulties such as paralysis, tremor, or injury to hands or arms with inability to grasp or lift utensils to mouth; cognitive impairments affecting coordination or remembering to eat; age; and/or developmental issues may require input of multiple providers and therapists to develop individualized plan of care.*²
- Auscultate for presence and character of bowel sounds *to determine ability and readiness of intestinal tract to handle digestive processes (e.g., hypermotility accompanies vomiting or diarrhea, while absence of bowel sounds may indicate bowel obstruction).*
- 🖋️ Determine psychological factors that may affect food choices. Perform psychological assessment as indicated *to assess body image and congruency with reality or to identify factors (e.g., dementia, severe depression) that may be interfering with client's appetite and food intake.*²

- Note occurrence of amenorrhea, tooth decay, swollen salivary glands, or report of constant sore throat. *May be signs of eating disorder, such as bulimia, affecting eating patterns and requiring additional evaluation.*^{5,6}
- Review usual activities and exercise program, noting repetitive activities (e.g., constant pacing) or inappropriate exercise (e.g., prolonged jogging). *Individuals with dementia may pace or be in constant motion, increasing energy needs. Clients who have eating disorders, such as anorexia or bulimia, may use obsessive activities as weight-control measures.*⁶

NURSING PRIORITY NO. 2 To evaluate degree of deficit:

- Assess current weight, compared to usual weight and norms for age and body size *to identify changes (e.g., sudden loss related to medical illness versus ongoing chronic depression with anorexia and weight loss; toddler with failure to meet growth expectations) that affect choice of intervention and help clarify expectations.*
- Obtain weights using same scale, same time of day, and same clothing as much as possible *to provide for accurate comparison to evaluate effectiveness of therapeutic regimen.*²
-  Calculate growth percentiles in infants/children using growth chart *to identify deviations from the norm.*⁴
-  Measure or calculate body fat, body water, and muscle mass (via triceps skinfold or other anthropometric measurements) or calculate body mass index (BMI) *to establish baseline parameters and assist in determining therapeutic goals. Note: BMI = weight (lb)/height (inches squared) × 703 according to the Centers for Disease Control and Prevention. Desirable adult BMI is 18.5 to 24.9. A BMI of 17 or below is considered severely underweight, or clinically anorexic.*^{2,8,17}
- Observe for absence of subcutaneous fat or muscle wasting, loss of hair, fissuring of nails, delayed healing, gum bleeding, swollen abdomen, etc., that indicate protein-energy malnutrition.⁹
-   Perform or review results of nutritional assessment using screening tools such as the Malnutrition Universal Screening Tool, the Veterans Affairs Nutrition Status Classification system, the screening tool developed by Brugler et al., or the Mini Nutritional Assessment (MNA). *Note: In 2006, Guigoz reported that the MNA had been used in 36 studies to assess the nutritional status of 8,596 hospitalized older adults worldwide; of these, 50% to 80% were classified as either at risk for malnourishment or malnourished.*^{11–14}
-   Review laboratory studies (e.g., serum albumin, prealbumin, transferrin, amino acid profile, iron, blood urea nitrogen, nitrogen balance studies, glucose, liver function, electrolytes, total lymphocyte count, indirect calorimetry). *Baseline screening may be done to determine whether more in-depth evaluation is needed. Note: Brugler et al. found that the characteristics that correlated best with malnutrition-related complications were occurrence of a wound, poor oral intake, malnutrition-related admission diagnosis, serum albumin value, hemoglobin value, and total lymphocyte count.*^{2,14}

NURSING PRIORITY NO. 3 To establish a nutritional plan that meets individual needs:

-  Collaborate with interdisciplinary team *to set nutritional goals when client has specific dietary needs, malnutrition is profound, or long-term feeding problems exist.*^{2,7,9}
-  Calculate client's energy and protein requirements using basal energy expenditure and the Harris-Benedict (or similar) formula. *The essential nutritional requirements include the needs for energy, protein, and hydration, along with vitamins and electrolytes. Various factors may be considered in choosing a useful formula, including age, sex, disease state, stress associated with current illness, body size (e.g., obesity), and activity (e.g., bedbound versus out of bed).*¹⁵
- Establish ongoing method of evaluating intake (e.g., calories/day, percent of food consumed at each feeding) *to assist in determining both amount of food taken and what food groups are consumed or left uneaten, to identify nutritional deficits.*²
- Discuss with client/significant other (SO) aspects of diet that can remain unchanged *to preserve those that are valuable or meaningful to individual, and enhance sense of control. Negotiate with client aspects of diet that need to be changed, especially if eating or psychiatric disorder is limiting food intake.*

NURSING PRIORITY NO. 4 To address specific underlying condition/treatment needs:

-  Assist in treatments to correct or control underlying causative factors *to improve intake and utilization of nutrients.*^{2,7}
 -  Administer oral antifungal agent *to treat cutaneous lesions of the mouth (e.g., candidiasis) that limit client's ability or desire for food.*
 -  Medicate for pain or nausea and manage drug side effects *to increase physical comfort and appetite.*
 -  Provide pureed foods, formula tube feedings, or parenteral nutrition infusions when indicated by client's condition (e.g., wired jaws or paralysis following stroke) and degree of malnutrition. *Enteral route is preferred when oral feeding is not appropriate. Recent evidence suggests a beneficial effect of implementation of early enteral nutrition (EN) in trauma patients, and there is no convincing evidence regarding any harmful effect. Early EN is defined as the provision of a standard EN formula via any feeding tube route within 24 hours of initial injury or ICU admission. The systemic contraindications for EN remain to be clarified. Early parenteral nutrition (PN) is not recommended.*^{7,16}
 -  Consult occupational therapist *to identify appropriate assistive devices to facilitate independence in feeding and self-esteem.*
 -  Consult speech therapist *to develop specific exercises or activities to address swallowing difficulties related to neurological problems (e.g., stroke, amyotrophic lateral sclerosis).* (Refer to ND impaired Swallowing for additional interventions.)
 -  Refer for dental care *to correct missing teeth or poorly fitting dentures that affect client's ability to chew food or enjoy process of eating.*
 -  Develop or refer client to structured (behavioral modification) program for nutrition therapy, which may include documenting time/length of eating period, putting food in a blender, and tube feeding food not eaten. *These programs are used to change the maladaptive eating behaviors of clients with anorexia and bulimia and ensure adequate caloric intake. Because "control" is central to the etiology of these disorders, it is important to ensure that the client is perceived to be "in control."*⁶
 -  Recommend or support hospitalization for controlled environment, as indicated, in severe malnutrition or life-threatening situations.

NURSING PRIORITY NO. 5 To enhance dietary intake:

-   Avoid or limit withholding of food (e.g., prolonged NPO for surgery) as much as possible and reinstitute oral feedings as early as possible *to reduce adverse effects of malnutrition.*
-  Increase specific nutrients (e.g., protein, carbohydrates, fats, calories) as needed, providing client with preferred food and seasoning choices where possible *to enhance intake.*⁹
- Determine when client prefers or tolerates largest meal of the day. Maintain flexibility in timing of food intake *to promote sense of control and give client opportunity to eat when feeling more rested, less pain or nausea, family coming at mealtime, etc.*²
- Provide numerous small feedings as indicated; supplement with easily digested snacks *to reduce feeling of fullness that can accompany larger meals and to improve chances of increasing the amount of nutrients taken over 24-hr period.*⁵
- Promote adequate and timely fluid intake. *Fluid is essential to the digestive process and is often taken with meals. Fluids may need to be withheld before meals or with meals if interfering with food intake.*
- Encourage variety in food choices, varying textures and taste sensations (e.g., sweet, salty, fresh, methods of cooking) *to enhance food satisfaction and stimulate appetite.*²
- Offer and keep available to client finger foods and snacks *that are easy to self-feed.*
- Provide oral care before and after meals. *Reduces discomfort associated with nausea, vomiting, oral lesions, mucosal dryness, and halitosis, making eating easier or food more palatable.*
- Encourage use of lozenges, gum, hard candy, and beverages *to stimulate salivation when dryness is a factor.*
- Use alternative flavoring agents (e.g., lemon and herbs) *to enhance taste of foods, especially if salt is restricted.*

- Add nonfat milk powder to foods with a high liquid content (e.g., gravy, puddings, cooked cereal) and sugar or honey in beverages if carbohydrates are tolerated *to increase caloric value*.²
- Avoid foods that cause intolerances or increase gastric motility (e.g., gas-forming foods, hot or cold, spicy, caffeinated beverages, milk products, etc.) *to reduce postprandial discomfort that may discourage client from eating*.³
- Limit high-fat foods or fiber and bulk if indicated *because they may lead to early satiety*.
- Offer supplement drinks (or dispense in 2- to 4-oz portions several times/day). *Client may view this as a “medication” and thus will drink it, improving intake and energy level*.²
- Promote pleasant, relaxing environment, including socialization when possible. *Promotes focus on activity of eating, enhancing intake*.²
- Prevent or minimize unpleasant odors and sights or cooking odors. *Often have a negative effect on appetite or activate gag reflex*.
-  Administer pharmaceutical agents as indicated. *Appetite stimulants and dietary supplements and digestive drugs or enzymes, vitamins and minerals (e.g., iron), antacids, anticholinergics, antiemetics, antidiarrheals, etc., may be used to enhance intake, improve digestion, and correct nutritional deficiencies*.²

NURSING PRIORITY NO. 6 To promote wellness (Teaching/Discharge Considerations):

-  Discuss myths client/SO(s) may have about weight and weight gain *to address misconceptions and perhaps improve motivation for needed behavior changes*.
-  Emphasize importance of well-balanced, nutritious intake. Provide nutritional information as indicated, taking into account client's age and developmental stage (e.g., toddler, teenager, pregnant woman, elderly person with chronic disease), physical health and activity tolerance, financial and socioeconomic factors, and client's/SO's potential for management of underlying conditions. *For example, older adults need same nutrients as younger adults but in smaller amounts and with attention to certain components, such as calcium, fiber, vitamins, protein, and water*.³ *Infants/children require small meals and constant attention to needed nutrients for proper growth and development while dealing with child's food preferences and eating habits*.⁴
- Address financial issues and identify ways to meet dietary needs using nutrient-dense, low-budget foods.
- Involve SO(s) in treatment plan as much as possible *to provide ongoing support and increase likelihood of accomplishing dietary goals*.
-  Consult with dietitian/nutritional support team as necessary *for long-term needs*.
-  Involve client in developing behavior modification program appropriate to specific needs based on consistent, realistic weight gain goal. *Enhances commitment to change and likelihood of accomplishing desired outcomes*.^{5,6}
- Provide positive regard, love, and acknowledgment of “voice within” guiding client with eating disorder. *These efforts encourage the client to recognize maladaptive eating patterns as defense mechanisms to ease the emotional pain and begin to resolve underlying issues and develop more adaptive coping strategies for dealing with stressful situations*.⁶
- Weigh as needed/prescribed and document results *to monitor effectiveness of dietary plan*.
- Develop regular exercise and stress-reduction programs. *Enhances general well-being, improves organ function/muscle tone, and increases appetite*.
-  Review medical regimen and provide information or assistance as necessary. Discuss drug side effects and potential interactions with other medications and over-the-counter drugs.
-  Assist client to identify and access community resources such as nutrition assistance program, budget counseling, Meals on Wheels, community food banks, or other appropriate assistance programs.
-  Refer for dental hygiene and professional care, counseling or psychiatric care, and family therapy as indicated.
- Provide and reinforce client teaching regarding preoperative and postoperative dietary needs when surgery is planned.
- Assist client/SO(s) to learn how to blenderize food or perform tube feeding when indicated. *Promotes independence in self-care and sense of some degree of control in a difficult situation*.
-  Refer to home health resources for initiation and supervision of home nutrition therapy when used.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Baseline and subsequent assessment findings to include signs/symptoms and laboratory diagnostic findings.
- Caloric and nutrient intake.
- Individual cultural or religious restrictions, personal preferences.
- Availability and use of resources.
- Personal understanding and perception of problem.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Client's responses to interventions, teaching, and actions performed.
- Results of periodic weigh-in.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

readiness for enhanced Nutrition

Taxonomy II: Nutrition—Class 4 Metabolism (00163) [**Diagnostic Division:** Food/Fluid], Approved 2002; Revised 2013

DEFINITION: A pattern of nutrient intake, which can be strengthened.

DEFINING CHARACTERISTICS

Subjective

Expresses desire to enhance nutrition

Sample Clinical Applications: As a health-seeking behavior the client may be healthy, or this diagnosis can occur in any clinical condition

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Nutritional Status: Extent to which nutrients are ingested and absorbed to meet metabolic needs

Knowledge: Healthy Diet: Extent of understanding conveyed about a balanced nutritional diet

Weight Maintenance Behavior: Personal actions to maintain optimum body weight

Client Will (Include Specific Time Frame)

- Demonstrate behaviors to attain or maintain appropriate weight.
- Be free of signs of malnutrition.
- Be able to safely prepare and store foods.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Nutritional Counseling: Use of an interactive helping process focusing on the need for diet modification

Teaching: Prescribed Diet: Preparing a patient to correctly follow a prescribed diet

Weight Management: Facilitating maintenance of optimal body weight and percent body fat

NURSING PRIORITY NO. 1 To determine current nutritional status and eating patterns:

- Assess client's knowledge of current nutritional needs and ways client is meeting these needs. *Provides base-line for further teaching or interventions.*
- Assess eating patterns and food and fluid choices in relation to any health-risk factors and health goals. *Helps to identify specific strengths and weaknesses that can be addressed.*
- ∞ Verify that age-related and developmental needs are met. *These factors are constantly present throughout the lifespan, although differing for each age group. For example, older adults need the same nutrients as younger adults, but in smaller amounts and with attention to certain components, such as calcium, fiber, vitamins, protein, and water.¹ Infants/children require small meals and constant attention to needed nutrients for proper growth and development while dealing with child's food preferences and eating habits.²*
- 🌐 Evaluate influence of cultural and religious factors to determine what client considers to be normal dietary practice as well as to identify food preferences and restrictions and eating patterns that can be strengthened or altered if indicated.³
- Assess how client perceives food, food preparation, and the act of eating to determine client's feeling and emotions regarding food (including the use of food for celebrations or as a reward) and self-image.
- Ascertain occurrence of or potential for negative feedback from significant others (SOs). *May reveal control issues that could impact client's motivation for and commitment to change.*

- Determine patterns of hunger and satiety. *Helps identify strengths and weaknesses in eating patterns and potential for change (e.g., person predisposed to weight gain may need a different time for a big meal than evening or may need teaching as to what foods reinforce feelings of satisfaction).*
- Assess client's ability to shop for, safely store, and prepare foods to determine if health information or financial resources might be needed.

NURSING PRIORITY NO. 2 To assist client/SO(s) to develop plan to meet individual needs:

- Determine motivation and expectation for change. *Motivation to improve and high expectations can encourage client to make changes that will improve his or her life. However, presence of unrealistic expectations may hamper efforts. Client may actually be satisfied with current nutritional state and eating behaviors or may be changing some aspect of food intake or preparation in response to new dietary information or change in health status.*
-  Assist in obtaining or review results of individual testing (e.g., weight and height, body fat percent, lipids, glucose, complete blood count, total protein) to determine that client is healthy and/or identify dietary changes that may be helpful in attaining health goals.⁵
- Encourage client's beneficial eating patterns and habits (e.g., controlling portion size; eating regular meals; reducing high-fat, high-sugar, or fast-food intake; following specific dietary program; drinking water and healthy beverages). *Provides reinforcement and supports client's efforts to incorporate changes into lifestyle habits and continue with new behaviors.*⁶
- Provide instruction and reinforce information regarding special needs. *Client/SO may benefit from or desire assistance in learning new eating habits or following medically prescribed diets (e.g., very low calorie diet, tube feedings, diabetic or renal dialysis diet).*⁴
- Encourage the client to carefully read food labels, instructing in meaning of labeling, as indicated, to assist client/SO in making healthful choices.⁶
-  Consult with or refer to nutritionist/physician, as indicated. *Client/SO may benefit from advice regarding specific nutrition or dietary issues or may require regular follow-up to determine that needs are being met when following a medically prescribed program.*
-  Develop a system for self-monitoring to provide a sense of control and enable the client to track own progress as well as to assist in making informed choices.

NURSING PRIORITY NO. 3 To promote optimum wellness (Teaching/Discharge Considerations):

-  Review individual risk factors and provide additional information or response to concerns. *Assists the client with motivation and decision making.*
- Provide bibliotherapy and help client/SO(s) identify and evaluate resources he or she can access. *Reinforces learning, allows client to progress at own pace, and encourages client to be responsible for own learning. When referencing the Internet and nontraditional or unproven resources, the individual must exercise some restraint and determine the reliability of the source and information before acting on it.*
- Encourage variety and moderation in dietary plan to decrease boredom and encourage client in efforts to make healthy choices about eating and food.
- Discuss use of nutritional supplements and over-the-counter and herbal products. *Confusion may exist regarding the need for and use of these products in a balanced dietary regimen.*
-  Assist client to identify and access community resources when indicated. *May benefit from assistance, such as nutritional assistance program, budget counseling, Meals on Wheels, community food banks, and other assistance programs.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Baseline information, client's perception of need.
- Nutritional intake and metabolic needs.
- Motivation and expectations for change.

Planning

- Plan of care, specific interventions, and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Client's responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and actions to be taken.
- Support systems available, specific referrals made, and who is responsible for actions to be taken.

Obesity

Taxonomy II: Nutrition—Class 1 Ingestion (00232) [Diagnostic Division: Food/Fluid], Approved 2013; Revised 2017

DEFINITION: A condition in which an individual accumulates abnormal or excessive fat for age and gender that exceeds overweight.

RELATED FACTORS

Average daily physical activity is less than recommended for gender and age; energy expenditure below energy intake based on standard assessment (e.g., WAVE [weight, activity, variety in diet, excess] assessment); sedentary behavior occurring for ≥ 2 hours/day

Consumption of sugar-sweetened beverages; frequent snacking; high frequency of restaurant or fried food; portion sizes larger than recommended; solid foods as major food source at < 5 months of age

Disordered eating behaviors or perceptions; fear regarding lack of food supply

Excessive alcohol consumption

Shortened sleep time, sleep disorder

DEFINING CHARACTERISTICS**Objective**

ADULT: Body mass index (BMI) of $> 30 \text{ kg/m}^2$

CHILD < 2 years: Term not used with children this age

CHILD 2–18 years: Body mass index (BMI) > 95 th percentile or $> 30 \text{ kg/m}^2$ for age and gender

At Risk Population: Economically disadvantaged

(continues on page 592)

Obesity (continued)

Formula- or mixed-fed infants; overweight in infancy; rapid weight gain during infancy, including the first week, first 4 months, and first year; rapid weight gain during childhood

Premature pubarche

Heritability of interrelated factors; high disinhibition and restraint eating behavior score

Maternal diabetes mellitus, maternal smoking; paternal obesity

Associated Condition: Genetic disorder

Sample Clinical Applications: Bulimia nervosa, morbid obesity, diseases requiring long-term steroid use (e.g., chronic obstructive pulmonary disease [COPD]), conditions associated with immobility (e.g., stroke/paralysis, multiple sclerosis [MS], amputation), Alzheimer's disease, depression, developmental delay

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Weight Loss Behavior: Personal actions to lose weight through diet, exercise, and behavior modification

Knowledge: Diet: Extent of understanding conveyed about a balanced, nutritious diet

Nutritional Status: Extent to which nutrients are ingested and absorbed to meet metabolic needs

Weight: Body Mass: Extent to which body weight, muscle, and fat are congruent to height, frame, gender, and age

Client Will (Include Specific Time Frame)

- Verbalize a realistic self-concept or body image (congruent mental and physical picture of self).
- Participate in development of, and commit to, a personal weight loss program.
- Demonstrate appropriate changes in lifestyle and behaviors, including eating patterns, food quantity/quality, and exercise program.
- Attain desirable body weight with optimal maintenance of health.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Weight Reduction Assistance: Facilitating loss of weight and/or body fat

Nutrition Management: Providing and promoting a balanced intake of nutrients

Nutritional Counseling: Use of an interactive helping process focusing on the need for diet modification

NURSING PRIORITY NO. 1 To identify contributing factors/health status:

-  Obtain weight history, noting if client has weight gain out of character for self or family, is or was obese child, or used to be much more physically active than is now *to identify trends*. *Note: Obesity is now the most prevalent nutritional disorder among children and adolescents in the United States (45% of all adults and approximately 18% of youths ages 2 to 19 years).*¹ *Being overweight during older childhood is highly predictive of adult obesity, especially if a parent is also obese.*²
-  Assess risk and presence of factors or conditions associated with obesity (e.g., familial pattern of obesity; genetic disorders in children [e.g., Prader-Willi syndrome, Laurence-Moon-Biedls syndrome]; hypothyroidism; type 2 diabetes; reproductive dysfunction; menopause; chronic disorders, such as heart disease, kidney disease, chronic pain; food or other substance addictions; stressful or sedentary lifestyle; depression; use of certain medications such as steroids, birth control pills; physical disabilities or limitations; lack of socioeconomic resources for obtaining or preparing healthy foods) *to determine treatments and interventions that may be indicated in addition to weight management.*^{2,3}

- Ascertain current and previous dieting history. *Client may report normal or excessive intake of food, but calories and intake of certain food groups (e.g., sweets and fats) are often underestimated. Client may report experimentation with numerous types of diets, repeated dieting efforts (“yo-yo” dieting) with varying results, or may never have attempted a weight-management program.*
 -   Assess client’s knowledge of own body weight and nutritional needs and determine cultural expectations regarding size. *Although nutritional needs are not always understood, being overweight or having large body size may not be viewed negatively by individual because it is considered within relationship to family eating patterns and peer and cultural influences.² Ethnicity factors may influence the age of onset and the rapidity of weight gain. African American women and Hispanic women tend to experience weight gain earlier in life than Caucasians and Asians. Hispanic men tend to develop obesity earlier than African American and Caucasian men. Some cultures place importance on large body size (e.g., Samoan people or Cuban children).^{3,4} Note: In 2017, a Centers for Disease Control and Prevention (CDC) report noted that in the United States (in most states examined) non-Hispanic black adults, almost half (48.4%) were considered to have obesity and about 12.4% were considered to have extreme obesity. Among Hispanic adults, 42.6% were considered to have obesity, and about 7% were considered to have extreme obesity.⁵*
 -  Identify familial and cultural influences regarding food. *People of many cultures place high importance on food and food-related events, while some cultures routinely observe fasting days (e.g., Arab, Greek, Irish, Jewish) that may be done for health or religious purposes.⁴*
 -  Ascertain how client perceives food and the act of eating. *Individual beliefs, values, and types of foods available influence what people eat, avoid, or alter. Client may be eating to satisfy an emotional need rather than physiological hunger; not only because food plays a significant role in socialization but also because food can offer comfort, sense of security, and acceptance.^{3,4}*
 -  Assess dietary practices by means of diary covering 3 to 7 days. *Recall of foods and fluids ingested; times, patterns, and place of eating; whether alone or with other(s); and feelings before, during, and after eating can increase client’s understanding of eating behavior and serve as the basis for dietary modifications.^{6,7}*
 -  Identify problems with energy balance. *Studies indicate that few people can accurately estimate the number of calories they should consume in a day for a person their age, height, weight, and physical activity.⁸ Note: Eating and physical activity patterns that are focused on consuming fewer calories, making informed food choices, and being physically active can help people attain and maintain a healthy weight, reduce their risk of chronic disease, and promote overall health. Note: For people who are overweight or obese, this will mean consuming fewer calories from both foods and beverages.⁹*
 -  Review daily activity and regular exercise program for comparative baseline and to identify areas for modification. *Note: The 2008 National Health Interview Survey showed that only 33% of American adults participated in leisure-time physical activity on a regular basis.⁹*
 -   Obtain anthropometric measurements to determine presence and severity of obesity:
 -   Calculate body mass index (BMI) to estimate percentage of body fat. *Note: The CDC has standardized BMI calculations, removing age and sex differences for adults with obesity being defined as 30 and above. Note: Obesity is also divided into classes. Class 3 obesity is sometimes categorized as “extreme” or “severe” obesity (may replace term morbid obesity) and is defined as BMI equal to or greater than 40.¹³ The CDC has recommended that children (over age 2) and adolescents be considered obese if their BMI exceeds the 95th percentile on growth curves or exceeds 30 kg/m at any age. Note: Normal BMI in children changes as age and growth occurs and is also different between the sexes.¹⁴*
- Refer to ND Overweight for additional diagnostic studies information.
-  Collaborate in assessment and interventions for client with disordered eating habits or eating perceptions:
Obtain a comparative body drawing, having client draw self on wall with chalk and then standing against it and having actual body outline drawn to note difference between the two. *Determines whether client’s view of self-body image is congruent with reality.*
Ascertain occurrence of negative feedback from significant others (SOs). *May reveal control issues and impact motivation for change.*

Identify unhelpful eating behaviors (e.g., eating over sink; “gobbling, nibbling, or grazing”) and address kinds of activities associated with eating (e.g., watching television or reading, being unmindful of eating or food) *that result in taking in too many calories as well as eliminating the joy of food because of failure to notice flavors or sensation of fullness or satiety.*²

NURSING PRIORITY NO. 2 To establish weight-reduction program:

- **Refer to ND Overweight, Nursing Priority 2 for interventions common to weight-loss programs.**
-  Collaborate with nutritionist in addressing/implementing client’s specific needs (e.g., what foods to incorporate or limit, how to identify nutrient-dense foods and beverages). *A healthy eating pattern limits intake of sodium, solid fats, added sugars, and refined grains and emphasizes nutrient-dense foods and beverages (e.g., vegetables, fruits, whole grains, fat-free or low-fat milk and milk products), seafood, lean meats and poultry, eggs, beans and peas, and nuts and seeds.*⁹
-  Assist client in using technology to manage food choices. *Technology offers applications that can assist in monitoring dietary intake and food choices. Some calculate calories, providing immediate feedback and generating individualized reminders. The best applications include (1) a large database of foods with nutritional information for various serving sizes, (2) a bar scanner that allows users to add information about prepared foods to their database, (3) a calorie tracker that is easy to use, and (4) the ability to track other nutrients (e.g., carbohydrates, protein, calcium).*⁶
-  Engage client and family in structured weight loss programs, as indicated. *Approaches to the treatment of severely obese individuals may include lifestyle modifications, physical activity, very controlled diets, and intensive psychiatric interventions, including individual, group, and family therapy.*² *Note: DeBar et al. recently reported that an intensive, group therapy approach was superior to standard, family-based therapy in achieving lifestyle changes (e.g., less consumption of fast foods) and in reducing the BMI of overweight adolescents.*¹⁵
-  Refer to bariatric physician/surgeon, as indicated. *Evaluation for special measures may be needed (e.g., supervised fasting or bariatric surgery) for obese persons with comorbidities and for morbidly obese persons with BMI greater than 40. Currently there are several bariatric surgical procedures (e.g., gastric bypass [Roux-en-Y], laparoscopic adjustable gastric banding, biliopancreatic diversion [rare], vertical banded gastroplasty). At present, gastric bypass is the most successful procedure.*¹⁶

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

- **Refer to ND Overweight for related interventions.**

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including current weight, dietary pattern; perceptions of self, food, and eating; motivation for loss, support or feedback from SO(s).
- Results of laboratory and diagnostic testing.

Planning

- Plan of care, specific interventions, and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

risk for Occupational Injury

Taxonomy II: Safety/Protection—Class 4 Environmental hazards (00265) [**Diagnostic Division:** Safety], Approved 2016

DEFINITION: Susceptible to sustain a work-related accident or illness, which may compromise health

RISK FACTORS

Individual: Excessive stress; psychological distress

Improper use of personal protective equipment

Inadequate role performance, or coping strategies, or time management

Insufficient knowledge; misinterpretation of information

Unsafe acts of overconfidence; unsafe acts of unhealthy negative habits

Environmental: Distraction from social relationships; labor relationships

Exposure to biological agents, or radiation, or teratogenic agents

Exposure to extremes of temperature, or vibration

Inadequate physical environment; lack of personal protective equipment

Night shift work rotating to day shift work; shift workload

Occupational burnout; physical workload

(continues on page 596)

risk for Occupational Injury (continued)

Sample Clinical Applications: Any occupation and/or job setting has the potential for causing/aggravating injury

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Personal Safety Behavior: Personal actions to prevent unintentional physical injury to self

Risk Control: Environmental Hazards: Personal action to understand, prevent, eliminate, or reduce the threat of exposure to biological, chemical, physical, biochemical, or psychological hazards in personal environment

Physical Injury Severity: Severity of signs and symptoms of injuries to the body

Client Will (Include Specific Time Frame)

- Develop/engage in plan to address individual risk factors and safety hazards.
- Demonstrate proper body alignment to prevent injury when performing work-related activities.
- Conform to safety guidelines in the work place.
- Be free of injury.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Risk Identification: Analysis of potential risk factors, determination of health risks, and prioritization of risk-reduction strategies for an individual or group

Environmental Management: Worker Safety: Monitoring and manipulation of the worksite environment to promote safety and health of workers

NURSING PRIORITY NO. 1 To evaluate degree/source of risk inherent in work setting:

- Determine factors related to individual situation and extent of risk for injury/illness. *Influences scope and intensity of interventions to manage threats to safety, which are dynamic and constants in every life and situation.*¹²
- ∞ Note client's age, gender, developmental stage, decision-making ability, level of cognition and competence to determine client's ability to recognize danger and to protect self. *Note: Younger workers (14–24) are twice as likely to incur injuries than older workers, and women three times more likely than men, which may reflect client's ability or desire to protect self and influences choice of interventions or teaching.*³
- ☞ Ascertain client's history of injuries, medical conditions, and medications—prescribed, over-the-counter, vitamins and herbals. *Can impact client's ability to safely perform certain movements/activities and suggests possible choice of interventions. Note: Research suggests cannabis abuse can increase severity of time away from work following injury.*⁶
- ☞ Evaluate visual, auditory, tactile, and kinesthetic perception. *Ability to correctly perceive and respond to one's environment greatly impacts worker's safety and well-being. Note: Blue-collar workers, older worker, and Hispanic workers have highest rates of uncorrected visual and/or hearing impairment, creating safety issues.*⁷
- Identify employment/job specifics (e.g., works with dangerous tools/machinery, electricity, explosives, hazardous chemicals, first responder, healthcare worker, computer data entry, works alone or above ground). *Aides in identifying risks and individual safety needs.*

- Determine client's perception of individual safety and view of hazards in workplace, including exposure to violence. *Lack of knowledge of safety needs or appreciation of significance of individual hazards increases risk of injury.*¹² *Lack of focus on specific problem(s) can result in no change or may even result in increased injuries.*⁴
- Clarify client's awareness of Occupational Safety and Health Administration (OSHA) standards applicable to client. *Lack of awareness can limit client's ability to make best decisions to promote personal safety.*
-  Observe client performing routine work activities. *Musculoskeletal injuries are estimated to account for 33% of all workplace injuries. Proper body mechanics is vital for safe lifting, bending, reaching, stooping, pushing/pulling, repetitive motions, etc. Note: Hospital workers experience injuries nearly three times the rate of professional and business services. Even physical therapists incur musculoskeletal injuries, especially low back, in spite of their knowledge of body mechanics.*^{2,8,10}
- Evaluate workplace for environmental hazards and stressors (e.g., physical, biological, psychological, chemical, ergonomic) and their interrelationships. *May impair/negatively impact client's judgment and increase potential for injury. Furthermore, at a time of cost cutting and reorganization to sustain business profits/viability, organizational culture may deflect responsibility of occupational injuries onto the worker without adequately considering all factors contributing to the situation.*⁵

NURSING PRIORITY NO. 2 To assist client to reduce/correct individual risk factors:

- Review pertinent job-related safety regulations with client. *Provides information necessary for client to make informed decisions.*
- Develop plan with client to address individual needs and goals. *Being part of the solution increases likelihood of client commitment to the plan.*
- Identify facility/company resources available to decrease risk factors. *Solutions may be available at limited or no additional cost.*
- Modify work space as appropriate. *For example, for office worker consider ergonomic chair, elevated computer desk, head set/Bluetooth device, voice recognition computer program; industrial site might require better lighting, handrails on stairs, reflective paint marking floor step downs, containment barrier around chemical storage/mixing station, healthcare worker may need ceiling-mounted lifts to facilitate patient transfers, redesign of workstations with adjustable-height computer monitors.*⁸
- Instruct in safety techniques/procedures specific to client's situation, for example:^{8,9}
 - Wear appropriate protective gear—clothing/gowns, safety glasses/goggles, ear protectors, closed-toe/steel-toe footwear, gloves, mask/respirator, safety harness, helmet
 - Avoid operating mechanical equipment/vehicle when using substances, including over-the-counter and prescription, that may impair functioning
 - Adequate hydration/cooling in hot environments
 - Use proper body mechanics, frequent change of work position
 - Practice safe handling of sharps, double gloving during needlesticks, precautions with flammable materials, including oxygen
 - Proper handling of biologic materials/body fluids, chemical spills
 - Avoid mixing chemicals if possible; use in well-ventilated area
 - Practice situational awareness or being aware of what is happening around self and recognizing unsafe situations
- Encourage client to read chemical labels or Material Safety Data Sheets (MSDS notebook) *to be aware of primary hazards, safe storage and handling.*
- Identify location of eye wash station/shower, first-aid kit and safe use of automated external defibrillator (AED).

NURSING PRIORITY NO. 3 To promote optimum safety and well-being:

- Stress importance of adherence to lunch/break policy and using vacation or personal time regularly. *Too often workers feel compelled to work through break time or postpone time away because of short staffing or to meet deadlines.*

-  Refer to trainer or physical therapist for regular exercise program including focus on core strength/stability and flexibility. *Research suggests decreased core strength contributes to injuries of back and extremities.*¹
- Encourage participation in wellness programs/monitoring of chronic conditions. *Stress management, weight loss, smoking cessation, and monitoring of long-term health issues such as hypertension and diabetes can help reduce illness and time away from work.*
- Recommend keeping vaccinations up to date and obtaining yearly flu shots and immunizations recommended for occupational risks. *Reduces risk of acquiring illness in workplace.*⁸
- Support modified or light-duty work options as indicated. *Provides time for recovery while keeping worker engaged and reducing sense of isolation.*
-  Emphasize importance of reporting injuries/completing reports in timely manner. *While it is not unusual for minor injuries to go unreported, violence in the workplace is often accepted as “part of the job” and not reported but can cause significant psychological trauma and stress. Note: Workplace violence incidents requiring days off for worker to recuperate were four times more common in healthcare than in private industry.*^{8,11}
-  Obtain preventive screening/testing and initiate referrals to healthcare providers as appropriate. *Some chronic illnesses such as respiratory, some cancers, birth defects have long latencies between occupational exposure and clinical findings.*⁷

NURSING PRIORITY NO. 4 To promote safety in workplace:

- Identify applicable OSHA standards and workplace compliance with standards.
- Provide OSHA poster, copies of standards, and informational placards *to inform workers of their rights and responsibilities under OSHA.*
- Inform workers of hazardous substances to which they may be exposed.
- Use problem-solving framework such as Public Health Model *to systematically identify and prioritize problems or risks, identify interventions or develop new strategies to prevent injury/illness, implement activities, and evaluate and monitor results of interventions.*⁴
- Bring unsafe working conditions to employer’s attention.
- Develop corrective plan with all parties involved. *Effectiveness of program requires commitment of management and participation of employees to analyze safety data and identify appropriate solutions.*¹¹
- Initiate workplace health promotion programs based on identified health risk assessment (e.g., smoking cessation, weight loss, stress management).
- Provide incentives for meeting individual/group goals. *Rewards/bonuses for health and safety behaviors or number of injury-free days encourages continuation of efforts.*⁸
- Repair, replace, or correct unsafe equipment. Provide adaptive devices, e.g., step stool, handrails on moveable stairs, safety guard/shield on mechanical equipment.
- Provide protective devices such as locked external doors, gates at stairwells, emergency alarms/phone stations, metal detectors, trained security personnel.
- Initiate screening programs for environmental hazards, e.g., noise, pollutants, allergens, dust, asbestos, lead/other heavy metals, vapor intrusion, radon, diesel emissions.
-  Collaborate with appropriate agencies, e.g., public health, Environmental Protection Agency, to improve environmental hazards.
- Develop plan for long-term monitoring of health risks and evaluation of risk-reduction strategies. *Provides evidence of effectiveness of interventions, possible need for revision. Information also adds to the body of knowledge in the field.*^{4,10}

DOCUMENTATION FOCUS

Assessment/Reassessment

- Medical history including past injuries, current medications; sensory abilities.
- Client’s awareness of safety needs, view of individual hazards in workplace.

- Specific requirements of client's job.
- Evaluation of workplace environmental hazards and stressors.

Planning

- Plan of care and who is involved in the planning including outside/public partners.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcomes.
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Available resources, specific referrals made.

Overweight

Taxonomy II: Nutrition—Class 1 Ingestion (00233) [Diagnostic Division: Food/Fluid], Approved 2013; Revised 2017

DEFINITION: A condition in which an individual accumulates abnormal or excessive fat for age and gender.

RELATED FACTORS

Average daily physical activity is less than recommended for gender and age; energy expenditure below energy intake based on standard assessment (e.g., WAVE [weight, activity, variety in diet, excess] assessment); sedentary behavior occurring for ≥ 2 hours/day

Consumption of sugar-sweetened beverages; frequent snacking; high frequency of restaurant or fried food; portion sizes larger than recommended; solid foods as major food source at < 5 months of age

Disordered eating behaviors or perceptions; fear regarding lack of food supply

(continues on page 600)

Overweight (continued)

Excessive alcohol consumption
Shortened sleep time, sleep disorder

DEFINING CHARACTERISTICS

Objective

ADULT: Body mass index (BMI) of $>25 \text{ kg/m}^2$

CHILD <2 years: Weight-for-length >95 th percentile

CHILD: 2–18 years: Body mass index (BMI) >85 th percentile or $>25 \text{ kg/m}^2$ for age and gender

At Risk Population: ADULT: Body mass index (BMI) approaching 25 kg/m^2

CHILD <2 years: Weight-for-length approaching 95th percentile

CHILD 2–18 years: Body mass index (BMI) approaching 85th percentile or 25 kg/m^2

Children with high body mass index (BMI), or who are crossing body mass index (BMI) percentiles upward

Economically disadvantaged

Formula- or mixed-fed infants; overweight in infancy; rapid weight gain during infancy, including the first week, first 4 months, and first year; rapid weight gain during childhood

Premature pubarche

Heritability of interrelated factors; high disinhibition and restraint eating behavior score

Maternal diabetes mellitus, maternal smoking; paternal obesity

Associated Conditions: Genetic disorder

Sample Clinical Applications: Bulimia nervosa, morbid obesity, diseases requiring long-term steroid use (e.g., chronic obstructive pulmonary disease [COPD]), conditions associated with immobility (e.g., stroke/paralysis, multiple sclerosis [MS], amputation), depression, developmental delay

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Weight Loss Behavior: Personal actions to lose weight through diet, exercise, and behavior modification

Knowledge: Healthy Diet: Extent of understanding conveyed about a balanced, nutritious diet

Nutritional Status: Extent to which nutrients are ingested and absorbed to meet metabolic needs

Weight: Body Mass: Extent to which body weight, muscle, and fat are congruent to height, frame, gender, and age

Client Will (Include Specific Time Frame)

- Verbalize a realistic self-concept or body image (congruent mental and physical picture of self).
- Participate in development of, and commit to, a personal weight-loss program.
- Demonstrate appropriate changes in lifestyle and behaviors, including eating patterns, food quantity/quality, and exercise program.
- Attain desirable body weight with optimal maintenance of health.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Weight Reduction Assistance: Facilitating loss of weight and/or body fat

Nutrition Management: Providing and promoting a balanced intake of nutrients

Nutritional Counseling: Use of an interactive process focusing on the need for diet modification

NURSING PRIORITY NO. 1 To identify contributing factors/health status:

-  Obtain weight history, noting if client has weight gain out of character for self or family, is or was obese child, or used to be much more physically active than is now *to identify trends*. *Note: Unchecked weight gain can lead to obesity, which is now the most prevalent nutritional disorder among children and adolescents in the United States (45% of all adults and approximately 18% of youths ages 2 to 19 years).¹⁸ Being overweight during older childhood is highly predictive of adult obesity, especially if a parent is also obese.¹*
- Assess risk and presence of factors or conditions associated with obesity (e.g., familial pattern of obesity; decreased basal metabolic rate or hypothyroidism; type 2 diabetes; reproductive dysfunction; menopause; chronic disorders, such as heart disease, kidney disease, chronic pain; food or other substance addictions; stressful or sedentary lifestyle; depression; use of certain medications such as steroids, birth control pills; physical disabilities or limitations; lack of socioeconomic resources for obtaining or preparing healthy foods) *to determine treatments and interventions that may be indicated in addition to weight management.*^{1,3}
-  Assess client's knowledge of own body weight and nutritional needs and determine cultural expectations regarding size. *Although nutritional needs are not always understood, being overweight or having large body size may not be viewed negatively by individual because it is considered within relationship to family eating patterns and peer and cultural influences.¹ Ethnicity factors may influence the age of onset and the rapidity of weight gain. African American women and Hispanic women tend to experience weight gain earlier in life than Caucasians and Asians. Hispanic men tend to develop obesity earlier than African American and Caucasian men. Some cultures place importance on large body size (e.g., Samoan people or Cuban children).^{2,3}*
-  Identify familial and cultural influences regarding food. *People of many cultures place high importance on food and food-related events, while some cultures routinely observe fasting days (e.g., Arab, Greek, Irish, Jewish) that may be done for health or religious purposes.²*
- Ascertain how client perceives food and the act of eating. *Individual beliefs, values, and types of foods available influence what people eat, avoid, or alter. Client may be eating to satisfy an emotional need rather than physiological hunger, not only because food plays a significant role in socialization but also because food can offer comfort, sense of security, and acceptance.^{2,3}*
-  Evaluate client's routine medications. *Some medications can contribute to weight gain (e.g., cortisol and other glucocorticoids; sulfonylureas, tricyclic antidepressants, monoamine oxidase inhibitors; oral contraceptives; insulin [in excessive doses]; risperidone).⁶*
-  Assess dietary practices by means of diary covering 3 to 7 days. *Recall of foods and fluids ingested; times, patterns, and place of eating; whether alone or with other(s); and feelings before, during, and after eating can increase client's understanding of eating behavior and serve as the basis for dietary modifications. Note: Few people can accurately estimate the number of calories they should consume in a day for a person their age, height, weight, and physical activity.^{4,7,19}*
- Ascertain previous dieting history. *Client may report normal or excessive intake of food, but calories and intake of certain food groups (e.g., sweets and fats) are often underestimated. Client may report experimentation with numerous types of diets, repeated dieting efforts ("yo-yo" dieting) with varying results, or may never have attempted a weight-management program.*
-  Collaborate in assessment and interventions for client with disordered eating habits or eating perceptions: Obtain a comparative body drawing, having client draw self on wall with chalk and then standing against it and having actual body outline drawn to note difference between the two. *Determines whether client's view of self-body image is congruent with reality.*
Ascertain occurrence of negative feedback from significant others (SOs). *May reveal control issues and impact motivation for change.¹*
-  Review daily activity and regular exercise program *for comparative baseline and to identify areas for modification. Note: The 2008 National Health Interview Survey showed that only 33% of American adults participated in leisure-time physical activity on a regular basis.⁸*
-  Review laboratory test results (e.g., complete blood count with differential, full lipid panel, fasting glucose, A₁C, insulin levels; thyroid, leptins; proteins, Mini-Nutritional Assessment) *that may reveal medical*

conditions associated with obesity and identify problems that may be treated with alterations in diet or medications.^{5,10,20}

NURSING PRIORITY NO. 2 To determine weight-loss goals:

-  Obtain anthropometric measurements to determine presence and severity of obesity: Calculate body mass index (BMI) to estimate percentage of body fat. *Note: The Centers for Disease Control and Prevention (CDC) has standardized BMI calculations, removing age and sex differences for adults, with overweight being defined as 25 to 29.9 kg/m².^{21,21} The CDC has recommended that children (over age 2) and adolescents be considered overweight if the BMI exceeds the 85th percentile (and is less than the 95th percentile) on growth curves or exceeds 25 kg/m² at any age. *Note: Normal BMI in children changes as age and growth occurs and is also different between the sexes.*²²*
-  Determine waist circumference (WC), if indicated. *Some studies support that WC is more closely linked to cardiovascular risk factors than BMI alone because a high WC can occur in persons with normal or near normal BMIs. These sources indicate high risk if WC is greater than 35 inches (for women) and greater than 40 inches (for men), even if BMI is greater than 25 but is accompanied by family history of cardiovascular disease or diabetes or exists in conjunction with two or more chronic health conditions.*⁹
-  Evaluate body fat, body water, and muscle mass via scale skin caliper measurements and scale weight (direct measurement), bioelectric impedance analysis, dual-energy x-ray absorptiometry, and hydrostatic weighing (indirect measurement) per facility protocol. *Note: The CDC does not recommend these methods of measuring body weight (over BMI) because “they are not always readily available, and they are either expensive or need highly trained personnel. Furthermore, many of these methods can be difficult to standardize across observers or machines, complicating comparisons across studies and time periods.”*^{9,21}
- Determine client’s motivation for weight loss (e.g., for own satisfaction or self-esteem, to improve health status, to gain approval from another person). *Client is more likely to succeed and maintain desired weight when change is for self (e.g., acceptance of self “as is,” general well-being) rather than to please others.*
- Discuss myths client/SO may have about weight and weight loss to address misconceptions and possibly enhance motivation for needed behavior changes.

NURSING PRIORITY NO. 3 To establish weight-reduction program:

- Obtain commitment or contract for weight loss. *Verbal agreement to goals or written contract formalizes the plan and may enhance efforts and maximize outcomes.*
- Involve SO(s) in treatment plan as much as possible to provide ongoing support and increase likelihood of success.
-  Set realistic goals (short and long term) for weight loss. *Reasonable weight loss (1 to 2 lb/wk) has been shown to have more lasting effects than rapid weight loss, although sustaining motivation for small losses often makes it difficult for client to stick with a program. *Note: A loss of 5% to 10% of total body weight can reduce many of the health risks associated with obesity in adults.**^{1,12,13}
-  Collaborate with physician and nutritionist to develop and implement comprehensive weight-loss program that includes food, activity, behavior alteration, and support.
- Calculate calorie requirements based on physical factors and activity. *While many weight-reduction programs focus on portion size and food components (e.g., low-fat, high-protein, low-glycemic foods), reducing calorie intake is essential for weight loss. *Note: Decreasing calories by 500/day or expending 500 calories/day through exercise results in a weight loss of about 1 lb/wk.**⁶
-  Provide information regarding specific nutritional needs. *Individual may be deficient in needed nutrients (e.g., proteins, vitamins, or minerals) or may eat too much of one food group (e.g., fats or carbohydrates) and not enough of another food group (e.g., vegetables).*^{11,12} *Note: A recent CDC report revealed that between 2007 and 2010, children did not meet recommendations for the amount of fruit and vegetables they should eat, although fruit intake did increase, with fresh fruit replacing juices.*²³

- Discuss modifications to achieve healthy body weight.^{8,12–16,19}

 Eat from each food group (fruits, vegetables, whole grains, lean meats, low-fat dairy, oils).

Start with small changes, such as adding one more vegetable per day or introducing healthier versions of favorite foods.

Choose “nutrient-dense” forms of foods that provide substantial amounts of fiber, vitamins, electrolytes, and minerals.

Avoid saturated fats, trans fats, cholesterol, salt (sodium), and added sugars.

Focus on portion sizes: calorie-dense foods (high in fat and/or sugar) should be eaten in smaller quantities, whereas high-fiber foods can be eaten in larger quantities.

Discuss smart snacks (e.g., low-fat yogurt with fruit, nuts, apple slices with peanut butter, low-fat string cheese).

Emphasize need for adequate fluid intake and taking fluids between meals rather than with meals to provide fluid while leaving more room for food intake at meals *to assist in digestive process and to quench thirst, which is often mistakenly identified as hunger.*

-   Encourage involvement in planned activity program of client’s choice and within physical abilities. Refer to formal exercise program, if desired. *Moderately increased physical activity for 30 to 45 min for 5 days/wk can expend an additional 1,500 to 2,000 calories/wk, supporting both loss of pounds and maintenance of lower weight.^{12,14} Children should participate in vigorous physical activity throughout adolescence and limit time spent watching television and playing computer games to facilitate weight control.¹*
-  Recommend weighing only once/week, at the same time and wearing the same clothes, and graph it on chart. Measure and monitor body fat when possible *to track progress while focusing more on the idea of being health conscious and responsible than what scale may reveal.*
- Provide positive reinforcement and encouragement for efforts as well as actual weight loss. *Enhances commitment to program and enhances person’s sense of self-worth.*
-  Refer to bariatric physician/surgeon when indicated. *Evaluation for special measures may be needed (e.g., supervised fasting or bariatric surgery) for morbidly obese persons with BMI greater than 40. Refer to ND Obesity for related interventions.*

NURSING PRIORITY NO. 4 To promote wellness (Teaching/Discharge Considerations):

-   Assist in and encourage periodic evaluation of nutritional status and alteration of dietary plan. *May be desired or needed for addressing special needs (e.g., diabetes mellitus, age considerations, very low calorie or fasting) and monitoring health status.¹⁷*
- Emphasize importance of avoiding fad diets *that may be harmful to health and often do not produce long-term positive results.*
- Identify and encourage finding ways to reduce tension when eating. *Promotes relaxation to permit focus on act of eating and awareness of satiety.*
- Identify unhelpful eating behaviors (e.g., eating over sink; “gobbling, nibbling, or grazing”) and address kinds of activities associated with eating (e.g., watching television or reading, being unmindful of eating or food) *that result in taking in too many calories as well as eliminating the joy of food because of failure to notice flavors or sensation of fullness or satiety.*
- Review and discuss strategies to deal appropriately with stressful events *to avoid overeating as a means of coping.*
- Discuss importance of an occasional treat by planning for inclusion in diet *to avoid feelings of deprivation arising from self-denial.*
- Advise planning for special occasions (birthday or holidays) by reducing intake before event and/or eating “smart” *to redistribute or reduce calories and allow for participation in food events.*
- Discuss normalcy of ups and downs of weight loss: plateau, set point (at which weight is not being lost), hormonal influences, etc. *Prevents discouragement when progress stalls.*
- Encourage buying personal items and clothing *as reward for weight loss or other accomplishments. Suggest disposing of “fat clothes” to encourage positive attitude of permanent change and remove “safety valve” of having wardrobe available “just in case” weight is regained.*

-  Review prescribed drug regimen (e.g., appetite suppressants, hormone therapy, vitamin and mineral supplements) *for benefits or adverse side effects and drug interactions.*
- Recommend reading labels of nonprescription diet aids if used. *Herbals containing diuretics or ma huang (product similar to ephedrine) may cause adverse side effects in vulnerable persons.*
-   Encourage parents and school dietitians to model and offer good nutritional choices (e.g., offer vegetables, fruits, and lower-fat foods in daily meals and snacks) *to assist child in accepting healthy eating styles. Note: Studies have shown a high correlation between parents and children regarding patterns of food intake and food choices. Conversely, adult intake of fat has been shown to be higher when children under 17 are in the home (more pizza, cheese, processed food, junk food, and fast food).*^{1,15}
-  Refer to community support groups or psychotherapy, as indicated, *to provide role models and address issues of body image or self-worth.*
-  Provide contact number for dietitian/nutritionist and/or audiovisual materials, bibliography, and reliable Internet sites for resources *to address ongoing nutrition needs and dietary changes.*
- Refer to NDs disturbed Body Image, ineffective Coping, and Obesity for additional interventions, as appropriate.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including current weight, dietary pattern; perceptions of self, food, and eating; motivation for loss, support or feedback from SO(s).
- Results of laboratory and diagnostic testing.
- Results of interval weigh-ins.

Planning

- Plan of care, specific interventions, and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, weekly weight, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

risk for Overweight

Taxonomy II: Nutrition—Class 1 Ingestion (00234) [Diagnostic Division: Food/Fluid], Approved 2013; Revised 2017

DEFINITION: Susceptible abnormal or excessive fat accumulation for age and gender, which may compromise health.

RISK FACTORS

Average daily physical activity is less than recommended for gender and age; energy expenditure below energy intake based on standard assessment (e.g., WAVE [weight, activity, variety in diet, excess] assessment); sedentary behavior occurring for ≥ 2 hours/day

Consumption of sugar-sweetened beverages; frequent snacking; high frequency of restaurant or fried food; portion sizes larger than recommended; solid foods as major food source a < 5 months of age

Disordered eating behaviors or perceptions; fear regarding lack of food supply

Excessive alcohol consumption

Shortened sleep time, sleep disorder

At Risk Population: ADULT: Body mass index (BMI) approaching 25 kg/m^2

CHILD < 2 years: Weight-for-length approaching 95th percentile

CHILD 2–18 years: Body mass index (BMI) approaching 85th percentile or 25 kg/m^2

Children with high body mass index (BMI), or who are crossing body mass index (BMI) percentiles upward

Economically disadvantaged

Formula- or mixed-fed infants; overweight in infancy; rapid weight gain during infancy, including the first week, first 4 months, and first year; rapid weight gain during childhood

Premature pubarche

Heritability of interrelated factors; high disinhibition and restraint eating behavior score

Maternal diabetes mellitus, maternal smoking; paternal obesity

(continues on page 606)

risk for Overweight (continued)

Associated Condition: Genetic disorder

Sample Clinical Applications: Bulimia nervosa, diseases requiring long-term steroid use (e.g., chronic obstructive pulmonary disease [COPD]), conditions associated with immobility (e.g., stroke, paralysis, multiple sclerosis [MS], amputation), Alzheimer's disease, depression, developmental delay

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Weight Maintenance Behavior: Personal actions to maintain optimum body weight

Knowledge: Healthy Diet: Extent of understanding conveyed about a balanced, nutritious diet

Nutritional Status: Nutrient Intake: Nutrient intake to meet metabolic needs

Client/Caregiver Will (Include Specific Time Frame)

- Verbalize understanding of body and energy needs.
- Identify lifestyle and cultural factors that predispose to obesity.
- Demonstrate behaviors and lifestyle changes to reduce risk factors.
- Acknowledge responsibility for own actions and need to “act, not react” to stressful situations.

Sample NOC linkages:

Weight: Body Mass: Extent to which body weight, muscle, and fat are congruent to height, frame, gender, and age

Client Will (Include Specific Time Frame)

- Maintain weight at a satisfactory level for height, body build, age, and gender.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Weight Management: Facilitating maintenance of optimal body weight and percent body fat

Nutritional Counseling: Use of an interactive helping process focusing on the need for diet modification

Nutrition Management: Providing and promoting a balanced intake of nutrients

NURSING PRIORITY NO. 1 To assess potential factors for undesired weight gain:

- Note presence of factors or conditions that can contribute to weight gain or obesity (e.g., familial pattern of obesity; hypothyroidism; type 2 diabetes; pregnancy; menopause; chronic disorders [e.g., heart, kidney disease, chronic pain]; food, alcohol/other substance addictions; stressful and/or sedentary lifestyle; depression; use of certain medications [e.g., steroids, birth control pills, antipsychotics]; physical disabilities or limitations; lack of socioeconomic resources for obtaining or preparing healthy foods) *to determine treatment needs and possible behavioral changes for weight management.*¹
- ∞  Note client's particular situation and number/seriousness of risk factors *to help determine level of concern. For example, a high correlation exists between obesity in parents and children, which may reflect (in part) family patterns of food intake, exercise, selection of leisure activity (e.g., amount of television watching), family and cultural patterns of food selection. Also, family studies (e.g., twin and adoption) suggest genetic factors.*^{2,3}
-   Evaluate familial and cultural influences *that often place high importance on food and food-related events, groups that place importance on large body size, or frame of reference for “normal body weight”*

higher than standard indicators (e.g., athletes such as football players or wrestlers; African American women, Samoan people, Cuban children).²⁻⁴

-   Note client's age and activity level and exercise patterns to identify areas where changes might be useful to prevent obesity and promote health. For example, older adults need same nutrients as younger adults but in smaller amounts and with attention to certain components, such as calcium, fiber, vitamins, protein, and water.⁵ Infants/children require small meals and constant attention to needed nutrients for proper growth and development while dealing with child's food preferences and eating habits.⁶
-   Calculate growth percentiles in infants/children using growth chart specific to child's age and gender or BMI-for-age calculator if child is greater than 2 years old to identify deviations from the norm.^{2,7}
-  Review laboratory test results (e.g., complete blood count with differential, full lipid panel, fasting glucose, A₁C, insulin levels; thyroid, leptins; proteins, Mini-Nutritional Assessment) that may reveal medical conditions associated with obesity and identify problems that may be treated with alterations in diet or medications.⁸⁻¹⁰
- Assess eating patterns in relation to risk for obesity and disease conditions. Food choices and amounts of certain food groups are known to impact health (in both children and adults) and cause or exacerbate disease conditions (e.g., heart disease, diabetes, hypertension, gallstones, colon cancer).^{1,11}
- Determine patterns of hunger and satiety. Eating patterns often differ in those who are predisposed to weight gain and may include such factors as skipping meals (decreases the metabolic rate), fasting and binging (causes wide fluctuations in glucose and insulin), and eating or overeating in response to emotions (e.g., loneliness, anger, happiness).
- Note history of dieting and kinds of diets used. Client may have tried multiple diets with varying degrees of success in the past, but often has history of regaining weight ("yo-yo" dieting) or finding that diets are not desirable.
- Determine whether binging or purging (bulimia) is a factor to identify potential for eating disorder requiring in-depth intervention.
- Identify personality characteristics (e.g., rigid thinking patterns, external locus of control, negative body image or self-concept, negative monologues [self-talk], dissatisfaction with life) that are often associated with obesity and can impact choice and/or success of interventions.
- Determine psychological significance of food to the client (e.g., derives love and comfort from food, uses food to escape deep unhappiness, eats when stressed or anxious).
- Listen to concerns and assess motivation to prevent weight gain. If client's concerns regarding weight control are motivated for reasons other than personal well-being (e.g., partner's expectations or demands), the likelihood of success is decreased.

NURSING PRIORITY NO. 2 To assist client to develop preventive program to avoid weight gain:

-  Assess client's knowledge of nutritional needs and ways client is meeting these needs. Provides baseline for further teaching and/or interventions.
-  Provide information, as indicated, on nutrition, taking into account client's age and developmental stage (e.g., toddler, teenager, pregnant woman, elderly person with chronic disease), physical health and activity tolerance, financial and socioeconomic factors, and client's/significant other's (SO's) potential for management of risk factors.
-  Review and encourage client/caregiver to implement guidelines for achieving and maintaining healthy body weight:^{2,12}
 - Eat from each food group (fruits, vegetables, whole grains, lean meats, low-fat dairy, oils).
 - Start with small changes, such as adding one more vegetable/day or introducing healthier versions of favorite foods.
 - Choose "nutrient-dense" forms of foods that provide substantial amounts of fiber, vitamins, electrolytes, and minerals.
 - Avoid saturated fats, trans fats, cholesterol, salt (sodium), and added sugars.

Focus on portion sizes: calorie-dense foods (high in fat and/or sugar) should be eaten in smaller quantities, whereas high-fiber foods can be eaten in larger quantities.

Discuss smart snacks (e.g., low-fat yogurt with fruit, nuts, apple slices with peanut butter, low-fat string cheese).

Review healthy eating patterns or habits (e.g., eating slowly and only when hungry, stopping when full, avoiding skipping meals, eating foods from every food group, using smaller plates, chewing food thoroughly, making healthy food choices even when eating fast food).

Encourage involvement in planned exercises of client's choice and within physical abilities. Refer to formal exercise program, if desired.

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Provide information about individual risk factors *to enhance decision making and support motivation.*
-  Consult with nutritionist *to address client-specific issues (e.g., how to use food groups, how to read food labels and apply to self; how to help child avoid junk food, dietary restrictions that might be needed for certain chronic diseases such as kidney disease or diabetes).*
-  Provide information to new mothers about nutrition for developing babies *to reduce potential for childhood obesity related to lack of knowledge.*
-  Encourage parents and school dietitians to model and offer good nutritional choices (e.g., offer vegetables, fruits, and lower-fat foods in daily meals and snacks) *to assist child in accepting healthy food styles.*^{2,12}
- Encourage the client to make a commitment to lead an active life, to manage food habits, and to develop a system for self-monitoring *to provide a sense of control and assist with making choices.*
- Provide bibliography including reliable Internet sites for resources *to reinforce learning, address ongoing nutrition needs, support informed decision making.*
-  Refer to support groups and appropriate community resources for such things as food-buying assistance, cooking and food safety courses, and behavior modification as indicated. *Provides role models and assistance for making lifestyle changes.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Findings related to individual situation, risk factors, current caloric intake and dietary pattern; activity level.
- Baseline height and weight, growth percentile.
- Results of laboratory tests.
- Motivation to reduce risks or prevent weight problems.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs, noting who is responsible for actions to be taken.
- Specific referrals made.

acute Pain

Taxonomy II: Comfort—Class 1 Physical Comfort (00132) [**Diagnostic Division:** Pain/Discomfort], Approved 1986; Revised 2013

DEFINITION: Unpleasant sensory and emotional experience associated with actual or potential tissue damage or described in terms of such damage (International Association for the Study of Pain); sudden or slow onset of any intensity, from mild to severe, and with a duration of less than 3 months.

RELATED FACTORS

Biological injury agent [e.g., infection, ischemia, neoplasm]

Chemical injury agent

Physical injury agent [e.g., trauma, amputation, operative procedure, burn, heavy lifting, overtraining]

DEFINING CHARACTERISTICS

Subjective

Appetite change; hopelessness

Self-report of intensity using standardized pain scale [e.g., Wong-Baker FACES scale, visual analogue scale, numeric rating scale]

Self-report of pain characteristics using standardized pain instrument [e.g., McGill Pain Questionnaire, Brief Pain Inventory]

Proxy report of pain behavior/activity changes [e.g., family member, caregiver]

Objective

Change in physiological parameter [e.g., blood pressure, heart rate, respiratory rate, oxygen saturation]

Diaphoresis

Distraction behavior; expressive behavior

(continues on page 610)

acute Pain (continued)

Evidence of pain using standardized pain behavior checklist for those unable to communicate verbally [e.g., Neonatal Infant Pain Scale, Pain Assessment Checklist for Seniors with Limited Ability to Communicate]

Facial expression of pain; pupil dilation

Guarding behavior; protective behavior; positioning to ease pain

Self-focused; narrowed focus

Sample Clinical Applications: Traumatic injuries, surgical procedures, infections, cancer, burns, skin lesions, gangrene, thrombophlebitis, pulmonary embolus, neuralgia

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Pain Level: Severity of observed or reported pain

Pain Control: Personal actions to eliminate or reduce pain

Pain: Adverse Psychological Response: Severity of observed or reported adverse cognitive and emotional responses to physical pain

Client Will (Include Specific Time Frame)

- Report pain is relieved or controlled.
- Follow prescribed pharmacological regimen.
- Verbalize methods that provide relief.
- Demonstrate use of relaxation skills and diversional activities as indicated for individual situation.
- Verbalize sense of control of response to acute situation and positive outlook for the future.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Pain Management: Acute Alleviation or reduction of pain to a level that is acceptable to the patient in the immediate healing period following tissue damage from an identifiable cause such as trauma, surgery, or injury

Analgesic Administration: Use of pharmacological agents to reduce or eliminate pain

Environmental Management: Comfort: Manipulation of the patient's surroundings for promotion of optimal comfort

NURSING PRIORITY NO. 1 To assess etiology/precipitating contributory factors:

- Note possible pathophysiological and psychological causes of pain (e.g., inflammation, tissue trauma, burns, fractures, surgery; infections, heart attack, angina; abdominal conditions [e.g., appendicitis, cholecystitis], grief, fear, anxiety, depression, personality disorders). *Acute pain is that which follows an injury, trauma, or procedure such as surgery or occurs suddenly with the onset of a painful condition (e.g., herniated disk, migraine headache, pancreatitis).*^{4,11}
- Assess for potential types of pain that may be affecting client, i.e., nociceptive pain or neuropathic pain. *Can aid in understanding reason for severity of pain associated with client's condition and point toward needed interventions for pain management. Note: **Nociceptive** pain results from actual tissue damage or potentially tissue-damaging stimuli. Subsets of nociceptive pain include **somatic** (typically localized and usually stemming from muscle, joint, bone, or connective tissue) and **visceral** (caused from damage to thoracic, pelvic, or abdominal viscera [organs], with localized pain occurring from some obstruction, distension or ischemia).*

Neuropathic pain is a complex pain syndrome caused by a variety of problems with nerves or the processing of nerve impulses. Neuropathic pain can become chronic after a gradual onset, such as with diabetic neuropathy, or have an acute onset related to direct nerve injury, such as might occur with severe trauma, surgery, or certain types of cancer and chemotherapy.^{4,9,11}

-  Note client's age, developmental level, and current condition (e.g., infant/child; critically ill; ventilated, sedated, or cognitively impaired client) *affecting ability to report pain parameters or response to pain and pain management interventions.*^{3,4,9,10,13–15}
- Determine history or presence of chronic conditions (e.g., multiple sclerosis, stroke, diabetes, depression) *that may also be associated with acute and chronic pain simultaneously, be associated with an exacerbation of pain symptoms, or interfere with accurate assessment of acute pain.*³
-  Note anatomical location of surgical incisions or procedures. *This can influence the amount of postoperative pain experienced; for example, vertical or diagonal incisions are more painful than transverse or S-shaped. Presence of known and unknown complication(s) may make the pain more severe than anticipated.*^{2,3,5}
-  Assess client's perceptions of pain, along with behaviors and cultural expectations regarding pain. *Client's perception of and expression of pain is influenced by age, developmental stage, underlying problem causing pain, cognitive, and behavioral and sociocultural factors.*⁶
-  Note client's attitude toward pain and use of specific pain medications, including any history of substance abuse. *Client may have beliefs restricting use of medications, may have a high tolerance for drugs because of recent or current use, or may not be able to take pain medications at all if participating in a substance abuse recovery program.*
- Note client's locus of control (internal or external). *Individuals with external locus of control may take little or no responsibility for pain management.*
-  Determine medications (e.g., skeletal muscle relaxants, antibiotics, antidepressants, anticoagulants), alcohol or other drugs currently being used, and any medication allergies *that may affect choice of analgesics.*^{2,3}
-  Collaborate with medical providers in pain assessment, including neurological and psychological factors (pain inventory, psychological interview) as appropriate when pain persists.
-  Assist with and review results of laboratory tests and diagnostic studies depending on results of history and physical examination.

NURSING PRIORITY NO. 2 To evaluate client's response to pain:

-  Obtain client's/significant other's (SO's) assessment of pain to include location, characteristics, onset, duration, frequency, quality, and intensity. Identify precipitating or aggravating and relieving factors *in order to fully understand client's pain symptoms. Note: Experts agree that attempts should always be made to obtain self-reports of pain. When that is not possible, credible information can be received from another person who knows the client well (e.g., parent, spouse, caregiver).*¹⁴ *Numerous studies have revealed that physicians and nurses need to be aware of their tendency to underestimate client's pain in early postoperative days.*¹⁶
-  Perform pain assessment each time pain occurs. Document and investigate changes from previous reports and evaluate results of pain interventions *to demonstrate improvement in status or to identify worsening of underlying condition/developing complications.*^{4,5,12}
-  Accept client's description of pain. Be aware of the terminology client uses for pain experience (e.g., young child may say "owie" or "hurt"; elderly may say "it aches so bad"). *Pain is a subjective experience and cannot be felt by others.*^{3,13} *Note: Some elderly clients experience a reduction in perception of pain or have difficulty localizing or describing pain, and pain may be manifested as a change in behavior (e.g., restlessness, loss of appetite, increased confusion or wandering, acting out, change in functional abilities).*¹⁵
-  Note cultural influences affecting pain response. *Verbal or behavioral cues may have no direct relationship to the degree of pain perceived (e.g., client may deny pain even when feeling uncomfortable, reactions can be stoic or exaggerated, reflecting cultural and familial norms). These factors affect client's and caregiver's attitudes and beliefs regarding the pain experience, expressions of pain, and expectations regarding pain management.*^{6,10}

-  Observe nonverbal cues (e.g., how client walks, holds body, guarding behaviors; sleeplessness; grimacing facial expressions; distraction behaviors, narrowed focus; crying, poor feeding, lethargy in infants). Ask others who know client well (e.g., spouse, parent) to identify behaviors that may indicate pain in persons who cannot communicate verbally. *Helpful in recognizing presence of pain; however, cues not congruent with verbal reports indicate need for further evaluation.*^{1-4,6}
- Assess for referred pain, as appropriate, *to help determine possibility of underlying condition or organ dysfunction causing pain to be perceived in area other than site of the problem.*⁹
-  Monitor vital signs during episodes of pain. *Blood pressure, respiratory and heart rate are usually altered in acute pain.*¹⁻³
- Ascertain client's knowledge of and expectations about pain management. *Provides baseline for interventions and teaching, provides opportunity to allay common fears and misconceptions (e.g., fears about addiction to opiates, belief that complete pain relief is possible in every situation) or to address expected side effects of analgesics (e.g., constipation).*
- Review client's previous experiences with pain and methods found either helpful or unhelpful for pain control in the past. *Useful in determining appropriate interventions.*
-  Be aware of client's "Right to Treatment" *that includes prevention of or adequate relief from pain⁵ and that failure to meet the standard of assessing for pain can be considered negligence. This means that the nurse is obligated to do everything within his/her professional capacity to relieve the pain when the client requests pain relief. Furthermore, professional standards require that nurses assess pain and reassess pain even when the client has not made a specific request.*¹⁷

NURSING PRIORITY NO. 3 To assist client to explore methods for alleviation/control of pain:

-  Determine client's acceptable level of pain and pain control goal. *Client may not be 100% pain free but may feel that a "3" is a manageable level of discomfort, while another may require medication for pain at the same level because the experience is subjective.*^{1-4,6}
- Determine factors in client's lifestyle (e.g., alcohol or other drug use or abuse) that can affect responses to analgesics and/or choice of interventions for pain management.¹⁰
- Note when pain occurs (e.g., only with ambulation, every night) *to medicate prophylactically as appropriate.*
-  Collaborate in treatment of underlying condition or disease processes causing pain and proactive management of pain (e.g., epidural analgesia, nerve blockade for postoperative pain, surgical plication of a nerve, implantation of nerve stimulator).
-  Work with client *to prevent rather than "chase" pain.* Use flow sheet to document pain, therapeutic interventions, response, and length of time before pain recurs. Instruct client to report pain as soon as it begins, *because timely intervention is more likely to be successful in alleviating pain.*⁷
- Encourage verbalization of feelings about the pain such as concern about tolerating pain, anxiety, and pessimistic thoughts *to evaluate coping abilities and to identify areas of additional concern.*^{1,7}
- Review procedures and expectations and inform client when treatments will hurt. Discuss pain management methods that will be used *to reduce concerns of the unknown and muscle tension associated with anxiety or fear.*
-  Use puppets or dolls for explanations and teaching, when indicated, *to demonstrate procedures for child and enhance understanding to reduce level of anxiety or fear.*
-  Provide or promote nonpharmacological pain management, such as:
a quiet environment and calm activities;
comfort measures (e.g., back rub, change of position, use of heat or cold compresses);
use of relaxation exercises (e.g., focused breathing, visualization, guided imagery);
diversional or distraction activities, such as television and radio, socialization with others, and commercial or individualized tapes (e.g., "white" noise, music, instructional);

-  presence of parent during painful procedures *to comfort child*;
identification of ways to avoid or minimize pain (e.g., *splinting incision during cough, keeping body in good alignment and using proper body mechanics, and resting between activities can reduce occurrence of muscle tension or spasms or undue stress on incision*).
-  Establish collaborative approach for pain management based on client's understanding about and acceptance of available treatment options. *Pharmacological management is based on client's symptomatology and mechanism of pain as well as tolerance for pain and for the various analgesics. Multimodal pain management may include pills, liquids, or suckers to take by mouth, skin patch, or suppository forms and injections, IV dosing, or patient-controlled analgesia (PCA), or regional analgesia (e.g., epidural and spinal blocking).*^{3,7,9,10,12}
-  Administer analgesics to maximal dosage as needed *to maintain "acceptable" level of comfort. The type of medication(s) ordered depends on the type and severity of pain (e.g., acetaminophen and NSAIDs are commonly used to treat mild to moderate pain, while opiates [e.g., morphine, oxycodone, fentanyl] are used to treat moderate to severe pain). Note: Various combinations of medications may be used at prescribed intervals.*^{3,8}
-   Notify physician/healthcare provider if regimen is inadequate to meet pain control goal. Assist client to prevent (rather than treat pain) and alter drug regimen based on individual needs. *Once established, pain is more difficult to suppress. Increasing dosage, changing medication, or using a stepped program (e.g., switching from injection to oral route, or lengthening time interval between doses) helps in self-management of pain.*^{2,5}
- Evaluate and document client's response to analgesics and assist in transitioning or altering drug regimen based on individual needs and planned interventions *to limit adverse effects, reduce risk of drug dependence, and deal with barriers to adequate use of analgesics.*
-  Evaluate for adverse medication effects (e.g., decrease in mental acuity, change in thought processes, confusion or delirium, urinary retention, severe nausea, vomiting, pruritus). *Intolerable symptoms that usually require change of medication(s).*^{3,7,8}
-  Demonstrate and monitor use of self-administration/PCA that involves client in plan *to administer own IV pain medication or bolus additional dose when on continual basis drip.*^{3,7,8}
-   Provide information and monitor use of site-specific medications (e.g., spinal, epidural, regional anesthesia) *that might be used for certain procedures such as back surgery, amputation, or labor and delivery.*^{2,7,8}
-  Instruct client in use of transcutaneous electrical stimulation unit when ordered.

NURSING PRIORITY NO. 4 To promote wellness (Teaching/Discharge Considerations):

-  Acknowledge the pain experience and convey acceptance of client's response to pain. *Reduces defensive responses, promotes trust, and enhances cooperation with regimen.*
- Encourage adequate rest periods *to prevent fatigue that can impair ability to manage or cope with pain.*
- Review nonpharmacological measures for lessening pain. *Relaxation skills and techniques such as self-hypnosis, biofeedback, and therapeutic touch have no detrimental side effects.*
- Provide information and discuss pain management before planned procedures. *The primary concern of most clients/families is pain and discomfort following surgery or invasive procedure.*
-  Encourage performance of individualized physical therapy/exercise program. *Promotes active role in preventing muscle spasms or contractures and enhances sense of control.*
- Discuss ways SO(s) can assist client with pain management. *Family members/SOs may provide assistance by transporting client to prevent walking long distances or by taking on client's strenuous chores, supporting timely pain control, encouraging eating nutritious meals to enhance wellness, and providing gentle massage to reduce muscle tension.*
- Identify specific signs/symptoms and changes in pain requiring evaluation by healthcare provider.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual assessment findings, including client's description of response to pain, specifics of pain inventory, expectations of pain management, and acceptable level of pain.
- Locus of control and cultural beliefs affecting response to pain.
- Prior medication use; substance abuse.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs, noting who is responsible for actions to be taken.
- Specific referrals made.

chronic Pain and chronic Pain Syndrome [CPS]

Taxonomy II: Comfort—Class 1 Physical Comfort (00133) [Diagnostic Division: Pain/Discomfort], Approved 1986; Revised 1996, 2013, 2017

DEFINITION: chronic Pain: Unpleasant sensory and emotional experience arising from actual or potential tissue damage or described in terms of such damage (International Association for the Study of Pain); sudden or slow onset of any intensity, from mild to severe, constant or recurring without an anticipated or predictable end and a duration of greater than three (>3) months.

Taxonomy II: Comfort—Class 1 Physical Comfort (0000255) [Diagnostic Division: Pain/Discomfort], Approved 2013

DEFINITION: chronic Pain Syndrome: Recurrent or persistent pain that has lasted at least three months, and that significantly affects daily functioning or well-being.

[Author Note: Pain is a signal that something is wrong. Chronic pain may be recurrent and periodically disabling (e.g., migraine headaches, kidney stones, prostatitis) or may be unremitting. It is a complex entity, combining elements from many other NDs, such as risk for Disuse Syndrome; decreased Diversional Activity Engagement; disturbed Body Image; compromised family Coping; interrupted Family Processes; Powerlessness; Self-Care deficit (specify); sexual Dysfunction; Social Isolation]. The nurse is encouraged to refer to other NDs as indicated.

RELATED FACTORS (CHRONIC PAIN)

Alteration in sleep pattern
Emotional distress; fatigue; whole-body vibration
Nerve compression; prolonged computer use; repeated handling of heavy loads
Increase in body mass index; malnutrition
Ineffective sexuality pattern; social isolation
Injury agent

DEFINING CHARACTERISTICS

Subjective (chronic Pain)

Self-report of intensity using standardized pain scale [e.g., Wong-Baker FACES scale, visual analogue scale, numeric rating scale]
Self-report of pain characteristics using standardized pain instrument [e.g., McGill Pain Questionnaire, Brief Pain Inventory]
Alteration in ability to continue previous activities
Alteration in sleep pattern; anorexia
Proxy report of pain behavior/activity changes [e.g., family member, caregiver]
[Preoccupation with pain]

Subjective (chronic Pain Syndrome)

Anxiety, fear; stress overload
Constipation
Disturbed sleep pattern, fatigue; insomnia

Objective (chronic Pain)

Evidence of pain using standardized pain behavior checklist for those unable to communicate verbally [e.g., Neonatal Infant Pain Scale, Pain Assessment Checklist for Seniors with Limited Ability to Communicate]
Facial expression of pain; self-focused

(continues on page 616)

chronic Pain and chronic Pain Syndrome [CPS] (continued)**Objective (chronic Pain Syndrome)**

Deficient knowledge

Impaired mood regulation; social isolation

Impaired physical mobility

Obesity

At Risk Population (Chronic Pain): Age >50 years; female gender

History of abuse; history of genital mutilation

History of over indebtedness; history of substance misuse/[abuse]

History of static work postures; history of vigorous exercise

Associated Condition (Chronic Pain): Chronic musculoskeletal condition; muscle injury; tumor infiltration

Contusion, crush injury; fracture; spinal cord injury

Genetic disorder; imbalance of neurotransmitters, neuromodulators, and receptors;

Immune disorder; impaired metabolic functioning; ischemic condition; prolonged increase in cortisol level

Post-trauma related condition

Sample Clinical Applications: Traumatic injuries, migraines, repetitive motion injury (carpal or cubital tunnel syndrome), osteoarthritis, rheumatoid arthritis; peripheral neuropathies in diabetes or AIDS, cancer, burns, endometriosis, neuralgia, gangrene**DESIRED OUTCOMES/EVALUATION CRITERIA****Sample NOC linkages:****Pain Control:** Personal actions to eliminate or reduce pain**Pain: Disruptive Effects:** Severity of observed or reported disruptive effects of chronic pain on daily functioning**Pain: Adverse Psychological Response:** Severity of observed or reported adverse cognitive and emotional responses to physical pain**Client Will (Include Specific Time Frame)**

- Verbalize and demonstrate (nonverbal cues) relief or control of pain or discomfort.
- Verbalize recognition of interpersonal and family dynamics, and reactions that affect the pain problem.
- Demonstrate or initiate behavioral modifications of lifestyle and appropriate use of therapeutic interventions.
- Verbalize increased sense of control and enhanced enjoyment of life.

Sample NOC linkage:

- **Family Coping:** Capacity of the family to manage stressors that tax family resources

Family/SO(s) Will (Include Specific Time Frame)

- Cooperate in pain management and rehabilitation programs. (Refer to ND readiness for enhanced family Coping.)

ACTIONS/INTERVENTIONS**Sample NIC linkages:****Pain Management: Chronic** Alleviation or reduction of persistent pain that continues beyond the normal healing period, assumed to be three months, to a level that is acceptable to the patient

Medication Management: Facilitation of safe and effective use of prescription and over-the-counter drugs
Relaxation Therapy: Use of techniques to encourage and elicit relaxation for the purpose of decreasing undesirable signs and symptoms such as pain, muscle tension, or anxiety

NURSING PRIORITY NO. 1 To assess etiology/precipitating factors:

- Identify contributing physical factors where known. *These factors associated with chronic pain and CPS appear to include (1) musculoskeletal disorders such as osteoarthritis, rheumatoid arthritis, and fibromyalgia; (2) back pain from various causes such as disc herniation, vertebral fractures, muscular strains/sprains, over-use syndromes such as tendonitis, and bursitis, as well as pelvic disorders; (3) neurological disorders, such as spinal/other conditions causing nerve impingement, and radiculopathies and neuropathies with direct or referred pain; (4) urological disorders such as bladder neoplasms, chronic urinary tract infections or stones, testicular torsion, prostatitis; (5) gastrointestinal disorders such as colitis, gastroesophageal reflux, inflammatory bowel disease, and pancreatitis; (6) reproductive/gynecological disorders including endometriosis, disorders of ovaries, prolapse, intrauterine contraceptive devices, etc.; and (7) miscellaneous/other causes including trauma (including childhood physical and sexual abuse), cardiovascular disease, peripheral vascular disease, and complications of medical treatments such as chemotherapy, radiation, or surgery.*^{2,8}
- Evaluate for presence of/suspected psychological disorders. *Psychological factors may include (but are not limited to) depression, anxiety, somatization, posttraumatic stress disorders, substance abuse, compulsive sexual behaviors, eating disorders, and bipolar personality disorders. Testing may be indicated if organic cause of pain cannot be found, when psychological factors are known to exist, or when pain problems are prolonged and/or life-limiting.*¹²
-  Assist in and/or review diagnostic testing, including physical (e.g., selected tests for identifying and/or monitoring suspected for known disease states; urine or blood toxicology for drug detoxification or therapy; imaging studies), neurological, and psychological evaluations (e.g., Minnesota Multiphasic Personality Inventory, pain inventory, psychological interview). *Note: While additional diagnostic studies may be indicated when advanced treatment of the client with CPS is initiated, care should be exercised in avoiding duplication of tests. This prevents unnecessary costs, as well as inadvertent reinforcement of client's psychological need for "something to be physically wrong."*²
-  Evaluate emotional/psychological components of individual situation. *Individuals with certain psychological syndromes (e.g., major depression, somatization disorder, hypochondriasis) are prone to develop CPS. Note: The Institute for Chronic Pain reports that "it is a common and consistent finding in the research that, as a group, people with chronic pain tend to report much higher rates of having experienced trauma in their past, when compared to people without chronic pain. Thus the high rate of past trauma (e.g., combat, domestic violence, sexual assault, childhood neglect and physical/sexual abuse, terrorism) in people with chronic pain suggests a relationship to the development of chronic pain."*^{2,6,12,16}
-  Determine if client has history of physical or sexual abuse as a child. *A review of the literature shows that abuse in childhood is a strong predictor of depression and physical complaints, both expanded and unexplained, in adulthood.*^{13,16}
-  Evaluate client's pattern of coping and locus of control (internal or external). *Passive and avoidant behavioral patterns or lack of active engagement in self-management activities can contribute to diminished activity and perpetuation of chronic pain. Individuals with external locus of control may take little or no responsibility for pain management.*¹³
-  Determine relevant cultural and spirituality factors affecting pain response. *Pain is accepted and expressed in different ways (e.g., moaning aloud or enduring in stoic silence); some may magnify symptoms to convince others of reality of pain or believe that suffering in silence helps atone for past wrongdoing.*³ *A person with chronic pain who identifies himself or herself as a spiritual being may report the link to divine help as empowering him/her to use strategies for healing.*^{14,15}

-  Note gender and age of client. *There may be differences between women and men as to how they perceive and/or respond to pain. Pain in children, ethnic minorities, or cognitively impaired persons is often underestimated and undertreated. Recent studies are revealing large numbers of pediatric clients with chronic pain issues affecting academic attendance and function.¹¹ While the prevalence of chronically painful conditions (e.g., arthritis) and illnesses (e.g., cancers) is common in the elderly, they may be reluctant to report pain.^{4,7}*
-  Evaluate current and past analgesic or narcotic drug use and nonprescription drug use (including alcohol). *Provides clues to options to try or avoid and identifies need for changes in medication regimen, as well as possible need for detoxification program.*

NURSING PRIORITY NO. 2 To determine client response to chronic pain situation:

-  Evaluate pain behavior, noting past and current pain experience, using pain rating scale or diary, and including functional effects and psychological factors. *Pain behaviors can include the same ones present in acute pain (e.g., crying, grimacing, withdrawal, narrowed focus), but may also include other behaviors (e.g., dramatization of complaints, depression, drug misuse). Pain complaints may be exaggerated because of client's perception that pain reports are not believed or because client believes caregivers are discounting reports of pain.¹²*
-  Provide comprehensive assessment of pain problem, noting its duration, who has been consulted, and what therapies (including alternative/complementary) have been used. *The pathophysiology of chronic pain is multifactorial. If the condition causing the persistent pain is physiological and noncurable (e.g., terminal cancer), all diagnostics and treatments may have been exhausted and pain management becomes the primary goal. If medical treatments are ongoing for painful conditions (e.g., spinal stenosis, pancreatitis, endometriosis, arthritis), consultations with specialists may be helpful in finding curative or palliative treatments. If pain is present without a clear etiology or continues unabated, complex rehabilitation techniques may be required, incorporating physical, occupational, psychological, and recreational therapies.^{1,2,12}*
-  Note lifestyle effects of pain. *Major effects of chronic pain on the client's life can include depressed mood, fatigue, weight loss or gain, sleep disturbances, reduced activity and libido, excessive use of drugs and alcohol, dependent behavior, and disability seemingly out of proportion to impairment.^{2,4,12}*
-  Assess degree of personal maladjustment of the client such as isolationism, anger, irritability, loss of work time or employment, and school absenteeism. *Chronic pain reduces client's coping abilities and psychological well-being, often resulting in problems with relationships and life functioning.^{11,12}*
-  Determine issues of secondary gain for the client/significant others (SOs), such as financial or insurance compensation pending, legal or marital or family concerns, and school or work issues, which may be present if there is marked discrepancy between claimed distress and objective findings or there is a lack of cooperation during evaluation and in complying with prescribed treatment.⁵
- Note codependent components and enabling behaviors of caregivers/family members *that support continuation of the status quo and may interfere with progress in pain management or resolution of situation.*
- Note availability and use of personal and community resources. *Client/SO may need many things (e.g., equipment, financial resources, vocational training, respite services, placement in rehabilitation facility) in order to manage painful conditions and/or concerns or difficulties associated with condition.*
-  Make home visit when indicated, observing such factors as client's safety, equipment, adequate lighting, or family interactions, *to note impact of home environment on the client and to determine changes that might be useful in improving client's life (e.g., grab bars in bathrooms and hallways, wider doors, ramps, assistance with activities of daily living, housekeeping, yard work).*
- Acknowledge and assess pain matter-of-factly, avoiding undue expressions of concern, as well as expressions of disbelief about client's suffering. *Conveying an attitude of empathic understanding of client's disabling distress can have a beneficial impact on client's perception of health.*

NURSING PRIORITY NO. 3 To assist client to deal with pain:

-  Encourage participation in multidisciplinary pain management plan. *Comprehensive team may include physical medicine specialist; physical, occupational, recreational, and vocational therapists; and emotional or*

behavioral therapists to address complex issues of unresolved pain issues, to set goals for pain relief, and to develop an individualized treatment and evaluation plan. Treatments could involve extended-relief oral pain medications or dermal patches, nerve-blocking injections or an implanted pump, and massage and other hands-on therapies, as well as counseling and home exercise programs.⁸

- Discuss pain management goals and review client expectations versus reality because it may be that while pain cannot be completely resolved, it can be significantly reduced or managed to the degree that client can participate in desired or needed life activities, thus improving quality of life.⁸
- Discuss the physiological dynamics of tension and anxiety and how this affects pain.
-  Administer or encourage client use of analgesics, as indicated. Medications may be available in pills, liquids, or suckers to take by mouth, and in injection, skin patch, and suppository forms. Different medications or combinations of drugs may be used such as opioids/narcotics, nonopioids, and adjuvant medications (e.g., muscle relaxants, anticonvulsants, antidepressants, serotonin and norepinephrine reuptake inhibitors) to manage persistent pain so that client may find relief and increase level of function.^{2,8,12} Note: Studies support that people with intense pain can take very high doses of opioids without experiencing side effects. “Some people with intense pain receive such high doses that the same dose would be fatal if taken by someone who was not suffering from pain. In chronic pain that same high dose can control pain and still allow the person to be wide awake enough to do his or her activities of daily living.”¹
-  Provide consistent and sufficient medication for pain relief, tailored to the individual, especially in those who tend to be undermedicated (e.g., elderly, cognitively impaired, person with lifelong pain, those with terminal cancer). Medications may need to be scheduled around the clock (not just administered “as needed”), doses titrated either up or down, and dose maximized to optimize pain relief while managing side effects.⁷
-  Recommend or employ nonpharmacological interventions, methods of pain control (e.g., heat or cold applications, progressive muscle relaxation, biofeedback, deep breathing, meditation, visualization or guided imagery, posture correction and muscle strengthening exercises, water therapy, electrical stimulation, massage, acupuncture, Therapeutic Touch) to obtain comfort, improve healing, and decrease dependency on analgesics.⁹
-  Address medication misuse with client/SO and refer for appropriate counseling or interventions when addiction is known or suspected to be interfering with client’s well-being. Most people (if they don’t already have a substance [drug or alcohol] abuse problem) don’t become addicted to pain medications even when used on a long-term basis. These individuals will take the pain medications in order to go about the business of their lives. Addicts may misrepresent their pain levels and their activities in order to obtain pain medications or progressively higher doses of medications, and they require specialized evaluation and interventions.^{1,2,5}
- Assist family in developing a program of coping strategies (e.g., staying active even when modified activities are required, living a healthy lifestyle). Positive reinforcement and encouraging client to use own control can aid in focusing energies on more productive activities.¹⁰
- Encourage limiting attention to pain behaviors when appropriate (e.g., discussing pain for only a specified time; acknowledging “I’m sorry your pain returned today, but you need to go to school”; actively practicing relaxation or coping skills). Reduces focus on pain, especially if client is highly dependent on pain for secondary gain issues or is addicted to medications.⁶
- Encourage client to use positive affirmations (e.g., “I am healing,” “I am relaxed,” “I love this life”). Have client be aware of internal-external dialogue. Say “cancel” when negative thoughts develop. Negative thinking can exacerbate feelings of hopelessness, and replacing those thoughts with positive ones can be helpful to pain management.
- Encourage right-brain stimulation with activities such as love, laughter, and music. These actions can release endorphins, enhancing sense of well-being.
- Encourage use of subliminal tapes to bypass logical part of the brain by reinforcing “I am becoming a more relaxed person” and “It is all right for me to relax.”
-  Use tranquilizers, narcotics, and analgesics sparingly. These drugs are physically and psychologically addicting and promote sleep disturbances, especially interference with deep rapid eye movement sleep. Client may need to be detoxified if many medications are currently used.
- Be alert to changes in pain characteristics that may indicate a new physical problem or developing complication.

NURSING PRIORITY NO. 4 To promote wellness (Teaching/Discharge Considerations):

-  Provide anticipatory guidance to client with condition in which pain is common and educate about when, where, and how to seek intervention or treatments.
-  Discuss potential for developmental delays in child with chronic pain. Identify current level of function and review appropriate expectations for individual child.
-  Instruct client/SO in medication administration, including use of patient-controlled analgesia pumps, as indicated. Review safe use of analgesics, including side effects requiring home management (e.g., constipation) or adverse effects requiring medical intervention (e.g., possible drug reactions). *Appropriate instruction in home management increases the accuracy and safety of medication administration.*
- Encourage and assist family member/SO(s) to learn home-care interventions. *Massage and other nonpharmacological pain management techniques benefit the client through reduction of pain level and sense that client is not alone/has support of SO.*
-  Incorporate desired folk healthcare practices and beliefs into regimen whenever possible. *Has been shown to increase compliance with pain management treatment plan.*¹²
-  Identify and discuss potential hazards of unproved or nonmedical therapies or remedies.
- Assist client and SO(s) to learn how to heal *by developing sense of internal control, by being responsible for own treatment, and by obtaining the information and tools to accomplish this.*
- Recommend that client and SO(s) take time for themselves. *Provides opportunity to reenergize and refocus on living/tasks at hand.*
- Address client's preferences and wishes for incurable pain or end-of-life pain management via advance directives *in order to assist family/SO in attending to client's needs.*⁷
- Identify community support groups and resources to meet individual needs (e.g., yard care, home maintenance, transportation). *Proper use of resources may reduce negative pattern of "overdoing" heavy activities and then spending several days in bed recuperating.*
-  Refer for counseling (e.g., individual, family, marital therapy, parent effectiveness classes) as needed. *Presence of chronic pain affects all relationships and family dynamics.*
- Refer to NDs compromised family Coping and ineffective Coping.

DOCUMENTATION FOCUS**Assessment/Reassessment**

- Individual findings, including duration of problem, specific contributing factors, previously and currently used interventions.
- Perception of pain, effects on lifestyle, and expectations of therapeutic regimen.
- Locus of control and cultural beliefs affecting response to pain.
- Family's/SO's response to client and support for change.
- Availability and use of resources.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

labor Pain

Taxonomy II: Comfort—Class 1 Physical Comfort (00256) [Diagnostic Division: Pain/Discomfort], Approved: 2013

DEFINITION: Sensory and emotional experience that varies from pleasant to unpleasant, associated with labor and childbirth.

RELATED FACTORS

To Be Developed

DEFINING CHARACTERISTICS

Subjective

Pain; uterine contraction; perineal pressure
Increase or decrease in appetite; nausea; vomiting
Alteration in urinary functioning, sleep pattern

Objective

Alteration in blood pressure/heart rate/respiratory rate
Distraction/expressive behavior; protective behavior; positioning to ease pain
Alteration in muscle tension; diaphoresis
Alteration in neuroendocrine functioning
Narrowed focus; self-focused; pupil dilation
Facial expression of pain

(continues on page 622)

labor Pain (continued)

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Pain Control: Personal actions to eliminate or reduce pain

Client Satisfaction: Pain Management: Extent of positive perception of nursing care to relieve pain

Client Will (Include Specific Time Frame)

- Participate in decision making for pain management plan to include personal preferences and cultural beliefs.
- Engage in nonpharmacological measures to reduce discomfort/pain.
- Report pain at manageable level.

Partner/Labor Coach Will (Include Specific Time Frame)

- Participate in labor process, providing client's desired level of support.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Intrapartal Care: Monitoring and management of stages one and two of the birth process

Analgesic Administration: Intraspinal: Administration of pharmacologic agents into the epidural or intrathecal space to reduce or eliminate pain

NURSING PRIORITY NO. 1 To determine client's individual needs:

-  Assess stage of labor; perform vaginal exam, noting nature and amount of vaginal show, cervical dilation, effacement, fetal station, and fetal descent. *Choice and timing of medication are affected by degree of dilation and contractile pattern.*¹¹
-  Note timing of initiation of prenatal care and participation in childbirth education classes. *Economic, emotional, and cultural concerns can limit the mother's access or involvement in preparation for labor, increasing her need for information and support during the labor and delivery process.*¹ Also, research suggests classes and prenatal preparation may help decrease client's perception of pain.²
-  Evaluate degree of discomfort through verbal and nonverbal cues; note cultural influences on pain response. *Attitudes and reactions to pain are individual and based on past experiences, understanding of physiological changes, and familial/cultural expectations (e.g., the Filipino culture values stoicism and Chinese patients may refuse pain medication the first time it is offered).*^{9,11}
-  Ascertain presence of a birth plan, individual expectations, and cultural or religious beliefs affecting the labor and delivery process. *Birth plan provides information about client's childbirth preferences. Cultural influences may include how the laboring mother views pain management, as well as who attends the mother during the birth process (e.g., Hispanic and Asian women usually prefer their mothers be present, in Arab cultures the mother or sister of the baby's father is preferred). If cultural/religious preferences are not elicited, clients may not have the ability to follow their traditional practices, negatively impacting the birthing experience.*^{9,11,12}
- Determine availability and preparation of support person(s). *Presence of a supportive partner, family/friend, or a doula can provide emotional support and enhance level of comfort, reducing analgesia. A doula provides labor coaching and support throughout the birthing process to both the mother and her partner.*^{1,6}

NURSING PRIORITY NO. 2 To engage client in nonpharmacological pain management techniques:

-  Provide/encourage use of comfort measures (e.g., back/leg rubs, sacral pressure, back rest, mouth care, repositioning; cool, moist cloths to face and neck, hot compresses to perineum, abdomen; perineal care, linen changes). *Promotes relaxation and hygiene, enhancing feeling of well-being, and may reduce the need for analgesia or anesthesia. Position changes can also enhance circulation and reduce muscle tension.*¹¹
- Assess client's desire for physical touch during contractions. *Touch may serve as a distraction, reduce anxiety, and provide encouragement, aiding in maintaining sense of control and reducing pain. Note: Remain respectful of client's preferences regarding touch.*²
- Coach use of appropriate breathing/relaxation techniques and abdominal effleurage based on stage of labor. *May block pain impulses within the cerebral cortex through conditioned responses and cutaneous stimulation and gives client a means of coping with and controlling the level of discomfort.*¹¹
- Recommend client void every 1 to 2 hr. *Reduces bladder distention, which can increase discomfort and prolong labor.*¹¹
-  Review birth plan. Provide information about stage of labor and projected delivery, available analgesics, usual responses/side effects (client and fetal), and duration of analgesic effect in light of current situation. *Empowers client to make informed choice about means of pain control. Client may not be able to anticipate the degree of labor pain she will experience and may need to reevaluate her options as labor progresses. Note: Being able to move about and change positions at will can be important for some clients and impact their pain management choices.*^{6,8}
-  Assist with complementary therapies as indicated (e.g., acupressure/acupuncture, hypnosis, yoga). *Some clients and healthcare providers may prefer a trial of therapies theorized to stimulate/regulate contractions, reduce muscle tension, and mediate perception of pain before pursuing pharmacological interventions. For example, hypnosis may reduce fear, tension, and raise pain threshold, reducing need for analgesia. Research suggests acupressure may shorten labor time in addition to diminishing pain level.*¹⁰ *Note: Differences in cultural and regional acceptance of these options as well as provider technique can impact the effectiveness of these interventions.*^{1,2}
- Provide for a quiet environment that is adequately ventilated, dimly lit, and free of unnecessary personnel. Offer soothing music as appropriate. *Nondistracting environment provides optimal opportunity for rest and relaxation between contractions. Music may also reduce stress/anxiety, lift client's spirits, and decrease perception of pain.*²
- Discuss appropriateness/timing of hydrotherapy (shower, hot tub) as client desires. *Warm water during the first stage of labor stimulates the release of endorphins and relaxes muscles, enhancing circulation and tissue oxygenation with reduction in use of analgesia.*¹⁻³
- Offer encouragement, provide information about labor progress, and provide positive reinforcement for client's/couple's efforts. *Provides emotional support, which can reduce fear, lower anxiety levels, and help minimize pain.*¹¹

NURSING PRIORITY NO. 3 To provide more intensive pain management measures:

-  Time and record the frequency, intensity, and duration of uterine contractile pattern per protocol. *Information necessary for choosing appropriate interventions and preventing or limiting undesired side effects of medication.*¹¹
-  Review birth plan, provide positive feedback for efforts to date, and be supportive of client's decisions regarding pain management. *Each labor and delivery experience is different and can challenge prenatal expectations. Changes in stated pain management preferences (e.g., unmedicated to medicated birth) can lead to client feeling disappointed or a failure at a life process. Acceptance and support from the nurse can enhance coping and promote a more positive birth experience.*⁷
-  Administer analgesic, such as butorphanol tartrate (Stadol) or meperidine hydrochloride (Demerol), by IV during contractions or deep intramuscular (IM) if indicated during active phase of stage I labor. *IV route provides more rapid and equal absorption of analgesic, and IM route may require up to 45 min to reach*

adequate plasma levels. Patient-controlled IV remifentanyl provides better analgesia and patient satisfaction during the first and second stages of labor than other opioids but can cause serious maternal side effects. Effectiveness of opioids may be limited with the primary effect being sedation. Note: Administering IV drug during uterine contraction decreases amount of medication that immediately reaches fetus.^{2,3,4}

- Monitor maternal vital signs and fetal heart rate (FHR) variability after drug administration. Note drug's effectiveness and the physiological response. Narcotics can have a depressant effect on fetus, particularly when administered 2 to 3 hr before delivery.¹¹
- Provide safety measures (e.g., encourage client to move slowly, bed in low position, raise side rails) as indicated post-medication administration. Regional block anesthesia produces vasomotor paralysis, so sudden movement may precipitate hypotension and risk for fall.¹¹
-  Prepare for/assist with neuraxial anesthesia (i.e., epidural, spinal, combined spinal epidural, continuous epidural infusion, intermittent epidural bolus, client-controlled infusion epidural) using an indwelling catheter. Research supports this method is the most effective in obtaining maternal pain relief once active labor is established. Note: Use of ultra-low-dose epidural is being promoted to achieve pain control without negative effect on client's ability to sense contractions and push effectively.^{2,5,11}
- Monitor FHR electronically and note decreased variability or bradycardia. Decreased FHR variability is a common side effect of many anesthetics/analgesics. These side effects can begin 2 to 10 min after administration of anesthetic and may last for 5 to 10 min on occasion.¹¹
- Monitor level of block per protocol. Migration of decreased sensation from belly button (dermatome T-10) to tip of breastbone (approximately T-6) increases risk of respiratory depression and profound hypotension.¹¹
- Turn client side to side periodically during continuous infusions. Promotes even distribution of drug to prevent "one-sided" or unilateral block.
- Inform client of onset of contractions as appropriate. Client may "sleep" and/or encounter partial amnesia between contractions, impairing her ability to recognize contractions as they begin and her ability to initiate pain management techniques.¹¹
- Provide information about type of regional analgesia/anesthesia available at stage II specific to the delivery setting (e.g., local, pudendal block, lumbar epidural reinforcement, spinal block). Although client is stressed, she still needs to be in control and make informed decisions regarding anesthesia.

NURSING PRIORITY NO. 4 To support delivery process:

-  Note perineal bulging or vaginal show. Discomfort levels increase as cervix dilates, fetus descends, and small blood vessels rupture.¹¹
- Assist client in assuming optimal position for bearing down (e.g., squatting or lateral recumbent). Proper positioning with relaxation of perineal tissue optimizes bearing-down efforts and facilitates labor progress, reducing discomfort.¹¹
-  Assist with reinforcement of medication via indwelling lumbar epidural catheter when caput is visible. Reduces discomfort associated with episiotomy, forceps application if needed, and fetal expulsion.¹¹
-  Assist as needed with administration of local anesthetic just before episiotomy if performed. Anesthetizes perineum tissue for incision/repair purposes.¹¹

DOCUMENTATION FOCUS

Assessment/Reassessment

- Stages of labor, results of vaginal exam, status of fetus/fetal monitoring.
- Client's degree of preparation and expectations for labor process.
- Choice of support person(s).

Planning

- Specifics of birth plan.
- Plan of care and who is involved in planning.

Implementation/Evaluation

- Response to actions and interventions performed.
- Attainment or progress toward desired outcomes.

Discharge Planning

- Postpartal pain management choices.

impaired Parenting

Taxonomy II: Role Relationships—Class 1 Caregiving Roles (00056) [Diagnostic Division: Social Interaction], Approved 1998; Revised 1998, 2017

DEFINITION: Inability of the primary caretaker to create, maintain, or regain an environment that promotes the optimum growth and development of the child.

RELATED FACTORS

Infant or child

Prolonged separation from parent

Temperament conflicts with parental expectations

Parental

Alteration in sleep pattern; nonrestorative sleep pattern; sleep deprivation; depression

Conflict between partners; father or mother of child uninvolved; insufficient family cohesiveness

Insufficient or late-term prenatal care; insufficient resources, or access to resources

Failure to provide safe home environment; inability to put child's needs before own

Inadequate childcare arrangements; insufficient transportation

Ineffective communication skills or coping strategies; insufficient problem-solving skills

Insufficient parental role model; insufficient valuing of parenthood; insufficient social support

(continues on page 626)

impaired Parenting (continued)

Insufficient response to infant cues; insufficient knowledge about child development or health maintenance or parenting skills

Low self-esteem, unrealistic expectations; role strain

Preference for physical punishment

DEFINING CHARACTERISTICS

Subjective

Parental Perceived inability to meet child's needs

Frustration with child; perceived role inadequacy

Objective

Infant or child

Frequent accidents or illness; failure to thrive

Low academic performance; delay in cognitive development

Impaired social functioning; behavior disorder [e.g., attention deficit, oppositional defiant]

History of trauma/abuse

Insufficient attachment behavior; diminished separation anxiety; runaway from home

Parental

Decrease in cuddling; inappropriate care-taking skills or childcare arrangements

Inconsistent care; neglects needs or inflexibility in meeting needs of child; decrease in ability to manage child; speaks negatively about child; rejection or abandonment of child

Failure to provide safe home environment; inappropriate stimulation

Inconsistent behavior management; hostile; punitive

At Risk Population: *Infant or child*

Prematurity; developmental delay

Gender other than desired

Difficult temperament

Parental

Change in family unit; relocation; single parent; young parental age

Insufficient cognitive readiness for parenting; unwanted or unplanned pregnancy

Closely spaced or high number of pregnancies; difficult birthing process; multiple births

Economically disadvantaged; low educational level; unemployment; work difficulty

History of abuse [physical, psychological, or sexual], or being abusive; history of substance misuse/ [abuse]; legal difficulties

History of mental illness

Associated Condition: *Infant or child*

Alteration in perceptual abilities; behavioral disorder

Chronic illness; disability condition

Parental

Alteration in cognitive functioning

Physical illness; disabling condition

Sample Clinical Applications: Prematurity, multiple births, genetic or congenital defects, chronic illness (parent/child), substance abuse, physical or psychological abuse, major depression, developmental delay, schizophrenia

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Knowledge: Parenting: Extent of understanding conveyed about provision of a nurturing and constructive environment for a child from 1 year through 17 years of age

Parenting Performance: Parental actions to provide a child with a nurturing and constructive physical, emotional, and social environment

Child Development: [specify age]: Milestones of physical, cognitive, and psychosocial progression by [specific age]

Parent Will (Include Specific Time Frame)

- Verbalize realistic information and expectations of parenting role.
- Verbalize acceptance of the individual situation.
- Participate in appropriate classes, such as a parenting class.
- Identify own strengths, individual needs, and methods or resources to meet them.
- Demonstrate appropriate parenting behaviors.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Parenting Promotion: Providing parenting information, support, and coordination of comprehensive services to high-risk families

Family Integrity Promotion: Childbearing Family: Facilitation of the growth of individuals or families who are adding an infant to the family unit

Developmental Enhancement: Child [or] Adolescent: Facilitating or teaching parents/caregivers to facilitate the optimal gross motor, fine motor, language, cognitive, social, and emotional growth of pre-school and school-age children. Facilitating optimal physical, cognitive, social, and emotional growth of individuals during the transition from childhood to adulthood

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Note family constellation: two-parent, single, extended family, or child living with other relative such as grandparent/sibling. *Helps identify problem areas and strengths to formulate plans to change situation that is currently creating difficulties for the parents.*³
-  Review type, severity, duration of problem and contribution of, as well as impact on, individual family members. *Affects choice of interventions; for example, when abuse is the problem, it is an act of commission, whereas neglect is considered an act of omission. These behaviors indicate the presence of problems with relationships and/or parenting skills and individual problems such as inability to deal with stressors, substance abuse, mental illness, cognitive limitations, or criminality.*¹
-  Note negative statements about child, signs of trauma/failure to thrive, and history of recurring accidents/illness. *May reflect physical or psychological abuse or neglect necessitating appropriate actions as legally and professionally indicated if child's safety is a concern. Note: Safety of child is paramount and needs to be dealt with immediately.*⁵
- Determine developmental stage of the family (e.g., new child, adolescent, child leaving or returning home). *These maturational crises bring changes in the family that can be stressful to parents and the family. Provides direction for improving parenting skills and family interactions.*¹

- Assess family relationships among individual members and with others, family boundaries, and needs of individual members. *These factors are critical to understanding individual family dynamics and developing strategies for change.*³
-  Assess parenting skill level, taking into account the individual's intellectual, emotional, and physical strengths and weaknesses. *Parents with significant impairments may need more education or support. Ineffective parenting and unrealistic expectations contribute to problems of abuse and neglect. Understanding normal responses and progression of developmental milestones can help parents understand and cope with changes.*¹
-  Observe attachment behaviors between parental figure and child, recognizing cultural background. *Failure to bond effectively is thought to affect subsequent parent-child interaction. Behaviors such as eye-to-eye contact, use of en face position, and talking to the infant in a high-pitched voice are indicative of attachment behaviors in American culture but may not be appropriate in another culture.*^{1,4}
-  Note presence of factors in the child (e.g., birth defects, hyperactivity) that may be related to difficulties of parenting. *Unanticipated needs of the child may affect attachment and caretaking needs. Parents have an ideal of what is expected in a child, and when circumstances dictate otherwise, they may experience feelings of sadness and anger.*¹ Refer to ND complicated Grieving.
- Evaluate physical challenges or limitations of parent. *Presence of complicating factors (e.g., visual or hearing impairment, quadriplegia, severe depression, mental illness) may affect ability to care for a child and indicate need for additional planning to assist the parent.*¹
-  Determine presence and effectiveness of support systems, role models, extended family, and community resources available to the parent(s). *Lack of or ineffective use of support systems increases risk of continued inability to parent effectively.*⁵
- Note absence from home setting or lack of child supervision by parent. *Demands of working long hours, out of town, and multiple responsibilities, such as working and attending educational classes, will affect relationship between parent and child and ability to provide the care and nurturing necessary for children to grow and prosper.*⁷

NURSING PRIORITY NO. 2 To foster development of parenting skills:

- Create an environment in which relationships can be developed and needs of each individual met. *Learning is more effective when individuals feel safe and free to express feelings and concerns without fear of judgment.*^{6,7}
- Make time for listening to concerns of the parent(s). *Listening conveys respect and acceptance, enabling parent(s) to openly discuss needs and desires regarding the situation and future plans.*²
- Emphasize positive aspects of the situation. *Maintaining a hopeful attitude toward the parent's capabilities and potential for improving the situation will help the parent to manage what is happening more effectively.*¹
- Note staff attitudes toward parent/child and specific problem or disability. *The need for disabled parents to be seen as individuals and evaluated apart from a stereotype are crucial to helping individuals to cope with a difficult situation. Negative attitudes are detrimental to promoting positive outcomes.*³
- Encourage expression of feelings, such as helplessness, anger, and frustration. Set limits on unacceptable behaviors. *When feelings are expressed openly, they can be acknowledged and dealt with, enabling parent(s) to move forward in dealing with illness or situation. Individual may express anger by acting-out behaviors, which need to be restrained before damage is done to self, self-esteem, others, or environment.*^{5,6}
- Acknowledge difficulty of situation and normalcy of feelings. *Individuals feel validated when difficulty is recognized, enhancing feelings of acceptance.*¹
-  Recognize stages of grieving process when the child is disabled or other than anticipated. *Expectation of a "normal" or desired child (e.g., having a girl instead of boy, child with a prominent birthmark or birth defect such as cleft palate) results in grieving for the loss of that expectation.*^{1,8}
- Allow time for parents to express feelings and deal with the "loss." *Each person grieves at own pace, and allowing this time facilitates the process.*⁸
- Encourage attendance at skill classes, such as parent effectiveness. *Helps parents to develop communication and problem-solving techniques that promote positive relationships between parent and child.*^{6,7}

- Emphasize parenting functions rather than mothering/fathering skills. *By virtue of gender, each person brings something to the parenting role; however, nurturing tasks can be done by both parents.*¹

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Involve all available members of the family in learning. *Promotes understanding and effective communication when each individual has the same information and is able to ask questions and clarify what has been heard.*^{2,5}
- Provide information appropriate to the situation, including time management, limit setting, and stress-reduction techniques. *Facilitates satisfactory implementation of plan and new behaviors.*⁵
- Discuss parental beliefs about child-rearing, punishment, and rewards. *Identifying these beliefs allows opportunity to provide new information regarding effective alternatives to spanking and/or yelling and what actions can be substituted for more effective parenting.*
-  Develop support systems appropriate to the situation. *Extended family, friends, social worker, home-care services may be needed to help parents cope positively with what is happening.*³
- Assist parent to plan time and conserve energy in positive ways. *Enables individual to cope more effectively with difficulties as they arise.*³
- Encourage parents to identify positive outlets for meeting their own needs. *Going out for dinner or dating and making time for their own interests and each other promotes general well-being and helps reduce burnout.*^{3,9}
-  Refer to appropriate support or therapy groups as indicated. *Underlying issues may interfere with adaptation to situation, and additional support may help individuals to deal more effectively with them.*⁵
-  Identify community resources (e.g., child-care services). *Will assist with individual needs to provide respite and support.*²
-  Report and take necessary actions, as legally and professionally indicated, if child's safety is a concern. *Parents/caregivers who engage in corporal punishment as a technique to ensure desired behavior in a child are at risk for abusive behavior and increase the possibility of childhood depression.*⁵
- Refer to NDs ineffective Coping, compromised family Coping, risk for Violence [specify], Self-Esteem [specify], and interrupted Family Processes for additional interventions as appropriate.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including parenting skill level, deviations from normal parenting expectations.
- Family makeup and developmental stages.
- Interactions between parent and child.
- Availability and use of support systems and community resources.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Parent(s)/child's responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modification to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

readiness for enhanced Parenting

Taxonomy II: Role Relationships—Class 1 Caregiving Roles (00164) [Diagnostic Division: Social Interaction], Approved 2002; Revised 2013

DEFINITION: A pattern of providing an environment for children to nurture growth and development, which can be strengthened.

DEFINING CHARACTERISTICS

Subjective

Parent expresses desire to enhance parenting

Parent expresses desire to enhance emotional support of children/other dependent person

Children express desire to enhance home environment

Sample Clinical Applications: As a health-seeking behavior, the client/family may be healthy or this diagnosis can be associated with any clinical condition

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Parenting Performance: Parental actions to provide a child with a nurturing and constructive physical, emotional, and social environment

Knowledge: Parenting: Extent of understanding conveyed about provision of a nurturing and constructive environment for a child from 1 year through 17 years of age

Parenting: Psychosocial Safety: Parental actions to protect a child from social contacts that might cause harm or injury

Client Will (Include Specific Time Frame)

- Verbalize realistic information and expectations of parenting role.
- Identify own strengths, individual needs, and methods or resources to meet them.
- Participate in activities to enhance parenting skills.
- Demonstrate improved parenting behaviors.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Parent Education: Childrearing Family: Assisting parents to understand and promote the physical, psychological, and social growth and development of their toddler, preschool, or school-age child/children

Parent Education: Adolescent: Assisting parents to understand and help their adolescent children

Parenting Promotion: Providing parenting information, support, and coordination of comprehensive services to high-risk families

NURSING PRIORITY NO. 1 To determine need/motivation for improvement:

- Ascertain motivation and expectations for change. *Motivation to improve and high expectations can encourage client to make changes that will improve skills. However, unrealistic expectations may hamper efforts.*
- Note family constellation, such as two-parent, single, extended family, or child living with other relative such as a grandparent/sibling, or relationship of dependent person (e.g., foster family). *Understanding makeup of the family provides information about needs to assist them in improving their family connections.*¹
- ∞ Determine developmental stage of the family (e.g., new child, adolescent, child leaving or returning home, retirement). *These maturational crises bring changes in the family that can provide opportunity for enhancing parenting skills and improving family interactions.*
- Assess family relationships and identify needs of individual members, noting any special concerns that exist, such as birth defects, illness, and hyperactivity. *The family is a system, and when members make decisions to improve parenting skills, the changes affect all parts of the system. Identifying needs, special situations, and relationships can help to develop plans to bring about effective change.*¹
- Assess parenting skill level, taking into account the individual's intellectual, emotional, and physical strengths and weaknesses. *Identifies areas of need for education, skill training, and information on which to base plan for enhancing parenting skills.*^{2,4}
- 🌐 Observe attachment behaviors among parent(s) and child(ren), recognizing cultural background, which may influence expected behaviors. *Behaviors such as eye-to-eye contact, use of en face position, and talking to infant in high-pitched voice are indicative of attachment behaviors in American culture but may not be appropriate in another culture. Failure to bond is thought to affect subsequent parent-child interactions.*^{3,4}
- Determine presence and effectiveness of support systems, role models, extended family, and community resources available to the parent(s). *Parents desiring to enhance abilities and improve family life can benefit by role models that help them strengthen own style of parenting.*^{2,3}
- 🌐 Note cultural or religious influences on parenting, expectations of self/child, and sense of success or failure. *Expectations may vary with different cultures; for example, Arab Americans hold children to be sacred, but child-rearing is based on negative rather than positive reinforcements, and parents are stricter with girls than boys. These beliefs may interfere with ability to improve parenting skills when there is conflict between the two.*^{3,4}

NURSING PRIORITY NO. 2 To foster development of parenting skills:

- Create an environment in which relationships can be strengthened and needs of each individual family member can be met. *A safe environment in which individuals can freely express their thoughts and feelings optimizes learning and positive interactions among family members, enhancing relationships.*^{2,5}
- Make time for listening to concerns of the parent(s). *Promotes sense of importance and of being heard and identifies accurate information regarding needs of the family for enhancing relationships.*²
- Encourage expression of feelings, such as frustration and anger while setting limits on unacceptable behaviors. *Identification of feelings promotes understanding of self and enhances connections with others in the family. Unacceptable behaviors result in feelings of anger and diminished self-esteem and can lead to problems in family relationships.*³

- Emphasize parenting functions rather than mothering/fathering skills. *By virtue of gender, each person brings something to the parenting role; however, nurturing tasks can be done by both parents, enhancing family relationships.*⁵
-  Encourage attendance at skill classes, such as parent effectiveness training. *Assists in developing communication skills of active listening, “I” messages, and problem-solving techniques to improve family relationships and promote a win-win environment.*²

NURSING PRIORITY NO. 3 To promote optimum parenting skills/wellness:

-  Involve all members of the family in learning. *The family system benefits from all members participating in learning new skills to enhance family relationships.*¹
- Encourage parents to identify positive outlets for meeting their own needs. *Activities such as going out for dinner/dating and making time for their own interests and each other promotes general well-being, enhances family relationships, and improves family functioning.*²
- Provide information as indicated, including time management and stress-reduction techniques. *Learning about positive parenting skills and understanding growth and developmental expectations and ways to reduce stress and anxiety promotes individual’s ability to deal with problems that may arise in the course of family relationships.*^{1,6}
- Discuss current “family rules,” identifying areas of needed change. *Rules may be imposed by adults rather than through a democratic process, involving all family members, leading to conflict and angry confrontations. Setting positive family rules with all family members participating can promote an effective, functional family.*^{2,6}
- Discuss need for long-term planning and ways in which family can maintain desired positive relationships. *Each stage of life brings its own challenges, and understanding and preparing for each stage enables family members to move through them in positive ways, promoting family unity and resolving inevitable conflicts with win-win solutions.*⁶

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including parenting skill level, parenting expectations, family makeup, and developmental stages.
- Availability and use of support systems and community resources.
- Motivation and expectations for change.

Planning

- Plan for enhancement, who is involved in planning.

Implementation/Evaluation

- Family members’ responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Modification to plan.

risk for impaired Parenting

Taxonomy II: Role Relationships—Class 1 Caregiving Roles (00057) [Diagnostic Division: Social Interaction], Approved 1978; Revised 1998; 2013, 2017

DEFINITION: Susceptible to primary caretaker difficulty in creating, maintaining, or regaining an environment that promotes the optimum growth and development of the child, which may compromise the well-being of the child.

RISK FACTORS

Infant or child

Prolonged separation from parent
Temperament conflicts with parental expectations

Parental

Alteration in sleep pattern; nonrestorative sleep pattern; sleep deprivation; depression
Conflict between partners; father or mother of child uninvolved; insufficient family cohesiveness
Insufficient or late-term prenatal care; insufficient resources, or access to resources
Failure to provide safe home environment; inability to put child's needs before own
Inadequate child-care arrangements; insufficient transportation
Ineffective communication skills or coping strategies; insufficient problem-solving skills
Insufficient parental role model; insufficient valuing of parenthood; insufficient social support
Insufficient response to infant cues; insufficient knowledge about child development or health maintenance or parenting skills
Low self-esteem, unrealistic expectations; role strain
Preference for physical punishment

At Risk Population: *Infant or child*

Prematurity; developmental delay
Gender other than desired
Difficult temperament

Parental

Change in family unit; relocation; single parent; young parental age
Insufficient cognitive readiness for parenting; unwanted or unplanned pregnancy
Closely spaced or high number of pregnancies; difficult birthing process; multiple births
Economically disadvantaged; low educational level; unemployment; work difficulty
History of abuse [physical, psychological, or sexual], or being abusive; history of substance misuse/ [abuse]; legal difficulties
History of mental illness

Associated Condition: *Infant or child*

Alteration in perceptual abilities; behavioral disorder
Chronic illness; disability condition

(continues on page 634)

risk for impaired Parenting (continued)

Parental

Alteration in cognitive functioning

Physical illness; disabling condition

Sample Clinical Applications: Prematurity, multiple births, genetic or congenital defects, chronic illness (parent/child), substance abuse, physical or psychological abuse, major depression, developmental delay, schizophrenia

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Parenting Performance: Parental actions to provide a child a nurturing and constructive physical, emotional, and social environment

Knowledge: Parenting: Extent of understanding conveyed about provision of a nurturing and constructive environment for a child from 1 year through 17 years of age

Social Support: Reliable assistance from others

Client Will (Include Specific Time Frame)

- Verbalize awareness of individual risk factors.
- Identify own strengths, individual needs, and methods or resources to meet them.
- Demonstrate behavior or lifestyle changes to reduce potential for development of problem or reduce or eliminate effects of risk factors.
- Participate in activities, classes to promote growth.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Parenting Promotion: Providing parenting information, support, and coordination of comprehensive services to high-risk families

Parent Education: Childrearing Family: Assisting parents to understand and promote the physical, psychological, and social growth and development of their toddler, preschool, or school-aged child

Family Integrity Promotion: Promotion of family cohesion and unity

- Refer to ND impaired Parenting for Actions/Interventions and Documentation Focus.

disturbed Personal Identity

Taxonomy II: Self-Perception—Class 1 Self-Concept (00121) [Diagnostic Division: Ego Integrity], Approved 1978; Revised 2008, 2017

DEFINITION: Inability to maintain an integrated and complete perception of self.

RELATED FACTORS

Stages of growth, alteration in social role

Cultural incongruence; discrimination; perceived prejudice

Dysfunction in family processes

Low self-esteem; manic states
Cult indoctrination

DEFINING CHARACTERISTICS

Subjective

Alteration in body image; delusional description of self
Fluctuating feeling about self; feelings of strangeness or emptiness
Confusion about goals, cultural values, or ideological values
Gender confusion
Inability to distinguish between internal and external stimuli

Objective

Inconsistent behavior
Ineffective relationships or role performance
Ineffective coping strategies

At Risk Population: Developmental transition; situational crisis

Exposure to toxic chemical

Associated Conditions: Dissociative identity disorder; psychiatric disorder

Organic brain disorder

Pharmaceutical agent

Sample Clinical Applications: Schizophrenia, dissociative disorders, borderline personality disorder, developmental delay, autism, gender identity conflict, dementia, traumatic injury (e.g., amputation, spinal cord injury [SCI], brain injury)

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Identity: Distinguish between self and non-self and characterize one's essence

Distorted Thought Self-Control: Self-restraint of disruption in perception, thought processes, and thought content

Anxiety Self-Control: Personal actions to eliminate or reduce feelings of apprehension, tension, or uneasiness from an unidentifiable source

Client Will (Include Specific Time Frame)

- Acknowledge threat to personal identity.
- Integrate threat in a healthy, positive manner (e.g., state anxiety is reduced, make plans for the future).
- Verbalize acceptance of changes that have occurred.
- State ability to identify and accept self (long-term outcome).

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Self-Esteem Enhancement: Assisting a patient to increase his/her personal judgment of self-worth

Self-Awareness Enhancement: Assisting a patient to explore and understand his/her thoughts, feelings, motivations, and behaviors

Mood Management: Providing for safety, stabilization, recovery, and maintenance of a patient who is experiencing dysfunctionally depressed or elevated mood

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Ascertain client's perception of the extent of the threat to self and how client is handling the situation. *Many factors can affect an individual's self-image: illness (chronic or terminal), injuries, changes in body structure (amputation, spinal cord damage, burns), and client's view of what has happened will affect development of plan of care and interventions to be used.*^{1,6}
- Determine speed of occurrence of threat. *An event (such as an accident or sudden diagnosis of diabetes or cancer) that has happened quickly may be more threatening.*⁷
- Ask client to define own body image. *Body image is the basis of personal identity, and client's perception will affect how changes are viewed, may prevent achievement of ideals and expectations, and have a negative effect.*¹
- ∞ Note age of client. *An adolescent may struggle with the developmental task of personal/sexual identity, whereas an older person may have more difficulty accepting or dealing with a threat to identity, such as progressive loss of memory or aging body changes.*³
- Assess availability and use of support systems. Note response of family/significant others (SOs). *During stressful situations, support is essential for client to cope with changes that are occurring. Engaging family in choosing supportive interventions will help client and family members deal with situation or illness.*³
- ∞ Note withdrawn or automatic behavior, regression to earlier developmental stage, general behavioral disorganization, or display of self-mutilation behaviors in adolescent or adult and delayed development, preference for solitary play, and unusual display of self-stimulation in child. *Indicators of poor coping skills and need for specific interventions to help client develop sense of self and identity. Inability to identify self interferes with interactions with others.*³
- Be aware of physical signs of panic state (e.g., heart palpitations, trembling, shortness of breath, chest pressure or pain). *Presence of severe anxiety state may progress to panic when concerns seem overwhelming to client. (Refer to ND Anxiety.)*
- Determine presence of hallucinations or delusions or distortions of reality. *Indicators of presence of psychosis and need for immediate interventions to deal with inability to distinguish between self and non-self.*^{1,3}

NURSING PRIORITY NO. 2 To assist client to manage/deal with threat:

- Make time to listen to client, encouraging appropriate expression of feelings, including anger and hostility. *Conveys a sense of confidence in client's ability to identify extent of threat, how it is affecting sense of identity, and how to deal with feelings in acceptable ways.*^{7,8}
- 🍷 Note use of alcohol or other drugs. *Individual may turn to these substances to relieve painful feelings, especially in the presence of fearful diagnoses (e.g., cancer, multiple sclerosis).*⁸
- Provide a calm environment. *Feelings of anxiety are contagious, and calm surroundings can help client to relax, maintain control, and be able to think more clearly about how illness or situation can be managed effectively.*⁹
- Use crisis intervention principles when indicated. *May be necessary to help client restore equilibrium when situation escalates.*¹
- Discuss client's commitment to an identity. *Those who have made a strong commitment to an identity tend to be more comfortable with self and happier than those who have not.*³
- Assist client to develop strategies to cope with threat to identity. *Reduces anxiety, promotes self-awareness, and enhances self-esteem, enabling client to deal with threat more realistically.*¹⁰
- Engage client in activities appropriate to individual situation. *Using activities such as a mirror for visual feedback and tactile stimulation to reconnect with parts of the body (amputation, unilateral neglect) can help to identify self as an individual.*²
- Provide for simple decisions, concrete tasks, and calming activities. *Promotes sense of control and positive expectations to enable client to regain sense of self.*³
- Allow client to deal with situation in small steps. *May have difficulty coping with larger picture when in stress overload. Taking small steps promotes feelings of success and ability to manage illness or situation.*⁹

- Encourage client to develop and participate in an individualized exercise program. *While walking is an excellent beginning program, it is helpful to choose activities that client enjoys. Exercise releases endorphins, thereby reducing stress and anxiety, promoting a sense of well-being.*¹
- Provide concrete assistance as needed. *Until basic-level needs, such as activities of daily living and food, are met, individual is unable to deal with higher-level needs. Once these needs are met, client can begin to deal with threat to identity.*¹
- Take advantage of opportunities to promote growth. Realize that client will have difficulty learning while in a dissociative state. *Alterations in mental status can interfere with ability to process information, and new information can increase confusion and disorientation.*³
- Maintain reality orientation without confronting client's irrational beliefs. *Client may become defensive, blocking opportunity to look at other possibilities. Arguing does not change the perceptions and can interfere with or damage nurse-client relationship.*¹
- Use humor judiciously when appropriate. *While humor can lift spirits and provide a moment of levity, it is important to note the mood or receptiveness of the client before using it.*³
-  Discuss options for dealing with issues of gender identity. *Identification of client's concerns about role dysfunction or conflicting feelings about sexual identity will indicate need for therapies, possible gender-change surgery when client is a transsexual, or other available choices.*²
- Refer to NDs disturbed Body Image, Self-Esteem [specify], and Spiritual Distress.

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Provide accurate information about threat to and potential consequences for individual in current situation. *Fear and anxiety regarding the threat represented by the illness or situation can be potentiated by lack of knowledge, unknown consequences, and inaccurate beliefs. Accurate information can help client incorporate new knowledge into changed self-concept.*⁷
- Assist client and SO(s) to acknowledge and integrate threat into future planning. *A diagnosis, accident, etc., can require major life changes, such as wearing identification bracelet when prone to mental confusion, a new lifestyle to accommodate change of gender for transsexual client, or a diet and medication routine with the diagnosis of diabetes mellitus. Planning can help the client to make the changes required to move forward with new life.*^{4,5}
-  Refer to appropriate support groups. *May need additional assistance, such as day-care program, counseling or psychotherapy, gender identity, family or marriage counseling, or parenting classes.*²

DOCUMENTATION FOCUS

Assessment/Reassessment

- Findings, noting degree of impairment.
- Nature of and client's perception of the threat.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Client's response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

Exposure to toxic chemical

Associated Condition: Dissociative identity disorder; psychiatric disorder

Organic brain disorder

Pharmaceutical agent

Sample Clinical Applications: Traumatic injury (e.g., amputation, spinal cord injury, traumatic brain injury), substance abuse, dementia, schizophrenia, borderline personality disorders, dissociative disorders, developmental delay, autism, gender identity conflict

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Personal Identity: Personal actions that distinguish self and non-self and characterize one's essence

Distorted Thought Self-Control: Self-restraint of disruption in perception, thought processes, and thought control

Anxiety Self-Control: Personal actions to eliminate or reduce feelings of apprehension, tension, or uneasiness from an unidentifiable source

Client Will (Include Specific Time Frame)

- Acknowledge concern about potential threat to identity.
- Exhibit reality-based thinking with appropriate thought content.
- Integrate perceived threat in a healthy manner (e.g., accept self in current situation, look to the future).
- Use effective coping strategies to deal with situation/stressors.

ACTIONS/INTERVENTIONS**Sample NIC linkages:**

Self-Awareness Enhancement: Assisting a patient to explore and understand his/her thoughts, feelings, motivations, and behaviors

Self-Esteem Enhancement: Assisting a patient to increase his/her personal judgment of self-worth

Coping Enhancement: Facilitation of cognitive and behavioral efforts to manage perceived stressors, changes, or threats that interfere with meeting life demands and roles

NURSING PRIORITY NO. 1 To assess risk/contributing factors:

-  Ascertain client's perception of threat to self and how it is being dealt with. *Many factors can impinge on client's life and cause concern about possibility of changes that will make life different.*^{1,5,12,13,15}
- Ask client to define own body image. *The basis of personal identity is body image, and perception of changes may affect client's view in a negative or positive manner.*^{1,6,12,18}
- Determine whether issues of gender identity are a concern. *Client may have conflicting feelings about how to deal with realization he or she is homosexual or transsexual.*^{10,12}
-  Note age of individual. *Changes affect persons differently depending on their stage of life. The maturational changes of adolescence may generally be viewed as positive, while the older person may view aging changes in a negative way.*^{2,12,13,15,17}
-  Identify cultural affiliations/discontinuity. *Individuals belonging to subcultures or cults tend to come into conflict with the greater societal views affecting one's perception of self and perception of reality, often resulting in isolation from outside support groups and reluctance to engage in therapeutic interventions.*^{12,19–21}
- Determine type and speed of changes that are imminent. *The diagnosis of a chronic illness, such as diabetes versus a terminal illness or a traumatic injury or disfiguring surgery that will change how life is lived, may be threatening, as the thought of how different life will be affects the individual.*^{1,6,12,14,15}
- Note availability and use of support systems, including attitude of family/significant others. *Having a positive support system can help individual get through difficult situations/illness.*^{3,4,6,14}
-  Assess behaviors such as withdrawal, general behavioral disorganization, and delayed development. *Poor coping skills will affect how client deals with possibility of disturbance in personal identity by changes occurring in life.*^{2,6,11,13}
- Discuss use of alcohol and other drugs. *Individuals often use these substances to avoid painful stressors.*^{2,15}
- Note signs of anxiety. *Use of inadequate coping strategies to deal with changes affecting lifestyle may result in exacerbation of symptoms in anxious person. (Refer to ND Anxiety.)*
-  Determine distortions of reality/symptoms of mental illness. *Requires more in-depth psychological counseling/medication to help client distinguish between self and non-self.*^{2,11,12,15,18}

NURSING PRIORITY NO. 2 To assist client to manage/deal with stressors:

- Listen/Active-listen, making time to encourage client to express feelings, including anger and hostility. *Possibility of changes in life may affect sense of self and identity.*^{6,7,9}

- Discuss client's concerns without confronting unreal ideas. *Irrational beliefs may interfere with ability to manage situation and maintain reality-based perception of self.*^{2,6}
- Encourage client and family to maintain a calm environment and positive attitude. *Anxiety is contagious and can interfere with client's efforts to maintain control and deal with the situation.*^{8,16}
- Help client to identify strategies to cope with current situation/possibility of threat. *Having a plan can reduce anxiety and promote self-esteem.*^{2,3,14}
- Use humor when appropriate. *In an established nurse-client relationship, humor can be useful to help client look at reality of situation.*¹⁶
- Provide activities applicable for client's situation. *For example, viewing body part/using a mirror for visual feedback or tactile stimulation to reconnect with parts of the body (i.e., amputation) or participation in monitored social interactions helps client to confront fear and see self as an individual who is still worthwhile.*^{1,18}
- Support client in making decisions and plans for the future. *Provides opportunity for client to feel in control and promotes positive expectations.*^{3,14}
-  Develop an individualized exercise program. *Releases endorphins, reducing stress and promoting a sense of well-being.*^{5,22}
- Refer to NDs disturbed Body Image, Self-Esteem (specify), and Spiritual Distress for additional interventions as appropriate.

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Provide accurate information/resources for issues client is concerned about. *Worrying about what might happen is counterproductive to dealing with reality, and information can help to lessen anxiety, allowing individual to deal with current situation.*^{3,4,7,18}
- Discuss potential changes in lifestyle that may occur with major diagnosis/accident. *Planning for these possibilities can enhance self-confidence and allow client to move forward with life.*^{1,5,7,8}
-  Refer to appropriate support groups. *Sharing concerns with others in group settings may help client to be realistic regarding concerns about effects of anticipated changes/life challenges.*^{3,4,8,18}
-  Explore community resources as appropriate. *Additional assistance such as day programs, individual/family counseling, and drug/alcohol-cessation programs can strengthen client's coping abilities and sense of control.*^{4,12,23,24}

DOCUMENTATION FOCUS

Assessment/Reassessment

- Findings, noting concerns about possible changes in lifestyle, future expectations.
- Reality of potential threat.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Client's response to interventions, teaching, and actions performed.

Discharge Planning

- Long-term needs, and who is responsible for actions to be taken.
- Specific referrals made.

risk for Poisoning

Taxonomy II: Safety/Protection—Class 4 Environmental Hazards (00037) [**Diagnostic Division:** Safety], Approved 1980; Revised 2006, 2013, 2017

DEFINITION: Susceptible to accidental exposure to, or ingestion of, drugs or dangerous products in sufficient doses that may compromise health.

RISK FACTORS

Internal

Emotional disturbance

Inadequate precautions against poisoning; inadequate knowledge of poisoning prevention

Inadequate knowledge of pharmacological agents; [narrow therapeutic margin of safety of specific pharmaceutical agents (e.g., therapeutic versus toxic level, half-life, method of uptake and degradation in body, adequacy of organ function)]

Occupational setting without adequate safeguards

Insufficient vision

External

Access to dangerous product

Access to pharmaceutical agent

(continues on page 642)

risk for Poisoning (continued)

Access to illicit drugs potentially contaminated by poisonous additives

[Use of multiple herbal supplements or megadosing]

Associated Condition: Alteration in cognitive function

Sample Clinical Applications: Substance abuse, dementia, cataracts, glaucoma, hepatitis, cirrhosis, renal failure, depression, suicidal ideation, developmental delay

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Risk Control: Drug Use: Personal actions to understand, prevent, eliminate, or reduce the threats to health associated with drug use

Knowledge: Medication: Extent of understanding conveyed about the safe use of medication

Safe Home Environment: Physical arrangements to minimize environmental factors that might cause physical injury in the home

Client/Caregiver Will (Include Specific Time Frame)

- Verbalize understanding of dangers of poisoning.
- Identify hazards that could lead to accidental poisoning.
- Correct external hazards as identified.
- Demonstrate necessary actions or lifestyle changes to promote safe environment.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Medication Management: Facilitation of safe and effective use of prescription and over-the-counter drugs

Environmental Management: Safety: Monitoring and manipulation of the physical environment to promote safety

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

-  Identify internal and external risk factors in client's environment, including presence of infants, young children, or frail elderly (*who are at risk for accidental poisoning*) and teenagers or young adults (*who are at risk for medication experimentation*); confused or chronically ill person on multiple medications; person with potential for suicidal action; person who partakes in illicit drug use/dealing (e.g., methamphetamines, opioids, cocaine, heroin); and person who manufactures drugs in home (e.g., methamphetamines).
-  Note age and cognitive status of client and care providers *to identify individuals who could be at higher risk for accidental poisoning. Babies, toddlers, and preschoolers are at risk because they are curious, like to put things into their mouths, and aren't aware of what's safe to eat. Certain medications (e.g., calcium channel blockers, sulfonyleureas, opiates, amphetamines, sodium channel blockers, and tricyclic antidepressants; drugs of abuse that are potentially fatal include opiates and all amphetamines [including methamphetamine and MDMA]) can kill a toddler with a single dose. While school-age children can recognize danger and are at lower risk of unintentional poisoning, they are at risk for inadvertent overdose when taking medications without adequate supervision or when taking medications belonging to another. Adolescents are at higher risk for experimentation due to natural inclination to take risks, peer pressure, and easy access to drugs. They are also at risk for suicide attempts (with overdose of medications, from illicit drug overdose or adverse reactions, alcohol toxicity).*^{1,8,10} *Note: A 2013 U.S. study revealed that 67,000 children (most between the ages of 2 and 5 years) were treated in emergency departments for accidental ingestion of OTC or adult prescription drugs*

found in the home.² Elderly persons are at risk because of the higher number of prescription and OTC medications they consume (polypharmacy) and because of visual and cognitive impairments, which can cause them to forget what medications have been consumed and in what amounts they were taken. Elderly persons are also likely to share medications. In addition, the presence of nutritional deficits and renal or hepatic degeneration can reduce ability to detoxify drugs. Note: One large study showed that certain medication classes such as analgesics, anticoagulants, anticonvulsants, asthma therapies, psychotherapeutics, and some cardiovascular agents were associated with high hazard factors.^{3,4}

- Assess mood, coping abilities, and personality styles (e.g., temperament, impulsive behavior, level of self-esteem) that may result in carelessness and increased risk-taking without consideration of consequences or suicidal actions. (Refer to ND risk for Suicide.)
- Determine client's allergies to medications and foods in order to avoid exposure to substances causing potentially lethal reaction.
-  Ascertain client's knowledge and use of medications. People may believe "if a little is good, a lot is better," placing them at risk for overdose and adverse drug effects or interactions. This belief pattern may also be responsible for client's use of multiple drugs at the same time (polypharmacy), which also can occur when multiple prescribers are unaware of each other or the client has multiple medical conditions requiring medications. Knowledge and use also affect the client's storage (e.g., may/may not use labeled bottles) and/or taking of medications that look alike (potentiating risk of overdose or adverse drug interactions). The elderly may unintentionally take the wrong medication at the wrong time or "double up," forgetting that they already took their daily dose of a prescription medicine.¹³
-  Determine specific drug hazards:
 -  Use of prescription, OTC medications, and culturally based home remedies. These have potential for intentional and accidental overdose, as well as dangerous interactions. Drugs that are therapeutic in small doses may be deadly when taken in excess (e.g., beta blockers, warfarin, digoxin). One of the most common problems is inadvertent overdosage of acetaminophen (Tylenol), either by increased dosing or by taking it with a combination product also containing acetaminophen. Note: In 2013, the American Association of Poison Control Center reported that drug classes most frequently involved in toxic exposures in adults were analgesics (11.5%), sedatives/hypnotics/antipsychotics (5.9%), and antidepressants (4.2%). In children of 5 years or less, the drugs were analgesics (9.8%), and topical preparations (6.1%).^{4,11}
 -  Availability or regular use of vitamins and mineral and herbal supplements. Vitamins (especially A and D) are toxic in large doses, and iron is especially harmful, often fatal to children.¹⁰ Herbal drugs can be a source of poisoning (usually when taken long term) due to toxicity of individual ingredients or from contaminants (e.g., mercury, lead, arsenic).
 -  Abuse of alcohol or other drugs (e.g., cocaine, methamphetamine, lysergic acid diethylamide, methadone). Those who abuse street drugs are at high risk for overdose because the purity of these drugs is largely unknown. A person may be trying to get high but unwittingly take more drugs than his/her body can handle. These substances have potential for adverse reactions, cumulative effects with other substances, and risk for intentional and accidental overdose. Note: As little as 1 oz of alcohol or a single dose of many drugs of abuse can cause serious injury/death in a small child.^{9,11}
-  Identify environmental hazards:
 - Storage of household chemicals (e.g., oven, toilet bowl, or drain cleaners; dishwasher products; bleach; hydrogen peroxide; fluoride preparations; essential oils; furniture polish; lighter fluid; lamp oil; kerosene; paints; turpentine; rust remover; lubricant oils; bug sprays or powders; fertilizers) are readily available toxins in various forms that are often improperly stored.⁵⁻⁹
 - Review client's home, employment, or work environment for exposure to chemicals, including vapors and fumes.
 - Refer to ND risk for Contamination for environmental issues.
-  Review results of laboratory tests and toxicology screening, as indicated. Guides treatment when overdose or accidental poisoning is known or suspected.

NURSING PRIORITY NO. 2 To assist in correcting factors that can lead to accidental poisoning:

-    Discuss medication safety with client/significant other (SO) according to individual needs:

Prevent accidental ingestion:^{3-7,11}

Emphasize importance of supervising infant/child, frail elderly, or individuals with cognitive limitations.

Keep medicines and vitamins out of sight and reach of children or cognitively impaired persons.

Use child-resistant or tamper-resistant caps and lock medication cabinets.

Recap medication containers immediately after obtaining current dosage. Do not leave open container behind.

Note: Many accidental poisonings occur when parent/caregiver steps away for a moment and child gets into product that was left out.

Code medicines for the visually impaired.

Tell client to turn on light if the room is dark and to put on glasses (if visually impaired) before taking or giving medications.

Refer to/administer children's medications as drugs, not candy, to prevent confusion.

Emphasize environmental safety regarding medications for all situations in which young child may be exposed (e.g., all rooms of the home, grandparents' home, day care, preschool).⁸

Discuss vitamin use (especially those containing iron) *that can be poisonous to children if taken in large doses or in small doses over time.*⁸⁻¹⁰

Prevent duplication/possible overdose:³⁻⁷

Review analgesic safety (e.g., acetaminophen is an ingredient in many OTC medications, and unintentional overdose can occur).¹²

Keep updated list of all medications (prescription, OTC, herbals, supplements) and review with healthcare providers when medications are changed, new ones are added, or new healthcare providers are consulted.

Keep prescription medication in original bottle with label. Do not mix with other medication or place in unmarked containers.

Have responsible SO(s)/home health nurse supervise medication regimen/prepare medications for the cognitively or visually impaired, or obtain prefilled medicine boxes from pharmacy.

Take prescription medications and OTC drugs as prescribed on label.

Do not adjust medication dosage.

Retain and read safety information that accompanies prescriptions about expected effects, nuisance side effects, reportable and adverse effects, and how to manage forgotten dose.

Prevent taking medications that interact with one another or OTC/herbals/other supplements in an undesired or dangerous manner:³⁻⁷

- Keep list of and reveal medication allergies, including type of reaction, to healthcare providers/pharmacist.
- Wear medical alert bracelet or necklace, as appropriate.
- Do not take outdated or expired medications. Do not save partial prescriptions to use another time.
- Encourage discarding outdated or unused drug safely (disposing in hazardous waste collection areas, not down drain or toilet).
- Do not take medications prescribed for another person.
- Avoid mixing alcohol with medications (potentiates effects of many drugs).
-  Coordinate care when multiple healthcare providers are involved to limit number of prescriptions and dosage levels.

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Discuss general poison-prevention measures.³⁻⁷

 Encourage parent/caregiver to place safety stickers on dangerous products (drugs and chemicals) to warn children of harmful contents.

 Teach children about hazards of poisonous substances and to "ask first" before eating or drinking anything.

 Review drug side effects, potential interactions, and possibilities of misuse or overdosing (as with vitamin megadosing, etc.).⁹

- ∞ Discuss issues regarding drug use in home (e.g., alcohol, marijuana, heroin) *to provide opportunity to address potential for client's/SO's accidental overdose or accidental ingestion by children when drugs or drug paraphernalia are in the home.*¹⁰
-  Provide list of emergency numbers (i.e., local or national poison control numbers, physician's office) to be placed by telephone *for use if poisoning occurs.*
-  Instruct caregiver in event of poisoning, to have product container on hand when contacting emergency provider.
-  Encourage client to obtain regular screening tests at prescribed intervals (e.g., prothrombin time/international normalized ratio for Coumadin; drug levels for Dilantin, digoxin; liver function studies when lipid-lowering agents [statins] are prescribed; renal and thyroid function and serum glucose levels for antimanics [lithium] use) *to ascertain that circulating blood levels are within therapeutic range and absence of adverse effects.*
-  ∞ Ask healthcare provider/pharmacist about any considered medications if pregnant, nursing, or planning to become pregnant, *as some drugs are dangerous to fetus or nursing infant.*
-  Refer substance abuser to detoxification programs, inpatient/outpatient rehabilitation, counseling, support groups, and psychotherapy.
-  Encourage participation in community awareness and education programs (e.g., cardiopulmonary resuscitation and first aid class, home and workplace safety, hazardous materials disposal, access emergency medical personnel) *to assist individuals to identify and correct risk factors in environment and be prepared for emergency situation.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Identified risk factors noting internal and external concerns.
- Drug allergies or sensitivities.
- Current medications prescribed or available to individual, use of OTC medications, herbals or supplements, illicit drug use.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modification to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

risk for perioperative Positioning Injury

Taxonomy II: Safety/Protection—Class 2 Physical Injury (00087) [Diagnostic Division: Safety], Submitted 1994; Revised 2006, 2013, 2017

DEFINITION: Susceptible to inadvertent anatomical and physical changes as a result of posture or positioning equipment used during an invasive/surgical procedure, which may compromise health.

RISK FACTORS

Immobilization

Associated Condition: Disorientation; sensoriperceptual disturbance from anesthesia

Edema

Emaciation; obesity

Muscle weakness

Sample Clinical Applications: Operative procedures, arthritis, obesity, malnutrition, peripheral vascular disease

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Physical Injury Severity: Severity of signs and symptoms of injuries to the body

Risk Control: Personal actions to understand, prevent, eliminate, or reduce modifiable health threats

Tissue Perfusion: Peripheral: Adequacy of blood flow through the small vessels of the extremities to maintain tissue function

Client Will (Include Specific Time Frame)

- Be free of injury related to perioperative disorientation or altered consciousness.
- Be free of untoward skin and tissue injury or changes lasting beyond 24 to 48 hr postprocedure.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Positioning: Intraoperative: Placement of the patient or body part to promote surgical exposure while reducing the risk of discomfort and complications

Skin Surveillance: Collection and analysis of patient data to maintain skin and mucous membrane integrity

Circulatory Precautions: Protection of a localized area with limited perfusion

NURSING PRIORITY NO. 1 To identify individual risk factors/needs:

-  Consider anticipated type and length of procedure, type of anesthesia to be used, and customary required position (e.g., supine, lithotomy, prone, lateral, sitting) *to increase awareness of potential postoperative complications. Studies show consensus of clinical opinion that perioperative nerve injury is a significant issue and that safe and correct positioning is crucial to avoid causing peripheral neuropathy during the anesthetic and/or surgical episode. Coppieters et al. suggest that there is evidence of several identifiable mechanisms that contribute to perioperative positioning injuries. These include stretch, traction, compression, generalized vascular ischemia, and metabolic derangement (e.g., diabetes and atherosclerosis).*^{1,2,6,9,12}
-  Review client's history, noting age, weight, height, nutritional status, physical limitations (e.g., prostheses, implants, range-of-motion restrictions) and preexisting conditions (vascular, respiratory, circulatory, neurological, immunocompromise). *These factors affect choice of position for the procedure (e.g., elderly person with no subcutaneous padding or severe arthritis). Presence of certain conditions can cause the risk of skin and tissue integrity problems during surgery (e.g., diabetes mellitus, hypertension and hypotension, tobacco use, obesity, presence of peripheral vascular disease, level of hydration, temperature of extremities).*^{1,2,8,10,12}
- Evaluate and document client's preoperative reports of neurological, sensory, or motor deficits *for comparative baseline of perioperative and postoperative sensations.*
-  Assess the individual's responses to preoperative sedation and medication, noting level of sedation or adverse effects (e.g., drop in blood pressure) and report to surgeon as indicated. *Hypotension is a common factor associated with nerve ischemia.*^{3,12}
- Evaluate environmental conditions/safety issues surrounding the sedated client (e.g., client alone in holding area, side rails up on bed and cart, use of tourniquets and arm boards, need for local injections) *that predispose client to potential tissue injury.*^{1,3,7,8}

NURSING PRIORITY NO. 2 To position client to provide protection for anatomic structures and to prevent injury:

-  Stabilize and lock transport cart or bed when transferring client to and from operating room table. Provide body and limb support for client during transfers, using adequate numbers of personnel *to prevent client fall or shear and friction injuries, as well as to prevent injury to personnel.*^{3,8,11}
-  Position client, using sufficient staff, appropriate positioning equipment or devices, and padding *to provide protection for anatomic structures and to prevent injury:*^{1-3,11}
 Keep head in neutral position (when client in supine position) and arm boards at less than a 90-degree angle and level with floor *to prevent neural injuries.*
 Maintain neck alignment and provide protection or padding for forehead, eyes, nose, chin, breasts, genitalia, knees, and feet *when client is in prone position.*
 Protect bony prominences and pressure points on dependent side (e.g., axillary roll for dependent axilla; lower leg flexed at hip, upper leg straight; padding between knees, ankles, and feet) *when client is in lateral position.*
 Place legs in stirrups simultaneously, adjusting stirrup height to client's legs, maintaining symmetrical position, and pad popliteal space as indicated *to reduce risk of peroneal and tibial nerve damage, prevent muscle strain, and reduce risk of hip dislocation when lithotomy position is used.*
- Check that positioning equipment is correct size for client, is firm and stable, and is adjusted accordingly.^{2,11}
- Use gel pads or similar devices over the operating room bed. *Decreases pressure at any given point by redistributing overall pressure across a larger surface area.*^{2,6}
- Limit use of pillows, blankets, molded foam devices, towels, and sheet rolls, *which may produce only a minimum of pressure reduction or contribute to friction injuries.*²
- Place safety straps strategically *to secure client for specific procedure.* Avoid pressure on extremities when securing straps *to limit possibility of compromising circulation and pressure injuries.*¹¹

- Realign or maintain body alignment during procedure as needed. *Changes in position may expose or damage otherwise protected body tissue. The position change may be planned or imperceptible and may result from adding or deleting positioning devices, adjusting the procedure bed in some manner, or moving the client on the procedure bed.*^{2,11}
- Apply and periodically reposition padding of pressure points/bony prominences (e.g., arms, shoulders, ankles) and neurovascular pressure points (e.g., breasts, knees, ears) *to maintain position of safety and prevent injury from prolonged pressure.*
- Protect body from contact with metal parts of the operating table, *which could produce electrical injury or burns.*^{1,4}
- Position extremities to facilitate periodic evaluation of hands, fingers, and toes. *Prevents accidental trauma from moving table attachments and allows for repositioning of extremities to prevent neurovascular injuries from prolonged pressure. Extremities should not extend beyond the end of operating table to reduce risk of compression or stretch injury.*^{8,11}
- Check peripheral pulses and skin color and temperature periodically *to monitor circulation.*
- Prevent pooling of prep and irrigating solutions and body fluids. *Pooling of liquids in areas of high pressure under client increases risk of pressure ulcer development and presents electrical hazard.*^{5,6}
- Reposition slowly at transfer and in bed (especially halothane-anesthetized client) *to prevent severe drop in blood pressure, dizziness, or unsafe transfer.*
- Position client following extubation *to protect airway and facilitate respiratory effort.*
- Determine specific postoperative positioning guidelines (e.g., head of bed slightly elevated following spinal anesthesia *to prevent headache*, turn to unoperated side following pneumonectomy *to facilitate maximal respiratory effort*).¹

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

- Maintain equipment in good working order *to identify potential hazards in the surgical suite and implement corrections as appropriate.*⁶
-  Provide perioperative teaching relative to client safety issues (including not crossing legs during procedures performed under local or light anesthesia, postoperative needs or limitations, signs/symptoms requiring medical evaluation) *to reduce incidence of preventable complications.*
- Inform client and postoperative caregivers of expected or transient reactions (e.g., low backache, localized numbness, and reddening or skin indentations, which should quickly resolve) *to help them identify problems or concerns that require follow-up.*
-  Assist with therapies and perform nursing actions, including skin care measures, application of elastic stockings, early mobilization *to enhance circulation and venous return, and to promote skin and tissue integrity.*
- Encourage and assist with frequent range-of-motion exercises *to prevent or reduce joint stiffness.*
-  Refer to appropriate resources, as needed.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Findings, including individual risk factors for problems in the perioperative setting and need to modify routine activities or positions.
- Periodic evaluation of monitoring activities.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.

Post-Trauma Syndrome

Taxonomy II: Coping/Stress Tolerance—Class 1 Post-Trauma Responses (00141) [Diagnostic Division: Ego Integrity], Submitted 1986; Revised 1998, 2010, 2017

DEFINITION: Sustained maladaptive response to a traumatic, overwhelming event.

RELATED FACTORS

Diminished ego strength; perceives event as traumatic; survivor role
 Environment not conducive to needs; insufficient social support
 Exaggerated sense of responsibility
 Self-injurious behavior

DEFINING CHARACTERISTICS

Subjective

Intrusive thoughts or dreams; nightmares; flashbacks;
 Heart palpitations; headache
 Hopelessness; shame; guilt/[survival guilt; guilt about behavior required for survival]
 Anxiety; fear; grieving; depression; horror
 Reports feeling numb
 Gastrointestinal irritation; [change in appetite]
 Alteration in concentration
 [Change in sleep; fatigue; loss of interest in usual activities, loss of feeling of intimacy or sexuality]

Objective

Alteration in mood; panic attacks
 Hypervigilance; exaggerated startle response; irritability; neurosensory irritability

(continues on page 650)

Post-Trauma Syndrome (continued)

Anger; rage; aggression

Avoidance behaviors; denial; repression; alienation

History of detachment; dissociative amnesia

Substance misuse/[abuse]; compulsive behavior; [poor impulse control]

Enuresis

[Difficulty with interpersonal relationships; dependence on others; work or school failure]

[Stages:

Acute: Begins within 6 months and does not last longer than 6 months

Chronic: Lasts more than 6 months

Delayed Onset: Period of latency of 6 months or more before onset of symptoms]

At Risk Population: Destruction of one's home; displacement from home

Event outside the range of usual human experience; history of being a prisoner of war; history of torture or criminal victimization

Duration of traumatic event

Exposure to disaster, war, or epidemic; exposure to event involving multiple deaths

History of abuse

Human service occupations

Serious accident; serious injury or threat to self or loved one

Witnessing mutilation or violent death

Sample Clinical Applications: Traumatic injuries, physical/psychological abuse, dissociative disorder

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Comfort Status: Psychospiritual: Psychospiritual ease related to self-concept, emotional well-being, source of inspiration, and meaning and purpose in one's life

Fear Self-Control: Personal actions to eliminate or reduce disabling feelings of apprehension, tension, or uneasiness from an identifiable source

Abuse Recovery: Emotional [or] Physical: Extent of healing of psychological/physical injuries due to abuse

Client Will (Include Specific Time Frame)

- Express own feelings and reactions, avoiding projection.
- Verbalize a positive self-image.
- Report reduced anxiety or fear when memories occur.
- Demonstrate ability to deal with emotional reactions in an individually appropriate manner.
- Demonstrate appropriate changes in behavior or lifestyle (e.g., share experiences with others, seek and get support from significant others [SOs] as needed, change in job or residence).
- Report absence of physical manifestations (e.g., pain, chronic fatigue).

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Support System Enhancement: Facilitation of support to patient by family, friends, and community

Counseling: Use of an interactive helping process focusing on the needs, problems, or feelings of the patient and significant others to enhance or support coping, problem-solving, and interpersonal relationships

Anxiety Reduction: Minimizing apprehension, dread, foreboding, or uneasiness related to an unidentified source of anticipated danger

NURSING PRIORITY NO. 1 To assess causative factor(s) and individual reaction:**Acute**

-  Observe for and elicit information about physical or psychological injury and note associated stress-related symptoms (e.g., numbness, headache, tightness in chest, nausea, pounding heart). *Anxiety is viewed as a normal reaction to a realistic danger or threat, and noting these factors can identify the severity of the anxiety the client is experiencing in the circumstances. In posttraumatic stress disorder (PTSD), this reaction is changed or damaged. People who have PTSD may feel stressed or frightened even when they're no longer in danger. Some factors that appear to increase the risk of PTSD are assaultive trauma or trauma that occurs at an early age.*^{2,12}
- Identify such psychological responses as anger, shock, acute anxiety, confusion, and denial. Note laughter, crying, calm or agitated, excited (hysterical) behavior, as well as expressions of disbelief, guilt and/or self-blame, and labile emotions. *Indicators of severe response to trauma that client has experienced and need for specific interventions.*⁷
- Assess client's knowledge of and anxiety related to the situation. Note ongoing threat to self (e.g., contact with perpetrator and/or associates) or perception of others as threatening. *Client may be aware but speak as though the incident is related to someone else. Flashbacks may occur with the individual reliving the incident/event.*⁷
- Note occupation (e.g., police, fire, rescue, emergency department staff, corrections officer, mental health worker, disaster responders, soldier or support personnel in combat zone, as well as family members). *These occupations carry a high risk for constantly being involved in traumatic events and the potential for exacerbation of stress response and block to recovery. In addition, family members are subjected to the same trauma because they see the same events repeated on TV news channels and hear stories repeated by their loved one(s) who were directly involved.*¹²
- Identify social aspects of trauma or incident (e.g., disfigurement, chronic conditions or permanent disabilities, loss of home or community) *that affect ability to return to normal involvement in activities and work.*⁷
-  Ascertain ethnic background, cultural and religious perceptions, and beliefs about the occurrence. *Client (or significant others) may believe occurrence is retribution from God or result of some indiscretion on client's part; client may in some way also blame self for the incident or occurrence. Individual's view of how he or she is coping may be influenced by cultural and community background, religious beliefs, and family influence.*^{3,7}
- Determine degree of disorganization (e.g., task-oriented activity is not goal directed, organized, or effective; individual is overwhelmed by emotion much of the time). *Presence of persistent frightening thoughts and memories, reliving the event, feeling emotionally numb and unable to be close to friends and family members, and suffering from sleep and eating problems interfere with ability to manage daily living, work, and relationships with others.*^{7,11}
- Identify whether incident has reactivated preexisting or coexisting situations (physical or psychological). *Traumas or difficulties in client's life and how they were dealt with will affect how the client views the current trauma.*⁵
- Determine disruptions in relationships (e.g., family, friends, coworkers, SOs). *Support persons may not know how to deal with client/situation and may be oversolicitous or withdraw; either of these actions will be counterproductive to client's ability to cope with situation.*⁷
- Note withdrawn behavior, use of denial, and use of chemical substances or impulsive behaviors (e.g., chain smoking, overeating). *Indicators of severity of anxiety and client's difficulty dealing with PTSD and need for interventions to address these behaviors.*⁷
- Be aware of signs of increasing anxiety (e.g., silence, stuttering, inability to sit still). *Increasing anxiety may indicate risk for violence or need for medication or other measures to decrease anxiety and help client manage feelings.*⁷
-  Note verbal and nonverbal expressions of guilt or self-blame when client has survived trauma in which others died. Validate congruency of observations with verbalizations. *Sense of own responsibility (blame) and guilt about not having done something to prevent incident or not having been "good enough" to deserve survival are strong beliefs, especially in individuals who are influenced by background, religious, and cultural factors.*¹

- Assess signs and stage of grieving for self and others. *Identification and understanding of stages of grief assist with choice of interventions, plan of care, and movement toward resolution.*¹
- Identify development of phobic reactions to ordinary articles (e.g., knives) and situations (e.g., walking in groups of people, strangers ringing doorbell). *These may trigger feelings from original trauma and need to be dealt with sensitively, accepting reality of feelings and stressing ability of client to deal with them.*¹

Chronic (in addition to previous assessment)

- Evaluate continued somatic complaints. Investigate reports of new or changes in symptoms. *Reports of physical symptoms, such as gastric irritation, anorexia, insomnia, muscle tension, and headache may accompany disorganization and need further evaluation and interventions.*¹
- Note manifestations of chronic pain or pain symptoms in excess of degree of physical injury. *Psychological responses may magnify or exacerbate physical symptoms, indicating need for interventions to help client deal with pain.*⁵
- Be aware of signs of severe or prolonged depression and note presence of flashbacks, intrusive memories, nightmares, panic attacks, and poor impulse control; problems with memory or concentration; thoughts and perceptions; and conflict, aggression, or rage. *Symptoms are not uncommon following a trauma of such magnitude, although client may feel that he or she is “going crazy.”*^{2,10}
- Assess degree of dysfunctional coping (including substance use or abuse, suicidal ideation) and consequences. *Identifies needs and depth of interventions required. Individuals display different levels of dysfunctional behavior in response to stress, and often the choice of chemical substances or substance abuse is a way of deadening the psychic pain.*¹

NURSING PRIORITY NO. 2 To assist client to deal with situation that exists:

Acute

- Allow the client to work through own kind of adjustment. If the client is withdrawn or unwilling to talk, do not force the issue. *Each person is an individual and has own ways of coping. Being there and allowing client to choose own path conveys sense of confidence in ability to deal with situation.*
- Listen for expressions of fear of crowds or people. *May indicate continuing anxiety and difficulty reentering normal activities.*⁷
- ∞ Ascertain or monitor sleep pattern of children as well as adults. *Sleep disturbances or nightmares may develop, delaying resolution, impairing coping abilities, and interfering with return to desired lifestyle.*⁵
- Be aware of and assist client to use ego strengths in a positive way by acknowledging ability to handle what is happening. *Enhances self-concept and reduces sense of helplessness and powerlessness, thus enabling client to move on with life.*
- Encourage client to learn stress-management techniques, such as deep breathing, meditation, relaxation, and exercise. *Reduces stress, enhancing coping skills and helping to resolve situation.*⁸
- 🏠 Assist in dealing with practical concerns and effects of the incident, such as court appearances, altered relationships with SO(s), and employment problems. *In the period immediately following the traumatic incident, individual is in a state of numbness and shock. Thinking becomes difficult, and assistance with practical matters will help manage necessary activities for the person to move through this time.*
- 🌐 Identify employment and community resource groups. *Provides opportunity for ongoing support to deal with recurrent stressors as individual regroups and moves forward.*⁹
- 💊 Administer anti-anxiety or sedative and hypnotic medications with caution.

Chronic

- Continue listening to expressions of concern. *May have recurring symptoms, thus necessitating the need to continue talking about the incident.*⁷
- Permit free expression of feelings (may continue from the crisis phase). Do not rush client through expressions of feelings too quickly and refrain from providing false reassurances. *Client may believe pain or anguish is misunderstood and may be depressed. Statements such as “You don’t understand” or “You weren’t there” are a defense—a way of pushing others away—and need to be responded to with empathy and concern.*

- Encourage client to talk out experience when ready, expressing feelings of fear, anger, loss, or grief. (Refer to NDs Grieving and complicated Grieving.) *Client may need to repeat story over and over and needs to be accepted and assured that feelings are normal for the unusual event experienced.*⁷
- Note whether feelings expressed appear congruent with events the client experienced. *Expressing feelings helps client recognize and identify them to enhance coping. Incongruity may indicate deeper conflict that can impede resolution.*⁸
- Encourage client to become aware and accepting of own feelings and reactions as being normal reactions in an abnormal situation. *There are no “bad” feelings, and awareness and acceptance enable client to deal with feelings once identified and move forward in recovery from traumatic event.*^{4,11}
- Acknowledge reality of loss of self that existed before the incident. Assist client to move toward an acceptance of the potential for growth that exists within client. *Recognition that individual can never go back to being the person he or she was before the incident allows progress toward life as a different person.*⁸
- Continue to allow client to progress at own pace. *Taking own time to talk about what has happened and allowing feelings to be fully expressed aids in the healing process. If rushed, client may believe he or she is not accepted or understood.*¹
- Give “permission” to express and deal with anger at the assailant or situation in acceptable ways. *Being free to express anger appropriately allows it to be dissipated so underlying feelings can be identified and dealt with, thus strengthening coping skills.*¹
- Avoid prompting discussion of issues that cannot be resolved. Keep discussion on practical and emotional level rather than intellectualizing the experience. *When feelings (the experience) are intellectualized, uncomfortable insights and/or awareness are avoided by the use of rationalization, blocking resolution of feelings and impairing coping abilities.*¹
-  Provide for sensitive, trained counselors/therapists and engage in therapies, such as psychotherapy in conjunction with medications, implosive therapy (flooding), hypnosis, relaxation, Rolfing, memory work, cognitive restructuring, eye movement desensitization and reprocessing, and physical and occupational therapies. *Although it is not necessary for the helping person to have experienced the same kind of trauma as the client, sensitivity and listening skills are important to helping the client confront fears and learn new ways to cope with what has happened. Therapeutic use of desensitization techniques (flooding, implosive therapy) provides for extinction through exposure to the fear. Body work can alleviate muscle tension. Some techniques (Rolfing) help to bring blocked emotions to awareness as sensations of the traumatic event are reexperienced.*⁷
-  Discuss use of psychotropic medication. *May be used to decrease anxiety, lift mood, aid in management of behavior; and ensure rest until client regains control of own self. Lithium may be used to reduce explosiveness; low-dose psychotropics may be used when loss of contact with reality is a problem.*⁶

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Assist client to identify and monitor feelings while therapy is occurring. *Promotes awareness and helps client know that control of feelings as they arise will help move beyond traumatic episode.*⁷
- Provide information about what reactions client may expect during each phase. Let client know these are common reactions and phrase in neutral terms of “You may or may not. . . .” *Knowledge of what may be experienced helps reduce fear of the unknown, thereby enabling client to manage reactions if they occur. Use of neutral terms lets client understand that not all reactions may occur in own situation.*
- Assist client to identify factors that may have created a vulnerable situation and that he or she may have power to change to protect self in the future. *While client is not responsible for event, may have unknowingly contributed to occurrence by his or her actions. Identifying those actions that are within client’s power to change provides sense of control over seemingly uncontrollable situations.*⁷
- Avoid making value judgments. *Client may be judging self and caregiver needs to convey nonjudgmental stance to allow individual to deal with feelings of guilt and recrimination, accepting fact that he or she did the best client was capable of in the circumstances.*

- Discuss lifestyle changes client is contemplating and how they may contribute to recovery. *Client needs to evaluate appropriateness of plans and look at long-range consequences (e.g., moving away from effective support group) to make the best choice for the future.*²
- Assist with learning stress-management techniques. *Deep breathing, counting to 10 before reacting negatively or with violence, reviewing the situation, and reframing skills assist client in developing constructive ways to cope with feelings of powerlessness and to regain control of self. Reframing stressors or situation in other words or positive ideas can help client recognize and consider alternatives.*²
-  Discuss drug regimen, potential side effects of prescribed medications, and necessity of prompt reporting of untoward effects.
- Discuss recognition of and ways to manage “anniversary reactions,” reinforcing normalcy of recurrence of thoughts and feelings at this time. *Understanding that these feelings are to be expected and planning for them help client get through the anniversary of the event with the least difficulty.*
-  Suggest support group for SO(s). *Family members may not understand client’s reactions and need help with understanding them and learning how to deal with client in the most helpful manner.*¹
-  Encourage psychiatric consultation. *May need additional therapy if client is unable to maintain control, is violent or inconsolable, or does not seem to be making an adjustment. Participation in a group may be helpful.*¹
-  Refer for long-term family/marital counseling, if indicated. *Additional and ongoing support or therapy may be needed to help family resolve crisis and look at potential for growth. Client problems affect family members and other relationships, and further counseling may help resolve issues of enabling behavior and communication problems.*⁹
- Refer to NDs ineffective Coping, Grieving, complicated Grieving, and Powerlessness.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, noting current dysfunction and behavioral or emotional responses to the incident.
- Specifics of traumatic event.
- Reactions of family/SO(s).
- Cultural or religious beliefs and expectations.
- Availability and use of resources.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Emotional changes.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

risk for Post-Trauma Syndrome

Taxonomy II: Coping/Stress Tolerance—Class 1 Post-Trauma Responses (00145) [Diagnostic Division: Ego Integrity], Submitted 1986; Revised 1998, 2013, 2017

DEFINITION: Susceptible to sustained maladaptive response to a traumatic, overwhelming event, which may compromise health.

RISK FACTORS

Diminished ego strength; perceives event as traumatic; survivor role

Environment not conducive to needs; insufficient social support

Exaggerated sense of responsibility

Self-injurious behavior

At Risk Population: Destruction of one's home; displacement from home

Event outside the range of usual human experience; history of being a prisoner of war; history of torture or criminal victimization

Duration of traumatic event

Exposure to disaster, war, or epidemic; exposure to event involving multiple deaths

History of abuse

Human service occupations

Serious accident; serious injury or threat to self or loved one

Witnessing mutilation or violent death

Sample Clinical Applications: Traumatic injuries, physical/psychological abuse, dissociative disorder

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Fear Level: Severity of manifested apprehension, tension, or uneasiness arising from an identifiable source

Fear Self-Control: Personal actions to eliminate or reduce disabling feelings of apprehension, tension, or uneasiness from an identifiable source

Grief Resolution: Personal actions to adjust thoughts, feelings, and behaviors to actual or impending loss

Client Will (Include Specific Time Frame)

- Verbalize absence of disabling apprehension.
- Demonstrate ability to deal with emotional reactions in an individually appropriate manner.

(continues on page 656)

risk for Post-Trauma Syndrome (continued)

- Deal with practical aspects of situation (e.g., court appearances, temporary housing, funeral services, rebuilding life).
- Report relief or absence of physical manifestations (pain, nightmares, flashbacks, fatigue) associated with event.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Crisis Intervention: Use of short-term counseling to help the patient cope with a crisis and resume a state of functioning comparable to or better than the precrisis state

Coping Enhancement: Facilitation of cognitive and behavioral efforts to manage perceived stressors, changes, or threats which interfere with meeting life demands and roles

Support System Enhancement: Facilitation of support to patient by family, friends, and community

NURSING PRIORITY NO. 1 To assess contributing factors and individual reaction:

- Identify client who survived or witnessed traumatic event (e.g., airplane or motor vehicle crash, mass shooting, fire destroying home and lands, robbery at gunpoint, other violent act) *to recognize individual at high risk for posttrauma syndrome.*
- Note occupation (e.g., police, fire, emergency services personnel, rescue workers, disaster responders, soldiers and support personnel in combat areas, and family members). *Studies reveal a moderate to high percentage of posttraumatic stress disorder (PTSD) cases develop in these populations when they have been exposed to one or more traumatic incidents and their exposure lasts over longer periods of time (e.g., working a bomb site or plane crash).¹⁰ In addition, family members are also at risk because they are subjected to the same trauma as they see the events repeated on TV news channels/hear stories repeated by their loved one(s) who were directly involved.*
-  Assess client risk for developing PTSD using screening tool (e.g., Breslau Short Screening Scale or similar) should client report experiencing a traumatic event. *Short self-report questionnaire or other screening tool with simple “yes” or “no” responses may help with early identification of client at risk for posttrauma response. Recognizing symptoms and providing immediate treatment may prevent the development of PTSD.¹²*
- Assess client’s knowledge of and anxiety related to potential for work-related trauma incident (e.g., shooting in line of duty or viewing body of murdered child); and number, duration, and intensity of recurring situations (e.g., emergency medical technician exposed to numerous on-the-job traumatic incidents; rescuers searching for victims of natural or human-caused disasters). *Having information about these situations enables individuals to think about and plan for eventualities so anxiety can be dealt with in a positive manner.⁶*
-  Ascertain ethnic background and cultural or religious perceptions and beliefs about the occurrence. *Client may believe occurrence is retribution from God, the result of some indiscretion on his or her part, or in some way blame self for the incident or occurrence. Individual’s view of how he or she is coping may be influenced by cultural background, religious beliefs, and family influence.⁶*
- Identify how client’s experiences may affect current situation. *Individual who has had previous experiences with traumatic events (e.g., firefighter who deals with trauma on a regular basis or person who has been involved in a trauma herself or himself) may be more susceptible to PTSD and ineffective coping abilities.¹*
- Listen for comments of guilt, humiliation, shame, or taking on responsibility (e.g., “I should have been more careful/gone back to get her”; “Don’t call me a hero; I couldn’t save my partner”; “My kids are the same age as the ones who died”). *Expressing guilt for actions that individual might have taken can lead to ruminations about lack of responsible behavior, leading to anxiety and PTSD.^{7,10,11}*

-  Note verbal and nonverbal expressions of guilt or self-blame when client has survived trauma in which others died. *Sense of own responsibility (blame) and guilt about not having done something to prevent incident or not having been “good enough” to deserve surviving are strong beliefs, especially in individuals who are influenced by family background, religious, and cultural factors.*¹
- Evaluate for life factors and stressors currently or recently occurring, such as displacement from home due to catastrophic event (e.g., illness or injury, fire, flood, violent storm, earthquake) happening to individual whose child is dying of cancer or who suffered abuse as a child. *Cumulative effects of multiple events can put the individual at higher risk for developing PTSD (acute added to delayed-onset reactions) and indicates need for preventive measures to be taken.*^{3,10}
- Identify client’s coping mechanisms. *Resolution of the posttrauma response is largely dependent on the coping skills the client has developed throughout own life and is able to bring to bear on current situation.*³
- Determine availability and usefulness of client’s support systems, family, social, community, etc., being aware that family members themselves or community in general may also be at risk. *Having an effective available support system and talking with them about what is happening can help client and family members resolve feelings and move on with life in a positive manner.*⁸

NURSING PRIORITY NO. 2 To assist client to deal with situation that exists immediately post incident:

Postincident

- Provide a calm, safe environment. *Client can deal with disruption of life more effectively when surrounded by quiet and by knowing he or she is safe.*⁹
- Assist with documentation for police report, as indicated, and stay with the client. *Developing accurate chain of evidence (maintaining sequencing and collection of evidence) and labeling each specimen and storing and packaging it properly provides important evidence for possibility of future prosecution.*¹
- Listen to and investigate physical complaints. *Physical injuries may have occurred during incident, which may be masked by emotional reactions and limit client’s ability to recognize them. These need to be identified and differentiated from anxiety symptoms so appropriate treatment may be instituted.*¹
- Identify supportive persons (e.g., loved ones, spiritual advisor or pastor). *Having unconditional support from loving and caring others can help the client cope with the situation and move on to live more fully.*¹
- Remain with client, listen as client recounts incident and concerns—possibly repeatedly. If client does not want to talk, accept silence. *Establishes trust, thus providing psychological support and allowing client opportunity to vent emotions.*³
- Encourage expression of feelings and reinforce that feelings and reactions to trauma are common and not indicators of weakness or failure. Note whether feelings expressed appear congruent with events the client experienced. *Expressing feelings helps client recognize and identify them to enhance coping. Incongruity may indicate deeper conflict that can impede resolution.*⁶
-  Help child to express feelings about event using techniques appropriate to developmental level (e.g., play for young child, stories or puppets for preschooler, peer group for adolescent). *Children are more likely to express in play what they may not be able to verbalize directly. Adolescents may benefit from groups, gaining knowledge, support, decreased sense of isolation, and improved coping skills.*²
- Assist with practical realities (e.g., temporary housing, money, notifications of family members, other needs). *Dealing with these issues is necessary and helps client remain connected to reality and maintain sense of control over daily living concerns.*¹

NURSING PRIORITY NO. 3 To assist client to deal with situation that exists:

-  Evaluate client’s perceptions of events and personal significance (e.g., police officer who is also a parent and is investigating death of a child). *Individuals perceive events depending on their previous experiences, cultural and religious background, and family of origin and will respond to any given trauma based on these factors. Incidents that touch a person’s own life will be more difficult to deal with and may have a deeper effect.*²

- Provide emotional and physical presence *to strengthen client's coping abilities. Spending time with the client promotes trust and provides an opportunity for client to think about what will help in the current situation.*³
- Observe for signs and symptoms of stress responses, such as nightmares, reliving an incident, poor appetite, irritability, numbness and crying, and family and relationship disruption. *These responses are normal in the early postincident time frame. If prolonged and persistent, the client may be experiencing PTSD.*⁷
- Identify and discuss client's strengths (e.g., very supportive family, usually copes well with stress) as well as vulnerabilities (e.g., client tends toward alcohol or other drugs for coping, client has witnessed a murder). *Knowing one's strengths and weaknesses helps client know what actions to take to cope with and prevent anxiety from becoming overwhelming.*⁷
- Discuss how individual coping mechanisms have worked in past traumatic events. *Awareness of previous successful experiences can help client remember coping skills that can be used to deal with current situation in a positive manner.*³

NURSING PRIORITY NO. 4 To promote wellness (Teaching/Discharge Considerations):

-  Educate high-risk persons and families about signs/symptoms of posttrauma response, especially if it is likely to occur in their occupation or life. *Awareness allows individual to be proactive and seek support and timely intervention as needed.*
- Encourage client to identify and monitor feelings on an ongoing basis. *Promotes awareness of changes in ability to deal with stressors, allowing prompt intervention when necessary.*⁴
- Encourage learning stress-management techniques, such as deep breathing, meditation, relaxation, and exercise. *Reduces stress, enhancing coping skills and helping to resolve situation.*⁵
- Recommend participation in debriefing sessions that may be provided following major events. *Dealing with the stressor promptly may facilitate recovery from event and prevent exacerbation. Debriefing is being used by many organizations who regularly deal with traumatic events to prevent the development of PTSD, although issues about best timing of debriefing continue to be debated.*³
- Explain that posttraumatic symptoms can emerge months or sometimes years after a traumatic experience and that help or support can be obtained when needed or desired if client begins to experience intrusive memories or other symptoms.
- Encourage individual to develop a survivor mentality. *People often have it within their means to head off life-threatening situations and even survive the worst when they plan for emergencies and think ahead about ways to survive, such as taking food, water, and protective gear on a day hike in case you get lost, fall and break a bone, or in other ways have to spend more time than anticipated.*⁹
-  Identify employment and community resource groups (e.g., Assistance Support and Self Help in Surviving Trauma, employee peer assistance programs, Red Cross or other survivor support services, Compassionate Friends). *Provides opportunity for ongoing support to deal with recurrent stressors as individual moves on with life.*¹¹
-  Refer for individual or family counseling, as indicated. *May need additional assistance to prevent continuation of anxiety and the onset of PTSD.*⁶

DOCUMENTATION FOCUS

Assessment/Reassessment

- Identified risk factors noting internal and external concerns.
- Client's perception of event and personal significance.
- Cultural or religious beliefs and expectations.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

Powerlessness

Taxonomy II: Coping/Stress Tolerance—Class 2 Coping Responses (00125) [Diagnostic Division: Ego Integrity], Approved 1982; Revised 2010, 2017

DEFINITION: The lived experience of lack of control over a situation, including a perception that one's own actions do not significantly affect an outcome.

RELATED FACTORS

Anxiety, low self-esteem; ineffective coping strategies

Caregiver role

Dysfunctional institutional environment

Insufficient knowledge to manage a situation

Insufficient social support; social marginalization; stigmatization

Pain

DEFINING CHARACTERISTICS

Subjective

Alienation; shame

Depression

Frustration about inability to perform previous activities; insufficient sense of control

Objective

Dependency

Inadequate participation in care

(continues on page 660)

Powerlessness (continued)

At Risk Population: Economically disadvantaged

Associated Condition: Complex treatment regimen

Illness or progressive illness; unpredictably of illness trajectory

Sample Clinical Applications: Chronic or debilitating conditions (e.g., chronic obstructive pulmonary disease [COPD], multiple sclerosis [MS]), cancer, spinal cord injury [SCI], major depressive disorder, somatization disorders; posttraumatic stress; sexual assault

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Personal Autonomy: Personal actions of a competent individual to exercise governance in life decisions

Health Beliefs: Perceived Control: Personal conviction that one can influence a health outcome

Participation in Healthcare Decisions: Personal involvement in selecting and evaluating healthcare options to achieve desired outcomes

Client Will (Include Specific Time Frame)

- Express sense of control over the present situation and hopefulness about future outcome.
- Verbalize positive self-appraisal in current situation.
- Make choices related to and be involved in care.
- Identify areas over which individual has control.
- Acknowledge reality that some areas are beyond individual's control.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Self-Responsibility Facilitation: Encouraging a patient to assume more responsibility for own behavior

Health System Guidance: Facilitating a patient's location and use of appropriate health services

Decision-Making Support: Providing information and support for a person who is making a decision regarding healthcare

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Identify situational circumstances (e.g., unfamiliar environment, immobility, diagnosis of terminal or chronic illness, lack of support system(s), lack of knowledge about situation) affecting the client at this time. *Knowing the specific situation of the client is essential to planning care and empowering the individual.*⁴
- Determine client's perception and knowledge of condition and treatment plan. *Identifying how client views and understands what is happening and what the plan of care entails is essential to begin to help client feel empowered.*²
- Ascertain client response to treatment regimen. Does client see reason(s) for and understand it is in the client's interest or is client compliant and helpless? *The manner in which the individual responds to the treatment indicates the depth of feelings of powerlessness and may interfere with progress.*⁴
- Identify client locus of control—internal (expressions of responsibility for self and ability to control outcomes—"I didn't quit smoking") or external (expressions of lack of control over self and environment—"Nothing ever works out"; "What bad luck to get lung cancer"). *Locus of control is a term used in reference to an individual's sense of mastery or control over events. Individuals view life change and stressful events differently. Those with internal locus of control tend to be more optimistic about their ability to deal with adversity even in the face of current difficulties. Individuals with external locus of control may attribute feelings of*

powerlessness to an external source perceiving it as beyond his or her control and will look to others to solve problems and take care of them.^{4,9}

-  Note cultural or religious factors that may contribute to how client views self and is handling current situation. *One's values and beliefs may dictate gender roles and the individual's expectations of control, influencing the client's belief in ability to manage situation, participate in decision making, and direct own life.*^{9,11}
- Assess degree of mastery client has exhibited in life. *How this individual has dealt with problems throughout life will help to understand feelings of powerlessness client is feeling during this crisis.*^{4,5}
- Determine if there has been a change in relationships with significant others (SOs). *Conflict in relationships may be contributing to sense of powerlessness. Domestic violence situations often leave the individuals involved feeling powerless to change what is happening.*⁴
-  Note availability/use of resources. *Client who has few options for assistance or who is not knowledgeable about how to use resources needs to be given information and assistance to know how and where to seek help.*³
-  Investigate healthcare providers and personal caregiver practices to determine if they support client control and responsibility. *Caregivers who do for the client what he or she is able to do for own self diminish client's sense of control. When client is given as much control over self as possible, sense of power is regained.*³

NURSING PRIORITY NO. 2 To assess degree of powerlessness experienced by the client:

- Listen to statements client makes, such as “They don’t care,” “It won’t make any difference,” and “Are you kidding?”²
- Note expressions that indicate “giving up,” such as “It won’t do any good.” *May indicate suicidal intent, indicating need for immediate evaluation and intervention.*⁶
- Note behavioral responses (verbal and nonverbal), including expressions of fear, interest or apathy, agitation, and withdrawal. *These responses can show depth of anxiety, feelings of powerlessness over what is happening, and indicate need for intervention to help client begin to look at situation with some sense of hope.*⁶
- Note lack of communication, flat affect, and lack of eye contact. *May indicate more severe state of mind, such as a psychotic episode, and need for immediate evaluation and treatment.*⁴
- Identify the use of manipulative behavior and reactions of client and caregivers. *Manipulation is used for management of powerlessness because of distrust of others, fear of intimacy, search for approval, and validation of sexuality.*^{1,9}

NURSING PRIORITY NO. 3 To assist client to clarify needs relative to ability to meet them:

- Show concern for client as a person. *Communicates value of the individual, enhancing self-esteem.*⁸
- Active-listen client’s perceptions and concerns and encourage questions. *Provides time for client to explore views and understand what is happening in order to come to some decisions about situation, enhancing sense of control.*^{8,10}
- Accept expressions of feelings, including anger and hopelessness. *Communicates empathy and understanding of reality of those feelings and provides a point of discussion to move toward sense of control.*⁴
- Avoid arguing or using logic with hopeless client. *Client will not accept that anything can make a difference. Arguing denies client's reality and may impede client-nurse relationship.*²
- Deal with manipulative behavior by being straightforward and honest with your communication and letting client know that this is a better way to get needs met. *When client makes a commitment to stop using manipulation in life, steps can be taken to recognize the behaviors and feelings and begin to change them. Keeping a journal can help to identify these issues.*⁹
- Express hope for the client. *Although client may not accept expressions of hope, there is always hope of something, and when options are explored, client may begin to see there is hope.*⁸
- Identify strengths, assets, and past coping strategies that were successful. *Helps client to recognize own ability to deal with difficult situation, providing sense of power.*⁵
- Assist client to identify what he or she can do for self. Identify things the client can and cannot control. *Accomplishing something can provide a sense of control and helps client understand that there are things he*

or she can manage. Accepting that some things cannot be controlled helps client to stop wasting efforts and refocus energy.¹

- Encourage client to maintain a sense of perspective about the situation. *Discussing ways client can look at options and make decisions based on which will be best leads to the most effective solutions for situation.*⁶

NURSING PRIORITY NO. 4 To promote independence:

-  Use client's locus of control to develop individual plan of care. *Tailoring care to the individual's ability will maximize effectiveness. For instance, client with internal control can take control of own care, and client with external control may need to begin with small tasks and add as tolerated, moving toward learning to take more control of care.*⁶
- Develop contract with client specifying goals agreed on. *When client is involved in planning, commitment to plan is enhanced, optimizing outcomes.*²
- Treat expressed decisions and desires with respect. Avoid critical parenting behaviors. *Listening to client and accepting what is said, no matter what the content, helps client hear own words and begin to process information and feelings. Comments that are heard as critical or condescending will block communication and growth.*^{1,10}
- Provide client opportunities to control as many events as energy and restrictions of care permit. *Promotes sense of control over situation and helps client begin to feel more confident about own ability to manage what is happening.*^{6,7}
- Discuss needs openly with client and set up agreed-on routines for meeting identified needs. *Minimizes use of manipulation. Manipulative behavior is often used to influence others to do what the person thinks he or she should do. Usually this results in defensiveness or outright rebellion against what is suggested, resulting in lack of trust and withdrawal on the part of the person being manipulated.*⁹
- Minimize rules and limit continuous observation to the degree that safety permits. *Provides sense of control for the client while maintaining a safe environment for the client.*⁶
- Support client efforts to develop realistic steps to put plan into action, reach goals, and maintain expectations. *Noting progress that is being made can provide a sense of control and diminish sense of powerlessness.*⁶
- Provide positive reinforcement for desired behaviors. *In behavioral therapy, the belief that when a behavior reinforces another behavior, the second behavior is called a "positive reinforcer," and the function is called "positive reinforcement." By providing this reinforcement, the desired behaviors are more likely to continue.*⁴
- Direct client's thoughts beyond present state to future when appropriate. *Focusing on possibilities in small steps can help the client see that there can be hope in small things each day.*^{1,8}
- Schedule frequent and regular contacts to let client know someone is interested and available. *Communicates caring and concern for client and needs, reinforcing sense of worthiness.*
- Involve SO(s) in client care as desired or appropriate. *Personal involvement by supportive family members can help client see the possibilities for resolving problems related to feelings of powerlessness.*⁶

NURSING PRIORITY NO. 5 To promote wellness (Teaching/Discharge Considerations):

-  Instruct in and encourage use of anxiety- and stress-reduction techniques. *Most individuals react to stress in predictable physiological and psychological ways. Feelings of powerlessness related to client's situation can be relieved by use of these techniques.*⁵
- Provide accurate verbal and written information about what is happening and discuss with client/SO(s). Repeat as often as necessary. *Providing information in different modalities allows better access and opportunity for increased understanding. People do not always hear every piece of information the first time it is presented because of anxiety and inattention, so repetition helps to fill in the missed information.*⁶
- Assist client to set realistic goals for the future. *Provides opportunity for client to decide what direction is desired and to gain confidence from completion of each goal.*¹⁰
- Assist client to learn and use assertive communication skills. *Practicing a new way of expressing thoughts and requests provides the client with a skill to achieve desires and improve relationships.*¹⁰

-  Facilitate return to a productive role in whatever capacity possible for the individual. Refer to occupational therapist or vocational counselor as indicated. *Feelings of powerlessness may result from inability to engage in or resume previous activities, and learning new ways to be productive enhances self-esteem and reduces feelings of powerlessness.*⁶
- Encourage client to think productively and positively and take responsibility for choosing own thoughts. *Negative thinking can result in feelings of powerlessness, and learning to use positive thinking can reverse this pattern, promoting feelings of control and self-worth.*⁶
- Model problem-solving process with client/SO(s). *Learning a problem-solving method that results in a win-win solution improves family relationships and promotes feelings of self-worth in those involved.*¹⁰
- Suggest client periodically review own needs and goals. *It is easy to become discouraged as time goes on, and reviewing, thinking about needs, and how previously set goals are relevant in the present helps to either renew those goals or develop new goals to meet current situation.*^{6,8}
-  Refer to support groups, counseling or therapy, etc., as indicated. *May need/desire additional assistance to resolve current problems, long-standing issues, or troubled relationships.*⁴

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, noting degree of powerlessness, locus of control, individual's perception of the situation.
- Specific cultural or religious factors.
- Availability and use of support system and resources.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Specific goals and expectations.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

risk for Powerlessness

Taxonomy II: Coping/Stress Tolerance—Class 2 Coping Responses (00125) [Diagnostic Division: Ego Integrity], Approved 2000; Revised 2010; 2013

DEFINITION: Susceptible to the lived experience of lack of control over a situation, including a perception that one's actions do not significantly affect an outcome, which may compromise health.

RISK FACTORS

Anxiety, low self-esteem; ineffective coping strategies
 Caregiver role
 Dysfunctional institutional environment
 Insufficient knowledge to manage a situation
 Insufficient social support; social marginalization; stigmatization
 Pain

At Risk Population: Economically disadvantaged

Associated Condition: Complex treatment regimen

Illness or progressive illness; unpredictably of illness trajectory

Sample Clinical Applications: New or unexpected diagnoses, chronic or debilitating conditions (e.g., chronic obstructive pulmonary disease [COPD], MS), cancer, SCI, major depressive disorder, somatization disorders

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Personal Autonomy: Personal actions of a competent individual to exercise governance in life decisions

Health Beliefs: Perceived Control: Personal conviction that one can influence a health outcome

Participation in Healthcare Decisions: Personal involvement in selecting and evaluating healthcare options to achieve desired outcome

Client Will (Include Specific Time Frame)

- Express sense of control over the present situation and hopefulness about future outcomes.
- Verbalize positive self-appraisal in current situation.
- Make choices related to and be involved in care.
- Identify areas over which individual has control.
- Acknowledge reality that some areas are beyond individual's control.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Self-Responsibility Facilitation: Encouraging a patient to assume more responsibility for own behavior

Health System Guidance: Facilitating a patient's location and use of appropriate health services

Decision-Making Support: Providing information and support for a person who is making a decision regarding healthcare

NURSING PRIORITY NO. 1 To assess causative/contributing risk factors:

- Identify situational circumstances (e.g., acute illness, sudden hospitalization, diagnosis of terminal or debilitating or chronic illness, very young or aging with decreased physical strength and mobility, lack of knowledge about illness, healthcare system). *Necessary information to develop individualized plan of care for client.*

- Determine client's perception and knowledge of condition and proposed treatment plan. *Identifying how client views and understands what is happening and what the plan of care entails is essential to help client feel empowered.*⁷
- Identify client's locus of control—internal (expressions of responsibility for self and ability to control outcomes—"I didn't quit smoking") or external (expressions of lack of control over self and environment—"Nothing ever works out," "What bad luck to get lung cancer"). *Locus of control is a term used in reference to an individual's sense of mastery or control over events. Individuals view life change and stressful events differently. Those with internal locus of control tend to be more optimistic about their ability to deal with adversity even in the face of current difficulties. Individuals with external locus of control may attribute feelings of powerlessness to an external source, perceiving it as beyond his or her control, and will look to others to solve problems and take care of them.*^{4,10}
- 🌐 Note cultural or religious factors that may contribute to how client views self and is handling current situation. *One's values and beliefs may dictate gender roles and the individual's expectations of control, influencing the client's belief in ability to manage situation, participate in decision making, and direct own life.*^{9,10}
- Assess client's self-esteem and degree of mastery client has exhibited in life situations. *Provides clues to client's ability to see self as in control and deal with current situation.*⁷
- 🏠 Note availability and use of resources, relationship with significant other (SO)/family and degree of support provided to client. *Presence of support system and ability to use resources appropriately facilitates problem-solving, enhancing sense of control. Client who has few options for assistance or who is not knowledgeable about how to use resources needs to be given information and assistance to know how and where to seek help.*³
- Listen to statements client makes that might indicate feelings of possibility of loss of control (e.g., "They don't care," "It won't make a difference," "It won't do any good"). *Indicators of sense of powerlessness and hopelessness and need for specific interventions to provide sense of control over what is happening.*⁴
- Determine congruency of responses (verbal and nonverbal) and note expressions of fear, disinterest or apathy, or withdrawal. *These responses can show depth of anxiety over what is happening and indicate need for intervention to help client begin to look at situation with sense of hope.*⁵
- Be alert for signs of manipulative behavior and note reactions of client and caregivers. *Manipulation may be used for management of powerlessness because of fear and distrust.*^{4,10}

NURSING PRIORITY NO. 2 To assist client to clarify needs and ability to meet them:

- Show concern for client as a person. Encourage questions. *Communicates value of the individual, enhancing self-esteem. Questions may reveal lack of information or concerns client may have.*⁸
- Make time to listen to client's perceptions of the situation as well as concerns. *Provides time for client to explore views and understand what is happening to come to some decisions about situation, enhancing sense of control.*⁵
- Accept expressions of feelings, including anger and reluctance to try to work things out. *Communicates unconditional regard for the client and encourages individual to think about options even though situation may be difficult.*⁵
- Express hope for client and encourage review of past experiences with successful strategies. *Provides an opportunity for person to remember and accept that he or she has managed difficult situations before and can apply these strategies in current situation.*⁴
- Assist client to identify what he or she can do to help self and what situations cannot be controlled. *Accomplishing something can provide a sense of control and helps client understand that there are things he or she can manage. Accepting that some things cannot be controlled helps client to stop wasting efforts and refocus energy.*^{1,2}

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

- 🏠 Encourage client to be active in own healthcare management and to take responsibility for choosing own actions and reactions. *Discussing ways client can look at options and make decisions based on which ones will be best lead to the most effective solutions for situation.*^{6,7}

- Involve client/SO(s) in planning process, using client's locus of control. *Tailoring care to the individual's ability will maximize effectiveness. For instance, client with internal control can take control of own care, and client with external control may need to begin with small tasks and add as tolerated, moving toward learning to take more control of care.*⁶
- Model problem-solving process with client and SOs. *Learning a problem-solving method that results in a win-win solution improves family relationships and promotes feelings of self-worth in those involved.*⁸
- Support client efforts to develop realistic steps to put plan into action, reach goals, and maintain expectations. *Noting progress that is being made can enhance sense of control.*⁶
- Provide accurate instructions in various modalities (e.g., verbal, written, audiovisual, Web sites) about what is happening and what realistically might happen. *Providing information in different formats allows better access and opportunity for increased understanding to support decision-making process.*⁶
- Identify resource books or classes for assertiveness training and stress reduction, as appropriate. *Reinforces learning and promotes self-paced review.*⁸
- Suggest client periodically review own needs and goals. *Reviewing needs and how previously set goals are relevant in the present helps to either renew those goals or develop new goals to meet current situation.*⁵
-  Refer to support groups for chronic conditions or disability (e.g., Multiple Sclerosis Society, Easter Seals, Alzheimer's, Al-Anon) or counseling or therapy, as appropriate. *May need additional assistance to manage difficulties of current situation.*⁴

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, noting potential for powerlessness, locus of control, individual's perception of the situation.
- Cultural values or religious beliefs.
- Locus of control.
- SO/family involvement and support.
- Availability and use of resources.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Specific goals and expectations.
- Attainment or progress toward desired outcomes.
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

readiness for enhanced Power

Taxonomy II: Coping/Stress Tolerance—Class 2 Coping Responses (00187) [**Diagnostic Division:** Ego Integrity], Approved 2006; Revised 2013, 2017

DEFINITION: A pattern of participating knowingly in change for well-being, which can be strengthened.

DEFINING CHARACTERISTICS

Subjective

Expresses desire to enhance awareness of possible changes, or to enhance knowledge for participation in change, or to enhance identification of choices that can be made for change

Expresses desire to enhance independence with actions for change or involvement in change

Expresses desire to enhance participation in choices for daily living, or in choices for health

Expresses desire enhance power

Note: Even though power (a response) and empowerment (an intervention approach) are different concepts, the literature related to both concepts supports the defining characteristics of this diagnosis.

Sample Clinical Applications: Any acute or chronic condition, or healthy individual looking to change life/improve well-being

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Personal Autonomy: Personal actions of a competent individual to exercise governance in life decisions

Health Promoting Behavior: Personal actions to sustain or increase wellness

Health Beliefs: Perceived Control: Personal conviction that one can influence a health outcome

Client Will (Include Specific Time Frame)

- Verbalize knowledge of what changes he or she wants to make.
- Express awareness of own ability to be in charge of changes to be made.
- Participate in classes or group activities to learn new skills.
- State readiness to take power over own life.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Self-Modification Assistance: Reinforcement of self-directed change initiated by the patient to achieve personally important goals

Decision-Making Support: Providing information and support for a person who is making a decision regarding healthcare

Health System Guidance: Facilitating a patient's location and use of appropriate health services

NURSING PRIORITY NO. 1 To determine need/motivation for improvement:

- Determine current situation and circumstances that client is experiencing, leading to desire to improve life. *Provides information to help client with planning for enhancing life.*⁸
- Ascertain motivation and expectations for change. *Motivation to improve and high expectations can encourage client to make changes that will improve his or her life. However, unrealistic expectations or motivation to please someone else may hamper efforts.*⁷
- Identify emotional climate in which client and relationships live and work. *The emotional climate has a great impact between people. When a power differential exists in relationships, the atmosphere is largely determined by the person or people who have the power.*⁴
- Identify client locus of control: internal (expressions of responsibility for self and ability to control outcomes) or external (expressions of lack of control over self and environment). *Understanding locus of control can help client to work toward positive, internal control as he or she develops sense of ability to freely choose own actions.*⁹
-  Determine cultural factors or religious beliefs influencing client's self-view. *These factors can be strong determinants in individual's ability to change and view self as powerful and may complicate growth process.*⁹
- Assess degree of mastery client has exhibited in his or her life. *Helps client to understand how he or she has functioned in the past, how that applies to current situation, and what is needed to improve.*
- Note presence of family/significant others that can or do act as support systems for client. *When family understands and supports client's desires and efforts, he or she is more likely to be successful.*
- Determine whether client knows or uses assertiveness skills. *Learning and enhancing these skills will help client to improve ability to take personal responsibility for own self and relationships with others.*^{1,3,5,7}

NURSING PRIORITY NO. 2 To assist client to clarify needs relative to ability to improve feelings of power:

- Discuss how client is currently involved in creating change in life. *Provides a baseline to measure growth and suggests possibilities for change.*⁸
- Active-listen client's perceptions and beliefs about the concept of power. *Enables client to identify underlying feelings and thoughts about this issue and how power can be gained in his or her life.*⁸
- Identify strengths, assets, and past coping strategies that were successful. *These strategies can be built on to enhance feelings of control.*⁶
- Discuss the importance of assuming personal responsibility for life and relationships. *This requires one to be open to new ideas and experiences, different values, and beliefs and to be inquisitive.*⁷
- Assist client in identifying things client can and or cannot control. *Avoids wasting time on things that are not in the control of the client.*⁸
- Treat expressed desires and decisions with respect. Avoid critical parenting expressions. *Individual may express thoughts and opinions that are creative and out of the ordinary, and critical parenting responses such as "That's a dumb idea" can crush person's brainstorming.*⁹

NURSING PRIORITY NO. 3 To promote optimum wellness, enhancing power (Teaching/Discharge Considerations):

-  Assist client to set realistic goals for the future. *Even though client is thinking creatively and brainstorming ideas, goals need to be planned step by step to reach the desired outcome.*⁶
- Provide accurate verbal and written information about client's concerns and life situation. *Reinforces learning and promotes self-paced review.*⁸
- Assist client to learn/use assertive communication skills. *These techniques require practice, but as the client becomes more proficient, they will help to develop relationships that are more effective.*^{2,3}
- Use "I" messages instead of "You" messages. *"I" messages acknowledge ownership of what is said, whereas "You" messages suggest the other person is wrong or bad, fostering resentment and resistance instead of understanding and cooperation.*⁸

- Discuss importance of paying attention to nonverbal communication. *Messages are often confusing or misinterpreted when verbal and nonverbal communications are not congruent.*⁹
- Help client learn to problem-solve differences. *Problem-solving process allows for each person involved to have input and promotes win-win solutions.*⁸
- Instruct and encourage use of stress-reduction techniques. *Relaxation helps individual to function more effectively, thus enhancing feelings of power.*⁹
-  Refer to support groups or classes, as indicated, assertiveness training, effectiveness training for women; “Be Your Best” training program. *Provides role models and allows individuals to learn from one another, thereby promoting problem-solving and enhancing learning.*⁷

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, noting determination to improve sense of power, locus of control.
- Motivation and expectations for change.
- Cultural or religious beliefs affecting self-view.
- Locus of control.

Planning

- Plan of care, specific interventions, and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Client’s responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

risk for Pressure Ulcer

Taxonomy II: Safety/Protection—Physical Injury 00249) [**Diagnostic Division:** Safety], Approved 2013, 2017

DEFINITION: Susceptible to localized injury to the skin and/or underlying tissue usually over a bony prominence as a result of pressure, or pressure in combination with shear (National Pressure Ulcer Advisory Panel [NPUAP, 2007]).

RISK FACTORS

Decrease in mobility; extended period of immobility on hard surface
 Dehydration; inadequate nutrition; self-care deficit
 Dry skin; scaly skin; skin moisture; use of linen with insufficient moisture wicking property
 Hyperthermia
 Incontinence
 Insufficient caregiver knowledge of pressure ulcer prevention, or of modifiable factors
 Pressure over bony prominence; shearing forces; surface friction
 Smoking

At Risk Population: ADULT: Braden scale score of <17

American Society of Anesthesiologists (ASA) Physical Status classification score ≥1

CHILD: Braden Q Scale score of ≤15

Low score on Risk Assessment Pressure Sore (RAPS) scale; history of pressure ulcer

New York Heart Association (NYHA) Functional Classification ≥1

Extremes of age or weight; female gender

History of cerebral vascular accident; trauma;

Associated Condition: Alteration in cognitive functioning

Alteration in sensation; edema

Anemia; cardiovascular disease; decrease in tissue oxygenation or perfusion; impaired circulation

Elevated skin temperature by 1–2°C

Physical immobilization; hip fracture

Lymphopenia, decrease in serum albumin; reduced triceps skin fold thickness

Pharmaceutical agent

Sample Clinical Applications: Para/quadruplegia; diabetes mellitus; obesity; CVA, coma, dementia; amputation; burns; peripheral vascular disease, thrombophlebitis

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Tissue Integrity: Skin and Mucous Membranes: Structural intactness and normal physiological function of skin and mucous membranes

Risk Control: Personal actions to understand, prevent, eliminate, or reduce modifiable health threats

Immobility Consequences: Physiological: Severity of compromise in physiological functioning due to impaired physical mobility

Client Will (Include Specific Time Frame)

- Display and maintain healthy skin in risk areas (e.g., bony prominences, skin folds) during time in care facility.
- Participate in prevention measures and treatment program.
- Verbalize understanding of risk factors and when to contact healthcare provider.
- Demonstrate behaviors or lifestyle changes to improve circulation (e.g., engage in regular exercise, cessation of smoking, weight reduction, disease management).

Client/Caregiver Will (Include Specific Time Frame)

- Participate in prevention measures.

ACTIONS/INTERVENTIONS**Sample NIC linkages:**

Skin Surveillance: Collection and analysis of patient data to maintain skin and mucous membrane integrity

Pressure Ulcer Prevention: Prevention of pressure ulcers for an individual at high risk for developing them

NURSING PRIORITY NO. 1 To assess risk and contributing factors:

- Identify presence of underlying condition that increases risk of pressure ulcer. *Skin integrity problems can be the result of (1) disease processes that affect circulation and perfusion of tissues (e.g., arteriosclerosis, venous insufficiency, hypertension, obesity, diabetes, malignant neoplasms), (2) medications (e.g., vasopressors, antidepressants; anticoagulants, corticosteroids, immunosuppressives, antineoplastics) that adversely affect or impair healing, (3) burns or radiation (can break down internal tissues as well as skin), and (4) nutrition and hydration (e.g., malnutrition deprives the body of protein and calories required for cell growth and repair; dehydration impairs transport of oxygen and nutrients).*¹⁻³
-  Evaluate client's risk for developing pressure injury upon admission to care, using NPUAP Pressure Injury Stages, Braden risk scale (or similar scale per facility policy) as listed above. *Using susceptibility factors of sensory perception, skin moisture, activity, mobility, nutritional status, friction, and shear potential, the client's risk can be quickly determined. Note: "Although the terms decubitus ulcer, pressure sore, and pressure ulcer have often been used interchangeably, the National Pressure Ulcer Advisory Panel (NPUAP) currently (2016) considers pressure injury the best term to use, given that open ulceration does not always occur."*^{6,9-11,14}
-  Determine client's age and developmental factors affecting skin/tissue health. *One of the structural differences in an infant's skin is that the skin cells are smaller and thinner than in an adult's skin, which can result in a weakened barrier to the environment. Infants are also predisposed to a dry, flaky, and impaired skin barrier.¹² However, studies have shown that similar to adult patients, acutely ill infants and children are at risk for pressure injury. The negative effect of immobility and physiological instability on a patient's skin does not discriminate on age or developmental level.¹³ In older adults, there are often comorbid conditions (e.g., end-stage renal disease, diabetes, peripheral vascular impairment), as well as decreased epidermal regeneration; fewer sweat glands; and less subcutaneous fat, elastin, and collagen, causing skin to become thinner, drier, and less responsive to pain sensations.*^{1,3-5}
-  Note skin color discoloration (e.g., nonblanchable erythema; persistent red, blue, or purple hues) in pressure areas suggestive of impaired tissue health. *Note: It may be necessary in a darker-skinned individual to focus more on other evidence of pressure injury development, such as boggy, induration, coolness, or increased warmth, as well as signs of skin discoloration.*⁵
- Note presence of compromised mobility, sensation, vision, hearing, or speech that may impact client's self-care as relates to skin and pressure area care.³
- Ascertain current medication regimen. *Individual may be receiving medications that contribute to development of pressure injuries or affect wound healing (e.g., NSAIDs, vasopressors, beta blockers, anticoagulants, inotropics, immunosuppressives, antineoplastics, some analgesics) and that can adversely affect the skin.*¹⁶
-  Review laboratory results (e.g., hemoglobin/hematocrit, blood glucose, blood and/or wound culture and sensitivities for infectious agents [viral, bacterial, fungal], albumin, prealbumin, transferrin, protein) to evaluate for potential risk factors or ability to heal. *Note: Albumin less than 3.5 correlates to decreased wound healing and increased incidence of pressure ulcers.*^{1,6,14}

NURSING PRIORITY NO. 2 To maintain optimal skin/tissue integrity:^{5,7,8,15}

-  Monitor for incontinence, changing diapers, briefs, padding, and bedding as needed. *Maintains skin that is clean, dry, and free of contaminants that can cause/exacerbate skin/tissue breakdown.*
- Develop regularly timed repositioning schedule for client with mobility and sensation impairments; encourage or assist with periodic weight shifts for client in chair *to reduce stress on pressure points and to promote circulation to tissues.*
- Use proper turning and transfer techniques and sufficient personnel when repositioning client. *Avoids movements that cause friction or shearing (e.g., pulling client with parallel force, dragging movements).*
- Use appropriate padding or pressure-reducing devices (e.g., egg crate, gel pads, heel rolls, or foam boots) or pressure-relieving devices (e.g., air or water mattress) when indicated *to reduce pressure on sensitive areas and enhance circulation.*
-  Participate in practices that prevent medical device related-pressure ulcers:
Choose the correct size of medical device(s) (e.g., endotracheal tube [ET], other tubings, anti-embolism stocking, splints) to fit the individual.
Remove or move the device daily to assess skin.
Avoid placement of device(s) over sites of prior or existing pressure ulceration.
-  Cushion and protect skin with cushioning in high-risk areas (e.g., nasal bridge, ears, sacrum, heels, occipital area of head in infants/small children).
Educate other care providers about client's devices and interventions for prevention of skin breakdown.
-  Provide optimum nutrition (including adequate protein, lipids, calories, trace minerals, and multivitamins [e.g., A, C, D, E]) *to promote skin and tissue health and to maintain general well-being.* Refer to nutritionist as indicated.
-  Provide adequate hydration (e.g., oral, tube feeding, IV, ambient room humidity) *to reduce and replenish transepidermal water loss.*

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Encourage regular inspection and monitoring of skin for changes or failure to heal. *Early detection and reporting to healthcare providers promotes timely evaluation and intervention.*
- Encourage good nutrition, adequate hydration, early and ongoing mobility, and range-of-motion and strengthening exercises *to enhance circulation and promote health of skin and other organs.*
- Discuss proper and safe use of equipment or appliances (e.g., heating pad, ostomy appliances, padding straps of braces).
- Encourage abstinence from smoking, *which causes vasoconstriction, impairing circulation.*

DOCUMENTATION FOCUS**Assessment/Reassessment**

- Individual findings, including specific risk factors, status of skin, and ability to manage/direct own care.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

ineffective Protection

Taxonomy II: Health Promotion—Class 2 Health Management (00043) [**Diagnostic Division:** Safety], Approved 1990; Revised 2017

DEFINITION: Decrease in the ability to guard self from internal or external threats such as illness or injury.

RELATED FACTORS

Inadequate nutrition
Substance misuse/[abuse]

DEFINING CHARACTERISTICS

Subjective

Anorexia
Chilling
Itching
Insomnia; fatigue; weakness

Objective

Deficient immunity
Impaired healing; alteration in clotting
Maladaptive stress response
Alteration in perspiration
Dyspnea; coughing

(continues on page 674)

ineffective Protection (continued)

Restlessness; immobility

Disorientation

Pressure ulcer

At Risk Population: Extremes of age

Associated Condition: Abnormal blood profile

Cancer, immune disorder

Pharmaceutical agent

Treatment regimen

Sample Clinical Applications: Cancer, AIDS, systemic lupus, substance abuse, tuberculosis, dementia, Alzheimer's disease, anorexia or bulimia nervosa, diabetes mellitus, thrombophlebitis, conditions requiring long-term steroid use (e.g., chronic obstructive pulmonary disease [COPD], asthma, renal failure), major surgery

Author Note: The purpose of this diagnosis seems to combine multiple NDs under a single heading for ease of planning care when a number of variables may be present. It is suggested that the user refer to specific NDs based on identified related factors and individual concerns for this client to find appropriate outcomes and interventions that are specifically tied to individual related factors that are present, such as the following:

Extremes of age: Includes concerns regarding body temperature or thermoregulation; memory or sensory-perceptual alterations; impaired mobility, risk for falls, sedentary lifestyle, or self-care deficits; risk for trauma, suffocation, or poisoning; and risk for skin or tissue integrity and fluid volume imbalances.

Inadequate nutrition: Brings up issues of nutrition and unstable blood glucose; risk for infection and delayed surgical recovery; impaired swallowing; impaired skin or tissue integrity; and trauma, problems with coping, and interrupted family processes.

Substance use/abuse: May be situational or chronic with problems ranging from impaired respirations, decreased cardiac output, impaired liver function, and fluid volume deficits to nutritional problems, infection, trauma, risk for self- or other-directed violence, and coping or family process difficulties.

Abnormal blood profile: Suggests possibility of fluid volume imbalances, decreased tissue perfusion, problems with oxygenation, activity intolerance, or risk for infection or injury.

Pharmaceutical agents, and treatment-related side effects or concerns: Includes ineffective tissue perfusion and activity intolerance; cardiovascular, respiratory, and elimination concerns; risk for infection, fluid volume imbalances, impaired skin or tissue integrity, and impaired liver function; pain, nutritional problems, fatigue, sleep difficulties, and ineffective health management; and emotional responses (e.g., anxiety, sorrow, grief, coping).

Sample NOC linkages:

Symptom Control: Personal actions to minimize perceived adverse changes in physical and emotional functioning

Blood Coagulation: Extent to which blood clots within normal period of time

Immune Status: Natural and acquired appropriately targeted resistance to internal and external antigens

Sample NIC linkages:

Postanesthesia Care: Monitoring and management of the patient who has recently undergone general or regional anesthesia

Bleeding Precautions: Reduction of stimuli that may induce bleeding or hemorrhage in at-risk patients

Infection Protection: Prevention and early detection of infection in a patient at risk

Surveillance: Purposeful and ongoing acquisition, interpretation, and synthesis of patient data for clinical decision making

*****Author Note:** It is suggested that the reader refer to specific NDs based on identified related factors or defining characteristics and individual client concerns to find appropriate assessments, outcomes, interventions, and documentation foci.

Rape-Trauma Syndrome

Taxonomy II: Coping/Stress Tolerance—Class 1 Post-Trauma Responses (000142) [**Diagnostic Division:** Ego Integrity], Approved 1980; Revised 1998, 2017

DEFINITION: Sustained maladaptive response to a forced, violent, sexual penetration against the victim's will and consent. [Rape is not a sexual crime but a crime of violence and is identified as sexual assault. Although attacks are most often directed toward women, men also may be victims.]

RELATED FACTORS

To Be Developed

DEFINING CHARACTERISTICS

Subjective

Embarrassment; humiliation; shame; guilt; self-blame
 Helplessness; powerlessness
 Shock; fear; anxiety; anger; thoughts of revenge
 Nightmares; alteration in sleep pattern
 Change in relationship(s); sexual dysfunction

Objective

Physical trauma; muscle tension/spasm
 Confusion; disorganization; impaired decision making
 Agitation; hyperalertness; aggression
 Mood swings; perceived vulnerability; dependency; low self-esteem; depression
 Substance misuse/[abuse]; history of suicide attempt
 Denial; phobias; paranoia; dissociative identity disorder

At Risk Population: Rape

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Abuse Recovery: Sexual: Extent of healing of physical and psychological injuries due to sexual abuse or exploitation

Coping: Personal actions to manage stressors that tax an individual's resources

Client Will (Include Specific Time Frame)

- Report absence of physical complications, pain, and discomfort.
- Deal appropriately with emotional reactions as evidenced by behavior and expression of feelings.
- Verbalize a positive self-image.
- Verbalize recognition that incident was not of own doing.
- Identify behaviors or situations within own control that may reduce risk of recurrence.
- Deal with practical aspects (e.g., court appearances).
- Demonstrate appropriate changes in lifestyle (e.g., change in job, residence) that contribute to recovery or seek and obtain support from significant others (SOs), as needed.
- Interact with individuals or groups in desired and acceptable manner.

(continues on page 676)

Rape-Trauma Syndrome (continued)

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Rape-Trauma Treatment: Provision of emotional and physical support immediately following a reported rape

Crisis Intervention: Use of short-term counseling to help the patient cope with a crisis and resume a state of functioning comparable to or better than the precrisis state

Counseling: Use of an interactive helping process focusing on the needs, problems, or feelings of the patient and significant others to enhance or support coping, problem-solving, and interpersonal relationships

NURSING PRIORITY NO. 1 To assess trauma and individual reaction, noting length of time since occurrence of event:

- Observe for and elicit information about physical injury and assess stress-related symptoms such as numbness, headache, tightness in chest, nausea, pounding heart, etc. *Indicators of degree of and reaction to trauma experienced by the client, which may occur immediately and in the days or weeks following the attack.*⁴
- Identify psychological responses such as anger, shock, acute anxiety, confusion, and denial. Note laughter, crying, calm or agitated, excited (hysterical) behavior, and expressions of disbelief or self-blame. *Victim may exhibit expressed response pattern (compound reaction), displaying these feelings openly and freely as manifestations of experiencing the trauma of rape/sexual assault and the accompanying feelings of fear of death, violation, powerlessness, and helplessness. On the other hand, client may exhibit controlled (silent) response pattern with little or no emotion expressed. Any emotion is appropriate, as each person responds in own individual way; however, inappropriate behaviors or acting out may require intervention.*^{3,4} Refer to NDs risk for self-/other-directed Violence.
- Note silence, stuttering, and inability to sit still. *May be signs of increasing anxiety, thus indicating need for further evaluation and intervention. Anxiety is suppressed and client does not talk about the trauma, resulting in an overwhelming emotional burden.*^{3,4}
- Determine degree of disorganization. *Initially, the individual may be in shock and disbelief, which is a normal response to the incident. The person may respond by withdrawing and be unable to manage activities of daily living, especially when the incident was particularly brutal, requiring assistance and treatment to enable her or him to recover and move on.*^{3,4}
- Identify whether incident has reactivated preexisting or co-existing situations (physical or psychological). *The presence of these factors can affect how the client views the current trauma. Previous traumatic incidents that have not been effectively resolved may compound the current incident.*¹
-  Ascertain cultural values or religious beliefs that may affect how client views incident, self, and expectations of significant other (SO)/family reaction. *Client may believe incident will bring shame on the family, blame self, or believe that family will blame client, thus affecting client's ability to reach out to others for support.*⁶
- Determine sexual orientation of the survivor. *Heterosexual men/boys may believe that they are now gay (after being sexually assaulted) and need to be assured that is not true. Gay, bisexual, or gay-identified may be targeted because of this. Healthcare providers may treat these individuals with suspicion, disregard, and disrespect, contributing to the survivor's sense of shame and guilt and making it more difficult to seek help.*⁵
- Determine disruptions in relationships (e.g., spouse/partner, family, friends, coworkers). *Many women find that they react to men in general in a different way, seeing them as reminders of the assault. Male survivors may withdraw entirely from sexual relations.*^{5,7}
- Identify development of phobic reactions to ordinary articles (e.g., knives) and situations (e.g., walking in groups of people, strangers ringing doorbell). *These are manifestations of extreme anxiety, and client may need treatment to learn how to manage feelings.*^{3,4}

- Note degree of intrusive repetitive thoughts, sleep disturbances. *Survivor may notice disruptions in activities of daily living, reliving the attack, thoughts of recrimination, self-blame (“Why didn’t I . . . ?”), and nightmares. Although these factors are distressing and upsetting, they are part of the normal healing process.*^{3,4}
- Assess degree of dysfunctional coping. *Client may turn to use of alcohol or other drugs, have suicidal or homicidal ideation, or display marked change in sexual behavior in an attempt to cope with traumatic event.*⁴

NURSING PRIORITY NO. 2 To assist client to deal with situation that exists:

- Explore own feelings regarding rape/incest issue prior to interacting with the client. *Since the feelings related to these incidents are so pervasive, the individual involved in caregiving needs to recognize own biases to prevent imposing them on the client.*¹

Acute phase/immediate care

-   Stay with the client—do not leave child unattended. Listen but do not probe. Tell client you are sorry this has happened and that she or he is safe now. *During this phase, the client experiences a complete disruption of life as she or he has known it, and presence of caregiver may provide reassurance and sense of safety.*^{2,4}
-  Involve rape or sexual assault response team or sexual assault nurse examiner when available. Provide a same-sex examiner when appropriate. *Presence of the response team trained to collect evidence appropriately and sensitively provides assurance to the survivor that she or he is being taken care of. Client may react to someone who is the sex of the attacker, and use of a same-sex examiner communicates sensitivity to her or his feelings at this difficult time.*¹¹
-  Be sensitive to cultural factors that may affect specifics of examination process. *For example, in some cultures, women cannot be examined without a male family member present. These issues need to be considered when treating the survivor.*⁶
-  Evaluate client as dictated by age, gender, and developmental level. *Age of the survivor is an important consideration in deciding plan of care and appropriate interventions. Note: While underreported, it is believed that 1 in 6 men are sexually assaulted and 1 in 6 boys will be sexually assaulted or abused before the age of 18.*^{5,8}
- Assist with documentation of incident for law enforcement officers and child-protective services reports, explaining each step of the procedure. Maintain sequencing and collection of evidence (chain of evidence), label each specimen, and store and package properly. *It is crucial to provide accurate information to law enforcement for potential legal proceedings when perpetrator is charged. Be careful to use nonjudgmental language. Words can carry legal implications that may affect subsequent proceedings.*¹
- Provide environment in which client can talk freely about feelings and fears. *Client needs to talk about the incident and concerns, such as issues of relationship with or response of SO(s), pregnancy, and sexually transmitted infections (STIs), so they may be dealt with in a positive manner.*¹⁰
- Provide information about emergency birth control and prophylactic treatment for STIs and assist with finding resources for follow-through. *Promotes client’s peace of mind and opportunity to prevent these conditions.*¹⁰
- Provide psychological support by listening and remaining with client. If client does not want to talk, accept silence. *May indicate silent reaction or controlled style of dealing with the occurrence in which the individual contains his or her emotions, using all his or her energy to maintain composure.*⁴
-  Listen to and investigate physical complaints. Assist with medical treatments, as indicated. *Emotional reactions may limit client’s ability to recognize physical injury.*⁴
- Assist with practical realities. *Client may be so emotionally distraught that she or he may not be able to attend to needs for such things as safe, temporary housing, money, or other issues that may need to be addressed. Assistance helps individual maintain contact with reality.*
- Determine client’s ego strengths and help him or her use them in a positive way by acknowledging client’s ability to handle what is happening. *Validation of belief that person can deal with what has happened and move forward with life promotes self-acceptance and helps client begin this process.*^{6,9}
- Identify supportive persons for this individual. *Client needs to know she or he can go to a strong system of friends, family, or advocate who will respond with empathy.*⁷

Postacute phase

- Allow the client to work through own kind of adjustment. Do not force issue if client is withdrawn or unwilling to talk (silent reaction). *Individuals react in many ways to the traumatic event of rape, and no response is abnormal. Factors that influence how the survivor deals with the situation are personality, support system, existing life problems and prior sexual victimization, relationship with the offender, degree of violence used, social and cultural influences, and ability to cope with stress.*^{2,4}
- Listen for expressions of fear (e.g., of perpetrator returning, of being in crowds or being alone, etc.). *May reveal developing phobias needing evaluation and appropriate interventions and ongoing therapy.*^{2,4}
- Discuss specific concerns and fears. Identify appropriate actions and provide information as indicated. *May need diagnostic testing for pregnancy, STIs, or other resources. Meeting these needs and providing information will help client begin the process of recovery.*¹⁰
- Include written instructions that are concise and clear regarding medical treatments, crisis support services, etc. Encourage return for follow-up. *Reinforces teaching and provides opportunity to deal with information at own pace. Follow-up appointment provides opportunity for determining how client is managing feelings and what needs may not have been met.*

Long-term phase

- Continue listening to expressions of concern. Note persistence of somatic complaints (e.g., nausea, anorexia, insomnia, muscle tension, headache). *May need to continue to talk about the assault. Repeating the story helps client to move on, but continued somatic concerns may indicate developing posttraumatic stress disorder.*^{6,8}
- Permit free expression of feelings (may continue from the crisis phase). Refrain from rushing client through expressions of feelings too quickly and avoid reassuring inappropriately. *Client may believe pain and/or anguish is misunderstood, and depression may limit responses.*^{1,6}
- Acknowledge reality of loss of self that existed before the incident. Assist client to move toward an acceptance of the potential for growth that exists within individual. *Following this traumatic event, the individual will not be able to go back to the person he or she was before. Life will always have the memory of what happened, and client needs to accept that reality and move on in the best way possible.*²
- Continue to allow client to progress at own pace. *The process of grieving is a very individual one, and each person needs to know that she or he can take whatever time needed to resolve feelings and move on with life.*⁴ (Refer to ND Grieving for additional interventions.)
- Give “permission” to express and deal with anger at the perpetrator and situation in acceptable ways. Set limits on destructive behaviors. *Facilitates resolution of feelings without diminishing self-concept.*⁶
- Keep discussion on practical and emotional level rather than intellectualizing the experience. *When the person talks about the incident intellectually, instead of identifying and talking about feelings, client avoids dealing with the feelings, thus inhibiting recovery.*¹
- 🏠 Assist in dealing with ongoing concerns about and effects of the incident, such as court appearance, STI, relationship with SO(s), etc. *Depending on degree of disorganization, client will need help to deal with these practical and emotional issues.*
- 🗣️ Provide for sensitive, trained counselors, considering individual needs. *Male/female counselors may be best determined on an individual basis, as counselor's gender may be an issue for some clients, affecting ability to disclose and deal with feelings.*¹

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

- 🏠 Provide information about what reactions client may expect during each phase. Let client know these are common reactions and phrase in neutral terms of “You may or may not . . . experience, know, be aware of. . . .” *Such information helps client anticipate and deal with reactions if they are experienced. Note: Be aware that although male rape perpetrators are usually heterosexual, the male victim may be concerned about his own sexuality and may exhibit a homophobic response.*¹
- Assist client to identify factors that may have created a vulnerable situation and that she or he may have power to change to protect self in the future. *While client needs to be assured that she or he is not to blame for*

incident, the circumstances of the incident need to be assessed to identify factors that are within the individual's control to avoid a similar incident occurring.⁶

- Avoid making value judgments. *The survivor often blames self about the incident and agonizes over the circumstances; therefore, nonjudgmental language is very important to help the person accept that the fault is not hers or his.*^{1,6}
- Discuss lifestyle changes client is contemplating and how they will contribute to recovery. *Helps client evaluate appropriateness of plans. In the anxiety of the moment, the individual may believe that changing residence, job, or other aspects of her or his environment will be healing. In reality, while this response is normal and represents an attempt to regain control over own life, these changes may not help and may make matters worse.*⁴
-  Encourage psychiatric consultation if client is violent, inconsolable, or does not seem to be making an adjustment. Participation in a group may be helpful. *May need intensive professional help to come to terms with the assault.*^{1,6}
-  Refer to family or marital counseling, as indicated. *When relationships with family members are affected by the incident, counseling may be needed to resolve the issues.*^{1,9}
- Refer to NDs Anxiety, ineffective Coping, Fear, Grieving, complicated Grieving, and Powerlessness, as appropriate.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including nature of incident, individual reactions and fears, degree of trauma (physical and emotional), effects on lifestyle.
- Cultural or religious factors.
- Reactions of family/SO(s).
- Samples gathered for evidence and disposition or storage (chain of evidence).

Planning

- Plan of action and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

ineffective Relationship

Taxonomy II: Role Relationships—Class 3 Role Performance (00223) [**Diagnostic Division:** Ego Integrity], Approved 2010; Revised 2017

DEFINITION: A pattern of mutual partnership that is insufficient to provide for each other's needs.

RELATED FACTORS

Stressors

Substance misuse/[abuse]

Unrealistic expectations

Ineffective communication skills

DEFINING CHARACTERISTICS

Subjective

Dissatisfaction with complementary relationship between partners

Dissatisfaction with physical or emotional need fulfillment between partners

Dissatisfaction with information or idea sharing between partners

Objective

Unsatisfying communication between partners

Insufficient balance in autonomy or collaboration between partners

Insufficient mutual respect between partners

Insufficient mutual support in daily activities between partners

Inadequate understanding of partner's compromised functioning

Delay in meeting of developmental goals appropriate for family life-cycle stage

Partner not identified as support person

At Risk Population: Developmental crisis

History of domestic abuse; incarceration of one partner

Associated Condition: Alteration in cognitive functioning in one partner

Sample Clinical Applications: Chronic conditions (e.g., MS, spinal cord injury, gastric bypass surgery, mental health problems, depression, anxiety, bipolar disorder, substance abuse, dementia), domestic violence

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Social Interaction Skills: Personal behaviors that promote effective relationships

Role Performance: Congruence of an individual's role behavior with role expectations

Social Involvement: Social interactions with persons, groups, or organizations

Client Will (Include Specific Time Frame)

- Verbalize a desire to improve relationship with partner.
- Acknowledge worth and value of partner as a key person.

- Seek information regarding physical and emotional needs of partner.
- Engage in effective communication skills for both partners.
- Participate in marital therapy sessions to learn ways to develop a satisfactory relationship.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Role Enhancement: Assisting a patient, significant other, and/or family to improve relationships by clarifying and supplementing specific role behaviors

Socialization Enhancement: Facilitation of another person's ability to interact with others

Conflict Mediation: Facilitation of a constructive dialogue between opposing parties with a goal of resolving disputes in a mutually acceptable manner

NURSING PRIORITY NO. 1 To assess current situation and determine needs:

-  Determine makeup of family, length of relationship, and financial situation—parents/children, older/younger, and other members of household. *Stressors of family relationships within a household, difficulties with child-rearing, older adult needing care, and financial difficulties can strain the relationship between partners.*^{2,3,7,8}
- Discuss individual's perception of own and other's needs and how partner sees own needs. *Identifies how each person sees situation and areas of agreement and disagreement, providing a basis for beginning plan of care.*^{3,6}
-  Determine each person's self-image and locus of control. *View of self as a positive or negative individual who is in control or controlled by others influences behavior and how partners react to each other.*^{3,4,7,12}
-  Assess emotional intelligence skills of each individual. *This is the ability to recognize and control one's own emotions and recognize the emotions of the other.*^{1,7}
-  Investigate cultural factors that may be affecting relationship and contributing to conflict. *Roles from family of origin for each person may promote conflict when beliefs clash and neither is willing to change or even discuss thinking.*^{3,4,12}
- Determine style of communication used by partners. *Poor communication is unclear and indirect leading to conflict, ineffective problem-solving, and poor emotional bonding in families with problems.*^{1,3}
-  Determine how family as a whole functions. *Personal and family history affects relationships between family members, and situational dynamics can create conflict as individuals take sides in disagreements, escalating the situation.*^{3,4,7}
- Ascertain ways in which family members deal with conflict. *Conflict is inevitable in relationships, and partners need to identify whether how they deal with it is effective or ineffective.*^{1,2,8}
-  Identify concerns about sexual aspects of relationship from both partners' viewpoints. *Intimacy is an important part of a relationship, and if both individuals are avoiding that activity, they will need to discuss specific ways to resolve these problems.*^{1,4,6,9}
- Note medical problems that may be affecting sexual relationship. *Conditions such as hysterectomy, prostatitis, breast cancer, and erectile dysfunction may cause partners to withdraw from one another.*^{8,10}

NURSING PRIORITY NO. 2 To assist partners to resolve existing conflict:

-  Maintain positive attitude toward partners and family members. *A safe environment allows individuals to speak freely, knowing they will not be judged for comments and opinions, so couple can get to the deeper roots of current situation.*^{1,6,7}

- Discuss surface symptoms of dysfunctional relationships and the fact that these are not the problems that need to be dealt with. *Individuals are often not aware of underlying emotions that are influencing their behavior and continue to focus on surface issues.*⁶
- Explore each partner's emotional needs. *Unconscious desires to gain acceptance, recognition, and a sense of being cared about or valued are often motivators for relationships.*^{6,7}
- Discuss and clarify nonverbal communication. *Partners need to be aware of and ask about the meaning of body language, tone of voice, and subtle movements that convey positive or negative messages. When these cues are misinterpreted, they can lead to misunderstandings.*^{1,6}
-  Assist partners/family to learn effective conflict resolution skills such as the win-win method. *Individuals have traditionally used ineffective means of solving conflict or avoided it altogether. Resolving to listen to each other's needs and agree on a mutually acceptable solution provides new ways to resolve problems and enhances relationship.*^{5,11}
- Provide information about the Active-listening technique. *Avoids giving advice and encourages other person to find own solution, enhancing self-esteem.*⁵
-  Have partners identify thoughts and feelings when starting a discussion with each other. *A system of thinking (a paradigm) forms the basis for how we look at and experience life and determines how we perceive our world, forming the basis for our reality, and exists below our level of conscience.*^{11,12}
-  Recommend individuals verify what they believe the other has said. *Allows speaker to correct misperception and respond more effectively.*^{1,5,11,12}
-  Have partners role-play a specific conflict that is a frequent issue. *Practicing how to defuse arguments and repair hurt feelings helps to identify other's feelings and use new skills for resolution.*¹¹
- Encourage partners to maintain a calm demeanor. *Regardless of circumstances, staying focused enables individuals to think more rationally and come to a desired solution.*⁵
- Discuss sexual concerns and provide opportunity for questions. *Conflict in the relationship inevitability affects these concerns and providing information and discussing them can enhance intimacy.*^{1,9}
-  Promote nonblameful self-disclosure when having a discussion. *Not placing blame results in a more considerate and respectful resolution.*^{7,11}

NURSING PRIORITY NO. 3 To promote optimal functioning (Teaching/Discharge Considerations):

-  Have partners acknowledge beliefs they have become aware of during therapy. *Unconscious thinking influences each person's view of the world in negative or positive ways.*^{1,11}
-  Encourage use of relaxation and mindfulness techniques. *Helps individuals to ease anxiety and learn to relate to each other in a calm manner.*⁷
- Discuss the use of humor and laughter in daily lives. *Helps to lighten difficult moments and provide opportunities to share fun moments.*⁶
- Recommend books and Web sites to provide additional information. *Encourages partners to seek and learn new ways to improve relationship.*³
-  Refer to support groups and classes as indicated. *Parenting, assertiveness, and financial assistance will help partners learn new skills as needed.*^{2,3,8,11}
-  Include all family members in discussions, as indicated. *Promotes involvement, provides opportunities for communication and clarification of family dynamics, and enhances commitment to achieving goals.*^{1,3,7}
-  Refer to other physical/psychological resources, as needed. *May need further treatment to address pathology and help partners understand other's needs.*^{2,6,8}

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual's perception of situation and self.
- Partner's views and expectations.
- How partners communicate and deal with conflict.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response of partners to plan, interventions, and actions performed.
- Attainment or progress toward desired outcomes.

Discharge Planning

- Long-range plan and who is responsible for actions to be taken.
- Referrals made.

readiness for enhanced Relationship

Taxonomy II: Role Relationships—Class 3 Role Performance (00207) [Diagnostic Division: Ego Integrity], Approved 2006; Revised 2013

DEFINITION: A pattern of mutual partnership to provide for each other's needs, which can be strengthened.

DEFINING CHARACTERISTICS

Subjective

Expresses desire to enhance:
 Communication between partners
 Satisfaction with information/idea sharing between partners
 Emotional need fulfillment for each partner

(continues on page 684)

readiness for enhanced Relationship (continued)

Satisfaction with physical or emotional need fulfillment for each partner

Satisfaction with complementary relation between partners

Mutual respect between partners

Autonomy or collaboration between partners

Understanding of partners' functional deficit

Sample Clinical Applications: Applicable in any setting, not dependent on presence of pathology although may be useful in chronic physical conditions or mental health challenges

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Social Interaction Skills: Personal behaviors that promote effective relationships

Role Performance: Congruence of an individual's role behavior with role expectations

Social Involvement: Social interactions with persons, groups, or organizations

Client Will (Include Specific Time Frames)

- Verbalize a desire to learn more effective communication skills.
- Verbalize understanding of current relationship with partner.
- Seek information to improve emotional and physical needs of both partners.
- Talk with partner about circumstances that can be improved.
- Develop realistic plans to strengthen relationship.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Role Enhancement: Assisting a patient, significant other, and/or family to improve relationships by clarifying and supplementing specific role behaviors

Socialization Enhancement: Facilitation of another person's ability to interact with others

NURSING PRIORITY NO. 1 To assess current situation and determine needs:

-  Determine makeup of family: parents/children, older/younger. *Life changes, such as developmental, situational, and health-illness, can affect the relationship between partners and require readjustment and thinking of ways to enhance situation.*¹
- Discuss client's perception of needs and how partner sees desire to improve relationship. *Identifies thinking and whether both partners see the situation in the same way and individual expectations for change.*⁴
- Identify use of effective communication skills. *May need to improve understanding of words partners use in discussion of sensitive subjects.*⁴
- Help client to identify thoughts and feelings when starting a discussion with partner. *A system of thinking (referred to as a paradigm) forms the basis for how we look at and experience life and determines how we perceive our world, forms the basis for our reality, and exists below our level of conscience.*⁴
- Ask partners how they deal with conflict. *Since conflict is a normal, natural, and inevitable part of life, this needs to be acknowledged, and individuals need to learn how to deal with it effectively.*⁴
- Ascertain client's view of sexual aspects of relationship. *Changes that occur with aging or medical conditions, such as hysterectomy or erectile dysfunction, can affect the relationship and need specific interventions to resolve.*²
-  Identify cultural factors relating to individual's view of role in relationship. *Although changing, in the United States, men may typically take care of financial affairs and car and house repairs, while women may manage household and caregiving roles.*¹

- Discuss how family as a whole functions. *Interrelationships with members of the family, personal and family history, and situational dynamics can impact the functioning of the whole family.*²

NURSING PRIORITY NO. 2 To assist the client to enhance existing relationship:

- Maintain positive attitude toward client. *Promotes safe relationship in which client can feel free to speak openly and plan for a positive future.*¹
- Have couple discuss paradigms that they have become aware of in own thinking that interfere with relationship. *These beliefs exist below our conscious mind, influencing our behavior and whether we see the world in negative or positive ways.*⁴
- Determine how each person views himself or herself as a positive or negative person. *One's self-image influences behavior and how he or she relates to others. When emotional needs are met, individuals relate to others in positive ways, while unmet needs result in low self-image and insecurity.*⁵
- Discuss the skills of emotional intelligence, which are important for maintaining positive relationships. *This is the ability to recognize and effectively control our own emotions and to recognize the emotions of others.*⁶
- Help couple to recognize that surface symptoms of dysfunctional relationships are not the problems that need to be dealt with. *Underlying emotions influence our behaviors, and individuals often are not aware of them and continue to deal with the superficial conflicts.*⁶
- Explore individual's emotional needs. *Relationships are often motivated by unconscious desires to gain acceptance, recognition, and a sense of being cared about or valued.*⁵
- Note client's awareness of nonverbal communications. *Body language, tone of voice, a roll of the eyes, or subtle movements convey strong messages, positive or negative, that need to be discussed and clarified.*⁶
- Discuss effective conflict-resolution skills. *People tend to be afraid of conflict because effective ways to deal with it have not been learned, and it often ends in a lose-lose situation.*⁴
- Encourage client to remain calm and focused regardless of circumstances. *Maintaining a calm demeanor helps individual to be able to think more clearly and be more rational in dealing with situation.*⁶
- Recommend cross-checking or verifying what listener believes speaker said. *Clarifies communication and allows speaker to respond or correct perception of listener as needed.*⁵
- Help partners to learn the win-win method of conflict resolution. *Although conflict can damage a relationship, learning to listen to each other's needs can assist partners to arrive at mutually acceptable solutions.*⁴
- Role-play ways to defuse arguments and repair injured feelings. *Provides a realistic situation wherein each person can identify own and partner's view and practice new ways of interacting.*⁶
- Provide open environment for partners to discuss sexual concerns and questions. *Problems may arise out of lack of information about these issues, and when individuals are comfortable with this knowledge, the relationship can be improved.*²
- Discuss nonblameful self-disclosure when having a dialogue. *Partners take turns talking about own needs and feelings without blaming the other, resulting in being able to find a solution in a climate of mutual consideration and respect.*⁴

NURSING PRIORITY NO. 3 To promote optimal relationship (Teaching/Discharge Considerations):

-  Provide information for partners, using bibliotherapy and appropriate Web sites. *Promotes continuation of learning about how to enhance relationship.*³
- Encourage couple to use humor and playfulness in their relationship. *Sharing laughter and enjoying life helps to weather difficult times that may occur.*⁶
- Discuss the importance of being an empathic, understanding, and nonjudgmental listener when either partner has a problem. *The expectation that the partner will be willing to help by listening eases the anxiety of talking about major problems.*⁵
- Encourage use of the skill of Active-listening. *This avoids giving advice and helps other person to find own solution, enhancing self-esteem.*⁴

-  Refer to support groups and classes on assertiveness and parenting, as indicated by individual needs.³
- Include family members in discussions as needed. *Knowing how the family relates as a whole will help improve relationships of partners as well as the other family members.*³
-  Refer for care as indicated by psychological or physical problems of either individual. *May need further treatment and explanation to help partner understand these situations.*¹

DOCUMENTATION FOCUS

Assessment/Reassessment

- Baseline information, individual's perception of situation and self.
- Reasons for desire to improve relationship and expectations for change.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response of partners to plan, interventions, and actions performed.
- Attainment or progress toward desired outcomes(s).

Discharge Planning

- Long-term plan and who is responsible for actions to be taken.

risk for ineffective Relationship

Taxonomy II: Role Relationships—Class 3 Role Performance (00229) [**Diagnostic Division:** Ego Integrity], Approved 2010; Revised 2013, 2017

DEFINITION: Susceptible to developing a pattern that is insufficient for providing a mutual partnership to provide for each other's needs.

RISK FACTORS

Stressors

Substance misuse/[abuse]

Unrealistic expectations

Ineffective communication skills

At Risk Population: Developmental crisis

History of domestic abuse; incarceration of one partner

Associated Condition: Alteration in cognitive functioning in one partner

Sample Clinical Applications: Chronic conditions (e.g., MS, spinal cord injury, gastric bypass surgery, mental health problems, depression, anxiety, bipolar disorder, substance abuse, dementia/Alzheimer's), domestic violence

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Social Interaction Skills: Personal behaviors that promote effective relationships

Role Performance: Congruence of an individual's role behavior with role expectations

Social Involvement: Social interactions with persons, groups, or organizations

Client Will (Include Specific Time Frames)

- Verbalize desire to make changes to meet each other's needs as appropriate.
- Express a desire to improve communication skills.
- Develop realistic plans to improve relationship.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Counseling: Use of an interactive helping process focusing on the needs, problems, or feelings of the patient and significant others to enhance or support coping, problem-solving, and interpersonal relationships

Role Enhancement: Assisting a patient, significant other, and/or family to improve relationships by clarifying and supplementing specific role behaviors

Socialization Enhancement: Facilitation of another person's ability to interact with others

NURSING PRIORITY NO. 1 To assess current situation and determine needs:

-  Determine makeup of family, length of relationship, and specific stressors. *Stressors of family—developmental issues, elderly parents needing assistance, financial difficulties, and domestic violence—strained relationships between partners.*^{2,3,7,8}
-  Identify how each partner sees own self-image and locus of control. *View of self as a positive or negative person who is in control or controlled by others influences how each relates to the other.*^{3,4,7,8,12}
- Discuss needs of each partner and how each views the other's needs. *Identifies misperceptions and areas of disagreement to provide a basis of planning for change.*^{1,3}
- Identify style of communication and understanding of nonverbal cues used by family members. *Poor communication and lack of understanding of what the other is saying, or inferring, leads to conflicts and lack of problem-solving.*^{1,3}
- Determine how partners deal with conflict. *Many individuals try to avoid conflict instead of working to resolve it.*^{5,6}
-  Identify cultural beliefs that affect how each person deals with daily activities in family. *Family of origin influences how individuals think roles are to be dealt with, and conflict arises if partners are not willing to discuss and change beliefs.*^{3,4,12}

- Identify medical problems/sexual concerns that may affect relationship. *Conditions such as prostate problems, breast cancer, hysterectomy, and erectile dysfunction can affect interactions between partners.*^{4,8,10}
-  Ascertain how couple deals with sexual aspects of their relationship. *When anger and conflict interfere with intimacy, couple may distant themselves from one another.*^{1,4,6,9}
-  Note how family as a whole functions. *Interactions among family members and situational dynamics provide information about need to improve relationships.*^{3,7}

NURSING PRIORITY NO. 2 To assist couple to improve relationship:

-  Maintain positive attitude in interactions with individuals. *Provides an environment in which clients feel comfortable and safe discussing problems openly.*^{1,6,7}
- Promote discussion of awareness of individuals' beliefs and thoughts that may strain relationship. *Enables individuals to begin to discuss potential problem areas.*^{3,6}
-  Have client identify thoughts and feelings when starting a conversation with partner. *Individuals have a system of thinking that forms the basis for reality, determines how we see the world, and exists below the level of our consciousness.*¹¹
-  Discuss the skills of emotional intelligence. *The ability to recognize and control own emotions and recognize emotions of others is important to maintain healthy relationships.*^{1,7}
- Explore each person's emotional needs. *Understanding that unconscious needs underlie desire to gain acceptance, recognition, and sense of being cared about or valued help client to deal more openly with these issues.*^{6,7}
- Assist partners to understand effects of nonverbal language. *Lack of awareness of body language, tone of voice, and subtle movements can be misinterpreted and need to be discussed and clarified.*^{1,6}
- Encourage couple to learn effective conflict-resolution skills. *Family may have used ineffective ways to deal with conflict, resulting in fighting and a lose-lose situation.*^{5,11}
-  Role-play a specific problem couple argues about, using the win-win method of resolution. *Practicing how to defuse arguments and repair hurt feelings helps to identify other's feelings and use new skills for resolution.*¹¹
- Encourage partners to practice remaining calm and focused regardless of circumstances. *When issue has previously resulted in violence, remaining calm can help individuals think more clearly and be more rational in dealing with situation, avoiding further conflict.*⁵
- Have each person verify what he or she heard the other person say. *Provides the opportunity for the speaker to correct or acknowledge what was said.*^{1,5,11}
-  Discuss issues/provide information about sexual relationship. *Conflict inevitably affects intimacy, and couple may need to resolve issues around this part of their life.*^{1,9}
-  Discuss use of nonblameful self-disclosure during discussions with partner. *Promotes an atmosphere of respect and mutual consideration in which individuals can talk about feelings and resolve problems.*^{7,11}

NURSING PRIORITY NO. 3 To promote optimal relationship between couple/family (Teaching/Discharge Considerations):

-  Involve all family members in discussions, as indicated. *Encourages input from each member so he/she feels heard and views self as part of the solution.*^{1,3,7,11}
- Encourage family members to use Active listening. *Avoids giving advice and allows others to find their own solution, enhancing self-esteem.*^{1,5,11}
- Discuss appropriate use of humor and playfulness in daily interactions. *Helps family members to enjoy life and makes difficult issues easier to deal with.*⁶
-  Encourage use of relaxation, mindfulness techniques. *Promotes calm manner and ability to deal with difficult issues more effectively.*⁷

- Recommend information sources, books, and Web sites as appropriate. *Provides additional resources to access information to assist couple in learning to deal with relationship/family issues.*³
- Identify community resources/support groups as appropriate. *Individuals who have successfully dealt with similar issues can provide role model for change and effective use of problem-solving skills.*^{2,3,8,11}
-  Refer to therapy as indicated. *May need further in-depth care to deal with individual physical/psychological problems.*^{2,6,8,11}

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual's perception of situation and self.
- Partner's views and expectations.
- How partners communicate and deal with conflict.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response of partners to plan, interventions, and actions performed.
- Attainment or progress toward desired outcomes.

Discharge Planning

- Long-range plan and who is responsible for actions to be taken.
- Any referrals made.

impaired Religiosity

Taxonomy II: Life Principles—Class 3 Value/Belief/Action Congruence (00169) [**Diagnostic Division:** Ego Integrity], Approved 2004; Revised 2017

DEFINITION: Impaired ability to exercise reliance on beliefs and/or participate in rituals of a particular faith tradition.

RELATED FACTORS

Anxiety; depression

Cultural or environmental barrier to practicing religion; spiritual distress

Fear of death

Ineffective caregiver or coping strategies

Insecurity; insufficient social support or sociocultural interaction

Pain

Insufficient transportation

DEFINING CHARACTERISTICS

Subjective

Distress about separation from faith community

Desire to reconnect with previous belief pattern or customs

Questioning of religious belief patterns or customs

Difficulty adhering to prescribed religious beliefs and rituals [e.g., ceremonies, regulations, clothing, prayer, services, holiday observances]

At Risk Population: Aging; hospitalization;

Life transition; personal or spiritual crisis; end-of-life crisis

History of religious manipulation

Associated Condition: Illness

Sample Clinical Applications: Any acute or chronic condition, palliative care, end-of-life situation

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Spiritual Health: Connectedness with self, others, higher power, all life, nature, and the universe that transcends and empowers the self

Client Will (Include Specific Time Frame)

- Express ability to once again participate in beliefs and rituals of desired religion.
- Discuss beliefs and values about spiritual or religious issues.
- Attend religious or worship services of choice, as desired.
- Verbalize concerns about end-of-life issues and fear of death.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Spiritual Growth Facilitation: Facilitation of growth in patients' capacity to identify, connect with, and call upon the source of meaning, purpose, comfort, strength, and hope in their lives

Religious Ritual Enhancement: Facilitating participation in religious practices

Spiritual Support: Assisting the patient to feel balance and connection with a greater power

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Determine client's usual religious and spiritual beliefs, values, and past spiritual commitment. *Provides a base-line for understanding current problem.*⁵
- Note client's/significant other's (SO's) reports and expressions of anger/concern, alienation from God, and sense of guilt or retribution. *Perception of guilt may cause spiritual crisis and suffering, resulting in rejection of religious beliefs or anger toward God.*⁶
- Determine sense of futility, feelings of hopelessness, and lack of motivation to help self. *Indicators that client may see no, or only limited, options or personal choices, and treatment needs to be directed at finding what happened in client's life to bring about these feelings.*⁵
-  Assess extent of depression client may be experiencing. *Some studies suggest that a focus on religion may protect against depression.*⁷
-  Note recent changes in negative behaviors (e.g., withdrawal from others or religious activities, dependence on alcohol or medications). *Lack of connectedness with self and others impairs ability to trust others or feel worthy of trust from others or God.*^{6,7}
-   Identify cultural values and expectations regarding religious beliefs or practices. *Individuals grow up in a family that instills a value system within them. As the person grows up, ideas, values, and expectations may change or be strengthened by new information, different questioning, and alternative viewpoints, which may affect current situation.*³
- Note socioeconomic status of individual/family. *Women who are poor may have high levels of personal religiosity yet participate less in organized religion because they may feel stigmatized by their situation (e.g., single mothers, those receiving public assistance, those engaging in a lifestyle that conflicts with church norms).*²

NURSING PRIORITY NO. 2 To assist client/SOs to deal with feelings/situation:

- Use therapeutic communication skills of reflection and active listening. *Communicates acceptance and enables client to find own solutions to concerns as situation is discussed and deeper meanings are discovered.*⁴
- Encourage expression of feelings about illness or condition or death. *As people age, they become more concerned about their own mortality, and others often see them as in poor health and as spiritual and religious. If they have been diagnosed with a long-term chronic or terminal illness, they may be feeling more angry and rejecting of God than seeking God's help.*^{5,8}
- Discuss personal beliefs that may hinder participation in religious activities. *Provides opportunity for self-reflection, such as own worthiness and ability to forgive self for past decisions/life choices.*
- Discuss differences between grief and guilt and help client to identify and deal with each. Point out consequences of actions based on guilt. *Individuals often feel guilty about the "what if's" of life. "If only I had done this!" "If only I had paid more attention!" "If only I had made him go to the doctor!" Most of these guilty feelings are not based on reality, and when they are acted on, the individual does not get the release he or she seeks.*⁵
- Suggest use of journaling and reminiscence. *Promotes life review and can assist in clarifying values and ideas, recognizing and resolving feelings and situation.*⁴
-  Encourage client to identify individuals who can provide needed support (e.g., spiritual advisor, parish nurse). *When client is seeking to restore reliance on religious beliefs, these providers can often be helpful.*⁶
- Review client's religious affiliation, associated rituals, and beliefs. *Helps client examine what was important in the past and may trigger some desire to reconnect with these previous beliefs.*⁶
- Provide opportunity for nonjudgmental discussion of philosophical issues related to religious belief patterns and customs. *Open communication can assist client to check reality of perceptions and identify personal options and willingness to resume desired activities.*¹
- Discuss desire to continue or reconnect with previous belief patterns and customs and perceived barriers. *As client begins to think about current feelings of alienation from previous religious connections, these discussions can help to clarify and allow client to think about how these beliefs can be regained.*⁵

- Identify ways to strengthen spiritual or religious expression. *There are multiple options for enhancing participation in faith community (e.g., joining prayer or study group, volunteering time to community projects, singing in the choir, reading spiritual writings).*
-  Involve client in refining healthcare goals and therapeutic regimen as appropriate. *Identifies role illness or condition is playing in current concerns about ability to participate and appropriateness of participating in desired religious activities.*⁷

NURSING PRIORITY NO. 3 To promote spiritual wellness (Teaching/Discharge Considerations):

-  Assist client to identify spiritual counselor who could be helpful (e.g., minister, priest, spiritual advisor who has qualifications or experience) in dealing with specific concerns of client. *Provides answers to spiritual questions, assists in the journey of self-discovery, and can help client learn to accept and forgive self.*⁶
- Provide privacy for meditation or prayer and performance of rituals, as appropriate. *Many individuals prefer to pray or meditate in private so they can concentrate without interruption or questions from others.*
-  Explore alternatives or modifications of ritual based on setting and individual needs and limitations. *Individual may not be able to go to a church or temple, so providing another setting—chapel in the facility or quiet room with appropriate religious artifacts or material—can provide the setting desired.*⁶
- Provide bibliotherapy, including list of relevant resources and Web sites for later reference, promoting self-paced learning and ongoing support.⁴

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including nature of spiritual conflict, effects of participation in treatment regimen.
- Physical and emotional responses to conflict.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcomes(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Available resources, specific referrals made.

readiness for enhanced Religiosity

Taxonomy II: Life Principles—Class 3 Value/Belief/Action Congruence (00171) [**Diagnostic Division:** Ego Integrity], Approved 2004; Revised 2013

DEFINITION: A pattern of reliance on religious beliefs and/or participation in rituals of a particular faith tradition, which can be strengthened.

DEFINING CHARACTERISTICS

Subjective

Expresses desire to enhance belief patterns or religious customs used in the past
 Expresses desire to enhance participation in religious experiences or practices [e.g., ceremonies, regulations, clothing, prayer, services, holiday observances]
 Expresses desire to enhance religious options, use of religious materials
 Expresses desire to enhance connection with religious leader
 Expresses desire to enhance forgiveness

Sample Clinical Applications: As a health-seeking behavior, the client/family may be healthy, or this diagnosis can be associated with any clinical condition or life process

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Spiritual Health: Connectedness with self, others, higher power, all life, nature, and the universe that transcends and empowers the self

Client Will (Include Specific Time Frame)

- Acknowledge need to strengthen religious affiliations and continue or resume previously comforting rituals.
- Verbalize willingness to seek help to enhance desired religious beliefs.
- Become involved in spiritually based programs of own choice.
- Recognize the difference between belief patterns and customs that are helpful and those that may be harmful.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Spiritual Growth Facilitation: Facilitation of growth in patients' capacity to identify, connect with, and call upon the source of meaning, purpose, comfort, strength, and hope in their lives

Religious Ritual Enhancement: Facilitating participation in religious practices

Spiritual Support: Assisting the patient to feel balance and connection with a greater power

NURSING PRIORITY NO. 1 To determine spiritual state/motivation for growth:

- Determine client's current thinking about desire to learn more about religious beliefs and actions.
-  Ascertain religious beliefs or cultural values of family of origin and climate in which client grew up. *Early religious training deeply affects children and is carried on into adulthood. Conflict between family's beliefs and client's current learning may need to be addressed.*⁷
-  Identify cultural values and expectations regarding religious beliefs and/or practices. *Individuals grow up in a family that instills a value system within them. As the person grows up, ideas, values, and expectations may change or be strengthened by new information, different questioning, and alternative viewpoints.*³

- Note socioeconomic status of individual/family. *Women who are economically disadvantaged may have high levels of personal religiosity, yet participate less in organized religion because they feel stigmatized by their situation (e.g., single mothers, those receiving public assistance, those engaging in a lifestyle that conflicts with church norms).*²
- Discuss client's spiritual commitment, beliefs, and values. *Enables examination of these issues and helps client learn more about self and what he or she desires/believes.*⁷
- Explore how spirituality and religious practices have affected client's life. *Some believe that the value of religiosity is the deepened sense of quality of life associated with practicing one's beliefs or tenets.*⁸
- Ascertain motivation and expectations for change. *The client's motivation needs to be for self and not for others, and client needs to understand own expectations to move forward with desire to improve status.*⁴

NURSING PRIORITY NO. 2 To assist client to integrate values and beliefs to strengthen sense of wholeness and achieve optimum balance in daily living:

- Establish nurse-client relationship in which dialogue can occur. *Client can feel safe in this relationship to say anything and know it will be accepted.*⁵
- Identify barriers and beliefs that may hinder growth or self-discovery. *Provides opportunity for self-reflection such as own worthiness and ability to forgive self for past decisions or life choices. Previous practices and beliefs may need to be considered and accepted or discarded in new search for religious beliefs.*⁸
-  Discuss cultural beliefs of family of origin and how they have influenced client's religious practices. *As client expands options for learning new or other religious beliefs and practices, these influences will provide information for comparing and contrasting new information.*⁷
- Explore connection of desire to strengthen belief patterns and customs to daily life. *Becoming aware of how these issues affect the individual's daily life can enhance ability to incorporate them into everything he or she does.*¹
- Identify ways in which individual can develop a sense of harmony with self and others. *Client may have some beliefs that may or may not be shared with others, and discussing these can clarify understanding by each individual.*¹

NURSING PRIORITY NO. 3 To enhance spiritual wellness (Teaching/Discharge Considerations):

-  Encourage client to seek out and experience different religious beliefs, services, and ceremonies, as desired. *Trying out different religions will give client more information to contrast and compare what will fit his or her belief system.*⁶
- Provide bibliotherapy or reading materials pertaining to spiritual issues. *Client may be interested in learning about new spiritual ideas, and finding resources that clarify thinking will help to develop own beliefs.*⁴
- Encourage client to engage in stress-reducing activities, such as meditation, relaxation exercises, or mindfulness (method of being in the moment). *Promotes general well-being and sense of control over self and ability to choose desired religious activities.*⁵
- Encourage participation in religious activities, worship or religious services, and prayer or study groups; volunteering in church choir or other needed duties; and reading/viewing religious materials and media. *Enhances client's knowledge and promotes connectedness with self, others, and/or higher power.*⁴
-  Refer to community resources (e.g., pastor, parish nurse, religion classes, other support groups).

DOCUMENTATION FOCUS

Assessment/Reassessment

- Assessment findings, including client perception of needs and desire for growth.
- Motivation and expectations for change.

Planning

- Plan for growth and who is involved in planning.

Implementation/Evaluation

- Response to activities, learning, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan.

Discharge Planning

- Long-term needs, expectations, and plan of action.
- Specific referrals made.

risk for impaired Religiosity

Taxonomy II: Life Principles—Class 3 Value/Belief/Action Congruence (00170) [**Diagnostic Division:** Ego Integrity], Approved 2004; Revised 2013, 2017

DEFINITION: Susceptible to an impaired ability to exercise reliance on religious beliefs and/or participate in rituals of a particular faith tradition, which may compromise health.

RISK FACTORS

Anxiety; depression

Cultural or environmental barrier to practicing religion; spiritual distress

Fear of death;

Ineffective caregiver or coping strategies

Insecurity; insufficient social support or sociocultural interaction

Pain

Insufficient transportation

At Risk Population: Aging; hospitalization;

Life transition; personal or spiritual crisis; end-of-life crisis

History of religious manipulation

Associated Condition: Illness

Sample Clinical Applications: Any acute or chronic condition, palliative care, end-of-life situation

(continues on page 696)

risk for impaired Religiosity (continued)

Sample **NOC** linkages:

Spiritual Health: Connectedness with self, others, higher power, all life, nature, and the universe that transcends and empowers the self

Client Will (Include Specific Time Frame)

- Express understanding of relation of situation or health status to thoughts and feelings of concern about ability to participate in desired religious activities.
- Seek solutions to individual factors that may interfere with reliance on religious beliefs or participation in religious rituals.
- Identify and use resources appropriately.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Religious Ritual Enhancement: Facilitating participation in religious practices

Spiritual Growth Facilitation: Facilitation of growth in patients' capacity to identify, connect with, and call upon the source of meaning, purpose, comfort, strength, and hope in their lives

Spiritual Support: Assisting the patient to feel balance and connection with a greater power

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Ascertain current situation (e.g., illness, hospitalization, prognosis of death, depression, lack of support systems, financial concerns). *Identifies problems client is dealing with in the moment that may be affecting desire to be involved with religious activities.*¹
- Note client's concerns, expressions of anger, and belief that illness or condition is result of lack of faith. *Individual may blame own self for what has happened and could reject religious beliefs and/or God.*
- Determine client's usual religious or spiritual beliefs and past or current involvement in specific church activities. *Provides an understanding of how client sees religion in own life before current disruption.*¹
-   Identify cultural values and expectations regarding religious beliefs and/or practices. *Individuals grow up in a family that instills a value system within them. As the person grows up, ideas, values, and expectations may change or be strengthened by new information, different questioning, and alternative viewpoints, which may affect current situation.*³
- Note quality of relationships with significant others and friends. *Individual may withdraw from others in relation to the stress of illness, pain, and suffering. Others may be encouraging client to rely on religious beliefs at a time when individual is questioning own beliefs in the current situation.*¹
- Note socioeconomic status of individual/family. *Women who are poor may have high levels of personal religiosity, yet participate less in organized religion because they feel stigmatized by their situation (e.g., single mothers, those receiving public assistance, those engaging in a lifestyle that conflicts with church norms).*²
- Assess lack of transportation or environmental barriers to participation in desired religious activities. *These barriers can be realistic in the face of such issues as poor bus systems, inability of individual to get to bus stop (physical problems of walking or distance to the bus stop), or inability to drive a car.*²
-  Ascertain substance use or abuse. *Individuals often turn to use of various substances in distress, and this can affect the ability to deal with problems in a positive manner.*⁶

NURSING PRIORITY NO. 2 To assist client to deal with feelings/situation:

- Develop nurse-client relationship. *Individual can express feelings and concerns freely when he or she feels safe to do so.*

-  Discuss personal beliefs that may hinder participation in religious activities. *Provides opportunity for self-reflection such as own worthiness and ability to forgive self for past decisions or life choices.*⁵
- Use therapeutic communication skills of active listening, reflection, and “I” messages. *Helps client to find own solutions to problems/concerns and promotes sense of control.*⁴
- Have client identify and prioritize current and immediate needs. *Dealing with current needs is easier than trying to predict the future. Also, it is important to take care of basic needs before moving on to higher needs.*⁴
- Provide time for nonjudgmental discussion of individual’s spiritual beliefs and fears about impact of current illness and/or treatment regimen. *Helps to clarify thoughts and promote ability to deal with stresses of what is happening.*
- Review with client past difficulties in life and coping skills that were used at that time. *Recalling problems with family, peers, and colleagues or individuals in position of authority can help client to remember how those were handled and how those skills could be used in current situation.*
- Encourage client to discuss feelings about death and end-of-life issues when illness or prognosis is grave. *People are often afraid to talk about the possibility of their own death for fear it will bring reality to self and upset family. Note: A 2015 study investigated whether spirituality/religiosity (S/R) plays an important role in the lives of cancer patients and in the work of health professionals who provide care for these patients. It was demonstrated that 94.1% of patients considered it important that health professionals addressed their spiritual beliefs, and 99.2% of patients relied on S/R to face cancer.*^{1,8}

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Have client identify support systems available. *Individual will usually know who can provide the best support for him/her in present situation. Family may not be the most supportive if they don’t want to accept the reality of client’s illness or situation.*⁵
- Help client learn relaxation techniques, meditation, guided imagery, and mindfulness (living in the moment and enjoying it). *Learning to relax can help client to process information and make decisions in a more positive manner.*⁴
- Take the lead from the client in initiating participation in religious activities, prayer, and other activities. *Client may be vulnerable in current situation and needs to be allowed to decide own participation in these actions. Living and participating in desired religious activities will help client to understand the tenets of his or her choice.*⁷
-  Refer to appropriate resources such as crisis counselor, governmental agencies, spiritual advisor (who has qualifications or experience dealing with specific problems such as death or dying process, relationship problems, substance abuse, suicide), hospice, psychotherapy, and Alcoholics or Narcotics Anonymous. *May require additional help to deal with current situation.*^{4,6}

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including risk factors, nature of current distress.
- Physical and emotional response to distress.
- Access to and use of resources.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Available resources and specific referrals made.

Relocation Stress Syndrome

Taxonomy II: Coping/Stress Tolerance—Class 1 Post-Trauma Responses (00114) [**Diagnostic Division:** Ego Integrity], Approved 1992; Revised 2000, 2017

DEFINITION: Physiological and/or psychosocial disturbance following transfer from one environment to another.

RELATED FACTORS

Move from one environment to another; significant environmental change
 Ineffective coping strategies; impaired psychosocial functioning; powerlessness
 Insufficient support system; insufficient predeparture counseling; unpredictability of experience
 Social isolation; language barrier

DEFINING CHARACTERISTICS

Subjective

Anxiety [e.g., separation]; anger
 Insecurity; worry; fear
 Loneliness; depression
 Unwillingness to move; concern about relocation
 Alteration in sleep pattern

Objective

Increase in verbalization of needs; preoccupation
 Pessimism; frustration
 Increase in physical symptoms or illness
 Withdrawal; aloneness; alienation
 Loss of identity or self-worth; low self-esteem; dependency

At Risk Population: History of loss

Associated Condition: Compromised health status; impaired psychosocial functioning
 Deficient mental competence

Sample Clinical Applications: Chronic conditions (e.g., multiple sclerosis [MS], asthma, cystic fibrosis), brain injury, stroke, dementia, schizophrenia, developmental delay, end-of-life/hospice care

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Psychosocial Adjustment: Life Change: Adaptive psychosocial response of an individual to a significant life change

Quality of Life: Extent of positive perception of current life circumstances

Coping: Personal actions to manage stressors that tax an individual's resources

Client Will (Include Specific Time Frame)

- Verbalize understanding of reason(s) for change.
- Demonstrate appropriate range of feelings and reduced fear.
- Participate in routine and special or social events, as able.
- Verbalize acceptance of situation.
- Experience no catastrophic event.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Relocation Stress Reduction: Assisting the individual to prepare for and cope with movement from one environment to another

Hope Inspiration: Enhancing the belief in one's capacity to initiate and sustain actions

Family Involvement Promotion: Facilitating participation of family members in the emotional and physical care of the patient

NURSING PRIORITY NO. 1 To assess degree of stress as perceived/experienced by client and determine issues of safety:

-  Determine situation or cause for relocation (e.g., planned move for new job, change in marital status, deployment or returning from military duty, loss of home or community due to natural or human-caused disaster, deterioration in health status or ability to care for self, caregiver burnout, older parent being requested to move closer to adult child). *Although nursing and medical research is early and inconclusive in validating the defining characteristics of relocation stress syndrome as a nursing diagnosis,^{1,7,12,13} the belief that stress associated with relocation can be extreme is widely accepted in society. The effects of relocation can be minimal and transient or very troubling and persistent.¹⁴*
-  Note client's age, developmental level, and role in family. *Age and position in life cycle make a difference in the impact of issues involved in relocating. For example, children can be traumatized by transfer to new school and loss of friends and familiar surroundings. Note: One major reason that children are negatively affected by moves is that moves they are often precipitated by family problems (e.g., a divorce, death of a significant other; job loss).² Older persons may be affected by loss of their long-term home with its memories, neighborhood setting, and support persons.⁸*
-  Identify cultural or religious concerns that may affect client's coping or impact social interactions and expectations. *Cultural norm may be that elders are cared for by family—not placed in a facility—causing client to feel abandoned, or individual may be required to defer to family decision maker and feel powerless in determining own destiny.⁸*
-  Note ethnic ties and primary language spoken and read. *During times of stress, individuals may revert to language of childhood. This affects healthcare providers who must try to reduce the client's feelings of alienation or confusion while communicating with client of another primary language or client who is displaced from cultural attachments.⁴*

- Ascertain if client participated in the decision to relocate and perceptions about change(s) and expectations for the future. *A forced relocation is much more stressful than one that is desired. Also, client may be concerned that move/or placement will deplete savings or be fearful of being a burden on family members.*
- Determine involvement of family/significant others (SOs). Note availability and use of support systems and resources. Ascertain presence or absence of comprehensive information and planning (e.g., when and how move took place, if the environment for the client is similar or greatly changed). *These factors can greatly affect client's ability to adjust to change.*
- Note signs of increased stress in recently relocated client. *Client may report or demonstrate irritability, withdrawal, crying, moodiness, problems sleeping, or fatigue; "new" physical discomfort or pain (e.g., stomachaches, headaches, back pain); change in appetite; increased use of alcohol or other drugs; or greater susceptibility to colds.*^{3,8,9}
- Observe behavior, noting presence of increasing anxiety, suspiciousness or paranoia, and defensiveness. Compare with SO's/staff's description of customary responses. *Relocation may temporarily exacerbate mental deterioration (cognitive inaccessibility) and impair communication (social inaccessibility).*
- Identify issues of safety that may be involved, such as difficulty adjusting to new environment (e.g., navigating streets or choosing correct bus; locating dining hall or bathroom in facility) or concerns of elopement or running away.

NURSING PRIORITY NO. 2 To assist client to deal with situation/changes:

-  Collaborate in treatment of underlying conditions (e.g., chronic confusional states, brain injury, posttrauma rehabilitation), and physical stress symptoms *that are potentially exacerbating relocation stress or that may affect the length of time that relocation is required.*
- Begin relocation planning with client and SOs as early as possible. Provide support and advocate for client who is unable to participate in decisions. *Having a well-organized plan for move with support and advocacy may reduce anxiety.*^{9,15}
- Encourage free expression of feelings about reason for relocation, including venting of anger; grief; loss of personal space, belongings, and friends; financial strains; powerlessness; etc. Acknowledge reality of situation and maintain hopeful attitude regarding move or change. *Bringing feelings out into the open helps clarify emotions and make feelings easier to deal with.*^{6,9} Refer to NDs relating to client's particular situation (e.g., ineffective Coping, Grieving) for additional interventions.
- Anticipate variety of emotions and reactions. *May vary from insomnia and loss of appetite to becoming involved with alcohol or other drugs, exacerbation of health problems, onset of serious illness, or behavioral problems.*
- Identify strengths and successful coping behaviors the individual has used previously. *Incorporating these into problem-solving builds on past successes.*
- Encourage client to maintain contact with friends (e.g., telephone, letters, e-mail, video/audiotapes, arranged visits) *to reduce sense of isolation.*
-  Provide client with information and list of local social groups, assistance organizations or community services (e.g., Welcome Wagon, senior citizens or teen clubs, churches, singles' groups, sports leagues) *to provide contacts for client to develop new relationships and learn more about the new setting.*⁶
-  Obtain interpreter (where language differences exist) *to exchange information with the client/SO regarding residence or relocation wishes and to make helpful referrals.*⁴
-  Refer to professionals (e.g., social worker, financial resources, mental healthcare provider, minister or spiritual advisor) if serious difficulties develop (e.g., depression, alcohol or other drug abuse, deteriorating behavior of child) *to assist client with special needs and/or persistent problems with adaptation.*^{3,10}
-  Take practical steps to alleviate stress for child. Encourage parents to walk with child to school or rehearse boarding the school bus, visit new classroom, contact friends child left behind, drive past places of interest to child, find a safe play place, unpack child's favorite toys, invite neighborhood children to a get-acquainted party, etc. *Helps child to maintain ties and develop new ones, thus reducing sense of loss and shifting focus to the future.*²

-  Facilitate client's adjustment to new environment or facility:^{5,8,9,11,16}
 Determine client's usual schedule of activities and incorporate into facility routine, as possible. *Reinforces sense of importance of individual.*
 Orient to surroundings and schedules and repeat directions, as needed.
 Introduce to new staff members, roommate, and other residents. Encourage sharing of life story with others.
 Provide clear, honest information about actions and events.
 Provide consistency in daily routine; maintain same staff with client in new facility, as possible, during adjustment phase.
 Address ways to preserve lifestyle (e.g., usual bath and bedtimes in new facility, involvement in church activities). *Helps reduce the sense of loss associated with move.*
 Encourage individual/family to personalize area with pictures, own belongings, etc., as soon as possible. *Enhances sense of belonging, self-expression, and creation of personal space.*
 Introduce socialization and diversional activities, such as meals with new acquaintances, art therapy, music, movies, etc. *Involvement increases opportunity to interact with others and form new friendships, thus decreasing isolation and stress reactions.*
 Encourage hugging and use of touch unless client prefers to abstain from hugging or is paranoid or agitated at the moment. *Human connection reaffirms acceptance of individual.*
 Place in private room, if appropriate, and include SO(s)/family in care activities, mealtime, etc. *Keeping client secluded may be needed under some circumstances (e.g., advanced Alzheimer's disease with fear or aggressive reactions) to decrease the client's stress reactions to new environment.*
 Deal with aggressive behavior by imposing calm, firm limits. Control environment and protect others from client's disruptive behavior. *Promotes safety for client/others.*
 Remain calm, place in a quiet environment, and provide a time-out to prevent escalation of disruptive behaviors (e.g., panic state, violence).
 Anticipate and address feelings of distress and grieving in family/caregivers when placing loved one in a different environment (e.g., nursing home, foster care). *Support and referrals may be needed to help SOs in practical issues and adjustment.*

NURSING PRIORITY NO. 3 To enhance adjustment (Teaching/Discharge Considerations):

-  Involve client in formulating goals and plan of care when possible. *Supports independence and commitment to achieving outcomes.*
- Encourage communication between client/family/SO to provide mutual support and problem-solving opportunities.³
- Discuss benefits of adequate nutrition, rest, and exercise to maintain physical well-being and reduce adverse effects of stressful situation.
- Instruct in anxiety- and stress-reduction activities (e.g., meditation, other relaxation techniques, exercise program, group socialization), as able, to enhance psychological well-being and coping abilities.
- Encourage participation in activities, hobbies, or personal interactions, as appropriate. *Promotes creative endeavors, stimulating the mind.*
- Identify community support or cultural or ethnic groups client can access.
- Support self-responsibility and coping strategies to foster sense of control and self-worth.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Assessment findings, individual's perception of the situation and changes, specific behaviors.
- Cultural or religious concerns.
- Safety issues.

Planning

- Note plan of care, who is involved in planning, and who is responsible for proposed actions.
- Teaching plan.

Implementation/Evaluation

- Response to interventions (especially time-out or seclusion), teaching, and actions performed.
- Sentinel events.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

risk for Relocation Stress Syndrome

Taxonomy II: Coping/Stress Tolerance—Class 1 Post-Trauma Responses (00149) [Diagnostic Division: Ego Integrity], Approved 2000; Revised 2013, 2017

DEFINITION: Susceptible to physiological and/or psychosocial disturbance following transfer from one environment to another that may compromise health.

RISK FACTORS

Move from one environment to another; significant environmental change
 Ineffective coping strategies; impaired psychosocial functioning; powerlessness
 Insufficient support system; insufficient predeparture counseling; unpredictability of experience
 Social isolation; language barrier

At Risk Population: History of loss

Associated Condition: Compromised health status; impaired psychosocial functioning
 Deficient mental competence

Sample Clinical Applications: Chronic conditions (e.g., multiple sclerosis [MS], asthma, cystic fibrosis), brain injury, stroke, dementia, schizophrenia, developmental delay

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Psychosocial Adjustment: Life Change: Adaptive psychosocial responses of an individual to a significant life change

Quality of Life: Extent of positive perception of current life circumstances

Grief Resolution: Personal actions to adjust thoughts and behaviors to actual or impending loss

Client Will (Include Specific Time Frame)

- Verbalize understanding of reason(s) for change.
- Express feelings and concerns openly and appropriately.
- Experience no catastrophic event.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Discharge Planning: Preparation for moving a patient from one level of care to another within or outside the current healthcare agency

Relocation Stress Reduction: Assisting the individual to prepare for and cope with movement from one environment to another

Emotional Support: Provision of reassurance, acceptance, and encouragement during times of stress

NURSING PRIORITY NO. 1 To identify risk/contributing factors:

-  Determine situation or cause for relocation (e.g., planned move for new job, deployment or returning from military duty, change in marital status, loss of home or community due to natural or human-caused disaster, deterioration in health status or ability to care for self, caregiver burnout, older parent being requested to move closer to adult child). *Although nursing research is early and inconclusive in validating the defining characteristics of relocation stress syndrome as a nursing diagnosis,^{1,3,7,8} the belief that stress associated with relocation can be extreme is widely accepted in society. The effects of relocation can be minimal and transient or very troubling and persistent.⁹*
-  Note client's age, developmental level, and role in family. *Age and position in life cycle make a difference in the impact of issues involved in relocating. For example, children can be traumatized by transfer to new school, loss of friends and familiar surroundings,² and older persons may be affected by loss of their long-term home with its memories, neighborhood setting, and support persons.⁴*
-  Identify cultural and/or religious concerns that may affect client's coping or impact social interactions and expectations. *Cultural norm may be that elders are cared for by family—not placed in a facility—causing client to feel abandoned, or individual may be required to defer to family decision maker and feel powerless in determining own destiny.⁴*
-  Note ethnic ties and primary language spoken and read. *During times of stress, individuals may lapse into language of childhood. This affects healthcare providers who must try to reduce client's feelings of alienation while communicating with client of another primary language or client who is displaced from cultural, familial attachments.⁵*
- Ascertain if client has participated in the decision to relocate, perceptions about change(s), and expectations for the future. *Decision may have been made without client's input or understanding of event or consequences, which can impact adjustment. A forced relocation is much more stressful than one that is desired. Client may be concerned that temporary placement will deplete savings or may be fearful of being a burden on family members and may have felt pressured to move.⁴*
- Note whether relocation will be temporary (e.g., extended care for rehabilitation therapies, moving in with family while house being repaired after fire) or long term or permanent (e.g., move from home of many years, placement in long-term care facility). *To some degree, a temporary relocation is usually easier to cope with*

than a permanent relocation. However, any anticipated disruption of the client's usual way of living is upsetting, and emotional responses aren't always congruent with the magnitude of the event.

- Determine involvement of family/significant others (SOs). Note availability and use of support systems and resources. Ascertain presence or absence of comprehensive information and planning (e.g., when and how move will take place, if the environment for the client will be similar or greatly changed). *These factors can greatly affect client's ability to cope with change.*

NURSING PRIORITY NO. 2 To prevent/minimize adverse response to change:

-  Collaborate in treatment of underlying conditions (e.g., chronic confusional states, brain injury, posttrauma rehabilitation) and physical stress symptoms *that could exacerbate relocation stress or that affect length of time that relocation may be needed.*
- Provide information to client/SO as early in process as possible *to eliminate misconceptions and facilitate decision-making process. This can include obtaining audiovisual materials or Web sites about the new home, city, region, or country.*^{5,6}
-  Discuss relocation or move with child. *Information for child must be aimed at level of understanding and interest.*² *Child lacks ability to put problem into perspective, so minor mishap may seem catastrophic. Also, child is more vulnerable to stress because he or she has less control over environment than most adults.*⁶
-  Avoid moving adolescent in middle of school year when possible. *Adolescent is vulnerable to emotional, social, and cognitive dysfunction because of the great importance of peer group and loss of friends and social standing caused by relocation.*⁶
-  Involve client in placement choices when possible (e.g., move to nursing home or adult foster care) *to provide client with some control over the situation.*
-  Encourage visit to new community, surroundings, or school before transfer when possible. *Provides opportunity to "get acquainted" with new situation, reducing fear of unknown.*
-  Suggest contact with someone (friend, family, business associate) who has been to or lived in new area where move is being planned *to absorb some of that person's experience and knowledge.*^{5,6}
- Take practical steps to alleviate stress for child. Encourage parents to walk with child to school or rehearse boarding the school bus, visit new classroom, contact friends child left behind, drive past places of interest to child, find a safe play place, unpack child's favorite toys, invite neighborhood children to a get-acquainted party, etc. *Helps child to maintain ties and develop new ones, reducing sense of loss and shifting focus to the future.*²
- Encourage free expression of feelings about reason for relocation. Acknowledge reality of situation and maintain hopeful attitude regarding move or change. *Bringing feelings out into the open helps clarify emotion and make feelings easier to deal with.*⁶

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Involve client in formulating goals and plan of care when possible. *Fosters sense of control and self-worth, supports independence and commitment to achieving outcomes.*
- Encourage client/SO to accept that relocation is an adjustment and that it takes time to adapt to new circumstances or environment.
- Instruct in anxiety- and stress-reduction activities (e.g., meditation, other relaxation techniques, exercise program, group socialization) as able *to enhance psychological well-being and coping abilities.*
- Provide client with information and list of organizations or community services (e.g., Welcome Wagon, senior citizens or teen clubs, churches, singles' groups, sports leagues) *to provide contacts for client to develop new relationships and learn more about the new setting.*¹⁰
- Discuss safety issues regarding new environment (e.g., how to navigate streets or choose correct bus, locate dining hall or bathroom in facility) and concerns of elopement or running away. *May help prevent adverse reactions.*
- Anticipate variety of emotions and reactions. *May vary from insomnia and loss of appetite to becoming involved with alcohol or other drugs, exacerbation of health problems, onset of serious illness, or behavioral problems. Awareness provides opportunity for timely intervention.*⁶
- Refer to ND Relocation Stress Syndrome for additional interventions.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Assessment findings, individual's perception of the situation/changes, specific behaviors.
- Cultural or religious concerns.
- Safety issues.

Planning

- Note plan of care, who is involved in planning, and who is responsible for proposed actions.
- Teaching plan.

Implementation/Evaluation

- Response to interventions (especially time-out/seclusion), teaching, and actions performed.
- Sentinel events.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

impaired Resilience

Taxonomy II: Coping/Stress Tolerance—Class 2 Coping Responses (00210) [Diagnostic Division: Ego Integrity], Approved 2008; Revised 2013, 2017

DEFINITION: Decreased ability to recover from perceived adverse or changing situations, through a dynamic process of adaptation.

RELATED FACTORS

Community violence

Disruption in family rituals or roles; inconsistent parenting

Disturbance in family dynamics; dysfunctional family processes; ineffective family adaptation

Inadequate or insufficient resources

Insufficient social support; perceived vulnerability

Multiple coexisting adverse situations; substance misuse/[abuse]

(continues on page 706)

impaired Resilience (continued)

DEFINING CHARACTERISTICS

Subjective

Depression; guilt; shame
 Impaired health status
 Renewed elevation of distress
 Decreased interest in academic or vocational activities

Objective

Ineffective coping skills; social isolation; low self-esteem
 Ineffective integration or sense of control

At Risk Population: Chronicity of existing crisis; new crisis; demographics that increase chance of maladjustment

Economically disadvantaged; ethnic minority status; exposure to violence

Female gender; large family size

Low intellectual ability or maternal educational level

Parental mental illness

Associated Condition: Psychological disorder

Sample Clinical Applications: Substance abuse, mental health issues—depression, phobia, bipolar disorder, schizophrenia; chronic illness—renal failure, heart failure, cancer; debilitating conditions—multiple sclerosis (MS), Parkinson's disease, obesity; domestic abuse or violence

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Personal Resiliency: Positive adaptation and function of an individual following significant adversity or crisis

Hope: Optimism that is personally satisfying and life-supporting

Family Resiliency: Capacity of a family to positively adapt and function following significant adversity or crisis

Client Will (Include Specific Time Frame)

Acknowledge reality of current situation or crisis.

Express positive feelings about self and situation.

Seek appropriate resources to change circumstances that affect adaptation and resilience.

Be involved in programs to address problems presenting in life (e.g., substance abuse, low self-esteem, poverty).

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Resiliency Promotion: Assisting individuals, families, and communities in development, use, and strengthening of protective factors to be used in coping with environmental and societal stressors

Hope Inspiration: Enhancing the belief in one's capacity to initiate and sustain actions

Family Mobilization: Utilization of family strengths to influence patient's health in a positive direction

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Determine individuals involved, family, children, ages, and current circumstances. *Understanding the family makeup provides information that will guide choice of interventions.*¹
- Note underlying stressors, health concerns, debilitating conditions, and mental health or behavioral issues, such as unemployment, poverty, diabetes, obesity, chronic obstructive pulmonary disease, Alzheimer's disease, and parental mental illness. *Provides information about situation to plan appropriate care.*^{1,5}
- Identify locus of control. *Individuals with external locus of control are less likely to feel in control or rely on their own abilities or judgment to manage a situation.*^{1,2,6}
- Determine client's education level, family dynamics, and parenting styles if relevant. *Drug use, violence, and poor impulse control affect ability of individual to develop resilience to adverse situations or crisis and may result in individual viewing self as a victim rather than a survivor.*^{1,3}
- Note communication patterns within the family. *Skills learned within the family can make the difference between whether the individual develops low self-esteem or has positive feelings about self.*
- Identify maladaptive coping skills used by individual and in the family. *The use of food or drugs to deal with feelings, acting-out behaviors or violence, devaluing education or importance of learning new skills, and focusing on the negative in situations lead to members learning these methods of dealing with problems and difficulties that arise, resulting in lack of ability to adjust positively and learn attributes of resiliency.*³
- ∞ Note parental status including age and maturity. *Young parents may lack ability to deal with family responsibilities, financial concerns, and low socioeconomic factors.*^{2,10}
- Ascertain stability of relationship, presence of separation or divorce. *Family members are vulnerable to breakup of the family unit and, depending on perception and circumstances, see it as causing long-term liability.*⁴
- Determine availability and use of resources, family, support groups, and financial. *Appropriate use can help individuals overcome and manage problems in their lives.*
- 🌐 Discuss religious and cultural beliefs held by the individual and family. *Including the members of the family in this discussion promotes the idea that they are partners in their healthcare and enables them to learn and have input into how these beliefs affect what they do. Knowing the role of the elements of culture in shaping and defining health behavior helps the family understand how this is important to them.*⁵

NURSING PRIORITY NO. 2 To assist client to improve skills to deal with adverse situations or crises:

- Encourage free expressions of feelings, including feelings of anger and hostility, setting limits on unacceptable behavior. *When feelings are verbalized, client begins to identify them and recognize how they affect personal behavior. Unacceptable behavior leads to feelings of shame and guilt if it is not controlled.*^{1,2}
- Listen to client's concerns and acknowledge difficulty of adversity and making changes in situation. *Often, individuals who are feeling that life is difficult begin to doubt their ability to deal with circumstances and are not able to see positive outcomes. Being listened to provides opportunity for client to feel valued, capable, and like a survivor rather than a victim.*³
- Help client to assume responsibility for own life, to look at situation as a challenge rather than an obstacle, and to refrain from viewing crisis as insurmountable. *Resilience is not something that people have or do not have; it is learned and developed in people as they deal with adversities of life. Taking care of oneself keeps the mind ready to deal with adverse situations.*^{3,6,9}
- Provide information at client's level of comprehension, being honest in explanations. *Provides data to assist in decision-making process and enhances client's cooperation in change process.*¹
- Have client paraphrase information provided during teaching session. *Assures client's understanding and provides opportunity to correct misunderstandings.*¹
- Promote parent involvement in developing a positive mind-set for fostering resilience in their children. *Parents are concerned that their children grow up to be competent adults. They can learn the parenting skills that promote optimal growth and resilience in their children for the problems they will face as grown-ups.*^{3,9}

- Facilitate communication skills between client and family. *Sometimes, individuals who find themselves in difficult situations withdraw because they do not know what to do or say. Helping the client to learn new ways to interact will not only help him or her but also help family members learn effective ways of communicating.*^{2,3,7}
- Focus on strengths of the individual as problems are being assessed and diagnosed. *Improving the future for the client is based on developing the capacity to deal successfully with the obstacles he or she meets in life.*³
- Encourage client/parents to model empathy with family members. *Empathy is an important interpersonal skill and a cornerstone of emotional intelligence.*⁸ *Children learn empathy when parents are empathic with them.*^{2,6}
- Discuss individual issues, such as obesity, substance use, poor impulse control, or violent behavior, providing information about the risks and helping client/parent understand how he or she can help family members develop habits that will promote physical and mental well-being. *For example, recent studies suggest that encouraging children to reduce sedentary behavior (e.g., watching TV, playing video games) can promote weight loss and reduce the intake of calorie-dense foods. Choosing enjoyable exercise and video games that provide for movement helps to improve feelings of satisfaction and sense of control.*^{3,9}

NURSING PRIORITY NO. 3 To promote resilience (Teaching/Discharge Considerations):

-  Reinforce that client is responsible for self, for choices made, and actions taken. *The road to resilience is developed by the individual accepting that change is a part of living and beginning to live life more fully.*^{3,9}
-  Provide or identify learning opportunities specific to individual needs. *Activities such as assertiveness, regular exercise, and parenting classes can enhance knowledge and help develop a resilience mind-set.*^{1,2,6}
- Discuss use of the problem-solving method to set mutually agreed-on goals. *As family accepts solutions that are acceptable to each member, their self-esteem is enhanced and individuals are more apt to follow through on decisions.*^{2,3,10}
- Provide anticipatory guidance relevant to current situation and long-term expectations. *Client may have many issues to resolve, and planning ahead can help client make changes, have hope for the future, and have a sense of control over his or her life.*
- Encourage client/parents to take time for themselves. *They may believe they need to devote all their time to the family and feel guilty if they take time for themselves. This provides an opportunity for personal growth, and respite allows individuals to pursue own interests and return to tasks of life or parenting with renewed vigor.*²
-  Refer to community resources as appropriate, such as social services, financial, domestic violence or elder abuse program, family therapy, divorce counseling, and special needs support services. *Appropriate support enhances ability to develop resilience in challenges client is dealing with.*¹⁰

DOCUMENTATION FOCUS

Assessment/Reassessment

- Findings, including specifics of individual situations or parental concerns, perceptions, expectations.
- Locus of control and cultural beliefs.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

readiness for enhanced Resilience

Taxonomy II: Coping/Stress Tolerance—Class 2 Coping Responses (00212) [Diagnostic Division: Ego Integrity], Approved 2008; Revised 2013

DEFINITION: A pattern of ability to recover from perceived adverse or changing situations through a dynamic process of adaptation, which can be strengthened.

DEFINING CHARACTERISTICS

Subjective

Expresses desire to enhance:

- Communication skills, relationships with others
- Use of coping skills, conflict management strategies
- Resilience, self-esteem, positive outlook
- Involvement in activities, own responsibility for action, sense of control
- Goal-setting, progress toward goal
- Support system, available resources, use of resources
- Environmental safety

Sample Clinical Applications: Chronic health conditions (e.g., asthma, diabetes mellitus, arthritis, systemic lupus, multiple sclerosis [MS], AIDS); mental health concerns (e.g., depression, anxiety, bipolar disorder, attention deficit-hyperactivity disorder)

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Personal Resiliency: Positive adaptation and function of an individual following significant adversity or crisis

Hope: Optimism that is personally satisfying and life-supporting

(continues on page 710)

readiness for enhanced Resilience (continued)

Family Resiliency: Capacity of a family to positively adapt and function following significant adversity or crisis

Client Will (Include Specific Time Frame)

- Describe current situation accurately.
- Identify positive responses currently being used.
- Verbalize feelings congruent with behavior.
- Express desire to strengthen ability to deal with current situation or crisis.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Resiliency Promotion: Assisting individuals, families, and communities in development, use, and strengthening of protective factors to be used in coping with environmental and societal stressors

Hope Inspiration: Enhancing the belief in one's capacity to initiate and sustain actions

Family Mobilization: Utilization of family strengths to influence patient's health in a positive direction

NURSING PRIORITY NO. 1 To determine needs and desires for improvement:

- Evaluate client's perception and ability to provide a realistic view of the situation. *Provides information about how the client views the situation and specific expectations to aid in formulating plan of care.*⁵
- Determine client's coping abilities in current situation and expectations for change. *Client may be stressed to the point of having difficulty coping, recognizing need to improve ability to manage.*^{4,6} *Motivation to improve and high expectations can encourage client to make changes that will improve his or her life. However, unrealistic expectations may hamper efforts.*
- Note client's verbal expressions indicating belief that he or she owns the responsibility for how to deal with adverse situation. *When client has internal locus of control, he or she accepts that life has its adversities and one needs to deal with them.*³
-  Discuss religious and cultural beliefs held by the individual. *Knowing the role of the elements of culture and religion in shaping and defining health behaviors and expectations of client helps determine individual needs and possible options.*¹
- Identify support systems available to client. *Having family and friends who are willing to listen as client works through problems can help to resolve them.*⁵

NURSING PRIORITY NO. 2 To assist client to enhance resilience to adverse situation:

- Active-listen and identify client's concerns about situation. *Reflecting client's statements helps to clarify what he or she is thinking and promotes accurate interpretation of reality.*²
- Determine previous methods of dealing with adversity. *Helps client to remember successful skills used in the past and see what might be helpful in current situation.*³
- Discuss desire to improve ability to handle adverse situations that arise throughout life. *The willingness to be open to change requires curiosity, listening to other's ideas and beliefs, and looking at new ways to do things.*³
- Discuss concept of what can be changed versus what cannot be changed. *Understanding that some things cannot be changed helps client to focus energies on those things that can be changed.*²
- Determine how client is dealing with activities of daily living. *While client may have some transient problems with sleeping or managing daily affairs, most people have the ability to function in a healthy manner over time.*⁶

- Help client to learn how to empathize with others. *Understanding own emotions as well as feelings of others enhances one's resiliency during stressful times.*⁴

NURSING PRIORITY NO. 3 To promote optimum growth and resiliency:

-  Provide factual information and anticipatory guidance relevant to current situation and long-term expectations. *Planning ahead allows for problem-solving and review of options in a relaxed atmosphere, reinforcing sense of control and hope for the future.*³
- Review factors that might impact individual's response to stress. *Genetic influences, past experiences, and existing conditions can determine whether the client's response is adaptive or maladaptive and help individual to be resilient.*³
- Encourage client to maintain or establish good relationships with family and friends. *These connections are important, and accepting help and support from others enhances own coping and strengthens resilience.*⁷
- Help client to avoid seeing situation as insurmountable. *Catastrophic thinking locks individual into believing he or she has no control over outcome. While one cannot change the fact of the circumstances, how individual interprets and responds is within his or her control.*⁷
- Recommend setting realistic goals and doing something regularly, even if it is small. *Moving toward goals encourages a feeling of accomplishment and self-esteem.*⁷
- Encourage client to maintain a hopeful outlook, nurture a positive view of self, and take care of self. *Keeping a long-term perspective and paying attention to own needs help maintain and build resilience.*⁷
-  Refer to classes and/or reading materials as appropriate. *Learning skills of meditation and assertiveness and engaging in enjoyable exercises help to foster resilience.*^{3,7}

DOCUMENTATION FOCUS

Assessment/Reassessment

- Baseline information, including client's perception of situation, view of own ability to be resilient, and support systems available.
- Ways of dealing with previous life problems.
- Motivation and expectations for change.
- Cultural or religious influences.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcomes(s).
- Modifications to plan.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

risk for impaired Resilience

Taxonomy II: Coping/Stress Tolerance—Class 2 Coping Responses (00211) [**Diagnostic Division:** Ego Integrity], Approved 2008; Revised 2013, 2017

DEFINITION: Susceptible to decreased ability to recover from perceived adverse or changing situations, through a dynamic process of adaptation, which may compromise health.

RISK FACTORS

Community violence

Disruption in family rituals or roles; inconsistent parenting

Disturbance in family dynamics; dysfunctional family processes; ineffective family adaptation

Inadequate or insufficient resources

Insufficient social support; perceived vulnerability

Multiple coexisting adverse situations; substance misuse/[abuse]

At Risk Population: Chronicity of existing crisis; new crisis; demographics that increase chance of maladjustment

Economically disadvantaged; ethnic minority status; exposure to violence

Female gender; large family size

Low intellectual ability or maternal educational level

Parental mental illness

Associated Condition: Psychological disorder

Sample Clinical Applications: Chronic or debilitating illness (e.g., Alzheimer's disease, multiple sclerosis [MS], Parkinson's disease, Crohn's disease, diabetes, heart failure, cancer, renal failure); mental health issues (e.g., depression, anxiety)

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Personal Resiliency: Positive adaptation and function of an individual following significant adversity or crisis

Hope: Optimism that is personally satisfying and life supporting

Family Resiliency: Capacity of a family to positively adapt and function following significant adversity or crisis

Client Will (Include Specific Time Frame)

- Acknowledge reality of individual situation or crisis.
- Verbalize feelings associated with chronic situation.
- Verbalize awareness of own ability to deal with problems.
- Identify resources for assisting with chronic and new adverse occurrence.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Resiliency Promotion: Assisting individuals, families, and communities in development, use, and strengthening of protective factors to be used in coping with environmental and societal stressors

Hope Inspiration: Enhancing the belief in one's capacity to initiate and sustain actions

Family Mobilization: Utilization of family strengths to influence patient's health in a positive direction

NURSING PRIORITY NO. 1 To determine individual stressors/potential challenges:

- Note underlying stressors, health concerns, debilitating conditions, and mental health or behavioral issues, such as unemployment, pregnancy, diabetes, Alzheimer's disease, and anxiety disorder. *Provides information about situation to plan appropriate care.*⁵
- Determine alcohol or other drug use, smoking, sleeping, and eating habits. *Affects ability to cope with added stress of crises effectively and in a healthy manner.*⁵
- Assess functional capacity and how it affects client's ability to manage daily needs. *Presence of physical impairments may bring additional stress to adverse situation and unplanned new crisis.*⁵
- Evaluate client's ability to verbalize and understand current situation and impact of new crisis. *Informed choice cannot be made without a good understanding of reality of situation.*⁵
- Note speech and communication patterns. *Provides information about level of education and ability to understand situation and relate problems to caregiver(s).*⁵
- Determine locus of control. *Individuals with external locus of control are less likely to feel in control or rely on their own abilities or judgment to manage a situation and may wait for someone else, or luck, to change the circumstances and make life better.*^{2,4,5}
- Evaluate client's current decision-making ability. *Crises affect individual's ability to think clearly and trust own ability to deal with situation.*³
- Ascertain stability of relationship, presence of separation or divorce, deteriorating health, or recent death of family member. *Family members are vulnerable to breakup of the family unit and, depending on perception and circumstances, may see it as causing long-term liability.*³

NURSING PRIORITY NO. 2 To assess coping skills and degree of resilience:

- Active-listen and identify client's perceptions of what has occurred as well as previous concerns. *Helps client to reflect back reality and distinguish between perceptions and actual events.*²
- Determine how adverse situation is affecting client's ability to deal with what is happening now. *When an unplanned situation occurs in addition to existing problems, it often results in decreased ability to maintain optimism.*^{3,5,8}
- Determine how individual has dealt with problems in the past. *Having client remember these skills helps client to recognize what can be used to enhance current response or address future challenges.*^{3,7}
-  Note cultural factors and religious beliefs that may affect situation. *Knowing how these factors shape and define health behavior and expectations of client/significant other (SO) helps determine individual needs and possible options.*¹
- Determine availability and use of resources, family, support groups, and financial. *Appropriate use can help individuals continue to manage problems in their lives and plan for future needs.*

NURSING PRIORITY NO. 3 To assist client to deal with current/future situation:

- Ask client what name he or she prefers. *Acknowledging how client wants to be addressed provides sense of self, promoting esteem.*⁵
- Encourage free expressions of feelings, including feelings of anger and hostility, setting limits on unacceptable behavior. *When feelings are verbalized, client begins to identify them and recognize how they affect personal behavior. Unacceptable behavior leads to feelings of shame and guilt if it is not controlled.*^{2,5}
- Allow client to react in own way without judgment by caregivers. Provide support and diversion as indicated. *Unconditional positive regard and support promote acceptance and help client to realize own ability to deal with situation.*⁶
- Listen to client's concerns and acknowledge difficulty of adversity and possible need to make changes. *Often, individuals who are feeling that life is difficult begin to doubt their ability to deal with circumstances. Being listened to provides opportunity for client to feel valued, capable, and like a survivor rather than a victim.*⁸
- Encourage communication with caregivers and SO(s). *Promotes effective interactions and common understanding of what is being said.*
- Provide reality orientation when necessary. *Depending on nature of crises, client may be disoriented by change in environment, serious diagnosis/treatment regimen, death of family member.*⁵
- Provide client with factual information and expected course of situation or crisis if known. *Knowledge helps to allay anxiety, enabling client to manage more effectively and begin to consider the possible resolution of the current situation.*⁷
- Focus on strengths of the individual as the problems are being assessed and diagnosed. *Treatment or intervention has often been based on a deficit model rather than a wellness approach. Improving the future for the client is based on strengthening the capacity to deal successfully with the obstacles he or she meets in life.*⁶

NURSING PRIORITY NO. 4 To promote optimum resiliency (Teaching/Discharge Considerations):

-   Provide or identify learning opportunities specific to individual needs. *Referral to activities, such as assertiveness training, regular exercise, parenting classes, can enhance knowledge and help develop a resilient mind-set.*^{2,3,5}
- Encourage an attitude of realistic hope. *Client can accept that change is a part of living, and while some goals cannot be attained because of crisis or new circumstances, new goals can be developed and life can move forward.*⁷
- Support client in evaluating current lifestyle and changes that will need to be made. *Helps to put things in perspective and develop new plans gradually to avoid undue anxiety.*⁹
- Provide anticipatory guidance relevant to current situation and long-term expectations. *Client may have many issues to resolve, and planning ahead can help client make changes, have hope for the future, and have a sense of control over his or her life.*³
-  Determine need or desire for religious, spiritual counselor and make arrangements for visit. *Spiritual needs are part of being human, and providing the client an opportunity to discuss concerns about what has happened helps to build resilience to face future stressors.*⁵
- Reinforce importance of clients/SO(s) taking time for themselves. *They may believe they need to devote all their time to the family and feel guilty if they take time for themselves. This provides an opportunity for personal growth; respite allows individuals to pursue own interests and return to tasks of life with renewed vigor.*^{2,9}
-  Refer to community resources as appropriate. *May need professional counseling, assistance with financial concerns, special needs support services, and child or parenting care in order to sustain move forward.*^{2,5}

DOCUMENTATION FOCUS

Assessment/Reassessment

- Assessment findings, including details of this client's situation or crisis, expectations.
- Client's degree of resiliency.

Planning

- Plan of care, and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Support systems available, specific referrals made.

[acute/chronic] urinary Retention

Taxonomy II: Elimination and Exchange—Class 1 Urinary Function (00023) **[Diagnostic Division: Elimination]**, Approved 1986; Revised 2017

DEFINITION: Inability to empty bladder completely.

RELATED FACTORS

To Be Developed

DEFINING CHARACTERISTICS**Subjective**

Sensation of bladder fullness
Dribbling of urine
Small or frequent voiding; dysuria

(continues on page 716)

[acute/chronic] urinary Retention (continued)**Objective**

Bladder distention

Absence of urinary output

Residual urine

Overflow incontinence

Associated Condition: Blockage in urinary tract; strong sphincter

High urethral pressure; reflex arc inhibition

Sample Clinical Applications: Benign prostatic hyperplasia (BPH), prostatitis, cancer, perineal surgery, birth trauma, urethral calculi, multiple sclerosis (MS), spinal cord compression, urinary tract infection (UTI), genital herpes**DESIRED OUTCOMES/EVALUATION CRITERIA****Sample NOC linkages:****Urinary Elimination:** Collection and discharge of urine**Symptom Control:** Personal actions to minimize perceived adverse changes in physical and emotional functioning**Knowledge: Acute Illness Management:** Extent of understanding conveyed about a reversible illness, its treatment, and the prevention of complications**Client Will (Include Specific Time Frame)**

- Verbalize understanding of causative factors and appropriate interventions for individual situation.
- Demonstrate techniques or behaviors to alleviate or prevent retention.
- Void in sufficient amounts with no palpable bladder distention, experience no postvoid residuals greater than 50 mL, and have no dribbling or overflow.

ACTIONS/INTERVENTIONS**Acute Retention****Sample NIC linkages:****Urinary Catheterization:** Insertion of a catheter into the bladder for temporary or permanent drainage of urine**Urinary Retention Care:** Assistance in relieving bladder distention**NURSING PRIORITY NO. 1** To assess causative/contributing factors:

- Note presence of pathological conditions, such as neurological injury or disease; kidney or bladder infection or stone formation; and reaction to medications, diagnostic dye, or anesthesia, *that can cause mechanical obstruction, nerve dysfunction, ineffective contraction, or decompensation of detrusor musculature, resulting in ineffective emptying of the bladder and urine retention.*²
- ∞ Note client's gender and age. *Retention is most common among men (young men due to renal calculi) and older men (where prostate abnormalities or urethral strictures cause outlet obstruction). In either gender, retention may be due to medications); neurogenic bladder such as occurs with diabetes, multiple sclerosis, Parkinson's disease; pelvic surgery; or any other condition resulting in bladder denervation.*^{7,8,10}
- Investigate reports of sudden loss of ability to pass urine, great difficulty passing urine, pain with urination, blood in urine. *May indicate acute urinary retention due to UTI or outlet obstruction Note: Chronic urinary retention is typically painless and associated with increased volume of residual urine.*^{2,8}

-  Review results of lab tests, such as urinalysis for presence of red and white blood cells, nitrates, glucose, bacteria, and cultures, as indicated. Blood may be tested for infection, electrolyte imbalance, and (in men) prostate-specific antigen *to determine presence of treatable conditions.*
-  Review medication regimen *for drugs that can cause or exacerbate retention (e.g., psychotropics, opiates, sedatives, alpha and beta blockers, anticholinergics, antihistamines, neuroleptics, anesthesia).*^{2,8}
- Determine anxiety level. *Client may be too embarrassed to void in presence of others or talk about problem with care providers.*
- Examine for fecal impaction, pelvic or perineal surgical site swelling, postpartal edema, vaginal or rectal packing, enlarged prostate, or other “mechanical” factors *that may produce a blockage of the urethra.*
- Strain urine for presence of stones or calculi *that may be causing outlet obstruction or to note when treatments are being effective in stone breakup and removal.*²

NURSING PRIORITY NO. 2 To determine degree of interference/disability:

- Ascertain if client can empty bladder completely, partially, or not at all, in spite of urge to urinate. *Signs of urinary retention caused by (1) blockage of the urethra or (2) disruption of complex system of nerves that connects the urinary tract with the brain. In men, blockage is most commonly caused by enlargement of the prostate, cancer, stones, and urethral stricture. Causes that can occur in both genders include scar tissue, injury (as in car crash or fall), blood clots, infection, tumors, and stones (rare). Disruption of nerves or nerve transmission or interpretation of signals can be caused by injury (e.g., spinal cord injury [SCI] or tumor; herniated disk, stroke), pelvic infections, surgery, and certain medications.*^{1,2}
- Determine if there has been any significant urine output in the previous 6 to 8 hr. *Small amount of urine may leak out of bladder but generally not enough to relieve symptoms.*
- Note recent amount and type of fluid intake. *Adequate fluid intake is necessary for production of healthy output. If client is not voiding in spite of adequate fluid intake, fluids may be restricted temporarily to prevent bladder overdistention until adequate urine flow is established.*
- Palpate height of the bladder. Ascertain whether client has sensation of bladder fullness and his or her level of discomfort. *Sensation and discomfort can vary depending on underlying cause of retention. Most people with acute retention also feel pain in lower abdomen (pelvis). Back pain, fever, and painful urination may be present with retention if the cause is urinary tract infection.*
-  Catheterize, or perform a bladder scan or ultrasound, for bladder residual after voiding *to determine presence and degree of urine retention.*³
-  Review results of diagnostic tests. *Urine flow rate, bladder capacity, and postvoid residual scanning may be done. Ultrasound, computed tomography (CT) scan, intravenous pyelogram, and cystoscopy can help locate the source of obstruction (e.g., lower or upper tract). Lumbar spine radiographs, CT scan, or magnetic resonance imaging may be done when retention is thought to be due to an acute spinal problem (e.g., herniated disk, spinal cord disruption, infection).*^{2,3}

NURSING PRIORITY NO. 3 To assist in treating/preventing retention:

-  Assist in treatment to relieve mechanical obstruction (e.g., removal of blockage—vaginal packing, bowel impaction) or apply ice *to reduce perineal swelling.*
-  Administer medications as indicated (e.g., antibiotics, stool softeners, pain relievers) *to treat underlying cause.*
- Provide privacy *to reduce retention caused by embarrassment or anxiety.*
- Assist client to sit upright on toilet or commode or stand *to provide functional position of voiding.*
- Encourage warm sitz bath or shower, voiding in tub or shower if need be. *Warm water stimulates bladder to relax and may facilitate voiding.*
- Use ice techniques or spirits of wintergreen, stroke inner thigh, and run water in sink or warm water over perineum if indicated *to stimulate reflex arc.*

- Instruct client with mild or moderate obstructive symptoms to “double void” by urinating, resting on toilet for 3 to 5 min, and then making a second attempt to urinate. *Promotes more efficient bladder evacuation by allowing the detrusor to contract initially and then rest and contract again.*¹
-  Drain bladder (using the appropriate catheter material and size) intermittently or catheterize with indwelling catheter to resolve acute retention. *Note: A variety of urethral catheters are available. Some have been developed specifically to lower the risk of catheter-associated infection, such as antiseptic or antibiotic impregnated catheters.*⁹
-  Prepare for more intensive interventions (e.g., reconstructive surgery, lithotripsy, prostatectomy) as indicated to remove source of obstruction, reconstruct sphincter, or provide for urinary diversion.

NURSING PRIORITY NO. 4 To promote optimal elimination (Teaching/Discharge Considerations):

-  Emphasize good voiding habits (e.g., four to six times/day). *Postponing or holding urination for prolonged periods can, over time, overstretch and weaken bladder muscles.*
- Encourage client to report problems immediately *so treatment can be instituted promptly.*
- Encourage adequate fluid intake, including use of acidifying fruit juices or ingestion of vitamin C or Mandelamine *to discourage bacterial growth and stone formation.*⁸
- Adjust fluid intake and timing if indicated, *to prevent bladder distention.*

Chronic Retention

Sample **NIC** linkages:

Urinary Retention Care: Assistance in relieving bladder distention

Urinary Catheterization: Intermittent: Regular periodic use of a catheter to empty the bladder

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Review medical history for diagnoses, such as congenital defects, neurological disorders (e.g., MS, polio), prostatic hypertrophy or surgery, birth canal injury or scarring, and SCI with lower motor neuron injury or bladder stones, *that may cause detrusor-sphincter dyssynergia (loss of coordination between bladder contraction and external urinary sphincter relaxation), detrusor muscle atrophy, or chronic overdistention because of outlet obstruction.*^{7,10}
- Determine presence of weak or absent sensory or motor impulses (as with cerebrovascular accidents, spinal injury, or diabetes) *that predispose client to compromised enervation or interpretation of sensory signals resulting in impaired urination.*⁷
-  Assess client's medication regimen (e.g., psychotropic, antihistamines, atropine, belladonna) *to consult with primary care provider regarding client's continued use of drugs that are known to potentiate urinary retention.*

NURSING PRIORITY NO. 2 To determine degree of interference/disability:

- Ascertain effect of condition on functioning and lifestyle. *Chronic urinary retention can limit client's desired lifestyle (e.g., daily activities, social functioning) and can lead to chronic incontinence and life-threatening complications (e.g., intractable UTIs, kidney failure).*⁴
- Instruct client/significant other (SO) to maintain voiding log, noting dribbling and frequency and timing of voiding *to determine severity of condition.*¹
- Determine presence and severity (0–10 scale) of bladder spasms, pelvic pain, and other discomforts.
-  Assist with urodynamic testing (e.g., uroflowmetry *to assess urine speed and volume*, cystometrogram *to measure bladder pressure and volume*, bladder scan *to measure retention or postvoid residual*, leak point pressure).²

NURSING PRIORITY NO. 3 To assist in treating/preventing retention:

-  Collaborate in treatment of underlying conditions (e.g., medications to treat BPH, reducing or eliminating medications responsible for retention, repairing perineal scarring or outlet obstruction), *which may correct or reduce severity of retention and associated overflow or total incontinence.*¹⁰

-  Instruct client/SO in management of voiding problems as indicated:
Attempt voiding in complete privacy *to reduce embarrassment and distractions.*
Void on frequent, timed schedule *to maintain low bladder pressure and prevent overdistention of bladder.*
Maintain consistent fluid intake *to wash out bacteria, avoid infections, and limit bladder stone formation.*⁴
Adjust fluid amount and timing if indicated *to prevent bladder distention.*
-  Establish regular self-catheterization program, as indicated, *to prevent reflux and increased renal pressures and to improve client's quality of life (e.g., ability to participate in desired or needed activities and social interactions).* Note: Clean intermittent catheterization is a treatment option for individuals who can urinate but cannot completely empty their bladder.⁴⁻⁶
-  Perform and instruct client/SO in Credé's method (client or caregiver applies light pressure or tapping on the bladder) or Valsalva's maneuver (client tries to breathe out without letting air escape through the nose or mouth) if appropriate *to stimulate bladder emptying.* Note: Client with SCI and spastic bladder may be able to "trigger" the bladder to contract and avoid having to use a catheter.⁷
-  Consult with urologist and prepare for more intensive interventions (e.g., reconstructive surgery, lithotripsy, prostatectomy) as indicated *to remove source of obstruction, reconstruct sphincter, or provide for urinary diversion.*
-  Refer for consideration of advanced or research-based therapies (e.g., implanted sacral, tibial, or pelvic electrical stimulating device) *for long-term management of retention.*⁴

NURSING PRIORITY NO. 4 To promote optimum elimination (Teaching/Discharge Considerations):

-  Establish regular schedule for bladder emptying whether voiding or using catheter.
- Instruct SO/caregiver(s) in clean intermittent catheterization techniques *so that more than one individual is able to assist the client in care of elimination needs.*⁹
- Instruct client/SO in care when client has indwelling (urethral or suprapubic catheter) or urinary diversion device (e.g., clean technique, emptying and cleaning of leg bag or drainage bag; irrigation and replacement) *to promote self-care, enhance independence, and prevent complications.*⁵
- Emphasize need for adequate fluid intake, including use of acidifying fruit juices or ingestion of vitamin C or Mandelamine. *Maintains renal function, prevents infection and formation of bladder stones, and reduces risk of encrustation around indwelling catheter.*
-  Discuss appropriate use of herbal products *such as saw palmetto to improve symptoms of BPH.*
-  Review signs/symptoms of complications *to promote timely contact with healthcare provider for evaluation and intervention.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including nature of problem, degree of impairment, and whether client is incontinent.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

parental Role Conflict

Taxonomy II: Role Relationships—Class 1 Role Performance (00064) [Diagnostic Division: Social Interaction], Approved 1988; Revised 2017

DEFINITION: Parental experience of role confusion and conflict in response to crisis.

RELATED FACTORS

Interruptions in family life due to home-care regimen [e.g., treatments, caregivers, lack of respite]
Intimidated by invasive modalities [e.g., intubation]; or by restrictive modalities [e.g., isolation]
Parent-child separation

DEFINING CHARACTERISTICS

Subjective

Perceived inadequacy to provide for child's needs
Concern about change in parental role; concern about family [e.g., functioning, communication, health]
Perceived loss of control over decisions relating to child
Guilt; frustration; anxiety; fear

Objective

Disruption in caregiver routines
Reluctance to participate in usual caregiver activities

At Risk Population: Change in marital status

Home care of child with special needs

Living in nontraditional setting

Sample Clinical Applications: Prematurity, genetic or congenital conditions, chronic illness (parent/child)

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Parenting Performance: Parental actions to provide a child a nurturing and constructive physical, emotional, and social environment

Role Performance: Congruence of an individual's role behavior with role expectations

Caregiver Lifestyle Disruption: Severity of disturbances in the lifestyle of a family member due to caregiving

Parent(s) Will (Include Specific Time Frame)

- Verbalize understanding of situation and expected parent's/child's role.
- Express feelings about child's illness or situation and effect on family life.
- Demonstrate appropriate behaviors concerning parenting role.
- Assume caretaking activities, as appropriate.
- Handle family disruptions effectively.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Parenting Promotion: Providing parenting information, support, and coordination of comprehensive services to high-risk families

Role Enhancement: Assisting a patient, significant other, and/or family to improve relationships by clarifying and supplementing specific role behaviors

Caregiver Support: Provision of the necessary information, advocacy, and support to facilitate primary patient care by someone other than a healthcare professional

NURSING PRIORITY NO. 1 To assess causative/contributory factors:

- Assess individual situation and parent's perception of and concern about what is happening and expectations of self as caregiver. *Identifies needs of the family to deal realistically with the current situation and what interventions are necessary to work toward identified goals.*⁵
- ∞ Note parental status, including age and maturity, stability of relationship, single parent, and other responsibilities. *Young parents may lack the necessary maturity to deal with unexpected illness of infant or child. Single parent may feel overwhelmed in trying to balance work and caretaking responsibilities. Increasing numbers of elderly individuals who were expecting retirement and a simpler life are providing full-time care for young grandchildren whose parents are unavailable or unable to provide care.*¹
- Ascertain parent's understanding of child's developmental stage and expectations for the future to identify misconceptions and strengths. *Parents often have no information regarding developmental stages and have unrealistic expectation of abilities of the child. Identifying what the parents know and providing information can help them deal more realistically with the situation.*¹
- Note coping skills currently used by each individual as well as how problems have been dealt with in the past. *Provides basis for comparison and reference for client's coping abilities in current situation.*¹
- 🧴 Determine use of substances (e.g., alcohol, other drugs, including prescription medications). *May interfere with individual's ability to cope/problem-solve and manage current illness/situation and indicates need for additional interventions.*⁸
- 🗺️ Determine availability and use of resources, including extended family, support groups, and financial. *Factors that may affect ability to manage illness, unexpected expenses, caregiving activities, etc.*¹
- 📝 Perform testing such as Parent-Child Relationship Inventory for further evaluation as indicated. *Provides information on which to develop plan of care and appropriate interventions.*¹
- 🌐 Determine cultural or religious influences on parenting expectations of self and child and sense of success or failure. *Parenting is one of the most important jobs individuals will have and one for which they are least prepared. Family of origin practices and beliefs will influence parenting style, and this information is crucial to developing a plan of care that meets their needs.*⁴

NURSING PRIORITY NO. 2 To assist parents to deal with current crisis:

- Encourage free verbal expression of feelings (including negative feelings of anger and hostility), setting limits on inappropriate behavior. *Verbalization of feelings enables parent(s) to sift through situation and begin to deal with reality of what is happening. Inappropriate behavior is not helpful for dealing with the situation and will lead to feelings of guilt and low self-worth.*²
- Acknowledge difficulty of situation and normalcy of feeling overwhelmed and helpless. Encourage contact with parents who experienced similar situation with child and had positive outcome. *Parents feel listened to when feelings are acknowledged, and hearing how other parents have dealt with situation can give them hope.*²
- Provide information in an honest and forthright manner at level of understanding of the client, including technical information when appropriate. *Helping client understand what is happening corrects misconceptions and helps to make decisions that meet individual needs.*^{3,12}
- Promote parental involvement in decision making and care as much as possible or desired. *When family members are involved in the process, it enhances their sense of control, and they are more likely to follow through on plans that are made.*²
- Encourage interaction and facilitate communication between parent(s) and child. *Sometimes people who find themselves in difficult or distressful situations tend to withdraw because they do not know what to do. Encouraging these interactions enables them to connect with one another to facilitate dealing with situation.*²
- Discuss problems of attachment disorder when diagnosed in an adopted child. *Children who have been adopted often suffer from problems of believing that they will not be loved, and parents need to learn reasons behind problems as well as skills to deal with them.*^{9,10}
- Promote use of assertiveness and relaxation skills. *Providing information and helping individuals learn these skills will help them to deal more effectively with situation or crisis.*⁶
-  Instruct parent in proper administration of medications and treatments as indicated. *May need to be involved in care, and knowing how to do these activities enhances their sense of control and comfort in their ability to handle situation.*⁵
-  Provide for and encourage use of respite care and parent time off. *Parents may believe they are being “selfish” if they take time out for themselves and that they have to remain with the child. However, parents are important, children are important, and the family is important, and when parents take time for themselves, it enhances their emotional well-being and promotes ability to deal with ongoing situation.*^{7,11}
- Help single parent distinguish between parental love and partner love. *New focus of parent’s attention or love may result in neglect of relationship with child. Attention needs to be given to both individuals for the relationships to flourish.*⁹

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Provide anticipatory guidance relevant to the situation and long-term expectations of the illness. *Encourages making plans for future needs, provides feelings of hope, and promotes sense of control over difficult situation.*¹²
- Encourage parents to set realistic and mutually agreed-on goals. *As family members work together, they can feel empowered and more apt to follow through on decisions that they are involved in making.*²
- Discuss infant attachment behaviors such as breastfeeding on cue, cosleeping, and babywearing (carrying baby around on chest or back), as appropriate. *Dealing with ill child and home-care pressures can strain the bond between parent/child. Activities such as these encourage secure relationships.*
- Provide and identify learning opportunities specific to needs. *Activities such as parenting classes, information about equipment use, and methods of troubleshooting can enhance knowledge and ability to deal with situation.*^{3,12}
-  Refer to community resources, as appropriate (e.g., visiting nurse, respite care, social services, psychiatric care or family therapy, well-baby clinics, special needs support services). *Provides additional assistance as needed to handle individual situation or illness.*⁵
- Refer to ND impaired Parenting for additional interventions.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Findings, including specifics of individual situation, parental concerns, perceptions, expectations.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Parent's responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for each action to be taken.
- Specific referrals made.

ineffective Role Performance

Taxonomy II: Role Relationships—Class 3 Role Performance (00055) [Diagnostic Division: Social Interaction], Approved 1978; Revised 1996, 1998, 2017

DEFINITION: A pattern of behavior and self-expression that does not match the environmental context, norms, and expectations.

[Note: There is a typology of roles, including sociopersonal (friendship, family, marital, parenting, community); home management; intimacy (sexuality, relationship building); leisure, exercise, and recreation; self-management; socialization (developmental transitions); community contributor; and religious, that can help to understand ineffective Role Performance.]

RELATED FACTORS

Alteration in body image

Conflict; stressors; domestic violence; substance misuse/[abuse]

(continues on page 724)

ineffective Role Performance (continued)

Depression; low self-esteem
 Inadequate role model; insufficient role preparation; unrealistic role expectations
 Insufficient support system, resources or rewards
 Inappropriate linkage to the healthcare system
 Pain

DEFINING CHARACTERISTICS

Subjective

Alteration in role perception; change in self-/other's perception of role
 Change in usual pattern of responsibility or in capacity to resume role
 Insufficient opportunity for role enactment
 Role dissatisfaction; role denial
 Discrimination; powerlessness

Objective

Insufficient knowledge of role requirements
 Ineffective adaptation to change; inappropriate developmental expectations
 Insufficient confidence, motivation, self-management, or skills
 Ineffective coping strategies; ineffective role performance
 Inadequate external support for role enactment
 Role strain, conflict, confusion, or ambivalence [failure to assume role]
 Uncertainty; anxiety; depression; pessimism
 Domestic violence; harassment; system conflict
At Risk Population: Developmental level inappropriate for role expectation; young age
 Economically disadvantaged; low educational level
 High demands of job schedule

Associated Condition: Neurological defect; personality disorder
 Physical illness; psychosis

Sample Clinical Applications: Chronic conditions (e.g., multiple sclerosis [MS], pain, chronic fatigue syndrome [CFS]), cancer, substance abuse, brain or spinal cord injury (SCI), major surgery, major depression, bipolar disorder, borderline personality disorder, schizophrenia

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Role Performance: Congruence of an individual's role behavior with role expectations

Coping: Personal actions to manage stressors that tax an individual's resources

Psychosocial Adjustment: Life Change: Adaptive psychosocial response of an individual to a significant life circumstance

Client Will (Include Specific Time Frame)

- Verbalize realistic perception and acceptance of self in changed role.
- Verbalize understanding of role expectations or obligations.
- Talk with family/significant others (SOs) about situation and changes that have occurred and limitations imposed.
- Develop realistic plans for adapting to new role or role changes.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Role Enhancement: Assisting a patient, significant other, and/or family to improve relationships by clarifying and supplementing specific role behaviors

Normalization Promotion: Assisting parents and other family members of children with chronic illnesses or disabilities in providing normal life experiences for their children and families

Values Clarification: Assisting another to clarify her/his own values in order to facilitate effective decision making

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Identify type of role dysfunction. *Life changes such as developmental (adolescent to adult), situational (husband to father, change in employment status, gender identity), and health-illness transitions can affect how client functions in usual role. This information is important to developing a plan of care and appropriate interventions and goals.*¹
- Determine client role in family constellation. *How client has functioned in the past (i.e., husband/father, wife/mother) provides a beginning point of reference for understanding changes that have occurred due to health alterations (mental or physical), lack of knowledge about role or role skills, lack of role model, or what other situation has occurred to bring about a role change.*¹
- Identify how client sees self as a man/woman in usual lifestyle and role functioning. *Each person has a perception of self that is important to know to understand changes that may be occurring.*¹
- Ascertain client's view of sexual functioning. *Changes (e.g., loss of childbearing ability following hysterectomy, erectile dysfunction following prostate surgery) can affect how client views self in role as male or female and may need specific interventions to resolve feelings of loss.*¹
-  Identify cultural factors relating to individual's gender roles. *Varies with the culture; for instance, for American Indians who are in matrilineal clans or band, women may make important decisions and male roles include rituals to protect family and community well-being. In Arab American families, men are expected to be responsible for financial affairs and women typically assume subordinate and caregiving roles.*⁴
- Determine client's perceptions and concerns about current situation. *May believe current role is more appropriate for the opposite sex (e.g., passive role of the "client" may be somewhat less threatening for women).*²
- Interview SO(s) regarding their perceptions and expectations. *The beliefs of the individuals directly involved with the client and the situation (e.g., parents bringing a new baby home from the hospital, adult child assuming responsibility for elder parent) are important to understanding the new roles the individuals are undertaking. Conflicts can arise when expectations vary from individual to individual.*⁵
- Determine client's socioeconomic status and linkage to the healthcare system. *People who are poor may not have healthcare insurance or access to care and perceive themselves as unworthy.*¹
- Identify availability and use of resources. *Individual may be unaware or have difficulty accessing community support or assistance programs.*
- Investigate history of incidents of domestic violence in the family. Refer to psychiatric, protective, support, and legal services, as appropriate. *The roles of perpetrator and survivor are difficult to alter without intensive therapy. Neither individual in this situation sees self as worthy and both have poor self-esteem. The perpetrator does not get what he or she wants through the use of violence, and the survivor (the battered person) often believes she or he deserves this treatment.*^{1,7}

NURSING PRIORITY NO. 2 To assist client to deal with existing situation:

- Discuss perceptions and significance of the situation as seen by client. *Provides opportunity to clarify any misperceptions and discuss changes client may have to make in regard to what has happened (e.g., loss of a limb, disfiguring surgery).*

- Maintain positive attitude toward the client. *Promotes safe relationship in which client can discuss changes that are occurring and plan for a positive future.*¹
- Provide opportunities for client to exercise control over as much of situation as possible. *Enhances self-concept and promotes commitment to goals.*¹
- Offer realistic assessment of situation and communicate hope. *Client may or may not accept reality, but opportunity to discuss issues and have a sense of hope can help client begin to accept reality.*⁶
-  Discuss and assist the client/SO(s) to develop strategies for dealing with changes in role related to past transitions, cultural expectations, and value or belief challenges. *Helps those involved deal with differences between individuals (e.g., adolescent task of separation in which parents clash with child's choices).*^{4,8}
- Acknowledge reality of situation related to role change and help client to express feelings of anger, sadness, grief, and depression. Encourage celebration of positive aspects of change and expressions of feelings. *Changes in role necessitated by illness, trauma, changes in family structure (new baby, child leaving home for college, elderly parent needing care), or any other circumstance result in a sense of loss and need to deal with the feelings that accompany the change.*^{1,5}
- Provide open environment for client to discuss concerns about sexuality. *Embarrassment can block discussion of sensitive subject and potentially impede progress. (Refer to NDs Sexual Dysfunction and ineffective Sexuality Pattern.)*⁷
- Educate about role expectations using written and audiovisual materials. *Using different modalities enables client to review material at leisure and begin to incorporate information into own thinking.*
- Identify role model for the client. *Offers opportunity for client to observe how someone else functions in a role that is new to him or her.*³
- Use techniques of role rehearsal to practice new role. *Provides opportunity for the client to try and develop new skills to cope with anticipated changes.*⁷

NURSING PRIORITY NO. 3 To promote role enhancement (Teaching/Discharge Considerations):

-  Make information available (including bibliotherapy, appropriate Web sites) for client to learn about role expectations and demands that may occur. *Provides opportunity to be proactive in dealing with changes, such as classes to help new parent(s) learn about new roles and credible Web sites for additional information regarding individual's specific concerns.*⁴
-  Discuss use of medication as appropriate. *Client may benefit from antidepressants to combat depression, or psychotropic medications may be required to address other mental health issues.*^{1,7}
- Accept client in changed role. Encourage and give positive feedback for changes and goals achieved. *Provides reinforcement and facilitates continuation of efforts.*
-  Refer to support groups, employment counselors, parent effectiveness classes, and counseling or psychotherapy, as indicated by individual need(s). *Provides ongoing support to sustain progress.*⁶
- Refer to NDs impaired Parenting and Self-Esteem [specify] as appropriate.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including specifics of predisposing crises or situation, perception of role change.
- Cultural or religious factors.
- Expectations of SO(s).
- Availability and use of resources.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications of plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

caregiver Role Strain

Taxonomy II: Role Relationships—Class 1 Caregiving Roles (00061) [Diagnostic Division: Social Interaction], Approved 1992; Revised 1998, 2000; 2017

DEFINITION: Difficulty in fulfilling care responsibilities, expectations and/or behaviors for family or significant others.

RELATED FACTORS

Care Receiver

Condition inhibits conversation
Dependency; problematic behavior; substance misuse/[abuse]
Discharged home with significant needs; increase in care needs
Unpredictability of illness trajectory; unstable health condition

Caregiver

Physical conditions; not developmentally ready for caregiver role
Competing role commitments; insufficient fulfillment of self or others' expectations
Ineffective coping strategies; insufficient energy, privacy, or recreation
Inexperience with caregiving; insufficient knowledge about community resources
Stressors; substance misuse/[abuse]

Unrealistic self-expectations; insufficient emotional resilience; isolation

Caregiver–Care Receiver Relationship

Abusive or violent relationship; presence of abuse
Pattern of ineffective relationships; codependency
Unrealistic care receiver expectations

Caregiving Activities

Around-the-clock care responsibilities; insufficient time; change in nature or complexity of care activities
Excessive caregiving activities; extended duration of caregiving required
Inadequate physical environment or insufficient equipment for providing care; insufficient assistance or respite for caregiver
Recent discharge home with significant care needs; unpredictability of care situation

(continues on page 728)

caregiver Role Strain (continued)

Family Processes

Family isolation; ineffective family adaptation; pattern of ineffective family coping
Pattern of family dysfunction; pattern of family dysfunction prior to the caregiving situation

Socioeconomic

Alienation; social isolation
Difficulty accessing assistance or support
Difficulty accessing/insufficient community resources
Insufficient transportation

DEFINING CHARACTERISTICS

Subjective

Caregiving Activities:

Apprehensiveness about: future ability to provide care or well-being of care receiver if unable to provide care; apprehensiveness about future health or institutionalization of care receiver

Caregiver Health Status: Physiological:

Fatigue; gastrointestinal distress; headache, rash, weight change
Hypertension; cardiovascular disease

Caregiver Health Status: Emotional:

Alteration in sleep pattern
Anger, emotional vacillation; depression; frustration, impatience; nervousness
Insufficient time to meet personal needs; stressors

Caregiver Health Status: Socioeconomic: Change in leisure activities; low work productivity; refusal of career advancement

Caregiver-Care Receiver Relationship:

Difficulty watching care receiver with illness
Grieving changes or uncertainty in relationship with care receiver
Family Processes: Concern about family members; family conflict

Objective

Caregiving Activities:

Difficulty performing or completing required tasks
Dysfunctional change in caregiving activities
Preoccupation with care routine

Caregiver Health Status: Physiological:

Cardiovascular disease; diabetes mellitus
Hypertension; weight change; rash

Caregiver Health Status: Emotional:

Anger, emotional vacillation; depression; frustration, impatience; nervousness
Ineffective coping strategies
Somatization

Caregiver Health Status: Socioeconomic: Low work productivity, refusal of career advancement; social isolation

Family Processes: Family conflict

At Risk Population: Care receiver's condition inhibits conversation

Developmental delay of caregiver or care receiver; prematurity
Female caregiver; partner of caregiver
Exposure to violence

Associated Condition: Care Receiver

Alteration in cognitive functioning; psychiatric or psychological disorder

Chronic illness; illness severity

Congenital disorder

Caregiver

Alteration in cognitive functioning; psychological disorder

Health impairment

[Note: The presence of this problem may encompass other numerous problems/high-risk concerns, such as decreased Diversional Activity Engagement, Insomnia, Fatigue, Anxiety, ineffective Coping, compromised family Coping or disabled family Coping, Decisional Conflict, ineffective Denial, Grieving, Hopelessness, Powerlessness, Spiritual Distress, ineffective Health Maintenance, impaired Home Maintenance, Sexual Dysfunction or ineffective Sexuality Pattern, readiness for enhanced family Coping, interrupted Family Processes, and Social Isolation. Careful attention to data gathering will identify and clarify the client's specific needs, which can then be coordinated under this single diagnostic label.]

Sample Clinical Applications:

Chronic conditions (e.g., severe brain injury, spinal cord injury [SCI], severe developmental delay), progressive debilitating conditions (e.g., muscular dystrophy, multiple sclerosis [MS], dementia or Alzheimer's disease, end-stage chronic obstructive pulmonary disease [COPD], renal failure, renal dialysis), substance abuse, end-of-life care, psychiatric conditions (e.g., schizophrenia, personality disorders).

DESIRED OUTCOMES/EVALUATION CRITERIA**Sample NOC linkages:**

Caregiver Role Endurance: Factors that promote family care provider's capacity to sustain caregiving over an extended period of time

Caregiver Stressors: Severity of biopsychosocial pressure on a family care provider caring for another over an extended period of time

Caregiver Well-Being: Extent of positive perception of primary care provider's health status

Caregiver Will (Include Specific Time Frame)

- Identify resources within self to deal with situation.
- Provide opportunity for care receiver to deal with situation in own way.
- Express more realistic understanding and expectations of the care receiver.
- Demonstrate behavior or lifestyle changes to cope with or resolve problematic factors.
- Report improved general well-being, ability to deal with situation.

ACTIONS/INTERVENTIONS**Sample NIC linkages:**

Caregiver Support: Provision of the necessary information, advocacy, and support to facilitate primary patient care by someone other than a healthcare professional

Family Involvement Promotion: Facilitating participation of family members in the emotional and physical care of the patient

Parenting Promotion: Providing parenting information, support, and coordination of comprehensive services to high-risk families

NURSING PRIORITY NO. 1 To assess degree of impaired function:

- Inquire about and observe physical condition of care receiver and surroundings as appropriate. *Important to determine factors that may indicate problems that can interfere with ability to continue caregiving.*⁴

- Assess caregiver's current state of health and functioning (e.g., caregiver has multiple medical issues; is unable to get enough sleep, has poor nutritional intake, personal appearance and demeanor are indicating stress). *Provides basis for determining needs that indicate caregiver is having difficulty dealing with role.*⁴
-  Determine use of medications/drugs (e.g., prescription, over-the-counter, or illicit drugs and/or alcohol). *Caregiver may turn to using these substances to deal with situation.*¹
- Identify safety issues concerning caregiver and receiver. *The stress and anxiety of caregiving situations can lead to inattention, and by identifying these issues, an opportunity is provided to correct problems before injury occurs.*¹
- Assess current actions of caregiver and how they are received by care receiver. *Caregiver may be trying to be helpful but is not perceived as helpful; may be too protective or may have unrealistic expectations of care receiver's abilities, which can lead to misunderstanding and conflict.*⁴
- Note choice and frequency of social involvement and recreational activities. *Caregiver needs to take time away from situation to maintain own sense of self and ability to continue in role.*¹
- Determine use and effectiveness of resources and support systems. *May not be aware of what is available or may need help in using them to the best advantage.*⁴

NURSING PRIORITY NO. 2 To identify the causative/contributing factors relating to the impairment:

-  Note presence of high-risk situations (e.g., elderly client with total care dependence on spouse; or caregiver with several small children, with one child requiring extensive assistance due to physical condition or developmental delays). *Such situations result in added stress (e.g., imposing unwanted role reversal, placing excessive demands on parenting skills).*⁴
- Determine current knowledge of the situation, noting misconceptions and lack of information. *May interfere with caregiver/care receiver's response to situation.*
-  Identify relationship of caregiver to care receiver (e.g., spouse/lover, parent/child, sibling, friend). *Close relationships may make it more difficult to remain separate when caring for care receiver. Note: Younger-aged family caregivers are at increased risk for lower levels of hope and higher levels of caregiver strain.*⁶
-  Determine quality of couple's relationship/presence of intimacy issues. *Disease/condition, caregiving activities, and possible change in role responsibilities may strain relationship, adding to sense of loss and unmet needs.*³
- Ascertain proximity of caregiver to care receiver. *Caregiver could be living in the home of care receiver (e.g., spouse or parent of disabled child) or could be adult child stopping by to check on elderly parent each day, providing support, food preparation, shopping, and assistance in emergencies. Note: There is added stress in maintaining own life and responsibilities when caregiver has to travel some distance to provide care.*^{4,10}
-  Note care receiver's physical and mental condition, as well as the complexity of therapeutic regimen. *Caregiving activities can be complex, requiring hands-on care, problem-solving skills, clinical judgment, and organizational and communication skills that can tax the caregiver, increasing likelihood of burnout.*^{7,10}
- Determine caregiver's level of involvement in and preparedness for the responsibilities of caring for the client and anticipated length of care. *Information needed to develop plan of care that takes into consideration who will provide care, timing, and any other factors to maintain coverage for situation.*⁴
- Ascertain physical and emotional health, developmental level and abilities, and additional responsibilities of caregiver (e.g., job, raising family). *Provides clues to potential stressors and possible supportive interventions.*^{10,11}
-   Assess caregiver as appropriate, using tool such as Burden Interview, Herth Hope Index, Caregiver Reaction Assessment, or Caregiver Strain Index to further determine caregiver's stressors and abilities, providing additional information to aid in planning.^{17,18}
-  Identify individual cultural factors and impact on caregiver. *Helps clarify expectations of caregiver and receiver, family, and community. Many cultures, such as Native American and Cuban, believe strongly in keeping care receivers in the home and caring for them.*⁵
- Identify presence and degree of conflict between caregiver/care receiver/family. *Stressful situations can exacerbate underlying feelings of anger and resentment, resulting in difficulty managing caregiving needs.*¹

- Determine pre-illness and current behaviors that may be interfering with the care or recovery of the care receiver. *Underlying personality of care receiver may create situation in which old conflicts interfere with current treatment regimen.*¹
- Note codependency needs and enabling behaviors of caregiver. *These behaviors can interfere with competent caregiving and contribute to caregiver burnout.*²

NURSING PRIORITY NO. 3 To assist caregiver to identify feelings and begin to deal with problems:

-  Establish a therapeutic relationship, conveying empathy and unconditional positive regard. *A compassionate approach blending the nurse's expertise in healthcare with the caregiver's firsthand knowledge of the care receiver can provide encouragement, especially in a long-term difficult situation.*^{10,12}
-  Acknowledge difficulty of the situation for the caregiver/family. *Research shows that the two greatest predictors of caregiver strain are poor health and the feeling that there is no choice but to take on additional responsibilities.*¹⁰
- Discuss caregiver's view of and concerns about situation. *Important to identify issues so planning and solutions can be developed.*⁷
- Encourage caregiver to acknowledge and express negative feelings. Discuss normalcy of the reactions without using false reassurance. *Individual needs to understand that all feelings are acceptable to be expressed and dealt with, but not acted on in the situation.*¹
- Discuss caregiver's life goals, perceptions, and expectations of self. *Clarifies unrealistic thinking and identifies potential areas of flexibility or compromise.*⁴
- Discuss caregiver's perception of impact of and ability to handle role changes necessitated by situation. *May not initially realize the changes that will be encountered as situation develops, and it helps to identify and plan for changes before they arise.*

NURSING PRIORITY NO. 4 To enhance caregiver's ability to deal with current situation:

- Identify strengths of caregiver and care receiver. *Bringing these to the individual's awareness promotes positive thinking and helps with problem-solving to deal more effectively with circumstances.*⁴
- Discuss strategies to coordinate caregiving tasks and other responsibilities (e.g., employment, care of children/other dependents, housekeeping activities). *Managing these tasks will reduce the stress associated with performing the activities of daily living.*¹
-  Facilitate family conference to share information and develop plan for involvement in care activities as appropriate. *Involving everyone promotes sense of control and ownership of plan and willingness to follow through on responsibilities.*
-  Identify classes or needed specialists (e.g., first aid and cardiopulmonary resuscitation classes, enterostomal specialist, physical therapist). *Provides information needed to manage tasks of caregiving more effectively, giving individuals more sense of control.*
-  Determine need for and sources of additional resources (e.g., financial, legal, respite care, educational, social, spiritual). *Can help to resolve problems that arise in the course of caregiving that are out of the knowledge or abilities of the individual. Solving these issues can relieve caregiver of anxiety and concern.*^{4,13}
- Provide information or demonstrate techniques for dealing with acting out, violent, or disoriented behavior. *Presence of dementia necessitates learning these techniques or skills to enhance safety of caregiver and receiver.*¹
-  Identify equipment needs and resources and appropriate adaptive aids. *Enhances the independence and safety of the care receiver and makes the task of caregiving easier.*
-  Provide contact person or case manager to partner with care provider(s) in coordinating care, providing physical and social support, and to assist with problem-solving as needed or desired. *As care receiver's condition declines or caregiving activities are prolonged/intensify, caregiver strain may escalate and psychological well-being of caregiver may decline. Ongoing support by health and social services promotes more effective caregiving and thereby lessens strain on caregiver.*^{2,10,14}

NURSING PRIORITY NO. 5 To promote wellness (Teaching/Discharge Considerations):

-  Advocate for and assist caregiver to plan for and implement changes that may be necessary (e.g., home-care providers, adult day care, eventual placement in long-term care facility). *As caregiving tasks become more difficult, other options need to be considered, and planning ahead can promote acceptance of necessary changes.*^{8,11,15}
- Encourage attention to own needs (e.g., eating and sleeping regularly, setting realistic goals, talking with trusted friend, periodic respite from caregiving), accepting own feelings, acknowledging frustrations and limitations, and being realistic about loved one's condition. *Supports and enhances caregiver's general well-being and coping ability.*^{15,16}
- Review signs of burnout (e.g., emotional or physical exhaustion, changes in appetite and sleep, withdrawal from friends/family or life interests). *Recognition of developing problem allows for timely intervention.*
- Discuss and demonstrate stress management techniques and importance of self-nurturing (e.g., pursuing self-development interests, hobbies, social activities, spiritual enrichment). *Being involved in activities such as these can prevent caregiver burnout.*^{4,15}
- Encourage involvement in caregiver support group. *Having others to share concerns and fears is therapeutic and provides ideas for different ways to manage problems, helping caregivers deal more effectively with the situation.*¹
-  Refer to classes or other therapies as indicated. *Provides additional information as needed.*
- Identify an available 12-step or other support/recovery program when indicated to provide tools to deal with enabling or codependent behaviors that impair level of function. *Provides a more structured environment to learn how to deal with problems of caregiving situation.*¹
-  Refer to counseling or psychotherapy as needed. *Intensive treatment may be needed in highly stressful situations.*
- Provide bibliotherapy of appropriate references and Web sites for self-paced learning and updated information and contact with other caregivers. *Further information can help individuals understand what is happening and manage more effectively.*⁹

DOCUMENTATION FOCUS**Assessment/Reassessment**

- Assessment findings, functional level and degree of impairment, caregiver's understanding and perception of situation.
- Identified risk factors.

Planning

- Plan of care and individual responsibility for specific activities.
- Identification of inner resources, behavior or lifestyle changes to be made.
- Needed resources, including type and source of assistive devices and durable equipment.
- Teaching plan.

Implementation/Evaluation

- Caregiver's/receiver's response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Plan for continuation or follow-through of needed changes.
- Referrals for assistance and evaluation.

risk for caregiver Role Strain

Taxonomy II: Role Relationships—Class 1 Caregiving Roles (00062) [Diagnostic Division: Social Interaction], Approved 1992; Revised 2010, 2013, 2017

DEFINITION: Susceptible to difficulty in fulfilling care responsibilities, expectations and/or behaviors for family or significant others, which may compromise health.

RISK FACTORS

Care Receiver

Dependency; problematic behavior; substance misuse/[abuse]
Discharged home with significant needs; increase in care needs
Unpredictability of illness trajectory; unstable health condition

Caregiver

Physical conditions; not developmentally ready for caregiver role
Competing role commitments; insufficient fulfillment of self or others' expectations
Ineffective coping strategies; insufficient energy, privacy, or recreation
Inexperience with caregiving; insufficient knowledge about community resources
Stressors; substance misuse/[abuse]

Unrealistic self-expectations; insufficient emotional resilience; isolation

Caregiver–Care Receiver Relationship

Abusive or violent relationship; presence of abuse
Pattern of ineffective relationships; codependency
Unrealistic care receiver expectations

Caregiving Activities

Around-the-clock care responsibilities; insufficient time; change in nature or complexity of care activities
Excessive caregiving activities; extended duration of caregiving required
Inadequate physical environment or insufficient equipment for providing care; insufficient assistance or respite for caregiver

(continues on page 734)

risk for caregiver Role Strain (continued)

Recent discharge home with significant care needs; unpredictably of care situation

Family Processes

Family isolation; ineffective family adaptation; pattern of ineffective family coping

Pattern of family dysfunction; pattern of family dysfunction prior to the caregiving situation

Socioeconomic

Alienation or social isolation

Difficulty accessing assistance or support

Difficulty accessing/insufficient community resources

Insufficient transportation

At Risk Population: Care receiver's condition inhibits conversation

Developmental delay of caregiver or care receiver; prematurity

Female caregiver; partner of caregiver

Exposure to violence

Associated Condition: *Care Receiver*

Alteration in cognitive functioning; psychiatric or psychological disorder

Chronic illness; illness severity

Congenital disorder

Caregiver

Alteration in cognitive functioning; psychological disorder

Health impairment

[Note: The presence of this problem may encompass other numerous problems/high-risk concerns, such as decreased Diversional Activity Engagement, Insomnia, Fatigue, Anxiety, ineffective Coping, compromised family Coping or disabled family Coping, Decisional Conflict, ineffective Denial, Grieving, Hopelessness, Powerlessness, Spiritual Distress, ineffective Health Maintenance, impaired Home Maintenance, Sexual Dysfunction or ineffective Sexuality Pattern, readiness for enhanced family Coping, interrupted Family Processes, and Social Isolation. Careful attention to data gathering will identify and clarify the client's specific needs, which can then be coordinated under this single diagnostic label.]

Sample Clinical Applications: Chronic conditions (e.g., severe brain injury, spinal cord injury [SCI], severe developmental delay), progressive debilitating conditions (e.g., muscular dystrophy, multiple sclerosis [MS], dementia/Alzheimer's disease, end-stage chronic obstructive pulmonary disease [COPD], renal failure, renal dialysis), substance abuse, end-of-life care, psychiatric conditions (e.g., schizophrenia, personality disorders)

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Caregiver Home Care Readiness: Preparedness of a caregiver to assume responsibility for the healthcare of a family member in the home

Caregiver Stressors: Severity of biopsychosocial pressure on a family care provider caring for another over an extended period of time

Family Resiliency: Capacity of a family to positively adapt and function following a significant adversity or crisis

Caregiver Will (Include Specific Time Frame)

- Identify individual risk factors and appropriate interventions.
- Demonstrate or initiate behaviors or lifestyle changes to prevent development of impaired function.
- Use available resources appropriately.
- Report satisfaction with current situation.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Caregiver Support: Provision of the necessary information, advocacy, and support to facilitate primary patient care by someone other than a healthcare professional

Family Support: Promotion of family values, interests, and goals

Parenting Promotion: Providing parenting information, support, and coordination of comprehensive services to high-risk families

NURSING PRIORITY NO. 1 To assess factors affecting current situation:

-  Note presence of high-risk situations (e.g., elderly client with total self-care dependence; having several small children, with one child requiring extensive assistance due to physical condition or developmental delays). *May necessitate role reversal resulting in added stress or places excessive demands on parenting skills. Identification of high-risk situations can help in planning and resolving problems before they can become unmanageable.*⁴
-  Identify relationship and proximity of caregiver to care receiver (e.g., spouse/lover, parent/child, friend). *There is added stress in maintaining own life and responsibilities when caregiver has to travel some distance to provide care.*¹¹ *Close relationships may create problems of codependency and identification that can be counterproductive to caregiving. Note: A 2015 study by the National Alliance for Caregiving (NAC) reports “there are 43.5 million informal, unpaid caregivers in the United States. Over half (60%) are female and around 49 years old, although one in 10 are 75 years of age or older, and are caregiving without any additional unpaid help. The majority (34.2 million) provide care on average of 24.4 hours a week, 60% of caregivers have to cut back their work hours or take a leave of absence, and 42% of all caregivers perform care without any training or preparation.”⁷ Younger-aged family caregivers are at increased risk for lower levels of hope and higher levels of caregiver strain.*²
- Determine current knowledge of the situation, noting misconceptions and lack of information. *May interfere with caregiver/care receiver’s response to situation.*
- Compare caregiver’s and receiver’s views of situation. *Different views need to be openly expressed so each person understands how other sees situation.*^{1,3}
- Note complexity of therapeutic regimen and physical and mental status of care receiver to ascertain potential areas of need (e.g., teaching, direct care support, respite). *Knowledge of these factors is necessary for planning adequate care for the individual. Plans for additional help may be necessary to prevent caregiver role strain.*¹
- Determine caregiver’s level of responsibility, involvement in care, and anticipated length of care. *Information that may indicate level of stress that could be anticipated for the situation. Progressive debilitation taxes caregiver and may alter ability to meet client’s and own needs.*⁴
-  Identify individual cultural factors and impact on caregiver. *Helps clarify expectations of caregiver/receiver, family, and community. Many cultures, such as Native American and Cuban, believe strongly in keeping care receiver in the home and caring for them.*⁵
- Ascertain caregiver’s physical and emotional health, developmental level and abilities, and additional responsibilities of caregiver (e.g., job, raising family). *Provides information indicative of ability of the individual to take on the task of caregiver, as well as clues to potential stressors and possible supportive interventions.*^{11,12}
-  Assess caregiver as appropriate, using tool such as Burden Interview, Herth Hope Index, Caregiver Reaction Assessment, or Caregiver Strain Index (not a comprehensive list) to further determine caregiver’s stressors and abilities providing additional information to aid in planning.^{6,7,9}
- Identify strengths and weaknesses of caregiver and care receiver. *Caregiver may not be aware of demands that will be expected. Knowing these factors helps to determine how to use them to advantage in planning and delivering care.*⁹

- Note any codependency needs of caregiver and plan for dealing appropriately with them. *Can contribute to burnout unless identified and dealt with.*¹⁵
- Verify safety of caregiver/receiver. *Identifying and correcting unsafe situations is crucial so both individuals can be assured of safety in dealing with difficult situation.*^{1,9}
- Determine available supports and resources currently used. *Helpful to identify if they are being used effectively.*⁴

NURSING PRIORITY NO. 2 To enhance caregiver's ability to deal with current situation:

- Establish a therapeutic relationship, conveying empathy and unconditional positive regard. *Promotes positive environment in which needs and concerns can be discussed and proactive solutions identified.*
-  Discuss strategies to coordinate care and other responsibilities (e.g., employment, care of children/dependents, housekeeping activities). *Such planning can prevent chaos and resultant burnout.*⁸
-  Facilitate family conference as appropriate to share information and develop plan for involvement in care activities. *When everyone is involved and listened to, each person is more likely to carry out his or her responsibilities.*⁴
-  Refer to classes and/or specialists (e.g., first-aid and cardiopulmonary resuscitation classes, enterostomal specialist, physical therapist) for special training as indicated. *Additional information that can help individuals involved feel more competent and able to deal with situation more effectively.*³
-  Identify additional resources, including financial, legal, and respite care. *Can help to resolve problems that arise in the course of caregiving that are outside of the knowledge or abilities of the individual. Solving these issues can relieve caregiver of associated anxiety and concern.*¹
- Identify equipment needs and resources, and appropriate adaptive aids. *Enhances the independence and safety of the care receiver and reduces chances for untoward incidents.*¹⁴
- Identify contact person or case manager as needed to coordinate care, provide support, and assist with problem-solving. *Assistance with planning minimizes problems that could arise.*¹⁰
- Provide information or demonstrate techniques for dealing with acting out, violent, or disoriented behavior. *Planning ways to deal with these behaviors before they occur promotes safety and enhances positive outcomes.*⁴
- Assist caregiver to recognize codependent behaviors (i.e., doing things for others that others are able to do for themselves) and how these behaviors affect the situation. *Provides options for changing behaviors in ways that enhance the caregiving situation.*¹⁵

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Review signs of burnout (e.g., emotional or physical exhaustion, changes in appetite and sleep, withdrawal from friends/family or life interests). Note: In the NAC (2015) study, it was reported that 38% of caregivers relay high emotional stress, whereas 19% report high physical stress; 18% report high to very high financial strain. All of these needs, especially physical stress, are closely related to the complexity of the situation, such as number of hours of caregiving, caregiver age, and needs of the care recipient. *Recognition of developing problem allows for timely intervention.*^{7,13}
-  Discuss and demonstrate stress management techniques and importance of self-nurturing (e.g., meeting personal needs, pursuing self-development interests, hobbies, social activities, spiritual enrichment). *Improves or maintains quality of life for caregiver and may provide caregiver with options to protect self.*^{6,13,14}
-  Encourage involvement in caregiver or other specific support group(s). *Opportunity to be with others in similar situations and discussing different ways to handle problems help caregiver deal with difficult role in positive ways.*¹
- Provide bibliotherapy of appropriate references and Web sites and encourage discussion of information. *Promotes retention of new information that can help caregiver manage more effectively.*¹
-  Advocate for and assist caregiver to plan for and implement changes that may become helpful or necessary for the care receiver. *Getting information and thinking about possibilities will help with decision making. These may include transportation, meal delivery, home healthcare services, home modification, and legal and financial counseling, as well as eventual placement in a long-term care facility and use of palliative or hospice*

services. As caregiving tasks at home become more difficult, other options need to be considered, and planning ahead can promote acceptance of necessary changes.^{8,12,13}

- Identify an available 12-step/other recovery or support program when indicated to provide tools to deal with codependent behaviors that impair level of function. Provides a more structured environment to learn how to deal with problems of caregiving situation in positive ways.³
-  Refer to counseling or psychotherapy as needed. May need additional help to resolve issues that are interfering with caregiving responsibilities.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Identified risk factors and caregiver perceptions of situation.
- Reactions of care receiver/family.

Planning

- Treatment plan and individual responsibility for specific activities.
- Teaching plan.

Implementation/Evaluation

- Caregiver/receiver response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals provided for assistance and evaluation.

Self-Care Deficit: bathing, dressing, feeding, toileting

Taxonomy II: Activity/Rest—Class 5 Self-Care (Bathing 00108, Dressing 00109, Feeding 00102, Toileting 00110)
[Diagnostic Division: Hygiene], Approved 1980; Nursing Diagnosis Extension and Classification Revision 1998, Bathing/
 Dressing/Toileting 2008; 2017

DEFINITION: Inability to independently perform or complete cleansing activities; put on or remove clothing; to eat; or to perform tasks associated with bowel and bladder elimination.

[Note: Self-Care also may be expanded to include the practices used by the client to promote health, the individual responsibility for self, and a way of thinking. Refer to NDs ineffective Health Maintenance and impaired Home Maintenance.]

RELATED FACTORS

Anxiety; decrease in motivation

Pain; weakness

Environmental barrier [mechanical restrictions such as cast, splint, traction, ventilator]

Impaired mobility; impaired ability to transfer

[Inability to perceive body part or spatial relationship]

DEFINING CHARACTERISTICS

Bathing Self-Care deficit

Impaired ability to: access bathroom [tub], gather bathing supplies, access water, regulate bathwater, wash or dry body

Dressing Self-Care deficit

Impaired ability to: choose clothing, gather clothing, pick up clothing, put clothing on upper or lower body, fasten clothing

Impaired ability to: put on/remove various items of clothing

Impaired ability to: use zipper or assistive device, maintain appearance

Feeding Self-Care deficit

Impaired ability to: prepare food, open containers

Impaired ability to: handle utensils, get food onto utensil, bring food to the mouth, use assistive device, pick up cup

Impaired ability to: manipulate food in mouth, chew food, swallow food or swallow sufficient amount of food, self-feed a complete meal or in an acceptable manner

Toileting Self-Care deficit

Impaired ability to: reach toilet, manipulate clothing for toileting, sit on or rise from toilet, complete toilet hygiene, flush toilet

Associated Condition: Alteration in cognitive functioning

Impaired ability to perceive body part or to spacial relationships; perceptual disorders

Neuromuscular; musculoskeletal impairment

Sample Clinical Applications: Arthritis, neuromuscular impairment (e.g., multiple sclerosis [MS], brain injury, stroke, Parkinson's disease, spinal cord injury [SCI]), chronic pain, chronic fatigue syndrome [CFS], depression, dementia, autism, developmental delay, end-of-life/hospice care

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Self-Care Status: Personal actions to perform basic personal care activities and instrumental activities of daily living

Self-Care: Bathing: Personal actions to cleanse own body independently with or without assistive device

Self-Care: Dressing: Personal actions to dress self independently with or without assistive device

Self-Care: Eating: Personal actions to prepare and ingest food and fluid independently with or without assistive device

Self-Care: Toileting: Personal actions to toilet self independently with or without assistive device

Client Will (Include Specific Time Frame)

- Identify individual areas of weakness and needs.
- Verbalize knowledge of healthcare practices.
- Demonstrate techniques or lifestyle changes to meet self-care needs.
- Perform self-care activities within level of own ability.
- Identify personal and community resources that can provide assistance.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Self-Care Assistance: Assisting another to perform activities of daily living

Bathing: Cleaning of the body for the purposes of relaxation, cleanliness, and healing

Dressing: Choosing, putting on, and removing clothes for a person who cannot do this for self

Feeding: Providing nutritional intake for patient who is unable to feed self

Bowel [or] Urinary Elimination Management: Establishment and maintenance of a regular pattern of bowel elimination/maintenance of an optimum urinary elimination pattern

NURSING PRIORITY NO. 1 To identify causative/contributing factors:

-  Determine age or developmental issues and existing conditions (e.g., heart or renal failure, SCI, malnutrition, pain, trauma, surgery) and cognitive or psychological factors (e.g., mental illness, brain injury, cerebrovascular accident, MS, Alzheimer's disease) affecting ability of individual to care for own needs. *Assists in setting realistic goals and creates baseline for evaluating effectiveness of interventions.*^{1,8}
- Identify other etiological factors present, including language barriers, speech impairment, visual acuity, loss of visual or spatial orientation, hearing problem, and emotional instability or lability *that can both affect and be affected by self-care needs and deficits*. Refer to NDs impaired verbal Communication, Unilateral Neglect, and [disturbed Sensory Perception (specify)] for related interventions.
-  Review medication regimen *for possible effects on alertness and mentation, energy level, balance, and perception*. *Note: All prescribed and over-the-counter medications have the potential for side effects, adverse effects, and interactions that may be harmful to the client or affect client's ability to provide self-care.*
- Assess barriers to participation in regimen *that can limit use of resources or choice of options (e.g., lack of information, insufficient time for discussion, psychological or intimate family problems that may be difficult to share, fear of appearing stupid or ignorant, social or economic limitations, work or home environment problems).*

NURSING PRIORITY NO. 2 To assess degree of disability:

- Identify degree of individual impairment and functional level according to a functional scale as below:¹⁶
 - 0—Completely independent
 - 1—Requires use of equipment or device
 - 2—Requires help from another person for assistance, supervision, or teaching
 - 3—Requires help from another person and equipment device
 - 4—Dependent, does not participate in activity
- *Note: Many instruments have been developed to assess client's functional status. In the community healthcare setting, a more complex assessment may be used (e.g., Lawton and Brody's scale of Instrumental Activities of*

Daily Living) to determine client's self-care abilities (e.g., to communicate by phone, drive, cook, shop, balance a checkbook, manage multiple medical appointments or medications, etc.). In an acute or long-term care setting, the assessment may be confined to personal care (e.g., Katz Activities of Daily Living Scale). These instruments are used (1) to determine client's safety issues and care needs upon admission and (2) to ascertain changes in functional abilities and quality of life as a result of client's condition and treatment.^{15,17}

- Note anticipated duration of disruption and intensity of care required. A wide variety of factors can impact self-care, some of which may be (1) invariable or permanent (e.g., quadriplegia or advanced dementia), (2) temporary (e.g., fractures requiring immobilization, mild stroke with potential for good recovery), and (3) variable (e.g., person having episode of severe depression or episodes of relapsing-remitting type MS).
- Assess cognitive functioning (e.g., memory, intelligence, concentration, ability to attend to task) to determine client's ability to participate in care and potential to return to normal functioning or to learn/relearn tasks.
- Determine individual strengths and skills of the client to incorporate into plan of care, enhancing likelihood of achieving outcomes.

NURSING PRIORITY NO. 3 To assist in correcting/dealing with deficit(s) in general:

-   Collaborate in treatment of underlying conditions to enhance client's capabilities and maximize rehabilitation potential.
-  Promote communication among all those involved in caring for or assisting the client. Enhances coordination and continuity of care.
- Active-listen client's/significant other's (SO's) concerns. Exhibits regard for client's values and beliefs, clarifies barriers to participation in self-care, provides opportunity to work on problem-solving solutions, and provides encouragement and support.^{8,10}
- Provide accurate and relevant information regarding current and future needs so that client can incorporate into self-care plans while minimizing problems (e.g., heightened anxiety, depression, resistance) often associated with change.⁹
- Promote client/SO participation in problem identification and desired outcomes. Can ease frustration of current loss of independence, enhancing recovery, optimizing outcomes, and supporting health promotion.¹⁰
- Establish "contractual" partnership with client/SO(s) if appropriate or indicated for motivation or behavioral modification.
- Practice and promote short-term goal setting and achievement to recognize that today's success is as important as any long-term goal, accept ability to do one thing at a time, and conceptualize self-care in a broader sense.
-  Instruct in or review appropriate skills necessary for self-care, using terms understandable to client (e.g., child, adult, cognitively impaired person) and with sensitivity to developmental needs for practice, repetition, or reluctance. Individualized teaching best affords reinforcement of learning. Sensitivity to special needs attaches value to the client's needs.¹
- Encourage client to use vision and hearing aids as appropriate. Improves reception and interpretation of sensory input to facilitate self-care.
- Perform or assist with meeting client's needs when he or she is unable to meet own needs (e.g., personal care assistance is part of nursing care and should not be neglected while promoting and integrating self-care independence).
- Anticipate needs and begin with familiar, easily accomplished tasks to encourage client and build on successes.
- Cue client, as indicated. A cognitively impaired or forgetful client can often successfully participate in many activities with cueing, which can enhance self-esteem and potentiate learning or relearning of self-care tasks.¹
- Maintain a supportive attitude and allow sufficient time for client to accomplish tasks to fullest extent of ability.
- Refrain from unnecessary conversation or interruptions that divert focus from the task at hand and can contribute to client's level of frustration.
- Avoid doing things for client that client can do for self, but provide assistance as needed. Client may be fearful or dependent, and although assistance is helpful in preventing frustration (and sometimes easier for the caregivers in terms of their time), it is important for client to do as much as possible for self to regain or maintain self-esteem, reduce helplessness, and promote optimal recovery.

- Review coping skills (e.g., assertiveness, interpersonal relations, decision making, problem-solving, stigma management, time management) *that are useful in managing a wide range of stressful conditions*. Encourage client to ask for assistance as needed or desired.⁹
- Schedule activities to conform to client's preferred schedule as much as possible (e.g., bathing at a relaxing time for client, rather than on a set routine).
- Plan activities to prevent or accommodate fatigue and/or exacerbation of pain to conserve energy and promote maximum participation in self-care.
- Identify energy-saving behaviors (e.g., sitting instead of standing when possible, organizing needs before beginning tasks). Refer to NDs Activity Intolerance and Fatigue for additional interventions.
-  Review medication needs (e.g., vitamins, nutritional supplements, pain reliever, antidepressants) *that may improve general well-being and ability to participate in self-care*.
-  Arrange for home visit, as indicated, to assess environmental concerns that can impact client's abilities to care for self in home. If necessary modifications are not feasible or cannot be made, client may require temporary or long-term relocation or regular home-care assistance.
-  Consult with rehabilitation professionals to identify and obtain assistive devices (e.g., modified eating utensils, modified clothing), mobility aids (e.g., rolling commode, shower chair), and home modification as necessary (e.g., adequate lighting; cutout under kitchen and bathroom sink; lowering cabinets and closet rods; handheld shower, raised toilet seat, grab bars for bathroom) *to optimize self-care efforts*.^{1,8,10}
-  Note availability and use of resources and supportive person(s) to ascertain that client has means for sharing common concerns, needs, and wishes, as well as access to social support and approval (e.g., support group participants, family members, professionals).⁹

NURSING PRIORITY NO. 4 To meet specific self-care needs:

Bathing deficit

-  Ask client/SO for input on bathing habits or cultural bathing preferences. *Creates opportunities for client to (1) keep long-standing routines (e.g., bathing at bedtime to improve sleep) and (2) exercise control over situation. This enhances self-esteem, while respecting personal and cultural preferences*.³
- Bathe or assist client in bathing, providing for any or all hygiene needs as indicated. *Type of bath (e.g., bed bath, towel bath, tub bath, shower) and purpose (e.g., cleansing, removing odor, simply soothing agitation) is determined by individual need. Note: Bathing is a healing rite and should be a comforting experience that focuses on the client's needs, rather than being a routinely scheduled task*.¹¹
- Obtain hygiene supplies (e.g., soap, toothpaste, toothbrush, mouthwash, lotion, shampoo, razor, towels) for specific activity to be performed and place in client's easy reach *to provide visual cues and facilitate completion of activity*.
- Ascertain that all safety equipment is in place and properly installed (e.g., grab bars, antislip strips, shower chair, hydraulic lift) and that client/caregiver(s) can safely operate equipment *to prevent injury to client and caregivers*.⁴
- Instruct client to request assistance when needed and place call device within easy reach *so client can summon help if bathing alone or stay with client as dictated by safety needs*.
-  Provide for adequate warmth (e.g., covering client during bed bath or warming bathroom). *Certain individuals (especially infants, the elderly, very thin or debilitated persons) are prone to hypothermia and can experience evaporative cooling during and after bathing*.⁵
- Determine that client can perceive water temperature and adjust water temperature safely or that water is correct temperature for client's bath or shower *to prevent chilling or burns. This step requires that client is cognitively and physically able to perceive hot and cold and to adjust faucets safely; otherwise, adequate supervision must be provided at all times*.⁵
- Assist client in and out of shower or tub as indicated. *Needs are variable (e.g., client may need to get into tub before running water; may require a shower chair; may be independent with one fixture and not another), requiring assessment of individual situations*.

- Assist with or cue client to complete hygiene steps (e.g., oral care, lotion application, applying deodorant, washing and styling hair). *These steps may be completed at same or different time as bathing, but are usually part of a regular routine that is necessary for client's physical well-being and emotional or social comfort.*

Dressing deficit

- Ascertain that appropriate clothing is available. *Client may not have sufficient clothing, clothing may be inadequate for situation or weather conditions, or clothing may need to be modified for client's particular medical condition or physical limitations.*
- Assist client in choosing clothing or lay out clothing as indicated. *May be needed when client has cognitive, physical, or psychiatric conditions affecting ability to choose appropriate pieces of clothing or to maintain a satisfactory appearance.*¹
- Dress client or assist with dressing, as indicated. *Client may need assistance in putting on or taking off items of clothing (e.g., shoes and socks, over-the-head shirt) or may require partial or complete assistance with fasteners (e.g., buttons, snaps, zippers, shoelaces).*
- Allow sufficient time for dressing and undressing *because tasks may be tiring, painful, and difficult to complete. Dressing may be done from seated position if balance is impaired.*
- Use adaptive clothing as indicated (e.g., clothing with front closure, wide sleeves and pant legs, Velcro or zipper closures). *These may be helpful for client with limited arm or leg movement or impaired fine motor skills or for cognitively impaired person who desires to dress self but cannot do so with regular clothing fasteners.*¹²
- Teach client to dress affected side first and then unaffected side (when client has paralysis or injury to one side of body) *to allow for easier manipulation of clothing.*¹²

Feeding deficit

- Assess client's need and ability to prepare and eat food as indicated (including shopping, cooking, cutting food, opening containers, managing environment, etc.). *Identifies specific assistance required.*^{1,2,13,17}
- Assess for and alleviate pain where possible *to improve client's desire for food, and ability to eat/manage necessary tasks for food preparation and eating*
- Have client sitting upright (out of bed at table) as much as possible *Improves posture for eating and better digestion, and promotes idea that eating is a social activity*
- Arrange tray/table place setting to facilitate self-feeding (e.g., rearrange items for easy access; remove plate and cup covers; unwrap utensils; open packets; cut up food; butter bread. *to reduce client's frustration or apathy, and to promote ease of accessing food*
- Encourage food and fluid choices reflecting individual likes and abilities and that meet nutritional needs *to maximize food intake.*
- Ascertain that client can swallow safely, checking gag and swallow reflexes, as indicated. Refer to ND impaired Swallowing for related interventions.
- Provide food and fluid of appropriate consistency *to facilitate swallowing.* Cut food into bite-size pieces *to prevent overfilling mouth and reduce risk of choking.*
- Assist client to handle utensils or in guiding utensils to mouth. *May require specialized equipment (e.g., rocker knife, plate guard, built-up handles) to increase independence or assistance with movement of arms and hands.* Provide nutritious finger foods where possible, if the client wants to feed self but experiences difficulty managing utensils
- Assist client with small cup, glass, or bottle for liquids, using straw or adaptive lids as indicated, *to enhance fluid intake while reducing spills.*
- Allow client time for intake of sufficient food *for feeling satisfied or completing a meal.*
- Use verbal cueing and prompting (e.g., "pick up your spoon," "take a bite," "chew," "swallow"), where indicated. *May improve client's efforts when distraction, depression, or cognitive issues are interfering.*
- Remove distractions (e.g., turn off TV, avoid interruptions such as people entering or leaving the area where possible) *when manners might be offensive to others or client could be embarrassed.*
- Assist client with social graces when eating with others; provide privacy *when manners might be offensive to others or client could be embarrassed.*

- Collaborate with nutritionist, speech-language pathologist, occupational therapist, or physician *for special diets, adaptive equipment, or feeding methods necessary to improve nutrition.*
- Feed client, allowing adequate time for chewing and swallowing, *when client is not able to obtain nutrition by self-feeding.* Avoid providing fluids until client has swallowed food and mouth is clear. *Prevents “washing down” foods, reducing risk of choking.*

Toileting deficit

- Provide mobility assistance to bathroom or commode or place on bedpan or offer urinal, as indicated. *Client might be impaired because of age, cognitive problems, weakness, or acute injury or illness, requiring a range of interventions from complete care to help with walking.*
- Direct or accompany cognitively impaired client to bathroom, as needed. *May need directions to the facilities or reminders to use the bathroom, etc.⁶*
- Observe for behaviors such as pacing, fidgeting, and holding crotch *that may be indicative of need for prompt toileting.*
- Provide privacy *to enhance self-esteem and improve ability to urinate or defecate.¹*
- Assist with manipulation of clothing if needed, *to decrease incidence of functional incontinence caused by difficulty removing clothing/underwear.⁷*
- Observe need for and assist in obtaining modified clothing or fasteners *to assist client in manipulation of clothing, fostering independence in self-toileting.*
- Provide or assist with use of assistive equipment (e.g., raised toilet seat, support rails, spill-proof urinals, fracture pans, bedside commode) *to promote independence and safety in sitting down or arising from toilet or for aiding elimination when client unable to go to bathroom.¹⁴*
- Keep toilet paper or wipes and hand-washing items within client’s easy reach *to enhance self-cleansing efforts.*
- Implement bowel or bladder training/retraining programs as indicated. *This may include developing a schedule for toileting and other interventions as seen in NDs bowel Incontinence, Constipation, urinary Incontinence [specify], and impaired Urinary Elimination.*

NURSING PRIORITY NO. 5 To promote optimal independence (Teaching/Discharge Considerations):

- Assist the client to become aware of rights and responsibilities in health and healthcare and to assess own health strengths—physical, emotional, and intellectual.
- Support client in making health-related decisions and assist in developing self-care practices and goals that promote health.
- Instruct in relaxation techniques (e.g., deep breathing, meditation, music, yoga) *to reduce frustration and enhance coping.*
- Provide for ongoing evaluation of self-care program *to note progress and identify changes in needs.*
- Modify program periodically *to accommodate changes in client’s abilities. Assists client to adhere to plan of care to fullest extent.*
- Encourage keeping a journal *to note progress and identify factors affecting ability to perform self-care activities and to foster self-care and self-determination.⁹*
- Review safety concerns. Modify activities and environment *to reduce risk of injury and promote successful community functioning.*
- Refer to home-care provider, social services, physical or occupational therapy, speech-language pathologist, and rehabilitation and counseling resources as indicated.
- Arrange consult with community resources (e.g., Meals on Wheels, home care or visiting nurse service, senior services, nutritionist) *to provide long-term support and additional forms of assistance that may improve client’s independence and self-care.¹*
- Review instructions from other members of the healthcare team and provide written copy. *Provides clarification and reinforcement and opportunities for periodic review by client/caregivers.*
- Discuss respite or other care options with family. *Allows them free time away from the care situation to renew themselves and enhances coping abilities.* Refer to ND Caregiver Role Strain for related interventions.

-  Assist or support family with alternative placements as necessary. *Enhances likelihood of finding individually appropriate situation to meet client's needs.*
- Be available for discussion of feelings (e.g., grieving, anger, frustration). *Provides opportunity for client/family to get feelings out in the open, realize the feelings are normal, and begin to problem-solve solutions as indicated.*
- Refer to NDs ineffective Coping, compromised family Coping, risk for Disuse Syndrome, risk for Falls/Injury/Trauma, impaired physical Mobility, Powerlessness, and situational low Self-Esteem, as appropriate.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, functional level, and specifics of limitation(s).
- Needed resources and adaptive devices.
- Availability and use of community resources.
- Who is involved in care and provides assistance.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications of plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Type of and source for assistive devices.
- Specific referrals made.

readiness for enhanced Self-Care

Taxonomy II: Activity/Rest—Class 5 Self-Care (00182) [**Diagnostic Division:** Teaching/Learning], Approved 2006; Revised 2013

DEFINITION: A pattern of performing activities for oneself to meet health-related goals, which can be strengthened.

DEFINING CHARACTERISTICS

Subjective

Expresses desire to enhance:

- Independence with life, health, personal development, or well-being
- Knowledge of self-care strategies
- Self-care

[Note: Based on the definition and defining characteristics of this ND, the focus appears to be broader than simply meeting routine basic activities of daily living (ADLs) and addresses independence in maintaining overall health, personal development, and general well-being.]

Sample Clinical Applications: Presence of chronic physical or psychological conditions, or any individual seeking improved well-being or independence in meeting own needs

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Self-Care Status: Ability to perform basic personal care activities and instrumental activities of daily living

Self-Care: Instrumental Activities of Daily Living (IADL): Ability to perform activities needed to function in the home or community independently with or without assistive device

Self-Direction of Care: Care recipient actions taken to direct others who assist with or perform physical tasks and personal healthcare

Client Will (Include Specific Time Frame)

- Maintain responsibility for planning and achieving self-care goals and general well-being.
- Demonstrate proactive management of chronic conditions, potential complications, or changes in capabilities.
- Identify and use resources appropriately.
- Remain free of preventable complications.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Self-Care Assistance: IADL: Assisting and instructing a person to perform instrumental activities of daily living (IADL) needed to function in the home or community

Self-Modification Assistance: Reinforcement of self-directed change initiated by the patient to achieve personally important goals

Self-Efficacy Enhancement: Strengthening an individual's confidence in his/her ability to perform a health behavior

NURSING PRIORITY NO. 1 To determine current self-care status and motivation for improvement:

- Determine individual strengths and skills of the client *to incorporate into plan of care, enhancing likelihood of achieving outcomes. Note: Assessment might include use of an instrument to evaluate client's current functional status, in addition to client's self-report. In the community healthcare setting, a complex assessment tool may be used (e.g., Lawton and Brody's scale of IADL to determine client's self-care abilities [e.g., to communicate by phone, drive, cook, shop, balance a checkbook, manage medical appointments or medications, etc.]). In an acute-care (or emergent) setting, the assessment may be confined to personal care (e.g., Katz Activities of Daily Living Scale). These instruments are used to determine (1) client's safety issues and care needs upon entry into acute care and (2) to ascertain changes in functional abilities as a result of client's condition and treatment.*⁴
- Ascertain motivation and expectations for change. *Motivation to improve and high expectations can encourage client to make changes that will improve his or her life. However, unrealistic expectations may hamper efforts.*
- Note availability and use of resources and supportive person(s) *to ascertain that client has means for sharing common concerns, needs, and wishes, as well as has access to social support and approval (e.g., support group participants, family members, professionals).*²
- ∞ Determine age, developmental issues, and presence of medical conditions resulting in specific deficits (e.g., loss of visual or spatial orientation affecting driving, muscular weakness affecting fine motor coordination, peripheral neuropathy impairing sensory interpretation, fractured ankle affecting ability to transfer or ambulate) *that could impact potential for growth or interrupt client's ability to meet own needs.*^{2,3}
- Assess for potential challenges to enhanced participation in self-care (e.g., language barrier with healthcare providers, lack of information, insufficient time for discussion; sudden or progressive change in health status, catastrophic events).

NURSING PRIORITY NO. 2 To assist client/significant other (SO) plan to meet individual needs:

- Discuss client's understanding of current situation *to determine areas that can be clarified or strengthened. When health changes occur, the ability to make necessary adaptations is influenced by a wide range of variables that include understanding the changes necessary, the readiness and motivation to change, and the motor and sensory abilities to execute those activities.*⁵
- Provide accurate and relevant information regarding current and future needs *so that client can incorporate into self-care plans while minimizing problems (e.g., stress, resistance) often associated with change.*¹
- Promote client/SO participation in problem identification and decision making. *Optimizes outcomes and supports health promotion.*³
- Review coping skills (e.g., assertiveness, interpersonal relations, decision making, problem-solving, stigma management, time management) *that are useful in managing a wide range of stressful conditions.* Encourage client to ask for assistance, as needed or desired.¹
- Active-listen client's/SO's concerns. *Exhibits regard for client's values and beliefs and provides opportunity to support positive responses and address questions or concerns.*²
- ☎ Encourage communication among those who are involved in the client's health promotion. *Periodic review provides clarification of issues, reinforcement of successful interventions, and possibility for early intervention, where needed, to manage chronic conditions.*

NURSING PRIORITY NO. 3 To promote optimum functioning (Teaching/Discharge Considerations):

- 🏠 Assist client to set realistic goals for the future. *Enhances likelihood of success and commitment to behavioral changes.*
- Support client in making health-related decisions and pursuit of self-care practices that promote health *to foster self-esteem and support positive self-concept.*
- Identify reliable reference sources (including Web sites) regarding individual needs and strategies for self-care. *Reinforces learning and promotes self-paced review.*

- Provide for ongoing evaluation of self-care program *to identify progress and needed changes for continuation of health and adaptation in management of limiting conditions.*
- Review safety concerns and modification of medical therapies or activities and environment, as needed, *to prevent injury and enhance successful functioning.*
-  Refer to home-care provider, social services, physical or occupational therapy, speech-language pathologist, rehabilitation, and counseling resources, as indicated or requested, *for education, assistance, and adaptive devices and modifications that may be desired.*
-  Identify additional community resources (e.g., senior services, handicap transportation van for appointments, accessible and safe locations for social or sports activities, Meals on Wheels) *to obtain additional forms of assistance that may improve client's independence and self-care.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including strengths, health status, and any limitation(s).
- Availability and use of resources, support person(s), assistive devices.
- Motivation and expectations for change.

Planning

- Plan of care, specific interventions, and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Client's responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Type of and source for assistive devices.
- Specific referrals made.

readiness for enhanced Self-Concept

Taxonomy II: Self-Perception—Class 1 Self-Concept (00167) [Diagnostic Division: Ego Integrity], Approved 2002; Revised 2013

DEFINITION: A pattern of perceptions or ideas about the self, which can be strengthened.

DEFINING CHARACTERISTICS

Subjective

Expresses:

- Desire to enhance self-concept, role performance
- Acceptance of strengths, limitations
- Confidence in abilities
- Satisfaction with thoughts about self, sense of worth
- Satisfaction with body image, personal identity

Objective

Actions congruent with verbal expressions

Sample Clinical Applications: As a health-seeking behavior, the client may be healthy or this diagnosis can occur in any clinical condition or life process

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Self-Esteem: Personal judgment of self-worth

Hope: Optimism that is personally satisfying and life-supporting

Personal Autonomy: Personal actions of a competent individual to exercise governance in life decisions

Client Will (Include Specific Time Frame)

- Verbalize understanding of own sense of self-worth.
- Participate in programs and activities to enhance self-esteem.
- Demonstrate behaviors or lifestyle changes to promote positive self-esteem.
- Participate in family, group, or community activities to enhance self-concept.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Self-Modification Assistance: Reinforcement of self-directed change initiated by the patient to achieve personally important goals

Self-Awareness Enhancement: Assisting a patient to explore and understand his/her thoughts, feelings, motivations, and behaviors

Self-Esteem Enhancement: Assisting a patient to increase his/her personal judgment of self-worth

NURSING PRIORITY NO. 1 To assess current situation and desire to enhance self-concept:

- Determine current status of individual's belief about self. *Self-concept consists of the physical self (body image), personal self (identity), and self-esteem, and information about client's current thinking about self provides a beginning for making changes to improve self.*^{1,2}
- Determine availability and quality of family/significant other (SO) support. *Presence of supportive people who reflect positive attitudes regarding the individual promotes a positive sense of self.*¹

- Identify family dynamics, both present and past. *Self-esteem begins in early childhood and is influenced by the perceptions of how the individual is viewed by significant others. Provides information about family functioning that will help to develop plan of care for enhancing client's self-concept.*^{1,2}
- Note willingness to seek assistance and motivation for change. *Individuals who have a sense of their own self-image and are willing to look at themselves realistically will be better able to achieve desired growth.*¹
-  Determine client's concept of self in relation to cultural or religious ideals and beliefs. *Culture and religion play a major role in view individual has of self in relation to self-worth.*⁹
-  Observe nonverbal behaviors and note congruence with verbal expressions. Discuss cultural meanings of nonverbal communication. *Incongruence between verbal and nonverbal communication requires clarification. Interpretation of nonverbal expressions is culturally determined and needs to be identified to avoid misinterpretation.*^{1,9}

NURSING PRIORITY NO. 2 To promote client sense of self-esteem:

- Develop therapeutic relationship. Be attentive, validate client's communication, maintain open communication, and use skills of active listening and "I" messages. *Promotes trusting situation in which client is free to be open and honest with self and others.*²⁻⁴
- Accept client's perceptions and view of current status. *Avoids threatening existing self-esteem and provides opportunity for client to develop realistic plan for improving self-concept.*³
- Be aware that people are not designed to be rational in their thinking. *Individuals must seek information—choosing to learn and to think rather than merely accepting/reacting—in order to have respect for self, facts, and honesty and to develop positive self-regard.*⁷
- Discuss client perception of self, confronting misconceptions and identifying negative self-talk. Address distortions in thinking, such as self-referencing (beliefs that others are focusing on individuals' weaknesses or limitations), filtering (focusing on negative and ignoring positive), and catastrophizing (expecting the worst outcomes). *Addressing these issues openly allows client to identify things that may negatively affect self-concept and provides an opportunity for change.*^{7,8}
- Have client review current and past successes and strengths. *Emphasizes fact that client is and has been successful in many actions taken.*^{1,8}
- Use positive "I" messages rather than praise. *Praise is a form of external control, coming from outside sources, whereas "I" messages allow the client to develop internal sense of self-worth.*^{4,5}
- Discuss what behavior does for client (positive intention). Ask what options are available to the client/SO(s). *Encourages thinking about what inner motivations are and what actions can be taken to enhance self-esteem.*³
- Provide reinforcement for progress noted. *Positive words of encouragement support development of effective coping behaviors and promotes continuation of efforts and personal growth.*⁶
- Encourage client to progress at own rate. *Adaptation to a change in self-concept depends on its significance to the individual and disruption to lifestyle.*³
- Involve in activities or exercise program of choice and promote socialization. *Enhances sense of well-being and can help to energize client.*^{6,8}

NURSING PRIORITY NO. 3 To promote enhanced sense of personal worth (Teaching/Discharge Considerations):

-  Assist client to identify personally achievable goals. Provide positive feedback for verbal and behavioral indications of improved self-view. *Increases likelihood of success and commitment to change.*^{3,6}
-  Refer to vocational or employment counselor and educational resources, as appropriate. *Assists with improving development of social or vocational skills.*³
- Encourage participation in classes, activities, or hobbies that client enjoys or would like to experience. *Provides opportunity for learning new information or skills that can enhance feelings of success, improving self-concept.*⁵

- Reinforce that current decision to improve self-concept is ongoing. *Continued work and support are necessary to sustain behavior changes and personal growth.*^{3,5}
- Discuss ways to develop optimism. *Optimism is a key ingredient in happiness and can be learned.*⁷
-  Suggest enrolling in assertiveness training classes. *Promotes learning to assist with developing new skills of voice control, posture, eye contact, or expression of feelings in an assertive, rather than aggressive or passive, manner to promote self-esteem.*³
- Emphasize importance of grooming and personal hygiene and assist in developing skills to improve appearance and dress for success. *Looking your best improves sense of self-worth, and presenting a positive appearance enhances how others see you. While these things are important, having an adequate foundation for the experience of competence and worth is essential to maintaining one's self-concept.*^{1,6}

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including evaluations of self and others, current and past successes.
- Interactions with others, family dynamics, lifestyle.
- Cultural or religious influences.
- Motivation for and willingness to change.

Planning

- Plan of care and who is involved in planning.
- Educational plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

chronic low Self-Esteem

Taxonomy II: Self-Perception—Class 2 Self-Esteem (00119) [**Diagnostic Division:** Ego Integrity], Approved 1988; Revised 1996, 2008, 2017

DEFINITION: Negative evaluation and/or feelings about one's own capabilities lasting at least 3 months.

RELATED FACTORS

Cultural or spiritual incongruence

Inadequate affection received; receiving insufficient approval or inadequate respect from others

Inadequate belonging or group membership

Ineffective coping with loss

DEFINING CHARACTERISTICS

Subjective

Shame; guilt

Underestimates ability to deal with situation

Rejection of positive feedback

Objective

Hesitant to try new experiences

Repeatedly unsuccessful in life events

Exaggerates negative feedback about self

Overly conforming; dependent on others' opinions

Poor eye contact

Nonassertive or indecisive behavior; passivity

Excessive seeking of reassurance

At Risk Population: Exposure to traumatic situation

Pattern of failure; repeated negative reinforcement

Associated Condition: Psychiatric disorder

Sample Clinical Applications: Chronic health conditions, degenerative diseases, eating disorders, substance abuse, depressive disorders, personality disorders, pervasive developmental disorders

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Self-Esteem: Personal judgment of self-worth

Personal Autonomy: Personal actions of a competent individual to exercise governance in life decisions

Hope: Optimism that is personally satisfying and life-supporting

Client Will (Include Specific Time Frame)

- Verbalize understanding of negative evaluation of self and reasons for this problem.
- Participate in treatment program to promote change in self-evaluation.
- Demonstrate behaviors or lifestyle changes to promote positive self-image.
- Verbalize increased sense of self-worth in relation to current situation.
- Participate in family, group, or community activities to enhance change.

(continues on page 752)

chronic low Self-Esteem (continued)

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Self-Esteem Enhancement: Assisting a patient to increase his/her personal judgment of self-worth

Self-Awareness Enhancement: Assisting a patient to explore and understand his/her thoughts, feelings, motivations, and behaviors

Body Image Enhancement: Improving a patient's conscious and unconscious perceptions and attitudes toward his/her body

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Determine factors in current situation that can exacerbate low self-esteem, noting age and developmental level of individual. *Identifying potentially aggravating occurrences (e.g., family crises, physical disfigurement from an accident or illness, feelings of abandonment by significant other [SO] resulting in social isolation) are important for developing plan of care and choosing appropriate interventions that help client develop a sense of self-worth.*¹
- Assess content of negative self-talk. Note client's perceptions of how others view him or her. *Constant repetition of negative words and thoughts reinforce idea that individual is worthless and belief that others view him or her in a negative manner. Identifying these negative ruminations and bringing them to the client's awareness enables person to begin to replace them with positive thoughts.*¹
- Note nonverbal behavior (e.g., nervous movements, lack of eye contact). *Incongruencies between verbal and nonverbal communication require clarification to ensure accuracy of interpretation.*^{1,5}
- Determine availability and quality of family/SO(s) support. *Family is an important component of how an individual views self. The development of a positive sense of self depends on how the person relates to members of the family, as they are growing up and in the current situation.*^{1,3}
- Identify family dynamics, present and past. *How family members interact affects an individual's development and sense of self-esteem. Whether family members are negative and nonsupportive, or positive and supportive, affects the needs of the client at this time.*⁴
-  Be alert to client's concept of self in relation to cultural and religious ideal(s). *Composition and structure of nuclear family influences individual's sense of who they are in relation to others in the family and in society. For example, Mexican American culture dictates that family comes first, the father is the authority in the family, and the behavior of the individual reflects on the entire family.*⁹
-  Determine degree of participation and cooperation with therapeutic regimen. *Maintaining scheduled medications (e.g., antidepressants, antipsychotics) and other aspects of the plan of care requires ongoing evaluation and possible changes in regimen.*^{1,2}
- Note willingness to seek assistance and motivation for change. *Determines client's degree of participation in adhering to therapeutic regimen.*^{1,10}

NURSING PRIORITY NO. 2 To promote client's sense of self-esteem in dealing with situation:

- Develop therapeutic nurse/client relationship. Be attentive, validate client's communication, provide encouragement for efforts, maintain open communication, and use skills of active listening and "I" messages. *Promotes trusting environment in which client is free to be open and honest with self and therapist so current situation can be dealt with most effectively.*^{1,4}
-  Collaborate in addressing/presenting medical issues and safety concerns. *Client's self-esteem may be affected by physical changes of current medical situation. Changes in body, such as weight loss or gain, chronic illness, or amputation, will affect how client sees self as a person. Attitude may contribute to feelings of depression and lack of attention to personal safety requiring evaluation and assistance.*^{1,3,7}

- Accept client's perceptions or view of situation. Avoid threatening existing self-esteem. *Promotes trust and allows client to begin to look at options for improving self-esteem.*^{2,8}
- Be aware that people are not designed to be rational in their thinking. *They must seek information—choosing to learn and to think rather than merely accepting or reacting—in order to have respect for self, facts, and honesty and to develop positive self-esteem.*^{1,13}
- Discuss client perceptions of self related to what is happening; confront misconceptions and negative self-talk. Address distortions in thinking, such as self-referencing (belief that others are focusing on individual's weaknesses or limitations), filtering (focusing on negative and ignoring positive), and catastrophizing (expecting the worst outcomes). *Addressing these issues openly provides opportunity for change.*^{1,3,10}
- Emphasize need to avoid comparing self with others. Encourage client to focus on aspects of self that can be valued. *Changing negative thinking can be effective in developing positive self-talk to enhance self-esteem.*^{2,5}
- Have client review current and past successes and strengths. *Often in the depths of despair and sense of failure in current situation, individual forgets positive aspects of his or her life. Bringing them to mind can remind client of these successes, enhancing sense of self-esteem.*^{3,4}
- Use positive “I” messages rather than praise. *Praise may be heard as manipulative and insincere and be rejected. Use of positive “I” messages communicates a feeling that is genuine and real and allows client to feel good about himself or herself, developing internal sense of self-esteem.*^{4,5}
- Discuss what behavior does for client (positive intention) and what options are available to the client/SO(s). *Helping client begin to look at what rewards are gained from current actions and what actions might be taken to achieve the same rewards in a more positive way can provide a realistic and accurate self-appraisal, enhancing sense of competence and self-worth.*^{1,3,10}
- Assist client to deal with sense of powerlessness. Refer to ND Powerlessness.
- Set limits on aggressive or problem behaviors such as acting out, suicide preoccupation, or rumination. Put self in client's place using empathy, not sympathy. *Preventing undesirable behavior prevents feelings of worthlessness. Suicidal thoughts need further evaluation and intervention. Use of empathy helps caregiver to understand client's feelings better.*^{1,2}
- Give reinforcement for progress noted. *Positive words of encouragement promote continuation of efforts, supporting development of coping behaviors.*^{2,4,10}
- Encourage client to progress at own rate. *Adaptation to a change in self-concept depends on its significance to individual, disruption to lifestyle, and length of crisis or condition.*^{1,2,5}
- Assist client to recognize and cope with events, alterations, and sense of loss of control. *Incorporating changes accurately into self-concept enhances sense of self-worth.*^{1,2,7}
- Involve in activities/exercise program and promote socialization. *Enhances sense of well-being and can help energize client.*^{1,5}

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Discuss inaccuracies in self-perception with client/SO(s). *Enables client and SOs to begin to look at misperceptions and accept reality, and look at options for change to improve sense of self-worth.*^{1,6,8}
- Model behaviors being taught, involving client in goal setting and decision making. *Facilitates client developing trust in his or her own unique strengths.*
- Prepare client for events or changes that are expected, when possible. *Providing time to adapt to changes allows client to prepare self and feel more confident in ability to manage the changes, enhancing sense of self-worth.*^{1,2,7}
- Provide structure in daily routine and care activities. *Knowing what to expect promotes a sense of control and ability to deal with activities as they occur.*^{1,2}
- Emphasize importance of grooming and personal hygiene. Assist in developing skills as indicated (e.g., makeup classes, dressing for success). *People feel better about themselves when they present a positive outer appearance.*^{1,3,5}
- Assist client to identify goals that are personally achievable. Provide positive feedback for verbal and behavioral indications of improved self-view. *Increases likelihood of success and commitment to change.*^{5,11}
-  Refer to vocational or employment counselor and educational resources as appropriate. *Assists with development of social or vocational skills, promoting sense of competence and self-responsibility.*^{1,2,5}

- Encourage participation in classes, activities, or hobbies that client enjoys or would like to experience. *Meaningful accomplishment, assuming self-responsibility, and participating in new activities engenders one's sense of competence and self-worth.*^{8,12}
- Reinforce that this therapy is a brief encounter in overall life of the client/SO(s), with continued work and ongoing support being necessary to sustain behavior changes and personal growth. *Provides individual with information and encouragement to build on for the future.*^{1,6,7}
-  Refer to classes to assist with learning new skills (e.g., assertiveness training, positive self-image, communication skills). *These skills can help client develop a sense of competence through realistic and accurate self-appraisal promoting self-esteem.*¹⁰
-  Refer to counseling or therapy and mental health or other special needs support groups as indicated. *May need additional intervention to develop needed changes.*^{1,10,11}

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including early memories of negative evaluations (self and others), subsequent and precipitating failure events.
- Effects on interactions with others, family dynamics, lifestyle.
- Specific medical or safety issues.
- Cultural or religious factors.
- Motivation for and willingness to change.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

risk for chronic low Self-Esteem

Taxonomy II: Self-Perception—Class 2 Self-Esteem (00224) [**Diagnostic Division:** Ego Integrity], Approved 2010; Revised 2013, 2017

DEFINITION: Susceptible to long-standing negative self-evaluating/feelings about self or self-capabilities, which may compromise health.

RISK FACTORS

Cultural or spiritual incongruence

Inadequate affection received; receiving insufficient approval or inadequate respect from others

Inadequate belonging or group membership

Ineffective coping with loss

At Risk Population: Exposure to traumatic situation

Pattern of failure; repeated negative reinforcement

Associated Condition: Psychiatric disorder

Sample Clinical Applications: Chronic health conditions, eating disorders, substance abuse, depression, personality/pervasive developmental disorders

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Self-Esteem: Personal judgment of self-worth

Coping: Personal actions to manage stressors that tax an individual's resources

Personal Resiliency: Positive adaptation and function of an individual following significant adversity or crisis

Client Will (Include Specific Time Frame)

- Acknowledge understanding of discrepancy between self and cultural/spiritual norms.
- Participate in therapy program to improve self-esteem.
- Demonstrate behaviors to change negative self-evaluation.
- Verbalize understanding of reason for failures and how to make changes for success.
- Participate in family, group, or community activities to enhance change.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Self-Esteem Enhancement: Assisting a patient to increase his/her personal judgment of self-worth

Coping Enhancement: Facilitation of cognitive and behavioral efforts to manage perceived stressors, changes, or threats that interfere with meeting life demands and roles

Socialization Enhancement: Facilitation of another person's ability to interact with others

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- ∞ Note age and developmental level of client and circumstances surrounding current situation. *Younger people may not have learned skills to deal with negative occurrences and/or rejection from others.*^{2,15}
- Elicit client's perceptions of current situation. *Provides understanding of underlying/aggravating occurrences (e.g., family crisis, loss of employment, academic failure, physical disfigurement from an accident or illness, relationship problems/divorce with feelings of abandonment by significant other [SO] resulting in social*

isolation) necessary for choosing interventions appropriate to assist client to address feelings and develop realistic sense of self-worth.^{1,15}

- Ascertain sense of control client perceives to have over self/situation. *Client's locus of control or the degree of control client believes he or she has may be a critical factor in ability to deal with current situation. Individuals with external locus of control tend to blame others for their problems rather than taking responsibility for their actions. As a result, they may feel helpless or powerless and look to others to solve problems and take care of them.*^{3,14,15}
- Determine client's awareness of self-destructive behavior, acting out, aggression, and suicidal thoughts. *Choices individual makes result from low self-esteem and pleasing others and lead to feelings of worthlessness.*^{1,8}
- Note content of negative self-talk and client's perception of how others see him or her. *As negative thoughts are repeated in one's head, they become the basis for believing that the individual is indeed worthless and others must agree with that conclusion.*^{1,3}
- Observe nonverbal behavior (e.g., nervous movements, lack of eye contact) and how it relates to verbal statements. *Incongruencies between verbal and nonverbal need to be clarified to be sure perceived meaning of communication is accurate.*¹⁰
-  Note religious and cultural factors that have influenced client. *Family of origin affects how one views self in relation to family members and others in society. For instance, Islamic families tend to be patriarchal, with the father exercising unmitigated power over female family members and making all decisions for them.*^{5,8}
- Determine family makeup and whether they are available and supportive. *Support of family is essential to client's self-esteem. Predominant world view is determined by the time an individual is 5 years of age.*^{3,15}
- Note family dynamics and how client interacts within the family. *Crucial to individual's development and self-esteem in a positive or negative way.*^{8,15}
-  Evaluate current medication regimen noting client adherence. *Maintaining therapeutic regimen requires ongoing evaluation to determine efficacy or need for change. The client who is asymptomatic or depressed may not feel the need to take prescribed medications. Other factors can also impact client's willingness to follow therapeutic plan (e.g., complexity of regimen, poor quality of the client-provider relationship, issues of access to care).*^{13,16}

NURSING PRIORITY NO. 2 To promote client's sense of self-esteem in dealing with changes in life:

- Establish therapeutic nurse/client relationship, maintaining open communication and using Active-listening and "I" messages. *Promotes a trusting environment in which client is free to talk about potential problems that may arise.*⁹
- Determine willingness to improve attitudes and sense of self. *Negative perceptions, sense of alienation, and lack of involvement in positive activities lead to sense of worthlessness. Making a commitment to change provides an opportunity to learn new ways to interact with others and choose activities that promote individual successes.*^{1,8}
- Address possible situations that client may be facing. *Sense of loss, lack of involvement in group, traumatic event, and repeated failures in attempts to change situation may discourage client from wanting to try to make life better.*^{1,15}
- Avoid challenging client's perception of events. *May threaten sense of self-esteem, limiting client's ability to check out perceptions and make own corrections.*¹¹
- Reinforce that people are not necessarily rational in their thinking. *They must seek information, choosing to learn and to think, rather than merely accepting or reacting, in order to have respect for self and develop positive self-esteem.*^{1,3,8,17}
- Discuss misperceptions and negative self-talk as well as distortions in thinking, such as self-referencing (belief that others are focusing on person's weaknesses or limitations), filtering (focusing on negative and ignoring positive), or catastrophizing (believing the worst will happen). *These issues keep individual believing in a negative, worthless view of self and need to be addressed before person can move on and improve life.*^{1,3}

- Discuss the problem of comparing self to others. Encourage client to focus on own positive aspects. *These actions will help individual to change negative thinking.*^{1,3}
- List current and previous successes. *Focusing on these can help the client realize that failures can be overcome.*¹
- Provide positive feedback, for verbal and behavioral indications of improved self-view, using “I” messages instead of praise. *Praise can be interpreted as insincere and manipulative and be rejected. Positive “I” messages convey a sense of acceptance and let the individual feel good about self, enhancing self-esteem and encouraging individual to continue efforts.*^{9,12}
- Ask client to think about what behavior does (positive intention) in relation to low self-esteem, reluctance to join groups, and seeing self as less than others. *As individual thinks about this aspect of behavior, awareness of having a choice to change life may facilitate positive changes.*^{3,8}
- Discuss feelings of powerlessness. *It is important to differentiate between what the client can control or change and what cannot be controlled. Inability of the client to make this distinction can cause client to feel defeated and increase sense of low self-esteem. Understanding that one is incapable of making everything right and perfect with all people, places, and things in life gives the individual the ability to retain the “locus of control.”*¹⁵ Refer to ND: Powerlessness.
- Contract with client/set limits on acting out and aggressive or self-destructive behaviors. *Aids in preventing negative behaviors that can result in/exacerbate feelings of worthlessness.*⁷ Refer to NDs risk for other/self-directed Violence and risk for Suicide for additional interventions.
- Encourage client to progress at own pace, providing reinforcement as progress is made. *Helps individual to value self and believe life changes can be made.*^{1,8}
- Promote socialization and involvement in exercise and activity programs. *Helps individual to realize involvement with others can lead to positive feelings about self.*^{4,6}

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Involve client in goal setting and decision making. *Facilitates trust and belief that change can be made and life can improve.*⁹
- Encourage client to structure daily activities so routine becomes manageable. *Promotes a sense of control and belief in own abilities.*⁶
- Discuss importance of grooming and personal hygiene, involvement in classes (i.e., Dress for Success). *Others often judge an individual by the outward appearance presented, as well as individual's own positive appraisal and sense of confidence.*¹⁰
- Refer to educational resources and vocational or employment counselor as indicated. *Promotes future success, reinforcing self-worth.*^{4,15}
-  Identify/refer to support groups and classes, such as assertiveness, communication skills, and parenting as appropriate. *These skills can help client develop or strengthen a sense of competence through realistic and accurate self-appraisal, promoting self-esteem.*^{4,6,12,15}
-  Review importance of adherence to medication regimen when prescribed. *A number of factors influence client's decisions about taking medications, including awareness of illness, beliefs about treatment, and side effects of medication. While education increases client's understanding of his or her illness/situation and treatment, it does not always improve compliance. Interventions such as individual or group counseling or compliance therapy based on cognitive-behavioral techniques may be useful in supporting personal growth and commitment to change.*^{13,16}

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, noting risk factors, client's perceptions, interaction with others.
- Cultural values or religious beliefs, locus of control.
- Family support, availability, and use of resources.

Planning

- Plan of care and who is involved in planning.
- Individual teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, actions performed, and changes that may be indicated.
- Attainment or progress toward desired outcomes.
- Modification to plan of care.

Discharge Planning

- Long-term needs and goals and who is responsible for actions to be taken.
- Specific referrals made.

risk for situational low Self-Esteem

Taxonomy II: Self-Perception—Class 2 Self-Esteem (00153) [**Diagnostic Division:** Ego Integrity], Approved 2000; Revised 2013, 2017

DEFINITION: Susceptible to developing a negative perception of self-worth in response to a current situation, which may compromise health.

RISK FACTORS

Alteration in body image or social role
 Pattern of helplessness; history of rejection; inadequate recognition
 Behavior inconsistent with values
 Decrease in control over environment
 Unrealistic expectations

At Risk Population: Developmental transition
 History of: abandonment, abuse, loss, neglect, rejection
 Pattern of failure

Associated Condition: Functional impairment
 Physical illness

Sample Clinical Applications: Traumatic injuries, surgery, pregnancy, newly diagnosed conditions (e.g., diabetes mellitus, hypertension), adjustment disorders, substance use, stroke, dementia

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Self-Esteem: Personal judgment of self-worth

Psychosocial Adjustment: Life Change: Adaptive psychosocial response of an individual to a significant life circumstance

Abuse Recovery: Emotional: Extent of healing of psychological injuries due to abuse

Client Will (Include Specific Time Frame)

- Acknowledge factors that lead to possibility of feelings of low self-esteem.
- Verbalize view of self as a worthwhile, important person who functions well both interpersonally and occupationally.
- Demonstrate self-confidence by setting realistic goals and actively participating in life situation.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Self-Esteem Enhancement: Assisting a patient to increase his/her personal judgment of self-worth

Coping Enhancement: Facilitation of cognitive and behavioral efforts to manage perceived stressors, changes, or threats that interfere with meeting life demands and roles

Self-Awareness Enhancement: Assisting a patient to explore and understand his/her thoughts, feelings, motivations, and behaviors

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Determine individual factors that may contribute to diminished self-esteem. *Proactive information allows identification of appropriate interventions to deal with current situation.*^{1,2}

- Identify basic sense of self-worth of client and image client has of self—existential, physical, and psychological. *The components of self-concept consist of the physical self or body image, the personal self or personal identity, and the self-esteem, with each aspect playing a role in the client's ability to deal with anticipated changes.*¹
- Note client's perception of threat to self in current situation. *Perception is more important than reality of what is happening. Some individuals view a potentially severe situation as something easily handled, while others may view a minor problem with anxiety and catastrophizing.*^{2,3}
- Ascertain sense of control client has (or perceives to have) over self and situation. *Individual with internal locus of control tends to perceive self in control of what is happening and will participate more actively in care and feel more sense of self-worth.*^{7,8}
-  Determine client awareness of own responsibility for dealing with situation, personal growth, etc. *Acceptance of responsibility for self enables client to feel more comfortable with treatment regimen and participate more fully, promoting self-esteem.*^{1,9}
- Assess family/significant other (SO) dynamics and support of client. *How family interacts with one another affects not only the development of self-esteem but also the maintenance of a sense of self-worth when client is facing an illness or crisis. Dysfunctional interactions may be detrimental to client's ability to deal with what is happening.*^{1,5}
-   Verify client's concept of self in relation to cultural or religious ideals. *Culture and religion play a major role in view individual has of self in relation to self-worth. Illness may interfere with this view; for instance, males in Mexican American culture are seen as the head of the household, and giving up this role because of illness can diminish self-esteem.*⁴ *Note: Recent studies support that self-esteem functions similarly across cultures.*¹⁰
- Assess negative attitudes and/or self-talk. *Contributes to view of situation as hopeless and/or difficult.*^{3,6}
-  Listen for or note self-destructive or suicidal thoughts or behaviors. *Indicates high level of stress and need for further evaluation and referral for mental health services.*^{1,6} Refer to ND risk for Suicide as appropriate.
- Note nonverbal body language. *Incongruencies between verbal and nonverbal communications require clarification to ensure accuracy of interpretation.*¹
- Identify previous adaptations to illness or disruptive events in life. *Provides information about how client handled those situations and may be predictive of current outcome.*¹
- Determine availability and use of support systems. *Feeling hopeless and alone lowers client ability to manage care and concentrate on healing. Support systems can provide role modeling and the help needed to engender hope and enhance self-esteem.*¹
- Note availability and use of resources to address specific need (e.g., rehabilitation services, home-care support, job placement). *Individual may be unaware or have difficulty accessing community supports or assistance programs.*

NURSING PRIORITY NO. 2 To assist client to deal with loss/change and maintain sense of positive self-esteem:

- Encourage expression of feelings and anxieties. *Facilitates grieving the loss.*
- Active-listen client's concerns without comment or judgment.
- Help client identify individual strengths and assets, reinforcing positive traits and self-view.
- Assist client to problem-solve situation and develop plan of action.
- Convey confidence in client's ability to cope with current situation.
- Mobilize appropriate support systems.

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Provide information to assist client in making desired changes. *Appropriate books, DVDs, or Internet resources allow client to learn at own pace.*

- Suggest participation in group or community activities or volunteer work *that can provide opportunity for success and positive feedback for accomplishments.*
- Involve significant others/extended family in treatment plan. *Increases likelihood they will provide appropriate support to client.*
-  Promote attendance in therapy or support groups as indicated.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including individual expressions of lack of self-esteem, effects on interactions with others, lifestyle.
- Underlying dynamics and duration (situational or situational exacerbating chronic).
- Cultural values or religious beliefs, locus of control.
- Family support, availability and use of resources.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, actions performed, and changes that may be indicated.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and goals, and who is responsible for actions to be taken.
- Specific referrals made.

situational low Self-Esteem

Taxonomy II: Self-Perception—Class 2 Self-Esteem (00120) [**Diagnostic Division:** Ego Integrity], Approved 1988; Revised 1996, 2000, 2017

DEFINITION: Development of a negative perception of self-worth in response to a current situation.

RELATED FACTORS

Alteration in body image or social role
 Pattern of helplessness; history of rejection; inadequate recognition
 Behavior inconsistent with values
 Decrease in control over environment
 Unrealistic expectations

DEFINING CHARACTERISTICS

Subjective

Helplessness; purposelessness
 Underestimates ability to deal with situation

Objective

Situational challenge to self-worth
 Self-negating verbalizations
 Indecisive or nonassertive behavior
At Risk Population: Developmental transition
 History of: abandonment, abuse, loss, neglect, rejection
 Pattern of failure

Associated Condition: Functional impairment
 Physical illness

Sample Clinical Applications: Traumatic injuries, surgery, pregnancy, newly diagnosed conditions (e.g., diabetes mellitus), adjustment disorders, substance use, stroke, dementia

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Self-Esteem: Personal judgment of self-worth

Psychosocial Adjustment: Life Change: Adaptive psychosocial response of an individual to a significant life circumstance

Personal Resiliency: Positive adaptation and function of an individual following significant adversity or crisis

Client Will (Include Specific Time Frame)

- Verbalize understanding of individual factors that precipitated current situation.
- Identify feelings and underlying dynamics for negative perception of self.
- Express positive self-appraisal.
- Demonstrate behaviors to restore positive self-image.
- Participate in treatment regimen or activities to correct factors that precipitated crisis.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Self-Esteem Enhancement: Assisting a patient to increase his/her personal judgment of self-worth

Coping Enhancement: Facilitation of cognitive and behavioral efforts to manage perceived stressors, changes, or threats that interfere with meeting life demands and roles

Support System Enhancement: Facilitation of support to patient by family, friends, and community

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Determine individual situation (e.g., family crisis, termination of a relationship, loss of employment, physical disfigurement) related to low self-esteem in the present circumstances. *Many factors are involved in a person's self-esteem, and this information is essential for planning accurate care.*¹
- Identify basic sense of self-esteem of client; image client has of self—existential, physical, and psychological. *The components of self-concept consist of the physical self or body image, the personal self or personal identity, and the self-esteem. Each aspect plays a role in the client's ability to deal with current situation/crisis.*¹
- Assess degree of threat and perception of client concerning crisis. *How individuals perceive themselves is based on the self-judgments they make. How the client sees the current situation in relation to ability to cope will affect his or her sense of self-worth and needs to be acknowledged and planned for to help client deal with feelings of low self-esteem.*^{1,2}
-  Ascertain sense of control client has (or perceives to have) over self and situation. *Client's locus of control or degree of control client believes or perceives he or she has may be a critical factor in ability to deal with current situation or crisis. Individuals with internal locus of control tend to be more optimistic about their ability to deal with adversity even in the face of current difficulties. Individuals with external locus of control will look to others to solve problems and take care of them.*¹⁻³
- Determine client's awareness of own responsibility for dealing with situation, personal growth, etc. *These factors enhance the ability of the client to effectively manage situation in a positive manner.*⁴
- Assess family/significant other (SO) dynamics and support of client. *How family members interact affects an individual's development and sense of self-esteem. Effective interactions among family members usually lead to positive support for the client in current situation. Dysfunctional interactions may be detrimental to client's ability to deal with what is happening.*^{2,3}
-   Verify client's concept of self in relation to cultural and religious ideals. *Self-esteem is developed by many factors, including genetics and environment. Cultural and religious influences during the individual's life affect beliefs about self, measure of worth, and ability to deal with current situation or crisis.*^{1,5} *Note: Recent studies support that self-esteem functions similarly across cultures.*⁶
- Determine past coping skills in relation to current episode. *Trust is built over time, and past experiences with failure or success will affect client's expectations regarding the eventual outcome of dealing with current illness or crisis.*^{8,9}
-  Assess negative attitudes or self-talk. *An individual who is feeling unimportant, incompetent, and not in control often is unconsciously saying negative things to himself or herself that contribute to a loss of self-esteem and an attitude of despair, affecting current situation.*^{1,7}
- Note nonverbal body language. *Incongruencies between verbal or nonverbal communication require clarification to ensure accuracy of interpretation.*^{1,2}
- Assess for self-destructive or suicidal thoughts or behavior. *Client who believes situation is hopeless often begins to consider suicide as an option. Refer to ND risk for Suicide as appropriate.*¹
- Identify previous adaptations to illness or disruptive events in life. *May be predictive of current ability to deal with situation and suggest eventual outcome.*¹

- 🏠 Note availability and use of resources to address specific need (e.g., rehabilitation services, home-care support, job placement). *Individual may be unaware or have difficulty accessing community supports or assistance programs.*

NURSING PRIORITY NO. 2 To assist client to deal with loss/change and recapture sense of positive self-esteem:

- 🧠 Assist with treatment of underlying condition when possible. *For example, cognitive restructuring and improved concentration in mild brain injury often result in restoration of positive self-esteem.*¹
- Encourage expression of feelings, anxieties; facilitate grieving the loss. *As client expresses feelings and anxieties, he or she begins to deal with the realities of the current situation and the loss that occurs with the changes of illness.*¹ Refer to ND Grieving as appropriate.
- Active-listen to client's concerns or negative verbalizations without judgment. *Conveys a message of acceptance and confidence in client's ability to deal with whatever occurs.*
- 📋 Identify individual strengths, assets, and aspects of self that remain intact and can be valued. Reinforce positive traits, abilities, and self-view. *Client may not see these in the anxiety and hopelessness of the immediate situation, and reminding client of own positive attributes can help him or her recover hope and develop a positive attitude about situation.*^{1,7}
- Help client identify own responsibility and control or lack of control in situation. *Accepting responsibility enables client to look realistically at what is under own control and what is not. When client stops expending energy on issues that cannot be controlled, energy is freed up to concentrate on more productive avenues.*^{1,8}
- Assist client to problem-solve situation, developing a plan of action and setting goals to achieve desired outcome. *Personal involvement enhances commitment to plan, optimizing outcomes.*
- Convey confidence in client's ability to cope with current situation. *Validation helps client accept own ability to deal with what is happening.*¹
- Mobilize support systems; identify individuals in similar circumstances. *Feeling hopeless and alone lowers client's ability to manage care and concentrate on healing. Support systems can provide role modeling and the help needed to engender hope and enhance self-esteem.*^{1,3}
- 📋 Provide opportunity for client to practice alternative coping strategies, including progressive socialization opportunities. *Involvement with others provides client with situation in which new actions can be tried out and validated or discarded to enhance feelings of self-worth.*^{1,3}
- Encourage use of visualization, guided imagery, and relaxation. *These strategies promote a positive sense of self and general well-being, enhancing client's coping ability.*¹
- Provide feedback about client's self-negating remarks or behavior, using "I" messages. *Allows client to experience a different view. "I" messages are a nonjudgmental way to let individual understand how behavior is perceived by or affecting others and self.*
- Encourage involvement in decisions about care when possible. *Promotes sense of control over what is happening, enhancing feelings of self-worth.*^{1,8}
- Give reinforcement for progress noted. *Positive words of encouragement promote continuation of efforts, supporting development of coping behaviors.*¹⁰

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

- 🏠 Assist client to identify personally achievable goals. *Increases likelihood of client's success and commitment to change.*^{2,10}
- Encourage client to look to the future and set long-range goals for achieving necessary lifestyle changes. *Supports view that this is an ongoing process, providing client with hope for the future.*^{1,3}
- Support independence in activities of daily living and mastery of therapeutic regimen. *Individuals who are confident are more secure and positive in self-appraisal.*^{1,2}
- 🧠 Promote attendance in therapy or support group as indicated. *Provides opportunity to discuss own situation and hear how others are dealing with similar problems, promoting new ideas about own ability to deal with issues.*^{1,9,10}

- Involve extended family/SO(s) in treatment plan as appropriate. *Enhances their understanding of what client wishes to accomplish, increasing likelihood they will provide appropriate support to client.*¹
- Provide information and bibliotherapy, including reliable Web sites as appropriate. *Reinforces learning, allowing client to progress at own pace. Promotes opportunity for making informed decisions and improving ability to deal with situation.*^{1,7}
-  Refer to vocational or employment counselor and educational resources, as appropriate. *Assists with development of social or vocational skills, promoting sense of competence and self-responsibility.*^{1,2}
- Suggest participation in group or community activities (e.g., assertiveness classes, volunteer work, support groups). *Provides opportunities for learning new information and being appreciated for contributions, enhancing sense of self-worth.*^{1,2}
-  Refer to counseling or therapy, mental health, or other special-needs support groups, as indicated. *May need additional support to deal with crisis.*^{1,10}

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, noting precipitating crisis, client's perceptions, effects on desired lifestyle/interaction with others.
- Cultural values or religious beliefs, locus of control.
- Family support, availability and use of resources.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, actions performed, and changes that may be indicated.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and goals and who is responsible for actions to be taken.
- Specific referrals made.

Self-Mutilation

Taxonomy II: Safety/Protection—Class 3 Violence (00151) [**Diagnostic Division:** Safety], Approved 2000; Revised 2017

DEFINITION: Deliberate self-injurious behavior causing tissue damage with the intent of causing nonfatal injury to attain relief of tension.

RELATED FACTORS

Absence of family confidant; disturbance in interpersonal relationships; feeling threatened with loss of significant relationship
 Ineffective communication between parent and adolescent; eating disorder
 Alteration in body image; low self-esteem
 Dissociation; emotional disturbance; labile behavior
 Irresistible urge for self-directed violence or to cut self
 Impulsiveness; ineffective coping strategies; inability to express tension verbally; mounting tension that is intolerable; requires rapid stress reduction
 Isolation from peers
 Negative feeling [e.g., depression, rejection, self-hatred, separation anxiety, guilt]; perfectionism; loss of control over problem-solving situation
 Pattern of inability to plan solutions or to see long-term consequences; use of manipulation to obtain nurturing relationship with others
 Substance misuse/[abuse]

DEFINING CHARACTERISTICS

Subjective

Self-inflicted burn
 Ingestion or inhalation of harmful substances or objects

Objective

Cuts or scratches on body
 Picking at wound
 Biting; abrading
 Insertion of object(s) into body orifice(s)
 Hitting
 Severing or constricting a body part

At Risk Population:

Adolescence
 Battered child; history of childhood abuse; history of self-directed violence; peers who self-mutilate
 Childhood illness or surgery; developmental delay
 Family divorce; family history of self-destructive behavior or substance abuse; violence between parental figures
 Incarceration; living in nontraditional setting
 Sexual identity crisis

Associated Condition: Autism

Borderline personality or character disorder; depersonalization
 Psychotic disorder

Sample Clinical Applications: Borderline personality, dissociative disorders, bipolar disorder, developmental delay, autism, eating disorders, substance abuse, physical or psychological abuse, gender identity crisis

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Mutilation Self-Restraint: Personal actions to refrain from intentional self-inflicted injury (nonlethal)

Impulse Self-Control: Self-restraint of compulsive or impulsive behaviors

Distorted Thought Self-Control: Self-restraint of disruptions in perception, thought processes, and thought content

Client Will (Include Specific Time Frame)

- Verbalize understanding of reasons for occurrence of behavior.
- Identify precipitating factors and awareness of arousal state that occurs prior to incident.
- Express increased self-concept or self-esteem.
- Seeks help when feeling anxious and having thoughts of harming self.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Behavior Management: Self-Harm: Assisting the patient to decrease or eliminate self-mutilating or self-abusive behaviors

Environmental Management: Safety: Monitoring and manipulation of the physical environment to promote safety

Limit Setting: Establishing the parameters of desirable and acceptable patient behavior

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Determine underlying dynamics of individual situation as listed in Related Factors. Note previous episodes of self-mutilation behavior. *Although some body piercing (e.g., ears, nose, lip, eyebrow) is generally accepted as decorative, piercing of multiple sites or industrial piercings are often an attempt to establish individuality, addressing issues of separation and belonging, but are not considered self-injury or self-mutilating behaviors.*^{1,7}
- Identify previous history of self-mutilative behavior and relationship to stressful events. *Self-injury is considered an attempt to alter a mood state and/or an outlet for negative emotions such as anger and shame. Information about previous behavior and precipitating factors is important to understanding and planning care in current situation.*^{1,7,9,11}
-  Determine presence of inflexible, maladaptive personality traits that reflect personality or character disorder. *Identification of impulsive, unpredictable, or inappropriate behaviors; intense anger; or lack of control of anger is important for planning appropriate interventions and plan of care. Clients diagnosed as borderline personality disorder are often unstable and prone to self-injury and need a specific treatment plan to diminish these behaviors.*^{1,9}
- Evaluate history of mental illness (e.g., borderline personality, identity disorder, bipolar disorder). *These illnesses may be the underlying cause of the self-injurious behavior.*^{1,2,10}
-  Note beliefs and cultural or religious practices that may be involved in choice of behavior. *Growing up in a family that did not allow feelings to be expressed, individual may believe that feelings are wrong or bad. Family dynamics may come out of religious or cultural expectations that support strict punishment for transgressions. Individuals may believe mental illness is the result of unacceptable actions, and feelings of guilt may lead to anxiety and subsequent self-injurious behaviors.*⁴
-  Note use or abuse of addicting substances. *May be indicative of attempt to treat self and needs further evaluation and additional intervention.*^{2,6,10}

-  Review laboratory findings (e.g., blood alcohol, polydrug screen, glucose, electrolyte levels). *Helpful for identifying drug use or medical problems that may be affecting behavior negatively.*¹

NURSING PRIORITY NO. 2 To structure environment to maintain client safety:

- Assist client to identify feelings leading up to desire for self-mutilation. *Early recognition of recurring feelings provides opportunity to seek other ways of coping.*⁵
-  Provide external controls or limit setting. *Reducing opportunities for client to self-mutilate can help client learn to stop the behavior.*^{4,8}
- Encourage appropriate expression of feelings. *Helps client to identify feelings and promote understanding of what leads to development of tension and subsequent injurious behavior.*²
-  Keep client in continuous staff view and do special observation checks during inpatient stay. *Promotes safety by recognizing escalating behaviors and providing timely intervention.*^{2,5}
-  Structure inpatient milieu to maintain positive, clear, open communication among staff and clients, with an understanding that “secrets are not tolerated” and will be confronted. *Prevents manipulative behavior, so client does not pit one staff member against another to fulfill own desires.*^{1,4,5}
-  Note feelings of healthcare providers/family, such as frustration, anger, defensiveness, and need to rescue. *Client may be manipulative, evoking defensiveness and conflict. These feelings need to be identified, recognized, and dealt with openly with staff/family and client.*⁴
-  Provide care for client’s wounds when self-mutilation occurs in a matter-of-fact manner. Refrain from offering sympathy or additional attention. *A matter-of-fact approach can convey empathy and concern but not undue concern that could provide reinforcement for maladaptive behavior and encourage its repetition.*²
-  Discuss use of medication, such as clozapine. *This medication has been shown to reduce acts of self-injurious behavior and help client maintain a more stable mood.*³
-  Develop schedule of or refer to alternative healthy, success-oriented activities. *Group or family therapy or groups such as Eating Disorders or a similar 12-step program based on individual needs; self-esteem activities, including positive affirmations; visiting with friends; and exercise help client to practice new behaviors in a supportive environment.*^{7,11}

NURSING PRIORITY NO. 3 To promote movement toward positive changes:

- Encourage client involvement in formulating plan of care and developing goals for preventing undesired behavior. *Being involved in own decisions can help to reestablish ego boundaries and enhance commitment to goals, optimizing outcomes and enhancing self-esteem.*^{2,5}
-  Develop a contract between client and counselor to enable the client to stay physically safe, such as “I will not cut or harm myself for the next 24 hours.” Renew contract on a regular basis and have both parties sign and date each contract. *Making a commitment in writing helps client to think before acting and can prevent new incidents of self-injury.*⁴
- Provide avenues of communication for times when client needs to talk. *Having an opportunity to discuss anxieties helps client to avoid cutting or damaging self.*^{4,6}
- Assist client to learn assertive behavior. Include the use of effective communication skills, focusing on developing self-esteem by replacing negative self-talk with positive comments. *Low self-esteem is a factor in this behavior, and by learning new ways of expressing self, client can begin to feel better and deal with anxieties in a more positive manner.*^{2,10}
- Choose interventions that help the client to reclaim power in own life (e.g., experiential and cognitive). *Beginning to think in a positive manner and then translating that into action provides reinforcement for using power to stop injurious behaviors and develop a more productive lifestyle.*²

NURSING PRIORITY NO. 4 To promote long-term safety (Teaching/Discharge Considerations):

-  Discuss commitment to safety and ways in which client will deal with precursors to undesired behavior. *Identifies specific precursors for individual and provides a plan for client to follow when anxiety becomes overwhelming.*^{2,8,10}

- Promote the use of healthy behaviors, identifying the consequences and outcomes of current actions. *As client develops a more positive attitude and accepts the idea that current actions are being destructive to desired life-style, new behaviors can help make needed changes.*²
- Identify support systems. *Knowing who client can turn to when anxiety becomes a problem helps to avoid injurious behavior.*¹
- Discuss living arrangements when client is discharged from inpatient program. *May need assistance with transition to changes required to avoid recurrence of self-mutilating behaviors.*^{2,10}
-  Involve family/significant other (SO) in planning for discharge and involve in group therapies as appropriate. *Promotes coordination and continuation of plan and commitment to goals.*^{2,6}
- Discuss the role neurotransmitters play in predisposing individual to beginning this behavior. *It is believed that problems in the serotonin system may make the person more aggressive and impulsive, and when combined with a home where they have learned that feelings are bad or wrong, this leads to turning aggression on self.*⁸
-  Provide information and discuss the use of medication as appropriate. *Antidepressant medications may be useful, but they need to be weighed against the potential for overdosing.*^{1,3}
- Refer to NDs Anxiety, Self-Esteem (specify), and impaired Social Interaction.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including risk factors present, underlying dynamics, prior episodes.
- Cultural or religious practices.
- Laboratory test results.
- Substance use or abuse.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Community resources, referrals made.

risk for Self-Mutilation

Taxonomy II: Safety/Protection—Class 3 Violence (00139) [**Diagnostic Division:** Safety], Approved 1992; Revised 2000, 2013, 2017

DEFINITION: Susceptible to deliberate self-injurious behavior causing tissue damage with the intent of causing nonfatal injury to attain relief of tension.

RISK FACTORS

Absence of family confidant; disturbance in interpersonal relationships; feeling threatened with loss of significant relationship

Ineffective communication between parent and adolescent; eating disorder

Alteration in body image; low self-esteem

Dissociation; emotional disturbance; labile behavior

Irresistible urge for self-directed violence or to cut self

Impulsiveness; ineffective coping strategies; inability to express tension verbally; mounting tension that is intolerable; requires rapid stress reduction

Isolation from peers

Negative feeling [e.g., depression, rejection, self-hatred, separation anxiety, guilt]; perfectionism; loss of control over problem-solving situation

Pattern of inability to plan solutions or to see long-term consequences; use of manipulation to obtain nurturing relationship with others

Substance misuse/[abuse]

At Risk Population:

Adolescence

Battered child; history of childhood abuse; history of self-directed violence; peers who self-mutilate

Childhood illness or surgery; developmental delay

Family divorce; family history of self-destructive behavior or substance abuse; violence between parental figures

Incarceration; living in nontraditional setting

Sexual identity crisis

Associated Condition: Autism

Borderline personality or character disorder; depersonalization

Psychotic disorder

Sample Clinical Applications: Borderline personality, dissociative disorders, bipolar disorder, developmental delay, autism, eating disorders, substance abuse, physical/psychological abuse, gender identity crisis

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Mutilation Self-Restraint: Personal actions to refrain from intentional self-inflicted injury (nonlethal)

Impulse Self-Control: Self-restraint of compulsive or impulsive behaviors

Distorted Thought Self-Control: Self-restraint of disruptions in perception, thought processes, and thought content

Client Will (Include Specific Time Frame)

- Verbalize understanding of reasons for occurrence of behavior.
- Identify precipitating factors and awareness of arousal state that occurs prior to incident.
- Express increased self-concept or self-esteem.

- Demonstrate self-control as evidenced by lessened (or absence of) episodes of self-mutilation.
- Engage in use of alternative methods for managing feelings and individuality.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Behavior Modification: Promotion of a behavior change

Calming Technique: Reducing anxiety in patient experiencing acute distress

Behavior Management: Self-Harm: Assisting the patient to decrease or eliminate self-mutilating or self-abusive behaviors

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Determine underlying dynamics of individual situation as listed in Risk Factors. Note the presence of conditions that may interfere with ability to control own behavior (e.g., psychotic state, mental retardation, autism) *and may lead to incidents of self-injury.*¹
- Assess for inflexible, maladaptive personality traits. *May reflect personality or character disorder (e.g., impulsive, unpredictable, inappropriate behaviors, intense anger or lack of control of anger) that may lead to self-mutilative behaviors.*¹
- Evaluate history of mental illness (e.g., borderline personality, identity disorder, bipolar disorder). *These illnesses may be the underlying cause of the self-injurious behavior.*^{1,2,10}
- Identify previous episodes of self-mutilating behavior (e.g., cutting, scratching, bruising). *Self-injury is considered an attempt to alter a mood state and/or an outlet for negative emotions such as anger and shame. Information about previous behavior and precipitating factors is important to understanding and planning care in current situation.*^{1,7-9,11} *Although some body piercing (e.g., ears) is generally accepted as decorative, piercing of multiple sites or industrial piercings are often an attempt to establish individuality, addressing issues of separation and belonging, but are not considered as self-injury or self-mutilating behaviors.*²
-  Note beliefs and cultural or religious practices that may be involved in choice of behavior. *Growing up in a family that did not allow feelings to be expressed, individual may believe that feelings are wrong or bad. Family dynamics may come out of religious or cultural expectations that support strict punishment for transgressions. Individuals may believe mental illness is the result of unacceptable actions, and feelings of guilt may lead to anxiety and subsequent self-injurious behaviors.*⁴
-  Determine use or abuse of addictive substances, including alcohol. *Individuals often use these substances to self-medicate feelings of anxiety and may increase the risk of suicide by sixfold.*^{2,8,10}
- Note degree of impairment in social and occupational functioning. *May dictate treatment setting (e.g., specific outpatient program or short-stay inpatient when client is experiencing extreme anxiety).*^{1,5,9}
-  Review laboratory findings (e.g., blood alcohol, polydrug screen, glucose, electrolyte levels). *Helpful for identifying drug use or medical problems that may be affecting behavior negatively.*¹

NURSING PRIORITY NO. 2 To structure environment to maintain client safety:

- Assist client to identify feelings and behaviors that precede desire for self-mutilation. *Early recognition of recurring feelings provides client opportunity to seek other ways of coping, including asking for help.*^{2,6}
- Provide external controls or limit-setting as indicated. *Decreases the opportunity to injure self and helps client think about reasons for actions and learn different ways to deal with them.*¹
- Encourage client to recognize and appropriately express feelings verbally. *Learning to express feelings enables client not only to recognize them, but also to begin to find acceptable and appropriate ways to deal with them.*^{6,7,11}

- Note feelings of healthcare providers/family, such as frustration, anger, defensiveness, distraction, despair and powerlessness, and need to rescue. *Client may be manipulating or splitting providers/family members, which evokes defensiveness and resultant conflict. These feelings need to be identified, recognized, and dealt with openly with staff/family and client.*¹
- Refer to alternative healthy, success-oriented activities. *Groups such as Eating Disorders or a similar 12-step program based on individual needs; self-esteem activities, including positive affirmations; visiting with friends; and exercise can help client to practice new behaviors in a supportive environment.*⁶

NURSING PRIORITY NO. 3 To promote movement toward positive actions:

-  Encourage client involvement in formulating plan of care and developing goals for preventing undesired behavior. *Being involved in own decisions can help to reestablish ego boundaries and enhance commitment to goals, optimizing outcomes and enhancing self-esteem.*^{2,5}
- Develop a contract between client and counselor to enable the client to stay physically safe, such as “I will not cut or harm myself for the next 24 hours.” Renew contract on a regular basis, signed and dated by both parties. *Discussing the contract gets issues out in the open and conveys a sense of acceptance of the client, while placing some of the responsibility for safety on the client.*^{1,2}
- Provide avenues of communication for times when client needs to talk. *Having an opportunity to discuss anxieties helps client to avoid cutting or damaging self.*^{4,6}
- Choose interventions that help the client to reclaim power in own life (e.g., experiential and cognitive). *As client experiences new ways of interacting with others, he or she can begin to think more positively about self-worth and changing behaviors.*^{2,10}
-  Identify the consequences and outcomes of current actions (e.g., ask “Does this get you what you want?” or “How does this behavior help you achieve your goals?”). *Provides client with opportunity to look at own behaviors in a different way and begin to understand how they are harmful rather than helpful. Contrasting healthy behaviors versus current actions can help client decide to change them. Dialectic behavior therapy is effective in reducing injurious behavior, along with the use of medication.*^{1,3,6}
- Assist client to learn assertive behavior rather than nonassertive or aggressive behavior. Include use of effective communication skills, focusing on developing self-esteem by replacing negative self-talk with positive comments. *By learning these new skills, client interacts with others and gets needs met in positive, acceptable ways, promoting self-worth and lessening anxiety and risk of injurious actions.*^{1,8}
- Discuss with client/family normalcy of adolescent task of separation and ways of achieving. *Helps individual members understand these actions and begin to recognize the normal from those that are of concern and need intervention.*^{1,6,9}
-  Involve client/family in group therapies as appropriate. *Group setting aids in promoting diffusion of anger and provides insight as to how negative, aggressive behavior affects others, making feedback easier to digest and understand.*²

NURSING PRIORITY NO. 4 To promote long-term safety (Teaching/Discharge Considerations):

-  Discuss commitment to safety and ways in which client will deal with precursors to undesired behavior. *Helps client verbalize anger and anxiety and understand how these feelings lead to desire to injure self and actions that can be taken to prevent this behavior.*^{4,6}
- Mobilize support systems. *These individuals often come from abusive families, and unresolved feelings of abandonment remain in adulthood. Positive support by many people in their lives can help them begin to overcome these feelings.*^{1,8,9}
-  Arrange for continued involvement in group therapy after discharge from program. *Remaining in this supportive environment can help client maintain new behaviors as he or she begins to increase responsibility for self and own action.*^{2,10}
-  Discuss and provide information about the use of medication as appropriate. *Antidepressant medications may be useful, but use needs to be weighed against potential for overdosing. Note: Medication may be tried for*

co-occurring disorders like depression or bipolar disorder. However, if the person has no co-occurring disorder, medications may be discouraged, as they can work to cover up feelings that a person has to work through in order to stop the self-harm behavior. Medications that stabilize moods, ease depression, and calm anxiety may be tried to reduce the urge to self-harm.^{1,3,12}

- Refer to NDs Anxiety, Self-Esteem (specify), and impaired Social Interaction.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including risk factors present, underlying dynamics, prior episodes.
- Cultural or religious practices.
- Laboratory test results.
- Substance use or abuse.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Community resources, referrals made.

Self-Neglect

Taxonomy II: Activity/Rest—Class 5 Self-Care (00193) [**Diagnostic Division:** Hygiene], Approved 2008; Revised 2017

DEFINITION: A constellation of culturally framed behaviors involving one or more self-care activities in which there is a failure to maintain a socially accepted standard of health and well-being (Gibbons, Lauder, & Ludwick, 2006).

RELATED FACTORS

Deficient executive function
 Fear of institutionalization
 Inability to maintain control; stressors
 Lifestyle choice; substance misuse/[abuse]

DEFINING CHARACTERISTICS

Objective

Insufficient personal or environmental hygiene
 Nonadherence to health activity

Associated Condition: Alteration in cognitive functioning; learning disability
 Frontal lobe dysfunction; Capgras syndrome
 Malingering
 Psychiatric or psychotic disorder

Sample Clinical Applications: Mental illness (as in related factors); terminal illness—cancer, amyotrophic lateral sclerosis (ALS); debilitating conditions—multiple sclerosis (MS), Parkinson's disease; alcohol/drug abuse

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Self-Care Status: Personal actions to perform basic personal care activities and instrumental activities of daily living (IADLs)

Health Promoting Behavior: Personal actions to sustain or increase wellness

Client Will (Include Specific Time Frame)

- Acknowledge difficulty maintaining hygiene practices.
- Demonstrate ability to manage lifestyle changes and medication regimen.
- Perform ADLs within level of own ability.

Caregiver Will (Include Specific Time Frame)

- Assist individual with personal and environmental hygiene as needed.
- Identify and assist client with medical, dental, and other healthcare appointments as indicated.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Self-Responsibility Facilitation: Encouraging a patient to assume more responsibility for own behavior

Self-Care Assistance: Assisting another to perform activities of daily living

Cultural Brokerage: The deliberate use of culturally competent strategies to bridge or mediate between the patient's culture and the biomedical healthcare system

NURSING PRIORITY NO. 1 To identify causative or precipitating factors:

-  Determine existing health problems, age, developmental level, and cognitive psychological factors, including presence of delusions affecting ability to care for own needs. Use an appropriate screening instrument, such as the Elder Assessment Instrument. *A wide variety of impairments can cause a person to neglect hygiene needs, particularly aging, homelessness, and dementia. Neglect and elder abuse are underreported, and the use of a good tool can help identify its presence.*^{2,3}
-  Identify other problems that may interfere with ability to care for self. *A visual or hearing impairment, language barrier, and emotional instability or lability can create difficulties for individual to manage daily tasks.*^{2,4}
- Note recent life events or changes in circumstances. *Losses (e.g., loved one, financial security, physical independence) can trigger or exacerbate self-neglect behaviors.*⁴
- Review circumstances of client illness, possible monetary rewards, and sympathy or attention from family. *On occasion, self-neglect may be malingering as an attempt to gain something from others or relinquish unwanted responsibilities.*
-  Perform mental status examination. *Mental illness (e.g., psychosis, depression, dementia) can affect individual's ability or desire to maintain self-care activities or care for home surroundings.*^{5,11}
-  Review studies evaluating frontal lobe dysfunction and possibility of Diogenes syndrome. *These clients present with severe self-neglect and may have coexisting medical and psychiatric conditions.*^{10,11}
-  Assess economic situation and living arrangements. *May live alone or with family members who are not helpful, may be homeless, and may have little or no financial resources, resulting in inability or lack of concern about personal well-being.*⁴
-  Determine availability and use of resources. *Depending on disability of client, agencies can work together to develop a plan to meet needs, noting whether individual is availing self of help.*⁶
- Interview significant other (SO)/family members to determine level of involvement and support. *Client may be exhibiting acting-out or paranoid behaviors, stressing caregivers who may not realize individual is unable to control self because of cognitive impairment.*³

NURSING PRIORITY NO. 2 To determine degree of impairment:

- Perform head-to-toe assessment, inspecting scalp and skin; noting personal hygiene, body odor, rashes, bruising, skin tears, lesions, burns, and presence of vermin; and inspecting oral cavity for gum disease, inflammation, lesions, loose or broken teeth, and fit of dentures. *Identifies specific needs and may reveal signs of trauma or abuse.*¹
-  Obtain weight. Perform nutritional assessment as indicated. *Neglecting oneself often includes not eating meals regularly or failing to eat nutritionally balanced foods. When alcoholism or drug abuse is a part of neglect, individual may be severely malnourished.*^{1,3}
-  Review medication regimen. *In addition to neglecting self-care activities, client will likely not pay attention to taking prescriptions as ordered, resulting in exacerbation of medical problem. Note: Some psychotropic medication may cause individual to "feel different" or not in control of self, resulting in reluctance to take drug.*³
- Determine willingness to change situation. *Depending on individual's situation (living alone, homeless, mental status), client may have difficulty committing to or be unwilling to change. May see change as a loss of independence.*^{3,11}

NURSING PRIORITY NO. 3 To assist in correcting/dealing with situation:

-  Develop multidisciplinary team specific to individual needs, such as case manager, physician, dietitian, physical or occupational therapist, rehabilitation specialist, and social worker, *to review assessment data and develop a plan appropriate to the individual situation, making use of client's capabilities and maximizing potential.*^{6,11}

- Establish therapeutic relationship with client, as well as family if available and willing to be involved. *Promotes trust and encourages input into planning process.*^{7,11}
- Identify specific priorities and goals of client/SOs. *Helps client to look at possibilities for dealing with difficult situation of no longer being able to maintain lifestyle and moving on to a new way of managing.*⁶
- Promote client/SOs participation in problem identification and decision making. *Enhances commitment to plan when individual has input and encourages participation, enhancing outcomes.*⁷
-  Evaluate need for safety, balancing client's need for autonomy. *The ethical challenge of providing individual safety within the current laws for client's right to refuse care in face of self-neglect and self-destructive behaviors that can impact others as well as the client is difficult to manage.*^{4,9}
-  Perform home assessment, as indicated. *Determines safety issues, cleanliness, compulsive hoarding, and neglected property concerns, so plans can be made to take care of these matters if client is to remain in the home.*⁷
- Instruct in or review skills necessary for caring for self, using terms appropriate to client's level of understanding. *When individual is cognitively impaired or otherwise has difficulty processing information, instructions need to be simplified.*⁵
- Plan time for listening to client's/SOs' concerns. *Provides opportunity to determine whether plan is being followed and what the barriers to participation may be.*⁷
- Refer to NDs Self-Care deficit [specify], ineffective Health Maintenance, impaired Home Maintenance, and [disturbed Sensory Perception] for additional interventions as appropriate.

NURSING PRIORITY NO. 4 To promote wellness (Discharge/Evaluation Criteria):

-  Establish remotivation or resocialization program when indicated. *Depending on where the client is residing, isolation may become a problem as individual withdraws from contact with others, and these programs may be helpful.*²
-  Assist with setting up medication regimen. *Client may need help with arranging medications in specific ways to assure correct administration, especially in the presence of cognitive impairment.*⁸
-  Discuss dietary needs and client's ability to provide nutritious meals. *May require support such as food stamps, community pantry, senior meal program, and Meals on Wheels.*¹
- Provide for ongoing evaluation of self-care program. *Helps to identify whether client is managing effectively or whether cognitive functioning is deteriorating and a new plan needs to be developed.*⁷
- Evaluate for appropriateness of providing a companion animal. *Taking responsibility for another life and sharing unconditional love can provide purpose and motivation for client to take more interest in own situation.*⁴
-  Refer to support services such as home care, day-care program, social services, food stamps, community clinic, physical or occupational therapy, and senior services as indicated. *Provides for long-term support to facilitate client's independence and general well-being.*⁸
-  Investigate alternative placements as indicated. *Client may require group home, assisted living, or long-term care, and it is best to place in least restrictive environment capable of meeting client's needs.*⁹
- Discuss need for respite for family members. *Care of cognitively impaired member can be wearing, and time away allows for renewing oneself and enhancing ability to cope with continued care responsibilities.*⁵
-  Refer for counseling as indicated. *Accurate mental health diagnoses may reveal the need for appropriate services: psychiatric, social, and home care.*⁶

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, functional level and limitations, mental status.
- Personal safety issues.
- Needed resources, possible need for placement.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcomes.
- Modifications of plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Type of assistance and resources needed.
- Specific referrals made.

[disturbed Sensory Perception (specify: visual, auditory, kinesthetic, gustatory, tactile, olfactory)]

Taxonomy II: Perception/Cognition—Class 3 Sensation/Perception (00122) [**Diagnostic Division:** Neurosensory], Approved 1978; Revised 1980, 1998 (by small group work 1996); Retired 2012

DEFINITION: Change in the amount or patterning of incoming stimuli accompanied by a diminished, exaggerated, distorted, or impaired response to such stimuli.

RELATED FACTORS

Insufficient environmental stimuli: therapeutically restricted environments (e.g., isolation, intensive care, bedrest, traction, confining illnesses, incubator); socially restricted environment (e.g., institutionalization, homebound, aging, chronic/terminal illness, infant deprivation), stigmatized (e.g., mentally ill/developmentally delayed/handicapped)

Excessive environmental stimuli

Altered sensory reception/transmission/integration

Biochemical imbalances (e.g., elevated blood urea nitrogen [BUN], ammonia; hypoxia; electrolyte imbalance; drugs, e.g., stimulants or depressants, mind-altering drugs)

Psychological stress; sleep deprivation

(continues on page 778)

[disturbed Sensory Perception] (continued)

DEFINING CHARACTERISTICS

Subjective

Change in sensory acuity (e.g., photosensitivity, hypoesthesias or hyperesthesias, diminished or altered sense of taste, inability to tell position of body parts [proprioception])

Sensory distortions

Objective

Change in sensory acuity; or in usual response to stimuli

Change in behavior pattern; restlessness; irritability

Change in problem-solving abilities; poor concentration

Disorientation; hallucinations; illusions

Impaired communication

Motor incoordination, altered sense of balance, falls (e.g., Ménière's syndrome)

Sample Clinical Applications: Glaucoma/cataract/other visual impairments; brain tumor, stroke, traumatic injury, amputation, surgery, immobility, peripheral neuropathy (e.g., diabetes), substance abuse, schizophrenia, autism spectrum disorders, developmental delay

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Sensory Function: Extent to which an individual correctly senses skin stimulation, sounds, proprioception, taste and smell, and visual images

Distorted Thought Self-Control: Self-restraint of disruptions in perception, thought processes, and thought content

Risk Control: Hearing/Visual Impairments: Personal actions to understand, prevent, eliminate, or reduce threats to hearing [or] visual function

Client Will (Include Specific Time Frame)

- Regain or maintain usual level of cognition.
- Recognize and correct or compensate for sensory impairments.
- Verbalize awareness of sensory needs and presence of overload and/or deprivation.
- Identify and modify external factors that contribute to alterations in sensory or perceptual abilities.
- Use resources effectively and appropriately.
- Be free of injury.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Communication Enhancement: Hearing [or] Vision Deficit: Use of strategies augmenting communication capabilities for a person with diminished hearing [or] vision

Peripheral Sensation Management: Prevention or minimization of injury or discomfort in the patient with altered sensation

Hallucination [or] Delusion Management: Promoting the comfort, safety, and reality orientation of a patient experiencing hallucinations [or] false, fixed beliefs that have little or no basis in reality

Environmental Management: Manipulation of the patient's surroundings for therapeutic benefit, sensory appeal, and psychological well-being

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Identify client with condition that can affect sensing, interpreting, and communicating stimuli, as noted in Related Factors. *Specific clinical concerns (e.g., neurological disease or trauma, intensive care unit confinement, surgery, pain, biochemical imbalances, psychosis, substance abuse, toxemia) have the potential for altering one or more of the senses, with resultant change in the reception, sensitivity, or interpretation of sensory input.*¹
- Be aware of current diagnosis or treatments (e.g., glaucoma, surgery, immobility, recent stroke, diabetes, mental illness; drug toxicity or side effects [e.g., halos around lights, ringing in ears]; middle-ear disturbances [altered sense of balance]) that can cause or exacerbate sensory problems.
- ∞ Note age and developmental stage. *Problems with sensory perception may be known to client/caregiver (e.g., child wearing hearing aid, elderly adult with known macular degeneration) where compensatory interventions are in place. Screening or evaluation may be required if sensory impairments are suspected but not obvious, as might occur when an infant is not progressing developmentally or an older individual has a gradual loss of sensory discrimination associated with aging, or sensory changes are associated with a sudden neurological event.*^{2,3,8}
- 🧪 Evaluate medication regimen and determine possible use or misuse of drugs (prescription, over the counter, illicit) to identify effects, side effects, adverse effects, or drug interactions that may be causing or exacerbating sensory or perceptual problems.
- 📋 Review results of sensory and motor neurological testing and laboratory studies (e.g., cognitive testing or laboratory values, such as electrolytes, chemical profile, arterial blood gases, serum drug levels) to note presence or possible cause of changes in response to sensory stimuli.

NURSING PRIORITY NO. 2 To determine degree of impairment:

- Assess ability to speak, hear, interpret, and respond to simple commands to obtain an overview of client's mental and cognitive status and ability to interpret stimuli.
- Evaluate sensory awareness (e.g., hot and cold, dull or sharp, smell, taste, visual acuity and hearing, gait, mobility, location or function of body parts). *Screening can be done in clinic or facility and may identify problems requiring more extensive evaluation.*
- Determine response to touch and painful stimuli to note whether response is appropriate to stimulus and whether it is immediate or delayed. *The sense of touch is usually maintained throughout life and may become more important if other senses are diminished. Different types of touch or contact are associated with different meanings (including communication of ideas, information, emotion).*³
- Observe for behavioral responses (e.g., illusions, hallucinations, delusions; withdrawal, hostility, crying, inappropriate affect; confusion or disorientation) that may indicate mental or emotional problems or chemical toxicity (as might occur with digoxin or other drug overdose or reaction) or be associated with brain or neurological trauma or infection.
- Note inattention to body parts and segments of environment and lack of recognition of familiar objects or persons. *Loss of comprehension of auditory, visual, or other sensations may be indicative of unilateral neglect or inability to recognize and respond to environmental cues.*⁹
- Ascertain client's perception of problem or changes. Note significant other's (SO's) observations of changes that have occurred and client's responses to changes. *Client may or may not be aware of changes (e.g., diabetic with neuropathy may not realize he or she has lost discrimination for pain in feet, parents may notice child's problem with coordination or difficulty with words).*
- Refer to additional NDs Anxiety, acute/chronic Confusion, risk for Disuse Syndrome, Unilateral Neglect, as appropriate and based on findings.

NURSING PRIORITY NO. 3 To promote normalization of response to stimuli:

General interventions

- Note degree of alteration or involvement (single or multiple senses) to determine scope and complexity of condition and needed interventions.

- Ascertain and validate client's perceptions. Listen to and respect client's expressions of deprivation *to assist in planning of appropriate care, to identify inconsistencies in reception and integration of stimuli, and to provide compassionate regard for client's feelings.*
- Provide means of communication as indicated by client's current situation.
- Document perceptual deficit in chart and code on wall in client's room, if needed, *so caregivers are aware of specific needs or limitations.*
- Avoid isolating client, physically or emotionally, *to prevent sensory deprivation and limit confusion.*
- Address client by name and have personnel wear name tags and reintroduce self, as needed, *to preserve client's sense of identity and orientation.*
- Reorient to time, place, and situation or events, as necessary, *to reduce confusion and provide sense of normalcy to client's daily life.*
- Explain procedures and activities, expected sensations, and outcomes. *Helpful in reducing anxiety associated with altered interpretation of environment.*
- Promote a stable environment with assignment of same personnel as much as possible *to promote continuity of care and limit confusion.*
- Provide appropriate sensory stimulation, including familiar smells and sounds, tactile stimulation with a variety of objects, and changing of light intensity and other cues (e.g., clocks, calendars).
- Eliminate extraneous noise or stimuli, including nonessential equipment, alarms, and audible monitor signals, when possible. *Reduces anxiety and exaggerated emotional responses or confusion associated with sensory overload.*
- Provide feedback *to assist client to separate reality from fantasy and altered perception.*
- Protect from bodily harm (e.g., falls, burns, positioning problems) *as client may not perceive pain or have impaired sense of position, thereby increasing the risk for falls.*
- Provide undisturbed rest and sleep periods *to reduce anxiety, agitation, or psychosis that can accompany sleep deprivation, particularly when client is confined to bed (e.g., intensive care unit).*
- Plan care with client/SO(s), as appropriate. *Enhances commitment to and continuation of plan, thus optimizing outcomes.*
- Encourage SO(s) to bring in familiar objects and to talk with and touch the client. *Client often can experience positive response to loved ones, thus enhancing recovery.*
-  Collaborate with other healthcare team members in providing rehabilitative therapies and stimulating modalities (e.g., music therapy, sensory training, remotivation therapy) *to achieve maximal gains in function and psychosocial well-being.*¹⁰
-  Limit and carefully monitor use of sedation, especially in older population *who are more sensitive to side effects.*
- Identify and encourage use of resources and prosthetic devices (e.g., hearing aids, computerized visual aid or glasses with a level plumb line for balance). *Useful for augmenting senses.*

Visual deficits

- Note particular vision problem (e.g., loss of visual field, change in depth perception, double vision, blindness) *that affects client's ability to perceive environment and learn or relearn motor skills.*³
- Speak to visually impaired or unresponsive client frequently, especially when first entering room or client's presence, *to provide auditory stimulation and prevent startle reflex. Note: A recent study on unconscious patients with brain injury supports the theory that sensory stimulation can enhance brain recovery.*¹²
- Approach from visually intact side, position objects to take advantage of intact visual field, and use eye patch, when needed, *to decrease sensory confusion when client has acute loss of vision or field of vision in one eye.*³
- Provide or encourage listening to music, radio, TV, talking books, and use of talking timepieces and computers, as appropriate.
- Supply adequate lighting for reading and activities.
- Place glasses or contacts where they can be easily found and encourage client to wear corrective lenses during waking hours.

- Arrange bed, personal articles, and food trays to take advantage of functional vision. *Enhances independence and safety.*
- Describe food and placement, feeding or assisting client as necessary (e.g., cooking, cutting food, offering finger food, placing food in clock-position on plate) *when vision impairments could hinder nutritional intake or cause social discomfort.*
- Assist client with picking out clothing *if problems with color discrimination cause mismatching.*³
- Color-code doors and drawers to assist client with low vision *in locating belongings or a particular site (e.g., bathroom).*

Auditory deficits

- Determine if client reads lips and turn toward/face client, making sure you have his/her attention, and enunciating words clearly.
- Encourage client's use of hearing aid when one is available.
- Lower the pitch of the voice and speak in tone that does not include shouting (*which increases the pitch of the voice*).³
- Speak slowly and distinctly; use simple sentences. Rephrase sentences rather than repeating them. Avoid asking multiple questions at one time *to enhance client's comprehension and ability to respond.*¹³
- Use touch to get the client's attention, if needed.
- Be aware and careful of facial expressions.
- Pay attention to background noise and reduce it to a minimum when attempting conversation. *Background noise is often amplified, causing misinterpretation of conversation or inability to hear words, and often results in overstimulation of senses.*³
-  Refer for periodic evaluation by audiologist *to note changes in acuity and determine if client might benefit from a hearing aid.*³

Kinesthetic and tactile deficits

- Encourage proper body positioning and alignment *to prevent muscle strain or injury.*
- Provide firm mattress or chair cushion *to maintain positioning and good posture.*
- Assist with or recommend periodic weight shifts *to enhance circulation and relieve tissue pressure, reducing risk of tissue damage.*
-   Provide tactile stimulation as care is given and when communicating with or comforting client (respecting cultural and personal preferences). *Communicates presence and connection with other human being because touching is an important part of caring, and the need for touch is a deep psychological need. Note: The meaning people associate with touching is culturally determined to a great degree. Always consider a patient's culturally defined sense of modesty when giving nursing care. A recent research study concludes that nurses touch patients to perform clinical tasks, communicate caring, and ensure comfort. Nurses must exercise clinical judgment in deciding when, where, and how to touch patients. In providing the patient's perspective on intimate touch (e.g., bathing, catheterization, other sensitive procedures), participants said they want to know before intimate touch is provided, why it's necessary, and what it will involve.*^{14,15}
-   Be aware that older clients may be more desirous of touch than younger people *because they have lost loved ones, their appearance may not be as attractive as it once was, and the attitude of the public toward older adults does not encourage physical contact with them. Note: A recent study found that comfort touch improved the perceptions of self-esteem, well-being and social processes, health status, life satisfaction and self-actualization, faith or belief, and self-responsibility in institutionalized older female residents.*^{3,16}
- Stimulate sense of touch (e.g., give client objects to touch, grasp; have client practice touching walls and other boundaries). *Aids in retraining sensory pathways to integrate reception and interpretation of stimuli.*
- Provide touch, using level of appropriate intensity (e.g., light, moderate, deep, strong), *depending on the need (e.g., light touch to get client's attention, stroking to convey love to infant).*^{3,4}
- Teach client/SO to frequently inspect skin and extremities for redness, pressure points, bony deformities, or skin trauma *when client is unable to sense pain and is prone to tissue injury.*⁵

Taste and smell

- Note taste and smell dysfunction (loss or distortion of function) that may be associated with chronic conditions (e.g., cystic fibrosis, chronic sinusitis, hypothyroidism, multiple sclerosis, Alzheimer's disease, head trauma) or may suggest a new or developing problem (e.g., zinc deficiency, dental conditions, allergies).⁶
-  Investigate reports of changes in tastes of foods (foods taste or smell odd), ability to salivate, or loss of appetite. *May reflect loss or distortion of smell and taste functions or side effects or interactions with medications.*^{3,6,7}
- Encourage client to chew food well and to experiment with a variety of food colors, textures, and flavor enhancers *to maximize taste sensation.*^{3,7}
- Discuss with client how he or she can check with others in observing for offensive or dangerous odors (e.g., body odor, spoiled foods, propane gas or smoke) *if sense of smell is diminished.*³
- Remove offensive odors from client's presence, *especially when client is immobile, debilitated, and/or suffering from oversensitivity to odors, nausea, or vomiting.*

NURSING PRIORITY NO. 4 To prevent injury/complications:

- Place call bell or other communication device within reach and verify that client knows where it is and how to use it.
- Provide safety measures (e.g., siderails or grab pole, bed in low position, adequate lighting, use of vision or hearing devices, assistance with walking, providing basic and specific information [e.g., "I am on your right side," "This water is hot," "Swallow now," "Stand up"]) *to protect client from injury or enhance client's ability to interpret stimuli.*¹⁰
- Monitor use of heating pads or lights and ice packs, the temperature of bath water, etc., *to reduce risk of thermal injury.*
- Position doors, rugs, and furniture so they are out of travel path and ambulate with assistance or strategically place grab bars *to aid in maintaining balance and reducing risk for falls.*
-  Refer for evaluation of vocational abilities and driving skills. *Changes in sensory reception or integration may impair ability to perform complicated tasks, putting client and others at risk for injury.*
- Refer to NDs risk for Falls, risk for Thermal Injury, and risk for Trauma.

NURSING PRIORITY NO. 5 To promote optimal functioning (Teaching/Discharge Considerations):

-  Provide explanations of and plan care with client, involving SO(s) as much as possible. *Enhances commitment to and continuation of plan, optimizing outcomes.*
-  Review ways to prevent or limit exposure to conditions affecting sensory functions (e.g., how exposure to loud noise and toxins can impair hearing; early childhood screening for speech and language disorders; vaccines to prevent measles, mumps, and meningitis, once known to be major causes of hearing loss).¹¹
- Assist client/SO(s) *to learn effective ways of coping with and managing sensory disturbances, anticipating safety needs according to client's sensory deficits and developmental level.*
- Demonstrate use and care of sensory prosthetic devices (e.g., assistive vision or hearing devices).
- Review home safety measures pertinent to deficits.
- Identify resources and community programs for acquiring and maintaining assistive devices.
-  Discuss need for regular evaluation of drug regimen, noting possible toxic side effects or interactions of both prescription and OTC drugs. *Prompt recognition of side effects allows for timely intervention or change in drug regimen.*
- Promote meaningful socialization and diversional activities as able (e.g., TV/radio, conversation, large print or talking books). Refer to NDs decreased Diversional Activity Engagement and Social Isolation for related interventions.
-  Refer to helping resources such as Society for the Blind, Self-Help for the Hard of Hearing, or local support groups, screening programs, etc., as indicated.
- Refer to additional NDs Anxiety, acute/chronic Confusion, and Unilateral Neglect as appropriate.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, noting specific deficit/associated symptoms, perceptions of client/SO(s).
- Safety issues.
- Assistive device needs.
- Availability and use of resources.

Planning

- Plan of care, including who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Available resources; specific referrals made.

Sexual Dysfunction

Taxonomy II: Sexuality—Class 2 Sexual Function (00059) [**Diagnostic Division:** Sexuality], Approved 1980; Revised 2006, 2017

DEFINITION: A state in which an individual experiences a change in sexual function during the sexual response phases of desire, excitation, and/or orgasm, which is viewed as unsatisfying, unrewarding, or inadequate.

RELATED FACTORS

Inadequate role model
Absence of privacy
Misinformation or insufficient knowledge about sexual function
Vulnerability
Presence of abuse; psychosocial abuse
Value conflict

DEFINING CHARACTERISTICS

Subjective

Change in sexual role
Perceived sexual limitation
Alteration in sexual activity, excitation, or satisfaction; decrease in sexual desire
Undesired change in sexual function
Seeking confirmation of desirability
Change in self-interest/interest toward others

At Risk Population: Absence of significant other

Associated Condition: Alteration in body function or structure [e.g., due to pregnancy, medication, surgery, anomaly, disease, trauma, radiation, etc.]

Sample Clinical Applications: Arthritis, cancer, major surgery, heart disease, hypertension, diabetes mellitus, spinal cord injury (SCI), multiple sclerosis (MS), traumatic injury, pregnancy, childbirth, abuse, depression

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Sexual Functioning: Integration of physical, socioemotional, and intellectual aspects of sexual expression and performance

Physical Aging: Normal physical changes that occur with the natural aging process

Abuse Recovery: Sexual: Extent of healing of physical and psychological injuries due to sexual abuse or exploitation

Client Will (Include Specific Time Frame)

- Verbalize understanding of sexual anatomy, function, and alterations that may affect function.
- Verbalize understanding of individual reasons for sexual problems.
- Identify stressors in lifestyle that may contribute to the dysfunction.
- Identify satisfying, acceptable sexual practices and alternative ways of dealing with sexual expression.
- Discuss concerns about body image, sex role, desirability as a sexual partner with partner/significant other (SO).

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Sexual Counseling: Use of an interactive process focusing on the need to make adjustments in sexual practice or to enhance coping with a sexual event or disorder

Teaching: Sexuality: Assisting individuals to understand physical and psychosocial dimensions of sexual growth and development

Values Clarification: Assisting another to clarify her/his own values in order to facilitate effective decision making

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Perform a complete history and physical, including a sexual history, noting usual pattern of functioning, level of desire, and problems, such as rape or abuse. *Establishes a database from which an individualized plan of care can be formulated.*
- Note vocabulary and style of communication used by the individual/significant other (SO). *Maximizes communication and understanding of words and meaning in an area that individual may find difficult to discuss. Knowing that male and female brains are organized differently may help with recognizing different styles of communication.*⁴
- Have client describe problem in own words. *Sexual dysfunction is divided into four categories—sexual desire (decreased libido), arousal (erectile dysfunction [ED] or aversion or avoidance of sex), orgasm (delay, absence), and sexual pain disorders (dyspareunia, vaginismus).*^{13,15} *Client's perception of the problem may differ from the care provider's, and plan of care needs to be based on client's perceptions for maximum effectiveness.*^{1,9}
- Be alert to comments of client. *Sexual concerns are often disguised as humor, sarcasm, or off-hand remarks. Many people are uncomfortable talking about sexual issues but want to discuss them with care provider, so they use this method to bring up the subject. It is important for the caregiver to recognize and acknowledge client's concern.*^{2,5}
- Determine importance of sex to individual/partner and client's motivation for change. *Both individuals may have differing levels of desire and expectations that may create conflict in relationship.*³
- Assess client's/SO's knowledge of sexual anatomy, function, and effects of current situation or condition (e.g., client's concern about penis size, failure with performance). *Basic knowledge is essential for understanding the problem and how it is affecting the individual. Lack of knowledge may impact client's understanding of situation and expectation for return to previous norm or change for the future.*^{3,7}
- Determine preexisting problems or conditions (e.g., illness, surgery, trauma) that may affect current situation and perception of individual/SO. *Physical conditions (e.g., arthritis, MS, hypertension, diabetes mellitus, fatigue, presence of a colostomy, urinary incontinence) can directly affect sexual functioning, or individual can believe that condition precludes sexual activity, such as recent myocardial infarction or heart surgery.*^{3,6,7,13,16,18}
- Identify stress factors in individual situation (e.g., marital or job stress, role conflicts). *Interpersonal problems (marital and relationship) and lack of trust and open communication between partners can contribute to difficulties. These factors may be producing enough anxiety to cause depression or other psychological reaction(s) that would cause physiological symptoms.*^{5,11}
- Observe behavior and stage of grieving when related to body changes, loss of a body part, or change in function (e.g., pregnancy, obesity, amputation, mastectomy, hysterectomy, menopause). *A change in body image can affect how individual views body in many aspects, but particularly in the sensitive area of sexual functioning and indicates need for information and additional support.*^{7,18}
-   Discuss cultural values or religious beliefs and conflicts present. *Client may feel guilt or shame about sexual desires or difficulties because of family beliefs about sex and genital area of the body and how sexuality*

was communicated to the client as he or she was growing up or through religious teachings. Note: Research indicates that measurement of acculturation may reveal information about an individual's unique behavioral pattern that is not evident when focusing solely on ethnic group comparisons.^{1,2,17}

- Explore with client the meaning of client's behavior. *Masturbation, for instance, may have many meanings or purposes, such as for relief of anxiety, sexual deprivation, pleasure, a nonverbal expression of need to talk, and a way of alienating.³ Or, client's inhibitions may be diminished by changes in cognition.¹²*
-  Review medication regimen and drug use (prescription, over the counter, illegal, alcohol) and cigarette use. *Antihypertensives may cause ED; monoamine oxidase inhibitors and tricyclics can cause erection or ejaculation problems and anorgasmia in women; selective serotonin reuptake inhibitor antidepressants can cause decreased libido or orgasm disorders; antihistamines may cause temporary vaginal dryness (dyspareunia); narcotics and alcohol produce ED and inhibit orgasm; and smoking creates vasoconstriction and may be a factor in ED. Evaluation of drug and individual response is important to determine accurate intervention.^{1,10,13,15}*
-  Review lab results (e.g., hormone levels, serum glucose, red blood cell count, drug levels). *Testing may reveal undiagnosed conditions, such as diabetes resulting in ED in men or anemia, affecting arousal. Inappropriate drug levels or hormone deficiencies—decreased estrogen in women and decreased testosterone in men and women—may result in decreased libido; and hypothyroidism may impair sexual arousal.*
-  Assist with or review diagnostic studies to determine cause of ED. *More than half of the cases have a physical cause such as diabetes, vascular problems, etc. Monitor penile tumescence during rapid eye movement sleep to determine physical ability. Men are embarrassed to bring up the subject with their healthcare provider even when they are seeing him or her for other conditions; unless the provider specifically asks, the subject is not addressed.^{6,8,9,13}*
-  Assist with or review diagnostic studies for female sexual disorders (e.g., vaginal photoplethysmography to assess vaginal blood flow and engorgement, vaginal pH to identify infection or diminished secretions, and biothesiometer to test sensitivity of clitoris and labia).¹⁶

NURSING PRIORITY NO. 2 To assist client/SO(s) to deal with individual situation:

- Establish therapeutic nurse-client relationship. *Promotes treatment and facilitates sharing of sensitive information and feelings in a safe environment.¹*
- Avoid making value judgments. *They do not help the client to cope with the situation. Nurse needs to be aware of and be in control of own feelings and response to client expressions and/or concerns. Client needs to be free to express concerns in whatever way is comfortable to individual.³ Even clients with limited cognition have a right to engage in intimate behaviors.¹²*
-  Assist with treatment of underlying medical conditions, including changes in medication regimen, weight management, cessation of smoking, etc. *Successful treatment/management of many conditions (e.g., cardiovascular, diabetes, arthritis) can improve sexual functioning. However, some treatments and medications also have deleterious effects on sexual abilities/desire.^{7,13–15}*
-  Collaborate with physical therapist/other specialist to identify mechanical aides that may be useful for clients with physical conditions/disabilities.
- Provide factual information about individual condition (e.g., premature ejaculation, female problems of dyspareunia; low sexual desire). *Accurate information helps client make informed decisions about own situation.^{2,8,15}*
- Determine what client wants to know to tailor information to client needs. *Providing too much information may be overwhelming and result in client not remembering something that is essential. Information affecting client safety and consequences of actions may need to be reviewed or reinforced.^{1,7,9}*
- Encourage and accept expressions of concern, anger, grief, and fear. *Individuals need to be free to express these feelings and be accepted so they can begin to deal with situation and move on in a positive way.^{6,13}*
- Assist client to be aware and deal with stages of grieving for loss or change. *Sexual dysfunction is often a result of losses such as breast cancer treatment or prostate surgery and need to be addressed in the context of the whole. Healthcare providers need to be willing to help client understand grieving issues.^{2,7,11}*

- Encourage client to share thoughts and concerns with partner and to clarify values or impact of condition on relationship. *Helps to identify issues in the relationship that may be related to the sexual dysfunction.*^{3,11,15}
- Provide for or identify ways to obtain privacy to allow for sexual expression for individual or between partners without embarrassment or objections of others. *Often caregivers do not think about the importance of providing this basic need for couples, but in any setting, privacy may be difficult to provide unless it is thought about and planned for.*^{6,12}
- Discuss client's rights regarding intimacy in residential or extended care settings with SO/family. Review appropriateness of home visits or provision for privacy for intimate contact. *Family members may not realize that the need for sexual expression is not limited by advancing age, declining cognition, or marital status, and they may be unaware that client has a right to engage in appropriate intimate behaviors.*¹²
- Assist client/SO(s) to problem-solve alternative ways of sexual expression. *When an illness or condition, such as arthritis or paraplegia, interferes with a couple's usual sexual activities, the couple needs to learn new ways to achieve satisfaction.*³
-  Provide information about availability of corrective measures, including medications such as papaverine, sildenafil (Viagra), or vardenafil (Levitra) for ED, or lubricating gels, hormone creams, or possibly hormonal replacement therapy for vaginal dryness and dyspareunia as appropriate.^{15,16}
-  Provide information about availability of corrective measures such as reconstructive surgery (e.g., penile or breast implants), Eros Therapy (handheld device used to improve blood flow to clitoris and external labia to increase sensitivity of tissues), or behavioral therapies (e.g., self-stimulation, sensate focus exercises, Masters & Johnson treatment strategies), when indicated. *Sexual problems, such as ED, female orgasmic disorders, and female sexual arousal disorders, may respond to these interventions, providing more satisfactory sexual life.*^{8,10,14–16}
-  Refer to appropriate resources as need indicates (e.g., healthcare coworker with greater comfort level and/or knowledgeable clinical nurse specialist or professional sex therapist, family counseling). *Not all professionals are knowledgeable or comfortable dealing with sexual issues, and referrals to more appropriate resources can provide client/couple with accurate assistance.*^{2,6,12}

NURSING PRIORITY NO. 3 To promote sexual wellness (Teaching/Discharge Considerations):

-  Provide sex education and explanation of normal sexual functioning when necessary. *Many individuals are not knowledgeable about these areas, and often providing accurate information can help assuage anxiety about unknowns, such as normal changes of aging, or provide an accurate basis for understanding problems being experienced.*^{6,15,16}
- Provide written material appropriate to individual needs. Include bibliotherapy and reliable Internet resources related to client's concerns. *Provides reinforcement for client to read and access at his or her leisure when ready to deal with sensitive materials.*^{3,6,7}
- Encourage ongoing dialogue and take advantage of teachable moments. *Within a therapeutic relationship, comfort is achieved and individual is encouraged to ask questions and be receptive to continuing conversation about sexual issues.*^{1,2}
- Demonstrate and assist client to learn relaxation or visualization techniques. *Stress is often a component of sexual dysfunction, and using these skills can help with resolution of problems.*^{2,5}
- Identify resources for assistive devices/sexual "aids." *These aids can enhance sex life of couple and prevent or help with problems of dysfunction.*^{3,6}
- Emphasize importance of engaging in regular self-examination as indicated (e.g., breast and testicular examinations). *Encourages client to participate in own health prevention activities, become more aware of potential problems, and become more comfortable with sexual self.*^{3,5}
-  Identify community resources for further assistance, such as Reach for Recovery, Can Surmount, and the Ostomy Association, to provide role models and to problem-solve issues.
-  Refer for further professional assistance concerning relationship difficulties, low sexual desire, and other sexual concerns such as premature ejaculation, vaginismus, and painful intercourse. *May need additional or*

continuing support to deal with individual situation or associated depression. Note: Referral to counselor expert in trauma may be preferred to assist sexual abuse survivors to overcome sexual difficulties.^{3,15}

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including nature of dysfunction, predisposing factors, perceived effect on sexuality and relationships.
- Cultural or religious factors, conflicts.
- Response of SO(s).
- Motivation for change.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Community resources, specific referrals made.

ineffective Sexuality Pattern

Taxonomy II: Sexuality—Class 2 Sexual Function (00065) [**Diagnostic Division:** Sexuality], Approved 1986; Revised 2006, 2017

DEFINITION: Expressions of concern regarding own sexuality.

RELATED FACTORS

Conflict about sexual orientation or variant preference
 Fear of pregnancy or sexually transmitted infection
 Impaired relationship with significant other; absence of privacy
 Inadequate role model
 Insufficient knowledge or skill deficit about alternatives related to sexuality

DEFINING CHARACTERISTICS

Subjective

Alteration in relationship with significant other (SO); change in sexual role
 Alteration in/difficulty with sexual activity or behavior
 Value conflict

At Risk Population: Absence of significant other

Sample Clinical Applications: Spinal cord injury (SCI), brain injury, stroke, sexually transmitted infection (STI), cancer, mastectomy, hysterectomy, menopause, prostatectomy, gender reassignment

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Sexual Identity: Acknowledgment and acceptance of own sexual identity

Child Development: Adolescence: Milestones of physical, cognitive, and psychosocial progression from 12 years through 17 years of age

Role Performance: Congruence of an individual's role behavior with role expectations

Client Will (Include Specific Time Frame)

- Verbalize understanding of sexual anatomy and function.
- Verbalize knowledge and understanding of sexual limitations, difficulties, or changes that have occurred.
- Verbalize acceptance of self in current (altered) condition.
- Demonstrate improved communication and relationship skills.
- Identify individually appropriate method of contraception.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Sexual Counseling: Use of an interactive process focusing on the need to make adjustments in sexual practice or to enhance coping with a sexual event or disorder

Teaching: Sexuality: Assisting individuals to understand physical and psychosocial dimensions of sexual growth and development

Teaching: Safe Sex: Providing instruction concerning sexual protection during sexual activity

Support System Enhancement: Facilitation of support to patient by family, friends, and community

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Obtain complete physical and sexual history, as indicated, including perception of normal function. *Sexuality is multifaceted beginning with one's body, biological sex, and gender (biological, social, and legal status as girl/boy, woman/man).*
- Note use of vocabulary (assessing basic knowledge) and comments or concerns about sexual identity. *Components of sexual identity include one's gender identity (how one feels about his or her gender) as well as one's sexual orientation (straight, lesbian, gay, bisexual, transgendered).*¹²
- Determine importance of sexual activity and a description of the problem in the client's own words. Be alert to comments of client/significant other (SO) that may attempt to discount or mask significance of concerns. *Sexual concerns are often disguised as sarcasm, humor, or off-hand remarks.*^{1,2} *Information about client's perception of the problem is essential to planning appropriate care to meet client's needs.*
-  Note cultural values or religious beliefs and conflicts that may exist. Elicit impact of perceived problem on SO/family. *Individuals are enculturated as they grow up, and depending on particular family views and taboos, these factors may create conflicts regarding variant sexual practices with resultant feelings of shame and guilt.*^{8,14–16}
- Assess stress factors in client's environment that might cause anxiety or psychological reactions. *Sexual variant behaviors, power issues involving SO, adult children, aging, employment, and loss of prowess related to illness or condition are often associated with stress in the client's life.*^{1,11}
- Explore knowledge of effects of altered body function or limitations precipitated by illness or medical treatment of alternative sexual responses and expressions (e.g., reassignment procedure). *Client needs to understand when conditions, such as undescended testicle in young male, gender change, and mutilating cancer surgery, have an effect on sexuality.*¹⁰
-  Review medication and substance use history (prescription medication, over-the-counter drugs, alcohol, illicit drugs). *Substance or prescription drug use may affect sexual functioning or be used to relieve anxiety of perceived sexually deviant behavior.*^{2,17}
- Explore issues and fears associated with sex. *Possibility of pregnancy, acquiring STIs, trust and control issues, inflexible beliefs, preference confusion, and altered performance need to be addressed so they may be understood and resolved.*^{3,13}
- Determine client's interpretation of the altered sexual activity or behavior. *May be a way of controlling partner, provide relief of anxiety or pleasure, or reflect a lack of partner. These behaviors, when related to body changes, including pregnancy, weight loss or gain, or loss of body part, may reflect a stage of grieving.*^{3,16}
-  Assess life-cycle issues, such as adolescence, young adulthood, menopause, and aging. *All people are sexual beings from birth to death. Stage of maturation/transition brings changes that affect sexual self and understanding of the normalcy can help individual grow with them.*^{7,16}

NURSING PRIORITY NO. 2 To assist client/SO to deal with individual situation:

- Provide atmosphere in which discussion of sexual problems is permitted and encouraged. *Sense of trust and comfort enhances ability to discuss sensitive matters and begin to resolve issues.*⁵
- Avoid value judgments. *They do not help the client to cope with the situation. Nurse needs to be aware of and in control of own feelings and responses to the client's expressions and/or concerns.*⁹
- Provide information about individual situation, determining client needs and desires. *Lack of knowledge may contribute to current situation, and providing desired information conveys message of importance and self-responsibility.*³
- Encourage discussion of individual situation and open expression of feelings without judgment. *Sexuality includes feelings, attitudes, relationships, self-image, ideals, and behaviors, and influences how one experiences the world.*¹² *Talking about sexual practices, concerns about sexual identity, or sexual issues related to illness or condition provides opportunity for resolution.*^{1,2}
- Provide specific suggestions about interventions directed toward the identified problems. *Being specific about actions client can take, such as alternate sexual positions when arthritis prevents movement, masturbation*

when no partner is available, use of condoms when infection is a concern, and positive discussion of normalcy of sexual behavior when identity is being questioned, can lead discussion in appropriate direction to begin to look for options or solutions.^{3,5}

- Identify alternative forms of sexual expression that might be acceptable to both partners. *Being able to communicate satisfactorily with partner and identifying ways to achieve sexual satisfaction for both is important to the relationship.*^{1,2}
- Discuss ways to manage individual devices or appliances. *Change in body image or medical condition may require the use of devices, such as an ostomy bag, breast prostheses, or a urinary collection device, that may affect how client views sexual activity. Providing information about ways to deal with these issues helps client to refocus attention on achieving satisfactory sexual experience.*^{6,7}
-  Discuss use of performance-enhancing medications, such as sildenafil (Viagra), vardenafil (Levitra), and tadalafil (Cialis). *Erectile dysfunction is a common occurrence as men age, and while frequently caused by an underlying physical condition or prescribed medication, psychological issues often accompany this problem. While an accurate diagnosis is necessary, there are many treatments available.*^{2,3,17} *Prescription drugs are popular, but the individual needs to feel desire and be sexually stimulated for them to work.*⁶
-  Determine concerns of older client regarding sexuality. *Myths abound regarding sexual activity as people grow older, and individual may believe he or she is no longer attractive or a satisfying sex life is no longer possible; accurate information can correct misperceptions.*^{6,7}
- Provide anticipatory guidance about losses that are to be expected. *Surgical procedures resulting in a major change in body image, whether planned (as in transsexual surgery) or unplanned (as in emergency bowel resection with resultant colostomy or traumatic amputation), result in a loss of known self, which needs specific intervention to integrate change.*^{3,9}
- Introduce client to individuals who have successfully managed a similar problem, when possible. *Provides a positive role model and support for problem-solving.*^{9,18}

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Provide factual information about problem(s) as identified by the client. *Specific facts about individual situation will provide client with knowledge needed to deal with what is happening, such as conflict with sexual orientation or variant preferences or impaired relationship with SO.*⁹
- Engage in ongoing dialogue with the client and SO(s) as situation permits. *As communication continues, new insights arise and understanding is enhanced.*^{2,4}
- Discuss methods, effectiveness, and side effects of contraceptives if indicated. *Assists individual/couple to make an informed decision on a method that meets own values or religious beliefs and allows client to meet needs and desires to plan for and/or prevent pregnancy.*^{1,5}
-  Refer to community resources as indicated. *May need additional information and support that can be obtained at resources such as Planned Parenthood, gender identity clinic, social services, etc.*^{9,14,18}
-  Refer for intensive individual/group psychotherapy, which may be combined with couple/family and/or sex therapy, as appropriate.¹⁸
- Refer to NDs disturbed Body Image, low Self-Esteem (specify), and Sexual Dysfunction.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including nature of concern, perceived difficulties, limitations or changes; specific needs or desires.
- Cultural or religious beliefs, conflicts.
- Response of SO(s).

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and teaching, and who is responsible for actions to be taken.
- Community resources, specific referrals made.

risk for Shock

Taxonomy II: Safety/Protection—Class 2 Physical Injury (00205) [Diagnostic Division: Circulation], Approved 2008; Revised 2013, 2017

DEFINITION: Susceptible to an inadequate blood flow to the body's tissues that may lead to life-threatening cellular dysfunction, which may compromise health.

RISK FACTORS

To Be Developed

Associated Condition: Hypotension

Hypovolemia

Hypoxemia, hypoxia

Infection, sepsis; systemic inflammatory response syndrome (SIRS)

Sample Clinical Applications: Gastrointestinal (GI) bleed, multiple trauma, disseminated intravascular coagulation (DIC); myocardial infarction, cardiomyopathy, malignant hypertension; pulmonary embolus, pneumothorax; spinal cord injury (SCI), anaphylaxis, sepsis

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Circulation Status: Unobstructed, unidirectional blood flow at appropriate pressure through large vessels of the systemic and pulmonary circuits

Blood Loss Severity: Severity of signs and symptoms of internal or external bleeding

Infection Severity: Severity of signs and symptoms of infection

Client Will (Include Specific Time Frame)

- Display hemodynamic stability as evidenced by vital signs within normal range for client and prompt capillary refill, adequate urinary output with normal specific gravity, and usual level of mentation.
- Verbalize understanding of disease process, risk factors, and treatment plan.
- Be afebrile and free of other signs of infection; achieve timely wound healing.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Shock Prevention: Detecting and treating a patient at risk for impending shock

Hypovolemia Management: Expansion of intravascular fluid volume in a patient who is volume depleted

Cardiac Care: Limitation of complications resulting from an imbalance between myocardial oxygen supply and demand for a patient with symptoms of impaired cardiac function

NURSING PRIORITY NO. 1 To assess causative/precipitating factors:

-  Note possible medical diagnoses or disease processes that can result in one or more types of shock such as major trauma with heavy internal or external bleeding; heart failure; head or spinal cord injury; allergic reactions to insect stings, medications, or foods; pregnancy-related complications; and intra-abdominal infections, ruptured appendix, open wounds, or other conditions associated with sepsis.¹
-  Assess for history or presence of conditions leading to **hypovolemic shock**, such as trauma, surgery, inadequate clotting, and anticoagulant therapy; GI or other organ hemorrhage; prolonged vomiting and diarrhea; diabetes insipidus; and misuse of diuretics. *These conditions deplete the body's circulating blood volume and ability to maintain organ perfusion and function.*^{1-3,10}
-  Assess for conditions associated with **cardiogenic shock**, including myocardial infarction, cardiac arrest, lethal ventricular dysrhythmias, severe valvular dysfunction, cardiomyopathies, and malignant hypertension. *These conditions directly impair the heart muscle and its ability to pump.*^{1-4,11}
-  Assess for conditions associated with **obstructive shock**, including pulmonary embolus, aortic stenosis, cardiac tamponade, and tension pneumothorax. *In these conditions the heart itself may be healthy but cannot pump because of conditions outside the heart that prevent normal filling or adequate outflow.*¹⁻³
-  Assess for conditions associated with **distributive shock—neural induced**, including pain, anesthesia, and SCI or head injury, or **chemical induced**, including peritonitis, sepsis, burns, anaphylaxis, and hyperglycemia. *These situations result in loss of sympathetic tone, blood vessel dilation, pooling of venous blood, and increased capillary permeability with shifting of fluids.*^{2,4}
- Monitor for persistent or heavy fluid loss, including wounds, drains, vomiting, gastrointestinal tube, and chest tube. Check all secretions and excretions for occult blood. Refer to NDs risk for Bleeding, deficient Fluid Volume, and risk for imbalanced Fluid Volume for additional interventions.^{3,4}

- Inspect skin, noting presence of traumatic or surgical wounds, erythema, edema, tenderness, petechiae, and rashes or hives, *for evidence of hemorrhage, localized infections, or hypersensitivity reaction.*^{5,7}
- Investigate reports of increased or sudden pain in wounds or body parts, *which could indicate ischemia or infection.*
- Be aware of invasive devices such as urinary and intravascular catheters, endotracheal tube, and implanted prosthetic devices *that potentiate risk for localized and systemic infections.*
-  Assess vital signs and tissue and organ perfusion *for changes associated with shock states.*¹⁻¹¹
Heart rate and rhythm—*noting progressive changes in heart rate (reflecting an attempt to increase cardiac output) and development of dysrhythmias suggesting electrolyte imbalances and hypoxia.*
Respirations—*noting rapid, shallow breathing, and use of accessory muscles (in an attempt to increase vital capacity and compensate for metabolic acidosis associated with poor tissue perfusion and anaerobic metabolism), which can progress to respiratory failure.*
Blood pressure—*noting hypotension (systolic blood pressure 90 mmHg [or lower] lasting more than 30 min), postural hypotension, and narrowed pulse pressure. May indicate hypovolemia and/or failure of cardiac pumping or compensatory mechanisms.*
Pulses and neck veins—*noting rapid, weak, thready peripheral pulses and congested or flat neck veins. Signs associated with changes in circulating volume, cardiac output, and progressive changes in vascular tone and/or capillary permeability.*
Temperature—*higher than 100.4°F (38°C) or lower than 96.8°F (36°C). Temperature changes in presence of elevated heart rate and respiratory rate along with mildly elevated white blood cells (WBCs) suggest SIRS, which can manifest in client without a documented infection, requiring prompt intervention to prevent progression to sepsis and septic shock.*^{5,6}
State of consciousness and mentation—*noting anxiety, restlessness, confusion, lethargy, or unresponsiveness. Can occur because of changes in oxygenation, acid-base imbalances, and toxins associated with hypoperfusion. Depressed mentation accompanied by neck stiffness may reflect central nervous system infection.*
Skin color and moisture—*noting overall flushing or pallor, bluish lips and fingernails and slow capillary refill, or cool or clammy skin. Changes are associated with altered systemic circulation and hypoperfusion.*
Urine output—*noting substantially decreased output. One of the most sensitive indicators of change in circulating volume or poor perfusion.*
Urine characteristics—*noting color and odor suggestive of infection source.*
Bowel sounds—*noting diminished or absent bowel sounds or other changes in GI function, such as vomiting, or change in color, amount, or frequency of stools, reflecting hypoperfusion of GI tract.*
-  Measure invasive hemodynamic parameters when available—central venous pressure, mean arterial pressure, and cardiac output—*to determine if intravascular fluid deficit or cardiac dysfunction exists.*
-  Obtain specimens of wounds, drains, central lines, and blood for culture and sensitivity *to identify offending organisms and to direct antimicrobial therapies.*⁸
-  Review lab data such as complete blood count with WBCs and differential; platelet numbers and function; other coagulation factors; tests for cardiac, renal, and hepatic function; pulse oximetry or arterial blood gases, serum lactate, and blood cultures; and urinalysis and urine cultures *to identify potential sources of shock and degree of organ involvement.*
-  Review diagnostic studies such as x-ray and electrocardiogram, echocardiogram and angiography with ejection fraction, and computed tomography or magnetic resonance imaging scans and ultrasound *to determine presence of injuries or disorders that could cause or lead to shock conditions.*
- Refer to NDs ineffective peripheral Tissue Perfusion, risk for decreased cardiac Tissue Perfusion, risk for ineffective cerebral Tissue Perfusion, risk for ineffective Gastrointestinal Perfusion, as indicated.

NURSING PRIORITY NO. 2 To prevent/correct potential causes of shock:

-   Collaborate in prompt treatment of underlying conditions, such as trauma, heart failure, and infections, and prepare for/assist with medical and surgical interventions *to maximize systemic circulation and tissue and organ perfusion.*

-  Administer oxygen by appropriate route (e.g., nasal prongs, mask, ventilator) *to maximize oxygenation of tissues.*
-  Administer fluids, electrolytes, colloids, and blood or blood products, as indicated, *to rapidly restore or sustain circulating volume and electrolyte balance and prevent shock states associated with dehydration and hypovolemia.*^{3,9,10}
-  Administer medications as indicated (e.g., vasoactive drugs, cardiac glycosides, thrombolytics, anticoagulants, antimicrobials, analgesics) *to treat conditions and maximize organ function.*⁴
- Provide client care with infection-prevention interventions, such as diligent hand hygiene, aseptic wound care or dressing changes, isolation precautions, and early intervention in potential infectious condition *to reduce incidence or progression of infection.*^{6,7}
-  Provide nutrition by best means—oral, enteral, or parenteral feeding. Refer to nutritionist or dietitian *to provide foods rich in nutrients, vitamins, and minerals needed to promote healing and support immune system health.*

NURSING PRIORITY NO. 3 Promote wellness (Teaching/Discharge Considerations):^{1,2,7,9}

-  Instruct client/significant other in ways to prevent and/or manage underlying conditions that cause shock, including heart disease, injuries, dehydration, and infection.
- Identify reportable signs and symptoms, including unrelieved pain anywhere in body, unresolved bleeding, excessive fluid loss, persistent fever and chills, and change in skin color accompanied by chest pain, *for timely evaluation and intervention.*
- Emphasize need for recognition of substances that cause hypersensitivity or allergic reactions (e.g., insects, medicines, foods, latex) *to reduce risk of anaphylactic shock state.*
-  Teach client purpose, dosage, schedule, precautions, and potential side effects of medications given to treat underlying conditions. *Enhances compliance with drug regimen, reducing individual risk.*
- Instruct in wound and skin care as indicated *to prevent infection and promote healing without complications.*
- Teach client/caregivers importance of good hand hygiene, clean environment, and avoiding crowds when ill, especially if client is immunocompromised.
-  Reinforce importance of immunization against infections such as influenza and pneumonia, especially in client with chronic conditions.
- Encourage consumption of healthy diet, participation in regular exercise, and adequate rest *for healing and immune system support.*
-  Recommend client at risk for hypersensitivity reactions wear medical alert device and maintain readily accessible emergency medication (e.g., Benadryl and/or Epi-pen).

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual risk factors such as blood loss, presence of infection.
- Assessment findings, including respiratory rate, character of breath sounds; heart rate and rhythm; temperature; frequency, amount, and appearance of secretions; presence of cyanosis; and mentation level.
- Results of laboratory tests and diagnostic studies.

Planning

- Plan of care, specific interventions, and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Client's responses to treatment, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs, identifying who is responsible for actions to be taken.
- Community resources for equipment and supplies post discharge.
- Specific referrals made.

impaired Sitting

Taxonomy II: Safety/Protection—Class 2 Activity/Exercise (000237) [**Diagnostic Division:** Safety], Approved 2013; Revised 2017

DEFINITION: Limitation of ability to independently and purposefully attain and/or maintain a rest position that is supported by the buttocks and thighs in which the torso is upright.

RELATED FACTORS

Insufficient endurance, energy or muscle strength
Malnutrition
Pain; self-imposed relief posture

DEFINING CHARACTERISTICS

Objective

Impaired ability to attain or maintain a balanced position of the torso; impaired ability to stress torso with body weight

Impaired ability to adjust position of one or both lower limbs on uneven surface

Impaired ability to flex or move both hips or knees

Associated Condition: Alteration in cognitive functioning; neurological or psychological disorder

Impaired metabolic functioning; sarcopenia

Orthopedic surgery; prescribed posture

Sample Clinical Applications: Neuromuscular disorders (e.g., multiple sclerosis [MS], amyotrophic lateral sclerosis [ALS], Parkinson's disease), traumatic injuries (e.g., fractures, spinal cord or brain injuries), rheumatoid arthritis, severe depression, dementia

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Knowledge: Body Mechanics: Extent of understanding conveyed about proper body alignment, balance, and coordinated movement

Balance: Ability to maintain body equilibrium

Body Mechanics Performance: Personal actions to maintain proper body alignment and to prevent musculoskeletal strain

Client Will (Include Specific Time Frame)

- Verbalize understanding of individual treatment regimen and safety measures.
- Attain and maintain sitting position that enables activities.
- Participate in activities of daily living (ADLs) and desired activities and prevent complications.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Positioning: Deliberative placement of the patient or a body part to promote physiological and/or psychological well-being

Exercise Therapy: Muscle Control: Use of specific activity or exercise protocols to enhance or restore controlled body movement

Body Mechanics Promotion: Facilitating the use of posture and movement in daily activities to prevent fatigue and musculoskeletal strain or injury

NURSING PRIORITY NO. 1 To identify causative/contributing factors:

-  Determine diagnosis that contributes to sitting balance problems (e.g., MS, arthritis, Parkinson's disease, cardiopulmonary disorders, back pain conditions with client use of compensatory positions to reduce pain; traumatic brain injury, spinal cord injury with hemi/paraplegia; lower-limb injuries or amputations; psychiatric conditions including severe depression, dementias). *These conditions can cause postural impairments, muscular weakness, and inadequate range of motion. Sensory deficits may also be involved (e.g., impaired proprioception and/or visual processing, cognitive impairments). Note: Several studies have shown that sitting balance is a valid predictor for functional outcome in patients with stroke, paraplegia, and brain injury.¹⁻⁶ Sitting and standing balance are of major concern when assessing amputee's ability to maintain the center of gravity over the base of support. Both balance and coordination are required for weight shifting from one limb to another; thus improving the potential for an optimal gait.⁷*
- Note factors affecting current situation (e.g., surgery, fractures, amputation, tubings [chest tube, indwelling catheter, IVs, pumps]; potential time involved [e.g., few hours in bed after surgery versus serious trauma requiring long-term bedrest or debilitating disease or pain limiting movement]). *Identifies potential impairments and determines type of interventions needed to provide for client's safety.*
-  Note older client's general health status. *Davis et al identified mobility as the most important functional ability that determines the degree of independence and healthcare-related quality of life (HRQoL) among older persons.⁸ While aging does not cause impaired mobility, per se, several aging-related changes can lead to immobility (e.g., sarcopenia with diminished endurance and core strength; impaired vision; loss of balance; decreased ability to quickly and adequately correct movements affecting center of gravity). Thus, falls are a major risk and source of morbidity and mortality.⁹⁻¹¹*
-  Assess nutritional and hydration status and client's report of energy level. *Deficiencies in nutrients and water, as well as electrolytes and minerals, can negatively affect energy and activity tolerance. Note: Research*

supports that the obese individual shows reduced seated functional reach abilities when compared to normal and overweight subjects.¹²

NURSING PRIORITY NO. 2 To assess functional ability:

- Determine functional status using a 0 to 4 scale, noting muscle strength and tone, joint mobility, cardiovascular status, balance, and endurance. *Identifies strengths and deficits (e.g., inability to sit upright, reach forward, or transfer safely from bed to wheelchair) and may provide information regarding potential for recovery (e.g., client with severe brain injury may have permanent limitations because of impaired cognition affecting memory, judgment, problem-solving, and motor planning).*^{1,14}
- Determine degree of perceptual or cognitive impairment and ability to follow directions. *Impairments related to age, chronic or acute disease condition, trauma, surgery, or medications require alternative interventions or changes in plan of care.*
-  Refer to physician and/or physical therapy specialists for special testing, as indicated. *May include many different functional tests (e.g., function in sitting test, balance performance monitor, Berger Balance Scale) to determine potential for improvement and direction for therapies.*¹³

NURSING PRIORITY NO. 3 To promote optimal level of function and prevent complications:

-  Assist with treatment of underlying condition(s) *to maximize potential for optimal function.*
- Encourage client's participation in self-care activities and in physical or occupational therapies. *Improves body strength and function and enhances self-concept and sense of independence. Note: Sitting balance affects ADLs, including feeding, dressing, bathing, transfers, and mobility.*
- Support trunk and extremities when in seated position, using pillows or rolls, braces, shoes, gel pads, etc., *to maintain upright position and optimal internal organ function and to reduce risk of pressure ulcers.*
- Demonstrate and assist with use of assistive devices (e.g., side rails, overhead trapeze, roller pads, safety belt, hydraulic lifts, chairs) *for position changes and safe transfers.*
- Avoid routinely doing for client those activities that client can do for self. *Caregivers can contribute to deficits by being overprotective or helping too much.*
- Provide for safety measures as indicated by individual situation, including environmental management and fall prevention. (Refer to ND risk for Falls.)
- Note changes in ability to do more or less self-care (e.g., hygiene, feeding, toileting, therapies) *to promote psychological and physical benefits of self-care and to adjust level of assistance as indicated.*
-  Collaborate with physical medicine specialist and occupational or physical therapists in providing range-of-motion exercise (active or passive), isotonic muscle contractions (e.g., sitting reach, push, and pull exercises), assistive devices, and activities.
-  Administer pain medications before activity as needed *to promote maximal effort and involvement in activity.*
-  Collaborate with nutritionist in providing nutritious foods and needed feeding assistance, maximizing client's abilities in ingesting and swallowing (upright position) *to optimize available energy for activities.*
- Refer to NDs Activity Intolerance, impaired bed Mobility, impaired physical Mobility, impaired Transfer Ability, impaired Standing, impaired wheelchair Mobility, and impaired Walking for additional interventions.

NURSING PRIORITY NO. 4 To promote wellness (Teaching/Discharge Considerations):

-  Encourage client's/significant other's (SO's) involvement in decision making as much as possible. *Enhances commitment to plan, optimizing outcomes.*
- Demonstrate use of mobility devices (e.g., walkers, strollers, scooters, braces, prosthetics) and have client/caregiver demonstrate knowledge about and safe use of device. Identify appropriate resources for obtaining and maintaining appliances or equipment. *Safe use of mobility aides promotes client's independence and enhances quality of life and safety for client and caregiver.*

- Discuss ways that client can exercise safely. *Options may be limited, but attending regular rehab sessions may provide best opportunity for improvement in function, including self-care, social independence, and recreation.*
-  Involve client and SO(s) in care, assisting them to learn ways of managing problems of immobility and imbalanced sitting, especially when impairment is expected to be long term. Refer to support and community services as indicated *to provide care, supervision, companionship, respite services, nutritional and ADL assistance, adaptive devices or changes to living environment, financial assistance, etc.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including level of function and ability to participate in specific or desired activities.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Discharge and long-term needs, noting who is responsible for each action to be taken.
- Specific referrals made.
- Sources of and maintenance for assistive devices.

impaired Skin Integrity

Taxonomy II: Safety/Protection—Class 2 Physical Injury 00046) [**Diagnostic Division:** Safety], Approved 1975, Revised 1998, 2017

DEFINITION: Altered epidermis and/or dermis.

RELATED FACTORS

External

Chemical injury agent
Hypothermia; hyperthermia
Humidity; moisture; excretions; secretions
Extremes of age

Internal

Alteration in fluid volume
Inadequate nutrition
Psychogenic factor [e.g., obsessive compulsive disorder]

DEFINING CHARACTERISTICS

Subjective

Pain; [itching, numbness of affected/surrounding area]

Objective

Alteration in skin integrity
Bleeding; hematoma, redness; localized area hot to touch
Foreign matter piercing skin

At Risk Population: Extremes of age

Associated Condition: Alteration in metabolism; hormonal change; immunodeficiency

Alteration in skin turgor, sensation, pigmentation

Arterial puncture; vascular trauma

Pharmaceutical agent; radiation therapy

Sample Clinical Applications: Anemias; arthritis; end-of-life conditions; contagious diseases, coronary artery disease; dementias; burns; diabetes mellitus, obesity; peripheral vascular disease, Raynaud's disease

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Tissue Integrity: Skin & Mucous Membranes: Structural intactness and normal physiological function of skin and mucous membranes

Wound Healing: Primary Intention: Extent of regeneration of cells and tissues following intentional closure

Wound Healing: Secondary Intention: Extent of regeneration of cells and tissues in an open wound

Client Will (Include Specific Time Frame)

- Display timely healing of skin lesions, wounds, or pressure sores without complication.
- Maintain optimal nutrition and physical well-being.
- Participate in prevention measures and treatment program.
- Verbalize feelings of increased self-esteem and ability to manage situation.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Wound Care: Prevention of wound complications and promotion of wound healing

Incision Site Care: Cleansing, monitoring, and promotion of healing in a wound that is closed with sutures, clips, or staples

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

-  Identify underlying condition or pathology involved. *Skin integrity problems can be the result of (1) disease processes that affect circulation and perfusion of tissues (e.g., arteriosclerosis, venous insufficiency, hypertension, obesity, diabetes, malignant neoplasms); (2) conditions that can be associated with rashes (e.g., contagious diseases such as measles, chicken pox; infections such as methicillin-resistant Staphylococcus aureus, toxic shock syndrome; skin disorders such as eczema; disorders caused by spiders/insects such as Lyme disease, lice, bedbugs; contact dermatitis such as occurs with latex allergy, poison ivy; autoimmune disorders such as lupus; internal diseases such as liver disease, celiac disease, kidney failure, iron deficiency anemia, thyroid problems, and cancers, including leukemia and lymphoma); (3) medications that adversely affect skin or impair healing (e.g., anticoagulants, antibiotics, corticosteroids, immunosuppressives, antineoplastics); (4) burns or radiation (can break down internal tissues as well as skin); and (5) nutrition and hydration (e.g., malnutrition deprives the body of protein and calories required for cell growth and repair, dehydration impairs transport of oxygen and nutrients).*^{1,2,5,12,19}
- Note: Disruption in skin integrity can be **intentional** (e.g., surgical incision) or **unintentional** (e.g., accidental trauma, drug effect, allergic reaction, rashes); and **open** (e.g., laceration, skin tears, penetrating wound, ulcerations) or **closed** (e.g., contusion, abrasion, rash).
- Evaluate client's health status in general terms. *Many factors (e.g., debilitation; immobility; use of restraints; extremes of age; mental status; dehydration or malnutrition; presence of chronic disease; occupational, treatment, and environmental hazards) can affect the ability of the skin to perform its functions (e.g., protection, sensation, movement and growth, chemical synthesis, immunity, thermoregulation and excretion).*^{3,4}
-  Determine client's age and developmental factors and ability to care for self. *Newborn/infant's skin is thin, provides ineffective thermal regulation, and nails are thin. Infant skin also has a higher absorption and deabsorption rate as compared with an adult's skin, which predisposes infants to a dry, flaky, and impaired skin barrier.⁹ Babies and children are prone to skin rashes associated with viral, bacterial, and fungal infections and allergic reactions. In adolescence, hormones stimulate hair growth and sebaceous gland activity.^{1,3,4,6} In adults, it takes longer to replenish epidermis cells, resulting in increased risk of skin cancers and infection. In older adults, there is decreased epidermal regeneration, fewer sweat glands, less subcutaneous fat, elastin, and collagen, causing skin to become thinner, drier, and less responsive to pain sensations.^{7,12}*
- Evaluate client's skin care practices and hygiene issues. *Individual's skin may be oily, dry and scaly, or sensitive and is affected by bathing frequency (or lack of bathing), temperature of water, and types of soap and other cleansing agents. Incontinence (urinary or bowel) and ineffective hygiene can result in serious skin impairment and discomfort.¹⁷*
- Note presence of compromised mobility, sensation, vision, hearing, or speech that may impact client's self-care as relates to skin care (e.g., diabetic with impaired vision probably cannot satisfactorily examine own feet).^{10,12}
- Ascertain allergy history. *Individual may be sensitive or allergic to substances (e.g., insects, grasses, medications, lotions, soaps, foods) that can adversely affect the skin.*
- Assess blood supply (e.g., capillary return time, color, warmth) and sensation of skin surfaces, pressure points, and broken or abraded skin areas on a regular basis to provide comparative baseline and opportunity for timely intervention when problems are noted.³

- Note distribution and scarcity of hair (e.g., *loss of hair on lower legs may indicate peripheral vascular disease*). Refer to ND risk for Peripheral Neurovascular Dysfunction for additional interventions.¹³
-  Calculate ankle-brachial index to *evaluate actual or potential for impairment of circulation to lower extremities. Result less than 0.9 indicates need for close monitoring or more aggressive intervention (e.g., tighter blood glucose and weight control in diabetic client).*¹⁴
- Determine treatment-related skin or tissue conditions (e.g., surgical incision, IV/invasive line insertion site, use of restraints). Assess surgical sites for *signs of infection (e.g., swelling, redness, pain)*; assess IV site for *infiltration (e.g., swelling, erythema, coolness, pain; failure of infusion) or evidence of extravasation (e.g., blistering, blanching, skin sloughing).*⁴ Evaluate skin surrounding restraints for abrasions, contusions, skin breaks, or skin color and temperature changes distal to restraints *suggesting impaired circulation.*
-  Review lab results (e.g., hemoglobin/hematocrit, blood glucose, blood and/or wound culture, sensitivities for infectious agents [viral, bacterial, fungal], albumin, protein) *to evaluate causative factors or ability to heal. Note: Albumin less than 3.5 correlates to decreased wound healing and increased incidence of pressure ulcers.*^{1,14,15}

NURSING PRIORITY NO. 2 To assess extent of involvement/injury:

-  Obtain a complete history of current skin condition(s) (especially in children where recurrent rash or lesions are common), including age at onset, date of first episode, duration, original site, characteristics of lesions, and any changes that have occurred. *Common skin manifestations of sensitivity or allergies are hives, eczema, and contact dermatitis. Contagious rashes include measles, rubella, roseola, chickenpox, and scarlet fever. Bacterial, viral, and fungal infections can also cause skin problems (e.g., impetigo, cellulitis, cold sores, shingles, athlete's foot, candidiasis, diaper rashes).*^{5,6,19}
- Perform routine skin inspections describing observed changes. Note color, temperature, surface changes, texture, and contours. Evaluate color changes in areas of least pigmentation (e.g., sclera, conjunctiva, nailbeds, buccal mucosa, tongue, palms, soles of feet). *Systematic inspection can identify improvement or changes for timely intervention.*

General wounds/lesions

- Describe rash or lesion, noting color, location, and significant characteristics (e.g., flat or raised rash, weeping or painful blisters, itching wheal) and surrounding information (e.g., exposure to contagious disease, reaction to medication, recent insect bite, ingrown toenail, sexually transmitted infection) *to assist in diagnosing problem and needed interventions.*
- Determine anatomic location and depth of skin or tissue injury or damage (e.g., epidermis, dermis, underlying issues) and describe (e.g., skin tear, partial or full-thickness burn) *to provide baseline and document changes.*^{3,12}
-  Utilize a skin integrity risk assessment tool (e.g., The International Skin Tear Advisory Panel (ISTAP) skin tears classification and risk assessment tool, or the Payne-Martin classification system) *to classify skin tears according to evidence-based practice guidelines.*²¹
- Photograph lesion(s) as appropriate *to document status and provide visual baseline for future comparisons.*
- Note character and color of drainage, when present (e.g., blood, bile, pus, stoma effluent), *which can cause or exacerbate skin irritation or excoriation.*

Pressure ulcers/decubitus

-  Determine, document, and reassess periodically (1) dimensions and depth in centimeters; (2) exudates—color, odor, and amount; (3) margins—fixed or unfixed; (4) tunneling or tracts; and (5) evidence of necrosis (e.g., color gray to black), or healing (e.g., pink or red granulation tissue) *to establish comparative baseline and evaluate effectiveness of interventions. Refer to ND risk for Pressure Ulcer for assessments and preventive interventions.*^{8,12,15}

NURSING PRIORITY NO. 3 To determine impact of condition:

- Determine if wound is acute (e.g., injury from surgery or trauma) or chronic (e.g., venous or arterial insufficiency), *which affects healing time and the client's emotional and physical responses. For example, an acute*

and noninfected wound can heal in about 4 weeks, while a chronic wound often does not progress through phases of healing in an orderly or timely fashion.⁸

- Determine client's level of discomfort (e.g., can vary widely from minor itching or aching to deep pain with burns or excoriation associated with drainage) *to clarify intervention needs and priorities.*
-  Ascertain attitudes of individual/significant others(s) about condition (e.g., cultural values, stigma). Obtain or review psychological assessment of client's emotional status, noting potential or sexual problems arising from presence of condition. *The healthy wholeness and beauty of skin impacts the client's body image and self-esteem. Lesions or wounds that disfigure can be especially devastating.*

NURSING PRIORITY NO. 4 To assist client with correcting/minimizing condition and achieving optimal healing:

- Practice and instruct client/caregiver(s) in scrupulous hand hygiene and clean or sterile technique *to reduce incidence of contamination or infection.*
-  Provide optimum nutrition (including adequate protein, lipids, calories, trace minerals, and multivitamins [e.g., A, C, D, E]) *to promote skin health and healing and to maintain general good health.*
-  Provide adequate hydration (e.g., oral, tube feeding, IV, ambient room humidity) *to reduce and replenish transepidermal water loss.*
-  **Manage itching conditions:**^{5,19,20}
Cover itchy area, trim nails, and wear gloves at night.
Apply cool, wet compresses.
Take a lukewarm bath with baking soda, uncooked oatmeal, or colloidal oatmeal—a finely ground oatmeal made for the bathtub (e.g., Aveeno).
Choose mild soaps without dyes or perfumes. Rinse the soap completely off body.
Use a mild, unscented laundry detergent when washing clothes, towels, and bedding.
Avoid substances that irritate skin or that cause an allergic reaction (e.g., nickel, jewelry, perfume or skin products containing fragrance).
Encourage use of stress-management techniques (e.g., biofeedback, meditation, yoga).
-  Apply high-quality moisturizing cream (e.g., Eucerin) or anti-itch creams (e.g., hydrocortisone cream, menthol, camphor, calamine) or topical anesthetics (e.g., lidocaine or benzocaine), concentrating on the areas where itching is most severe.
- Encourage client to verbalize feelings and discuss how or if condition affects self-concept. (Refer to NDs disturbed Body Image and situational low Self-Esteem.)
- Assist client to work through stages of grief and feelings associated with individual condition.
- Use touch, facial expressions, and tone of voice *to lend psychological support and acceptance of client.*
-  Refer for counseling and/or behavior modification therapy, if indicated. *Client may need additional medical/psychological interventions if itching is severe, prolonged, or believed to be psychogenic in origin.*²⁰
-  **Promote wound healing:**^{1,11–13,16}
Keep surgical area(s) clean and dry, carefully dress wounds, support incision (e.g., use of Steri-Strips, splinting when coughing), and stimulate circulation to surrounding areas *to assist body's natural process of repair.*
-  Consult with physician or wound specialist as indicated *to assist with developing plan of care for problematic or potentially serious wounds.*
-   Assist with débridement or enzymatic therapy as indicated (e.g., burns, skin tears, severe pressure sores) *to remove nonviable, contaminated, or infected tissue.*^{12,16}
- Use body temperature physiological solutions (e.g., isotonic saline) *to clean or irrigate wounds and prevent washout of electrolytes.*
- Cleanse wound with irrigation syringe or gauze squares, avoiding cotton balls or other products *that shed fibers.*
- Maintain appropriate moisture environment for particular wound (e.g., expose lesions or ulcer to air and light if excess moisture is impeding healing, use occlusive dressings to maintain a moist environment for autolytic débridement of wound) as indicated.^{12,16}

-  Use appropriate barrier dressings or wound coverings (e.g., semipermeable, occlusive, wet-to-damp, Duo-Derm, Tegaderm, hydrocolloid, hydrofiber or gel, hydropolymers), drainage appliances, and skin-protective agents for open or draining wounds and stomas *to protect wound and surrounding tissues from excoriating secretions or drainage and to promote wound healing.*^{12,16}
-  Administer topical or systemic drugs as indicated *for individual situation.*
-  **Prevent skin impairment:**^{3-5,7,11,13,17,18}
 - Maintain or instruct in overall skin hygiene (e.g., shower instead of bathe, wash thoroughly, pat dry, gently massage with lotion or appropriate cream) *to provide barrier to infection, reduce risk of dermal trauma, improve circulation, and enhance comfort.*
 - Cleanse skin after toileting and incontinent or diaphoretic episodes *to restore normal skin pH and flora and limit potential for infection.*
 - Use proper turning and transfer techniques. Avoid movements (e.g., pulling client with parallel force, dragging) *that cause friction or shearing.*
 - Encourage early ambulation or mobilization. *Reduces risks associated with immobility.*
 - Develop regularly timed repositioning schedule for client with mobility and sensation impairments, using turn sheet as needed; encourage or assist with periodic weight shifts for client in chair *to reduce stress on pressure points and to promote circulation to tissues.*
 - Use appropriate padding or pressure-reducing devices (e.g., heel rolls, foam boots, egg crate, gel pads) or pressure-relieving devices (e.g., air or water mattress) when indicated *to reduce pressure on sensitive areas and enhance circulation to compromised tissues.*
 - Avoid or limit use of plastic material (e.g., rubber sheet, plastic-backed linen savers) and remove wet or wrinkled linens promptly. *Moisture potentiates skin breakdown and increases risk for infection.*
 - Remove adhesive products with care, removing on horizontal plane, and using mineral oil or Vaseline for softening, if needed, *to prevent abrasions or tearing of skin.*
 - Secure dressings with tape (e.g., elastic, paper tape, nonadherent dressings) or Montgomery straps when frequent dressing changes are required. Use stockinette, tubular or gauze wrap, or similar product instead of tape to secure dressings and drains *to limit dermal injury.*¹²
 - Apply hot and cold applications judiciously *to reduce risk of dermal injury in persons with circulatory and neurosensory impairments.*
 - Avoid use of latex products *when client has known or suspected sensitivity.* Refer to ND Latex Allergy Response.

NURSING PRIORITY NO. 5 To promote wellness (Teaching/Discharge Considerations):

-  Discuss importance of skin and measures to maintain proper skin functioning. *The integumentary system is the largest multifunctional organ of the body and thus merits special care.*
- Review benefits of following medical regimen. *Enhances commitment to plan, optimizing outcomes.*
- Encourage regular inspection and monitoring of skin for changes or failure to heal. *Early detection and reporting to healthcare providers promotes timely evaluation and intervention.*
- Identify safety measures for client with persistent sensation impairments. *Proper care of skin and extremities during cold or hot weather (e.g., wearing gloves; clean, dry socks; properly fitting shoes or boots; face protection) reduces risk of injury.*^{10,14}
- Encourage continued mobility, activity, and range of motion *to enhance circulation and promote health of skin and other organs.*
- Discuss avoidance of products containing perfumes, dyes, preservatives (*may cause dermatitis reactions*) or alcohol, povidone-iodine, and hydrogen peroxide (*may hinder wound healing*).
- Encourage restriction or abstinence from smoking, *which causes vasoconstriction.*
- Review measures *to avoid spread or reinfection of communicable conditions.*
- Discuss proper and safe use of equipment or appliances (e.g., heating pad, ostomy appliances, padding straps of braces).

- Emphasize wisdom of limiting lengthy or unnecessary sun exposure, using high sun protection factor (SPF) sunblock and avoiding tanning beds.
- Assist client to learn stress reduction and alternate therapy techniques *to control feelings of helplessness and enhance coping ability.*
-  Refer to dietitian or certified diabetes educator as appropriate *to manage general well-being, enhance healing, and reduce risk of recurrence of diabetic ulcers.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Characteristics of lesion(s) or condition, ulcer classification.
- Causative or contributing factors.
- Impact of condition.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

risk for impaired Skin Integrity

Taxonomy II: Safety/Protection—Class 2 Physical Injury 00247] [**Diagnostic Division:** Safety], Approved 1975; Revised 1998, 2010, 2013, 2017

DEFINITION: Susceptible to alteration in epidermis and/or dermis, which may compromise health.

RISK FACTORS

External

Chemical injury agent
Hypothermia; hyperthermia
Excretions; secretions; humidity; moisture

Internal

Alteration in fluid volume
Inadequate nutrition
Psychogenic factor [e.g., obsessive compulsive disorder]

At Risk Population: Extremes of age

Associated Condition: Alteration in metabolism; hormonal change; immunodeficiency

Alteration in skin turgor, sensation, pigmentation

Arterial puncture; vascular trauma

Pharmaceutical agent; radiation therapy

Sample Clinical Applications: AIDs; atherosclerosis, anemias; arthritis; coronary artery disease; dementias; amputation; Buerger's disease, burns; CVA; COPD; CHF; diabetes mellitus, obesity; peripheral vascular disease, Raynaud's disease, thrombophlebitis

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Risk Control: Personal actions to understand, prevent, eliminate, or reduce modifiable health threats

Immobility Consequences: Physiological: Severity of compromise in physiological functioning due to impaired physical mobility

Tissue Integrity: Skin & Mucous Membranes: Structural intactness and normal physiological function of skin and mucous membranes

Client Will (Include Specific Time Frame)

- Identify individual risk factors.
- Verbalize understanding of treatment or therapy regimen.
- Demonstrate behaviors or techniques to prevent skin breakdown.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Risk Identification: Analysis of potential risk factors, determination of health risks, and prioritization of risk reduction strategies for an individual or group

Skin Surveillance: Collection and analysis of patient data to maintain skin and mucous membrane integrity

Pressure Management: Minimizing pressure to body parts

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Identify client with underlying conditions or problems that have potential for *skin integrity problems, such as (1) disease processes that affect circulation and perfusion of tissues (e.g., arteriosclerosis, venous insufficiency, hypertension, obesity, diabetes, malignant neoplasms), (2) medications (e.g., anticoagulants, corticosteroids, immunosuppressives, antineoplastics) that adversely affect or impair healing, (3) radiation (can break down internal tissues as well as skin), (4) nutrition and hydration (e.g., malnutrition deprives the body of protein and calories required for cell growth and repair; dehydration impairs transport of oxygen and nutrients), and (5) psychological stress and/or psychiatric conditions (e.g., skin excoriation is practiced to avoid increased anxiety or in reaction to a dreaded event, or may be elicited by an obsession). Disruption in skin integrity can be **intentional** (e.g., surgical incision) or **unintentional** (e.g., accidental trauma, drug effect, allergic reaction); and **open** (e.g., laceration, skin tears, penetrating wound, ulcerations) or **closed** (e.g., contusion, abrasion, rash).*^{1-5,14}
-  Note general health. *Many factors (e.g., debilitation; immobility; use of restraints; extremes of age; mental and psychiatric status; dehydration or malnutrition; presence of chronic disease; occupational, treatment, and environmental hazards) can affect the ability of the skin to perform its functions (e.g., protection, sensation, movement and growth, chemical synthesis, immunity, thermoregulation, and excretion).*^{1,2,14}
-  Determine client's age and developmental factors or ability to care for self. *Newborn/infant's skin is thin. Babies and children are prone to skin rashes associated with viral, bacterial, and fungal infections and allergic reactions. In adolescence, hormones stimulate hair growth and sebaceous gland activity. In adults, it takes longer to replenish epidermis cells, resulting in increased risk of skin cancers and infection. In older adults, there is decreased epidermal regeneration, fewer sweat glands, and less subcutaneous fat and elastin and collagen, causing skin to become thinner, drier, and less responsive to pain sensations.*^{1,3,4,6-8}
- Evaluate client's skin care practices and hygiene issues. *Individual's skin may be sensitive or oily, dry, and scaly, and it is affected by bathing frequency (or lack of bathing), temperature of water, and types of soap and other cleansing agents. Incontinence (urinary or bowel) and ineffective hygiene can result in serious skin impairment and discomfort.*
- Note presence of compromised vision, sensation, hearing, or speech *that may impact client's self-care as relates to skin care (e.g., diabetic with impaired vision probably cannot satisfactorily examine own feet).*⁹
- Ascertain allergy history. *Individual may be sensitive or allergic to substances (e.g., insects, grasses, medications, lotions, soaps, foods) that can adversely affect the skin.*
- Assess blood supply (e.g., capillary return time, color, warmth) and sensation of skin surfaces or affected area on a regular basis *to provide comparative baseline and opportunity for timely intervention when problems are noted.*
-  Calculate ankle-brachial index *to evaluate actual or potential for impairment of circulation to lower extremities. Result less than 0.9 indicates need for close monitoring or more aggressive intervention (e.g., tighter blood glucose and weight control in diabetic client).*^{10,11}
-  Review lab results (e.g., hemoglobin/hematocrit, blood glucose, albumin, protein) *to evaluate causative factors or ability to heal. Note: Albumin less than 3.5 correlates to decreased wound healing and increased incidence of pressure ulcers.*¹²

NURSING PRIORITY NO. 2 To maintain optimal skin integrity:^{1,2,8}

-  Perform routine skin inspections, assessing color, temperature, surface changes, texture, and contours. Evaluate color changes in areas of least pigmentation (e.g., sclera, conjunctiva, nailbeds, buccal mucosa, tongue, palms, soles of feet). Report potential problem areas (e.g., reddened/blanched areas, rashes) promptly. *Systematic inspection can identify developing problems and promotes early intervention, thus reducing likelihood of progression to skin breakdown.*¹⁴
-   Handle client gently (particularly infant, young child, elderly frail). *Epidermis of infants and very young children is thin and lacks subcutaneous depth that will develop with age. Skin of the older client is also thin, less elastic, and prone to injury, such as bruising and skin tears.*^{2,5}
- Practice and instruct client/caregiver(s) in scrupulous hand hygiene and clean or sterile technique, as appropriate, *to reduce incidence of contamination or infection.*
- Maintain and instruct in overall good skin hygiene (e.g., shower instead of bath, wash thoroughly, pat dry, gently massage with lotion or appropriate cream) *to reduce risk of dermal trauma, improve circulation, and promote comfort.*
-  Provide preventative skin care to incontinent client: Change continence pads or diapers frequently, cleanse perineal skin daily and after each incontinence episode, and apply skin protectant ointment *to minimize contact with irritants (urine, stool, excessive moisture).*¹³
- Cleanse skin after diaphoretic episodes *to maintain normal skin pH and flora and limit potential for infection.*
-  Develop regularly timed repositioning schedule for client with mobility and sensation impairments, using turn sheet, as needed; encourage or assist with periodic weight shifts for client in chair *to reduce stress on pressure points and to promote circulation to tissues.*
-  Use proper turning and transfer techniques. *Avoids movements that cause friction or shearing (e.g., pulling client with parallel force, dragging movements).*
- Pay special attention to bony prominences and other pressure points (e.g., heels, toes, elbows) when positioning client *to prevent pressure trauma and impaired circulation.*
- Provide foam, flotation, alternating pressure, or air mattress *to reduce or relieve pressure on skin, tissues, and lesions, decreasing tissue ischemia.*
- Use appropriate padding or pressure-reducing devices (e.g., egg crate, gel pads, heel rolls, or foam boots), when indicated, *to reduce pressure on sensitive areas and enhance circulation to compromised tissues.*
- Encourage ambulation. *Promotes circulation and reduces risks associated with immobility.*
- Provide for safety measures (e.g., assistive devices or sufficient personnel, grab bars, clear pathways, safe chairs, properly fitting hose and footwear, use of heating pads or lamps, restraints) during ambulation and other interventions *to reduce risk of dermal injury.*
- Avoid or limit use of plastic material (e.g., rubber sheet, plastic-backed linen savers) and remove wet or wrinkled linens promptly. *Moisture potentiates skin breakdown and increases risk for infection.*
- Use paper tape or a nonadherent dressing on frail skin and remove it gently, or use stockinette, tubular or gauze wrap, or other similar product instead of tape to secure dressings and drains *to limit dermal injury.*⁵
- Avoid use of latex products *when client has known or suspected sensitivity.* Refer to ND Latex Allergy Reaction.
- Apply hot and cold applications judiciously *to reduce risk of dermal injury in persons with circulatory and neurosensory impairments.*
- Provide adequate clothing or covers; protect from drafts *to prevent vasoconstriction and reduction of circulation to skin.*
- Keep bedclothes dry, use nonirritating materials, and keep bed free of wrinkles, crumbs, etc., *to prevent skin irritation.*
- Try colloidal bath, application of lotions, or careful use of ice pack *to decrease irritable itching.*
- Keep nails cut short, encouraging client *to refrain from scratching*, or suggest use of/obtain order for mittens (considered a restraint), if necessary, *to prevent dermal injury from scratching.*
- Refer to NDs impaired Skin Integrity and risk for Pressure Ulcer for additional interventions, as indicated.

NURSING PRIORITY NO. 3 To promote healthy skin (Teaching/Discharge Considerations):

-  Discuss importance of skin and measures to maintain proper skin functioning. *The integumentary system is the largest multifunctional organ of the body and thus merits special care.*
- Encourage regular inspection and monitoring of skin for changes and effective skin care in preventing skin problems. *Early detection and reporting to healthcare providers promotes timely evaluation and intervention.*
- Counsel diabetic and neurologically impaired client regarding the necessity of meticulous skin care, especially of lower extremities. *Healing of lower-extremity injuries tends to be more problematic in this population, resulting in increased incidence of amputation.*
- Avoid products containing perfumes, dyes, preservatives (*may cause dermatitis reactions*) or alcohol, povidone-iodine, and hydrogen peroxide (*may hinder healing*).
- Instruct in care of skin and extremities during cold or hot weather (e.g., wearing gloves, and clean, dry socks; properly fitting shoes or boots; face protection) *to reduce risk of tissue damage, especially in clients with impaired sensation.*
- Recommend elevation of lower extremities when sitting *to enhance venous return and reduce edema formation.*
- Encourage consistent exercise program (active or assistive) *to enhance circulation.*
- Discuss need for adequate nutritional intake (including adequate protein, lipids, calories, trace minerals, multivitamins) *to promote skin health and healing and to maintain general good health.*
- Determine fluid needs and sources for hydration (e.g., oral, tube feeding, ambient room humidity) *to reduce and replenish transepidermal water loss.*
- Encourage restriction or abstinence from smoking, *which can cause vasoconstriction.*
- Discuss importance of limiting lengthy or unnecessary sun exposure and avoiding use of tanning beds. Emphasize necessity of avoiding exposure to sunlight in specific conditions (e.g., systemic lupus, tetracycline or psychotropic drug use, radiation therapy) as well as potential for development of skin cancer.
- Advise use of high sun protection factor (SPF) sunblock or sunscreen, particularly on young child, client with fair skin (prone to burn), client using multiple medications, etc., *to limit skin damage (immediate and over time) associated with sun exposure.*

DOCUMENTATION FOCUS**Assessment/Reassessment**

- Individual findings, including individual risk factors.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.

Sleep Deprivation

Taxonomy II: Activity/Rest—Class 1 Sleep/Rest (00096) [Diagnostic Division: Activity/Rest], Approved 1998; Revised 2017

DEFINITION: Prolonged periods of time without sustained natural, periodic suspension of relative consciousness that provides rest.

RELATED FACTORS

Age-related sleep stage shifts; nonrestorative sleep pattern; sustained inadequate sleep hygiene; sustained circadian asynchrony
 Average daily physical activity is less than recommended for gender and age
 Environmental barrier; overstimulating environment
 Late day confusion
 Prolonged discomfort
 Sleep terror; sleep walking

DEFINING CHARACTERISTICS

Subjective

Decrease in functional ability
 Malaise; lethargy; fatigue
 Anxiety
 Perceptual disorders; heightened sensitivity to pain

Objective

Restlessness; irritability
 Alteration in concentration; decrease in reaction time
 Drowsiness; listlessness; apathy
 Fleeting nystagmus; hand tremors
 Confusion; transient paranoia; agitation; combativeness; hallucinations

At Risk Population: Familial sleep paralysis

Associated Condition: Conditions with periodic limb movement; nightmares
 Dementia
 Idiopathic central nervous system hypersomnolence; narcolepsy

Sleep apnea; sleep-related enuresis; sleep-related erections

Treatment regimen

Sample Clinical Applications: Chronic obstructive pulmonary disease (COPD), heart failure (nocturia), chronic pain, sleep apnea, pregnancy, postpartum, colic, dementia, Alzheimer's disease, anxiety disorders, posttraumatic stress disorder

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Sleep: Natural periodic suspension of consciousness during which the body is restored

Rest: Quantity and pattern of diminished activity for mental and physical rejuvenation

Pain Control: Personal actions to eliminate or reduce pain

Client Will (Include Specific Time Frame)

- Identify individually appropriate interventions to promote sleep.
- Verbalize understanding of sleep disorder.
- Adjust lifestyle to accommodate chronobiological rhythms.
- Report improvement in sleep and rest pattern.

Sample **NOC** linkages:

- **Family Coping:** Capacity of the family to manage stressors that tax family resources

Family Will (Include Specific Time Frame)

- Deal appropriately with parasomnias.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Sleep Enhancement: Facilitation of regular sleep/wake cycles

Anxiety Reduction: Minimizing apprehension, dread, foreboding, or uneasiness related to an unidentified source or anticipated danger

Environmental Management: Comfort: Manipulation of the patient's surroundings for promotion of optimal comfort

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

-   Note client's age and developmental stage. *The average adult requires 7 to 8 hours of sleep, although recent research indicates that the average total hours of sleep have decreased to less than 7 hours per night over the last few decades.¹⁷ Teenagers require about 9 hours, and infants require about 16 hours. Pregnant women and new mothers, while needing more sleep, usually are sleep deprived. Studies show that sleep disorders occur in 35% to 45% of children 2 to 18 years of age,^{13,17} and adolescents and young adults don't get enough sleep, have irregular sleep patterns, and are at risk for problem sleepiness.² Menopausal women often report interrupted sleep because of hot flashes or hormonal influences, and older people tend to sleep fewer hours and report less restful sleep and need for more sleep.^{1-5,12,13}*
- Determine presence of physical or psychological stressors. *These include multiple, varying factors, such as night-shift work hours or rotating shifts; pain (acute and chronic), current or recent illness, and hospitalization, especially in intensive care unit; death of a spouse or loss of a job; new baby in the home and inadequate sleep-promoting behaviors; etc.*

-  Note presence of diagnoses *that are known to affect sleep* (e.g., mental confusion or dementias, certain brain infections [e.g., encephalitis], brain injury, narcolepsy; chronic pain; obsessive/compulsive disorder, anxiety, depression, other major psychological disorders; drug or alcohol abuse; restless leg syndrome; sleep-induced respiratory disorders—sleep-disordered breathing, obstructive sleep apnea, childhood snoring with sleep apnea).^{4,5,19}
-  Evaluate medication regimen for products affecting sleep. *Diet pills or other stimulants, sedatives, anti-depressants, antihypertensives, diuretics, narcotics, agents with anticholinergic effects, and need for medications requiring nighttime dosing can inhibit getting to sleep or remaining asleep.*^{6,7,16}
-  Note environmental factors *affecting sleep* (e.g., unfamiliar or uncomfortable sleep environment, excessive noise and light, frequent checking of vital signs, uncomfortable temperature, roommate irritations or actions—snoring, watching television late at night) *that impair falling or staying asleep.* Note: *Clients in critical care units are known to experience lack of sleep or frequent disruptions, often compounding their illness.*⁷
-  Determine presence of parasomnias: nightmares or terrors, sleepwalking or talking, or other complex behaviors during sleep. *May occur at any age, with as many as 30% of children (peak age 4 to 8 years) having a sleep disorder at some time.*¹⁶ Note reports of terror, brief periods of paralysis, and sense of body being disconnected from the brain. *Occurrence of sleep paralysis, though not widely recognized in the United States, has been well documented elsewhere and may result in feelings of fear and reluctance to go to sleep. May require more extensive evaluation for serious sleep disorders.*^{8,14}

NURSING PRIORITY NO. 2 To assess degree of impairment:

-  Assess client's usual sleep patterns and current sleep disturbance, relying on client's/significant other's (SO's) report of problem. Incorporate screening information into in-depth sleep diary or testing if needed. *Usual sleep patterns are individual, but sleep loss has been shown to be the most common complaint reported in primary care settings;^{3,9} therefore, screening for the problem should be routine. Data collected from a comprehensive assessment is needed to determine etiology of challenging sleep disturbances, including the stage of sleep that is impaired.*⁷
- Ascertain quality of sleep for bed partner/family members. *Loud irregular snoring (sleep apnea), periodic nightmares or sleep terrors, sleep talking, sleepwalking, or involuntary muscle activity can interfere with sleep of bed partner/entire family.*¹⁶
- Determine client's sleep expectations. *Individual may have faulty beliefs or attitudes about sleep and unrealistic sleep expectations (e.g., "I must get 8 hours of sleep every night, or I can't accomplish anything").*⁹
- Ascertain duration of current problem and effect on life and functional ability. *Client may not get enough sleep and not realize that life functioning is being impaired (e.g., can't concentrate in school, falls asleep when stopped at a light while driving).*⁹
- Listen to subjective reports of sleep quality (e.g., "short, interrupted") and response from lack of good sleep (feeling foggy, sleepy, and woozy; fighting sleep; fatigue). *Helps clarify client's perception of sleep quantity and quality and response to inadequate sleep.*⁹
-  Observe for physical signs of fatigue. *Client may display restlessness, irritability, disorientation, frequent yawning, and/or other changes in mood, behavior, or performance (e.g., inability to tolerate stress, problems with concentration or learning). Fatigue, daytime sleepiness, and functional impairment have been reported as significant problems in teens and the elderly.*^{2,3,9,12,16,20}
- Determine interventions client has tried to date. *Helps identify appropriate options and may reveal additional interventions that can be attempted.*
- Distinguish client's beneficial bedtime habits from detrimental ones (e.g., drinking milk in the late evening [instead of coffee], restricting fluid intake, avoiding stimulating exercise, watching TV in bed, eliminating afternoon naps).
-  Instruct client and/or bed partner to keep a sleep-wake log to document symptoms and identify factors that are interfering with sleep.
-  Obtain a chronological chart to determine client's peak performance and sleep rhythms.

- Investigate anxious feelings *to help determine basis and appropriate anxiety-reduction techniques or behavioral therapy needs.*^{16,20}

NURSING PRIORITY NO. 3 To assist client to establish optimal sleep pattern:^{1,3,6,7,9–11,17,20}

-  Review medications being taken and their effect on sleep, suggesting modifications in regimen *if medications are found to be interfering.*
- Encourage client to restrict caffeine and other stimulating substances from late-afternoon and evening intake. Recommend avoidance of bedtime alcohol. *Alcohol and some medications can produce immediate sleep followed by early awakening or difficulty remaining asleep.*
- Avoid eating large evening or late-night meals.
- Recommend light bedtime snack (protein, simple carbohydrate, low fat) and/or glass of warm milk for individuals who feel hungry, ingested 15 to 30 min before retiring. *Sense of fullness and satiety can encourage sleep.*
- Limit evening fluid intake if nocturia is present *to reduce need for nighttime elimination.*
- Promote adequate physical exercise activity during day, finishing workout at least 3 hr before bedtime. *Enhances expenditure of energy and release of tension so that client feels ready for sleep or rest. Note: Rigorous exercise close to bedtime can delay onset of sleep.*
- Suggest abstaining from daytime naps or napping in the morning *to improve ability to fall asleep at night.*
- Recommend quiet relaxing activities prior to bedtime such as reading, listening to soothing music, and meditation *to reduce stimulation and promote relaxation.*
-  Discuss or implement effective age-appropriate bedtime rituals (e.g., going to bed at same time each night, brushing teeth, reading, drinking warm milk, rocking, story reading, cuddling, favorite blanket or toy) *to enhance client's ability to fall asleep, reinforce that bed is a place to sleep, and promote sense of security for child.*
- Provide back massage or other therapeutic touching activities, as appropriate. *Touch can be relaxing and emotionally pleasing, given that the client has SO's undivided attention for a few moments.*
- Provide calm, quiet environment for client, *to manage controllable sleep-disrupting factors (e.g., reduce noise and talking, dim lights, shut room door, adjust room temperature as needed, silence or reduce volume on phones, beepers, alarms, television, radios).*
-  Administer pain medication first *to make sure client is pain-free* and then sedatives or other sleep medications *(so that hypnotic will be more effective)* when indicated, noting client's response. Time pain medications for peak effect and duration *to reduce need for redosing during prime sleep hours.*
-  Discuss appropriate use of benzodiazepines when indicated. *May be useful in some clients for reducing risk of injury associated with sleepwalking or for management of severe sleep terrors. When possible, avoid use of longer-acting benzodiazepines in the elderly, as they are associated with prolonged sedation and increased risk of falls.*^{16,20}
- Instruct client to get out of bed, leave bedroom, and engage in relaxing activities *if unable to fall asleep* and not return to bed until feeling sleepy.
- Recommend and instruct client in relaxation techniques (e.g., visualization, breathing, yoga).
-  Refer for biofeedback, cognitive therapy, etc., *when measures that are more intensive are needed or desired to cope with stressors and promote relaxation.*
-  Collaborate with healthcare team for evaluation and treatment of more serious sleep problems (e.g., obstructive sleep apnea, narcolepsy, sleep paralysis, bed-wetting, nocturnal leg cramps, restless leg syndrome).^{13–16}
-  Refer to physician and/or sleep specialist for evaluation and management of obstructive sleep apnea, such as medical or surgical treatment of obesity, medications and/or structural surgery (e.g., alteration of facial structures, removal of tonsils and adenoids in children),¹⁵ or apnea/oxygenation therapy (continuous positive airway pressure, such as Respironics), *when sleep apnea is severe as documented by sleep-disorder studies.*²¹

NURSING PRIORITY NO. 4 To promote wellness (Teaching/Discharge Considerations):

-  Review possibility of next-day drowsiness or “rebound” insomnia and temporary memory loss *that may be associated with sleep disorders and prescription sleep medications.*
-  Discuss short-term use and appropriateness of over-the-counter sleep medications or herbal supplements. Note possible side effects and drug interactions.
-  Identify appropriate safety precautions (e.g., securing doors, windows, and stairways; placing client bedroom on first floor) and attach audible alarm to bedroom door *to alert parents when child is sleepwalking.*¹⁶
-  Refer to support group or counselor *to help deal with psychological stressors (e.g., grief, sorrow, chronic pain).* (Refer to NDs Grieving, chronic Sorrow, and chronic Pain.)
-  Encourage family counseling as indicated *to help deal with concerns arising from parasomnias (e.g., sleep talking, sleepwalking, night terrors).*
-  Refer to sleep specialist for sleep studies *when problem is unresponsive to customary interventions.*

DOCUMENTATION FOCUS**Assessment/Reassessment**

- Assessment findings, including specifics of sleep pattern (current and past) and effects on lifestyle/level of functioning.
- Medications used, interventions tried, previous therapies.
- Family history of similar problem.
- Effects of sleep disturbance on SO/family.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Client's response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

disturbed Sleep Pattern

Taxonomy II: Activity/Rest—Class 1 Sleep/Rest (00198) [**Diagnostic Division:** Activity/Rest], Approved 1980; Revised 1998, 2006

DEFINITION: Time-limited awakenings due to external factors.

RELATED FACTORS

Environmental barrier [e.g., ambient temperature/humidity, daylight/darkness exposure, ambient noise, unfamiliar setting]; immobilization

Nonrestorative sleep pattern [e.g., due to caregiver responsibilities, parenting practices, sleep partner]

Insufficient privacy; disruption caused by sleep partner

DEFINING CHARACTERISTICS

Subjective

Difficulty in daily functioning

Difficulty initiating sleep or maintaining sleep state; unintentional awakening

Feeling unrested; dissatisfaction with sleep

Sample Clinical Applications: Hospitalized or long-term care client, ill family member

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Sleep: Natural periodic suspension of consciousness during which the body is restored

Comfort Status: Environment: Environmental ease, comfort, and safety of surroundings

Client Will (Include Specific Time Frame)

- Report improved sleep.
- Report increased sense of well-being and feeling rested.
- Identify individually appropriate interventions to promote sleep.

(continues on page 816)

disturbed Sleep Pattern (continued)**ACTIONS/INTERVENTIONS****Sample NIC linkages:****Sleep Enhancement:** Facilitation of regular sleep/wake cycles**Environmental Management: Comfort:** Manipulation of the patient's surroundings for promotion of optimal comfort**NURSING PRIORITY NO. 1** To assess causative/contributing factors:

-  Identify presence of factors known to interfere with sleep, including current illness or hospitalization, new baby or sick family member in home, etc. *Sleep problems can arise from internal and external factors and may require assessment over time to differentiate specific cause(s). Note: Unresolved long-term disturbances in sleep are thought to be associated with dysfunction of the immune system, interference with wound healing, neurological and behavioral changes, and significant impairment of quality of life.^{1,10} Refer to ND Sleep Deprivation.*
- Ascertain presence of short-term alteration in sleep patterns, such as can occur with travel (jet-lag), sharing bed with new sleep partner, fighting with family member, crisis at work, loss of job, or death in family. *Helps identify circumstances that are known to interrupt sleep acutely but do not necessarily represent long-term conditions. These situations may require short-term interventions but are often resolved over time.²*
-  Note environmental factors, such as unfamiliar or uncomfortable room, excessive noise and light, uncomfortable temperature, frequent medical and monitoring interventions, and roommate actions (e.g., snoring, watching television late at night, wanting to talk). *These factors can reduce client's ability to rest and sleep at a time when more rest is needed. Note: Clients in critical care units are known to experience lack of sleep or frequent disruptions, often compounding their illness.^{3,5}*

NURSING PRIORITY NO. 2 To evaluate sleep and degree of dysfunction:

- Assess client's usual sleep patterns and compare with current sleep disturbance, relying on client's/significant other's report of problem *to ascertain intensity and duration of problems.*
- Listen to reports of sleep quality (e.g., "short, interrupted") and response from lack of good sleep (e.g., feeling foggy, sleepy, and woozy; fighting sleep; fatigue). *Helps clarify client's perception of sleep quantity and quality and response to inadequate sleep.⁴*
- Determine client's sleep expectations. *Individual may have faulty beliefs or attitudes about sleep and/or unrealistic sleep expectations (e.g., "I must get 8 hours of sleep every night, or I can't accomplish anything").⁴*
- Observe for physical signs of fatigue (e.g., restlessness, hand tremors, thick speech, drooping eyes, inattention, lack of interest in activities).
- Incorporate screening information into in-depth sleep diary or testing if needed. *Information collected from a comprehensive assessment may be needed to evaluate the type and etiology of sleep disturbance and identify useful treatment options.^{4,5}*

NURSING PRIORITY NO. 3 To assist client to establish optimal sleep/rest patterns:

-  Manage environment for hospitalized client.^{1,3,5-7}
Adjust ambient lighting *to maintain daytime light and nighttime dark.*
Provide privacy as indicated, such as requesting visitors to leave, closing room door, "quiet, patient sleeping" sign, etc.
Encourage usual bedtime activities such as washing face and hands and brushing teeth.

Provide bedtime care such as straightening bed sheets, changing damp linens or gown, and back massage to promote physical comfort.

 Offer or provide sleep aids such as earplugs, eyemasks, if desired. *Note: One small study found that use of these aids prolonged client sleep time.*¹¹

Turn on soft music, calm TV program, or quiet environment, as client prefers, to enhance relaxation.

 Minimize sleep-disrupting factors (e.g., shut room door; adjust room temperature as needed; reduce talking and other disturbing noises such as phones, beepers, alarms). *Studies show that use of these interventions can promote readiness for sleep and improve sleep duration and quality.*^{5,8}

Perform monitoring and care activities without waking client whenever possible. *Allows for longer periods of uninterrupted sleep, especially during night.*

Avoid or limit use of physical restraints in accordance with client's needs and facility policy.

-  Refer to physician or sleep specialist as indicated for specific interventions and/or therapies, including medications and biofeedback.
- Refer to NDs Insomnia and Sleep Deprivation for related interventions and rationale.

NURSING PRIORITY NO. 4 To promote optimal sleep (Teaching/Discharge Considerations):

-  Assure client that occasional sleeplessness should not threaten health and that resolving time-limited situation can restore healthful sleep. *Knowledge that occasional insomnia is universal and usually not harmful may promote relaxation and relief from worry, which can perpetuate the problem.*⁹
- Problem-solve immediate needs. *Short-term solutions (e.g., sleeping in different rooms if partner's illness is keeping client awake, acquiring a fan if sleeping quarters are too warm, getting a substitute to provide care to ill family member so client can get a good night's rest) may be needed until client adjusts to situation or crisis is resolved, with resulting return to more usual sleep pattern.*
- Encourage appropriate indoor light settings during day and night, especially exposure to bright light or sunlight in the morning; avoidance of daytime napping as appropriate for age and situation; and being active during day and more passive in evening. *Helps in promotion of normal sleep-wake patterns.*^{6,9}
- Encourage use of aids to block out light and sound, such as sleep mask, room-darkening shades, earplugs, and white noise.⁷
-  Discuss use and appropriateness of over-the-counter sleep medications or herbal supplements to provide assistance in falling and staying asleep.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Assessment findings, including specifics of sleep pattern (current and past) and effects on lifestyle and level of functioning.
- Specific interventions, medications, or previously tried therapies.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Available resources, specific referrals made.

readiness for enhanced Sleep

Taxonomy II: Activity/Rest—Class 1 Sleep/Rest (00165) [Diagnostic Division: Activity/Rest], Approved 2002; Revised 2013

DEFINITION: A pattern of natural, periodic suspension of relative consciousness to provide rest and sustain a desired lifestyle, which can be strengthened.

DEFINING CHARACTERISTICS

Subjective

Expresses desire to enhance sleep

Sample Clinical Applications: Postoperative recovery, chronic pain, pregnancy—prenatal/postpartal period, sleep apnea

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Sleep: Natural periodic suspension of consciousness during which the body is restored

Rest: Quantity and pattern of diminished activity for mental and physical rejuvenation

Comfort Status: Environmental: Environmental ease, comfort, and safety of surroundings

Client Will (Include Specific Time Frame)

- Identify individually appropriate interventions to promote sleep.
- Verbalize feeling rested after sleep.
- Adjust lifestyle to accommodate routines that promote sleep.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Sleep Enhancement: Facilitation of regular sleep/wake cycles

Relaxation Therapy: Use of techniques to encourage and elicit relaxation for the purpose of decreasing undesirable signs and symptoms such as pain, muscle tension, or anxiety

Environmental Management: Manipulation of the patient's surroundings for therapeutic benefit, sensory appeal, and psychological well-being

NURSING PRIORITY NO. 1 To determine motivation for continued improvement:

- Listen to client's reports of sleep quantity and quality. Determine client's perception of adequate sleep. *Reveals client's experience and expectations regarding sleep. Provides opportunity to address misconceptions or unrealistic expectations and plan for interventions.*
- Observe or obtain feedback from client/significant other(s) regarding usual bedtime, number of hours of sleep, and time of arising *to determine usual sleep pattern and provide comparative baseline for improvements.*
- Ascertain motivation and expectation for change. *Motivation to improve and high expectations can encourage client to make changes that will improve his or her life. However, unrealistic expectations may hamper efforts.*
- Note client report of potential for alteration of habitual sleep time (e.g., change of work pattern or rotating shifts) or change in normal bedtime (e.g., hospitalization). *Helps identify circumstances that are known to interrupt sleep patterns and that could disrupt the person's biological rhythms.*^{1,6}

NURSING PRIORITY NO. 2 To assist client to enhance sleep/rest:

-  Review client's usual bedtime rituals, routines, and sleep environment needs. *Provides information on client's management of the situation and identifies areas that might be modified when the need arises.*
-  Discuss or implement effective age-appropriate bedtime rituals for infant/child (e.g., rocking, story reading, cuddling, favorite blanket or toy). *Rituals can enhance ability to fall asleep, reinforce that bed is a place to sleep, and promote sense of security for child.*²
- Provide quiet environment and comfort measures (e.g., back rub, washing hands and face, cleaning and straightening sheets) for client in facility. *Promotes relaxation and readiness for sleep.*
-  Arrange care to provide for uninterrupted periods for rest. Explain necessity of disturbances for monitoring vital signs or other care when client is hospitalized. Do as much care as possible during night without waking client. *Allows for longer periods of uninterrupted sleep, especially during night.*
- Suggest limiting fluid intake in evening if nocturia or bed-wetting is a problem *to reduce need for nighttime elimination.*
- Provide instruction in use of necessary equipment. *Client may use oxygen or continuous positive airway pressure (CPAP) system to improve sleep/rest in presence of hypoxia or sleep apnea.*
- Discuss dietary matters, such as limiting chocolate, heavy meals, caffeine, or alcoholic beverages prior to bedtime, *which are substances known to impair falling or staying asleep. Use of alcohol at bedtime may help individual fall asleep, but ensuing sleep is then fragmented.*⁷
- Explore or implement use of warm bath, intake of light protein snack before bedtime, comfortable room temperature, soothing music, or favorite calming television show. *Nonpharmaceutical aids can enhance falling asleep without the undesired side effects associated with medications.*
- Investigate use of sleep mask, darkening shades or curtains, earplugs, and low-level background (white) noise in situations *where sleep might not come easily or be disturbed by environmental factors.*
- Recommend continuing same schedule for sleep throughout week—including days off. *Maintaining sleep pattern helps sustain biological rhythms.*

NURSING PRIORITY NO. 3 To promote optimum sleep:

-  Assure client that occasional sleeplessness should not threaten health. *Knowledge that occasional insomnia is universal and usually not harmful may promote relaxation and relief from worry.*³
- Encourage regular exercise during the day *to aid in stress control and release of energy. Note: Exercise at bedtime may stimulate rather than relax client and may actually interfere with sleep.*⁵
- Assist to develop individual program of relaxation (e.g., biofeedback, self-hypnosis, visualization, progressive muscle relaxation). *Reduces sympathetic response and stress to aid in inducing sleep.*⁴
- Address sleep management techniques that may be useful during stressful conditions or lifestyle changes (e.g., pregnancy, new baby, menopause, medical procedures, new job, moving, change in relationship, grief).
-  Recommend periodic review of medications. *Many prescription and over-the-counter (OTC) drugs can disrupt sleep.*

-  Advise using prescription or OTC sleep medications sparingly. *These medications, while useful for promoting sleep in the short term, can interfere with rapid eye movement sleep.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Assessment findings, including specifics of sleep pattern and effects on lifestyle/level of functioning.
- Any medications used, interventions tried, previous therapies.
- Motivation and expectations for change.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Client's response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

impaired Social Interaction

Taxonomy II: Role Relationships—Class 3 Role Performance (00052) [Diagnostic Division: Social Interaction], Approved 1986; Revised 2017

DEFINITION: Insufficient or excessive quantity or ineffective quality of social exchange.

RELATED FACTORS

Insufficient knowledge about ways to enhance mutuality
 Insufficient skills to enhance mutuality
 Communication barrier
 Disturbance in self-concept
 Impaired mobility
 Therapeutic isolation
 Sociocultural dissonance

Environmental barrier
Disturbance in thought processes

DEFINING CHARACTERISTICS

Subjective

Discomfort in social situations
Dissatisfaction with social engagement [e.g., belonging, caring, interest, shared history]
Family reports change in interaction

Objective

Impaired social functioning
Dysfunctional interaction with others

At Risk Population: Absence of significant other

Associated Condition: Therapeutic isolation

Sample Clinical Applications: Brain injury, stroke, cancer, neuromuscular disease (e.g., multiple sclerosis [MS]), cerebral palsy, substance abuse, Alzheimer's disease, schizophrenia, autism

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Social Interaction Skills: Personal behaviors that promote effective relationships

Child Development: (specify Middle Childhood or Adolescence): Milestones of physical, cognitive, and psychosocial progression from [6–11 or 12–17] years of age

Social Involvement: Social interactions with persons, groups, or organizations

Client Will (Include Specific Time Frame)

- Verbalize awareness of factors causing or promoting impaired social interactions.
- Identify feelings that lead to poor social interactions.
- Express desire or be involved in achieving positive changes in social behaviors and interpersonal relationships.
- Give self positive reinforcement for changes that are achieved.
- Develop effective social support system; use available resources appropriately.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Socialization Enhancement: Facilitation of another person's ability to interact with others

Behavior Modification: Social Skills: Assisting the patient to develop or improve interpersonal social skills

Complex Relationship Building: Establishing a therapeutic relationship with a patient to promote insight and behavioral change

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Review social history with client/significant others (SOs) and go back far enough in time to note when changes in social behavior or patterns of relating occurred or began. *For example, loss or long-term illness of loved one; failed relationships; loss of occupation, financial, or political (power) position; change in status in family hierarchy (job loss, aging, illness); and poor coping or adjustment to developmental stage of life, as with marriage, birth or adoption of child, or children leaving home, are situations that may affect quality of social exchange.*¹

-  Ascertain ethnic, cultural, or religious implications for the client. *These factors can dictate choice of behaviors and may even script interactions with others. Client may perceive behaviors as normal because of belief system or may have conflict regarding behaviors that are not accepted by larger society, such as homosexuality or gender identity disorder.*^{1,5,6}
-  Review medical history, noting stressors of physical or long-term illness/chronic conditions (e.g., stroke, cancer, MS, head injury, Alzheimer's disease), mental illness (e.g., schizophrenia), medications, substance use, debilitating accidents, learning disabilities (e.g., sensory integration difficulties, autism spectrum disorder, Asperger's disorder), and emotional disabilities. *Conditions such as these can isolate individual who feels disconnected from others, resulting in difficulty relating in social situations. Note: Evidence indicates that loneliness heightens sensitivity to social threats and can impair executive functioning, sleep, and mental and physical well-being.*^{3,4,11}
- Note presence of visual or hearing impairments. *Individuals with these conditions may find communication barriers are increased, social interaction is affected, and interventions need to be designed to promote involvement with others in positive ways.*^{1,3}
-   Determine family patterns of relating and social behaviors. Explore possible family scripting of behavioral expectations in the children and how the client was affected. *Parents are important in teaching their children social skills (e.g., sharing, taking turns, allowing others to talk without interrupting). Family may not have effective patterns of relating to others, and the child learns these skills in this setting. Often child reflects family expectations rather than own desires, which may result in conforming or rebellious behaviors.*^{2,6,10}
- Observe client while relating to family/SO(s) and note observations of prevalent patterns. *Identification of patterns will help with plan for change.*²
- Encourage client to verbalize feeling of discomfort about social situations. Note any causative factors, recurring precipitating patterns, and barriers to using support systems. *Identifies areas of concern and suggests possible ways to learn new skills.*²

NURSING PRIORITY NO. 2 To assess degree of impairment:

- Encourage client to verbalize perceptions of reasons for problems. Active listen, noting indications of hopelessness, powerlessness, fear, anxiety, grief, anger, feeling unloved or unlovable, problems with sexual identity, and hate (directed or not). *These feelings arise from the anxiety that comes with the need to participate with others in social situations and can interfere with work, friendships, and life in general.*^{5,7}
-  Observe and describe social and interpersonal behaviors in objective terms, noting speech patterns and body language (1) in the therapeutic setting and (2) in normal areas of daily functioning (if possible), including family, job, and social or entertainment settings. *Provides information about extent of anxiety client experiences in different settings and suggests possible interventions.*^{5,7}
- Determine client's use of coping skills and defense mechanisms. *Symptoms associated with social anxiety affect ability to be involved in social situations, making client's life miserable and seriously interfering with work, friendships, and family life.*^{5,7}
-  Evaluate possibility of client being the victim of or using destructive behaviors against self or others. (Refer to ND risk for other-directed/self-directed Violence.) *Problems of poor communication lead to frustration and anger, leaving the individual with few coping skills, and may result in destructive behaviors.*^{1,2,10}
- Interview family, SO(s), friends, spiritual leaders, coworkers, as appropriate. *Obtaining observations of client's behavioral changes from others associated with the individual provides a broader view of actual problems and how behavior affects client's life/others.*⁵

NURSING PRIORITY NO. 3 To assist client/SO(s) to recognize/make positive changes in impaired social and interpersonal interactions:

- Establish therapeutic relationship using positive regard for the person, Active listening, and providing safe environment for self-disclosure. *Client who is having difficulty interacting in social situations needs to feel comfortable and accepted before he or she is willing to talk about self and concerns.*^{1,2}

- Have client list behaviors that cause discomfort. *Anxiety usually has physical symptoms (e.g., a racing heart, dry mouth, shaky voice, blushing, sweating, nausea), and once it is recognized, client can choose to begin treatment to change.*^{5,7}
- Have family/SO(s) list client's behaviors that are causing discomfort for them. *Anxiety is contagious, and by identifying specific behaviors, all members of the family can begin to deal appropriately with them so they are diminished.*^{5,7}
- Review negative behaviors observed previously by caregivers, coworkers, etc. *Others may see behaviors and the problems associated with them, such as unwillingness to participate in necessary activities (eating in a public place, interviewing for a job) and may provide additional information needed to develop an appropriate plan of care.*¹
- Compare lists and validate reality of perceptions. Help client prioritize those behaviors needing change. *Each individual may have a different view of what constitutes a problem, and by comparing lists, each person hears how others view the problems, enabling the client/family to identify behaviors or concerns to be dealt with.*^{1,7}
- Explore with client and role-play means of making agreed-on changes in social interactions or behaviors (as determined earlier). *Client needs to learn social skills if he or she has never learned the elements of interacting with others in social settings. Role-playing one-on-one is less threatening and can help individual identify with another and practice new social skills.*⁵
- Role-play random social situations in therapeutically controlled environment with “safe” therapy group. Have group note behaviors, both positive and negative, and discuss these and any changes needed. *Having client participate in a controlled group environment provides opportunities to try out different behaviors in a built-in social setting where members can make friends and provide mutual advice and comfort.*^{1,5}
- Role-play changes and discuss impact. Include family/SO(s) as indicated. *Provides opportunity for person to recognize changes in feelings and behavior and enhances comfort with new behaviors.*⁴
- Provide positive reinforcement for improvement in social behaviors and interactions. *Encourages continuation of desired behaviors and efforts for change.*⁵
-  Participate in multidisciplinary client-centered conferences to evaluate progress. Involve everyone associated with client's care, family members, SO(s), and therapy group. *These conferences have the advantage of providing information from and to each participant in an atmosphere of trust where questions can be asked, decisions can be made, and goals for the future can be agreed on.*¹
- Work with the client to alleviate underlying negative self-concepts because they often impede positive social interactions. *By replacing negative thoughts with positive messages, client can reduce anxiety and develop a positive sense of self-esteem. While this is not an easy process, the rewards are great when client is willing to practice consistently.*²
- Involve neurologically impaired client in individual or group interactions as situation allows. *Individual may not be able to interact appropriately because of disabilities, but involvement in the group provides an opportunity to practice and relearn skills to enable reintegration into social situations.*^{1,8}
-  Refer for family therapy as indicated. *Social behaviors and interpersonal relationships involve more than the individual, and family may need additional help to resolve ongoing family problems.*^{1,2}

NURSING PRIORITY NO. 4 To promote wellness (Teaching/Discharge Considerations):

-  Encourage client to keep a daily journal in which social interactions of each day can be reviewed and the comfort or discomfort experienced noted with possible causes or precipitating factors. *Helps client to identify specific problem areas and begin to choose to take responsibility for own behavior(s).*^{5,7}
- Assist the client to develop positive social skills through practice of skills in real social situations accompanied by a support person. Provide positive feedback with the use of “I” messages during interactions with client. *Cognitive and behavioral methods can help individuals overcome fears with the help of a trusted person. “I” messages convey a positive message, individual does not feel criticized, and he or she is encouraged to continue new thinking and behaviors.*^{1,5}
-  Discuss the use of medications when indicated and monitor for effectiveness and side effects. *Several kinds of drugs have been found to be effective in the treatment of social anxiety problems; selective serotonin*

reuptake inhibitors (SSRIs), such as paroxetine (Paxil) and sertraline (Zoloft), are often the first choice. Anti-anxiety drugs, such as clonazepam (Klonopin), buspirone (BusPar), and alprazolam (Xanax), can reduce anxiety and may be used alone or in conjunction with SSRIs. Propranolol (Inderal) has been found to be useful for performance anxiety, and when taken an hour before the scheduled event, may suppress the physical symptoms of anxiety.^{5,7}

-  Seek community programs for client involvement that promote positive behaviors the client is striving to achieve. Encouraging reading materials, attending classes, community support groups, and lectures for self-help can help to alleviate negative self-concepts that lead to impaired social interactions.^{2,5}
-  Involve in a music-based program, if available. There is a direct correlation between the musical portion of the brain and the language area, and the use of these programs may result in better communication skills. Music has been used to calm, to enable feelings of safety, and to reduce the social distance between people.⁹
-  Encourage ongoing family or individual therapy as long as it is promoting growth and positive change. Be alert to possibility of therapy being used as a crutch. While therapy groups can be useful, individuals can become dependent on the process and not move on to managing on their own.¹
-  Provide for occasional follow-up for reinforcement of positive behaviors after professional relationship has ended. Change is difficult and identifying problems that may arise during these contacts can enhance maintenance and enable client/family to continue to progress.²
-  Refer to psychiatric clinical nurse specialist when indicated. May need additional assistance to promote long-term change.¹

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including factors affecting interactions, nature of social exchanges, specifics of individual behaviors, and type of learning disability present.
- Cultural or religious beliefs and expectations.
- Perceptions and response of others.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Community resources, specific referrals made.

Social Isolation

Taxonomy II: Comfort—Class 3 Social Comfort (00053) [**Diagnostic Division:** Social Interaction], Approved 1982; Revised 2017

DEFINITION: Aloneness experienced by the individual and perceived as imposed by others and as a negative or threatening state.

RELATED FACTORS

Difficulty establishing relationships; inability to engage in satisfying personal relationships
 Insufficient personal resources (e.g., poor achievement, poor insight, affect unavailable and poorly controlled)
 Developmentally inappropriate interests; social behavior incongruent with norms; values incongruent with cultural norms

DEFINING CHARACTERISTICS

Subjective

Aloneness imposed by others
 Insecurity in public; desires to be alone
 Inability to meet expectations of others; purposelessness
 Developmentally inappropriate interests; values incongruent with cultural norms
 Feeling different from others

Objective

Absence of support system; history of rejection
 Sad or flat affect; withdrawn; poor eye contact
 Disabling condition; illness
 Developmental delay
 Preoccupation with own thoughts; repetitive or meaningless actions; hostility
 Cultural incongruence; member of a subculture

Associated Condition: Alteration in wellness or mental status or physical appearance

Sample Clinical Applications: Traumatic injuries, facial scarring/acne, chemotherapy, AIDS, dementia, major depression, conduct disorder, developmental delay, paranoid disorders, schizophrenia

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Social Involvement: Social interactions with persons, groups, or organizations

Loneliness Severity: Severity of emotional, social, or existential signs and symptoms of isolation

Social Support: Reliable assistance from others

Client Will (Include Specific Time Frame)

- Identify causes and actions to correct isolation.
- Verbalize willingness to be involved with others.

(continues on page 826)

Social Isolation (continued)

- Participate in activities or programs at level of ability or desire.
- Express increased sense of self-worth.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Socialization Enhancement: Facilitation of another person's ability to interact with others

Behavior Management: Social Skills: Assisting the patient to develop or improve interpersonal social skills

Visitation Facilitation: Promoting beneficial visits by family and friends

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Determine presence of factors as listed in Related Factors and other concerns (e.g., elderly, female, adolescent, ethnic or racial minority, economically or educationally disadvantaged, hearing or visually impaired). *Identifying individual factors allows for developing an accurate plan of care for the client.*⁵
- Perform physical exam, paying particular attention to any illnesses. *Individuals who are isolated appear to be susceptible to health problems, especially coronary heart disease, although little is understood about why that is.*¹⁰
- Note onset of physical or mental illness and whether recovery is anticipated or condition is chronic or progressive. *Individual may withdraw from activities because of concern about how others view changes that occur due to illness, concern with own thoughts, and alterations in physical appearance or mental status. Anticipated length of illness may dictate choice of interventions.*^{1,4}
- Identify blocks to social contacts. *Reluctance to engage in social activities may be the result of problems such as physical immobility, sensory deficits, housebound for any reason, incontinence, financial constraints, and/or transportation difficulties. Individual may be afraid of what others might think of her or him, be concerned with embarrassing self, or not having money or means of transportation for desired activities.*¹
-  Ascertain implications of cultural values or religious beliefs for the client that may dictate choice of behaviors and may even script interactions with others. *Client may perceive behaviors as normal because of belief system or may have conflict regarding behaviors that may be unacceptable to the larger society, such as homosexuality or gender identity disorder.*^{1,5,6}
- Assess factors in client's life that may contribute to sense of helplessness. *Losses, such as a spouse, parent, or other, or presence of chronic pain or other disabling conditions may cause individual to withdraw, desire to be alone, and refuse to participate in therapeutic activities.*^{1,3}
-  Listen to comments of client regarding sense of isolation. Differentiate isolation from solitude and loneliness that may be acceptable or by choice. *Provides clues to what client is thinking and feeling about current situation. Client who chooses to be alone and is satisfied may not need further intervention. Note: Research indicates that perceived social isolation is a risk factor for, and may contribute to, poorer overall cognitive performance, faster cognitive decline, poorer executive functioning, increased negativity, and heightened sensitivity to social threats. These differences impact on emotions, decisions, behaviors, and interpersonal interactions.*^{3,5,11,12}
- Assess client's feelings about self, sense of ability to control situation, sense of hope, and coping skills. *If client is isolating self because of negative feelings, lack of hope, etc., measures to promote self-esteem will need to be taken.*
- Identify support systems available to the client, including presence of/relationship with extended family. *People with social anxiety often do not have support systems because of their withdrawal from contact with others. Often the family of origin may be anxious and does not provide the encouragement and support needed by a*

temperamentally inhibited child or may be too helpful, enabling client to withdraw further. It is difficult for these individuals to ask for help because they are afraid to meet new people and often find support only when they seek help for other conditions, such as depression.^{4,9}

- Identify behavior response of isolation. *Individual may display behaviors such as excessive sleeping or day-dreaming, which also may potentiate isolation.*^{7,10}
-  Note drug use (prescription and illicit). *Individual may begin to use drugs such as alcohol or cocaine to control anxiety in social situations.*⁷
- Review history and elicit information about traumatic events that may have occurred. (Refer to ND Post-Trauma Syndrome.) *While little is known about the origins of social anxiety disorders, clients who have experienced a traumatic event may withdraw from contact and suffer from anxiety when faced with having to deal with social situations.*^{1,5}

NURSING PRIORITY NO. 2 To alleviate conditions that contribute to client's sense of isolation:

- Establish therapeutic nurse-client relationship. *Promotes trust and acceptance, allowing client to feel safe and free to discuss sensitive matters without being judged.*²
- Spend time interacting with client and identify other resources available. *Getting to know client and identifying concerns about being involved in activities with others can lead to appropriate interventions. Other people such as volunteers, social workers, and chaplains may be able to spend time with client, enhancing circle of trusted people.*⁴
- Develop plan of action with client. Look at available resources; support risk-taking behaviors, financial planning, appropriate medical and self-care, etc. *Helping client to learn how to manage these issues of daily living can increase self-confidence and help individual to feel more comfortable in social settings.*⁵
- Introduce client to those with similar or shared interests and other supportive people. *Provides role models and encourages getting to know others who share feelings of anxiety, providing an opportunity to develop social skills and learn some ways of problem-solving to deal with anxiety.*^{2,5}
- Promote participation in recreational or special interest activities in setting that client views as safe. *These activities have the advantage of providing physical and mental stimulation for client who feels isolated and anxious in social settings.*^{2,9}
- Provide positive reinforcement when client makes move(s) toward other(s). *Acknowledges and encourages continuation of efforts, helping client toward independence.*^{1,7}
-  Identify foreign language resources for client who speaks another language. *A professional interpreter is important to ensure accuracy of interpretation; newspapers and radio programming in appropriate foreign language help client feel connected with own community.*^{6,8}
- Assist client to problem-solve solutions to short-term or imposed isolation. *Condition may require individual to be isolated from others for his or her and/or others' protection, and working together to decide how to manage loneliness can promote successful outcome.*^{1,3}
- Encourage open visitation when possible and/or telephone or computer contacts. *Maintains involvement with others, promoting social involvement, especially when client is unable to go out to activities.*³
- Provide environmental stimuli when client is confined. *Open curtains in room, display pictures of family or views of nature, promote television and radio listening, and provide Internet access to help client feel less isolated.*³
-  Provide for placement in sheltered community when necessary. *The individual who is mentally impaired may be unable to learn to participate in society and display socially acceptable behaviors and will benefit from an environment that offers structure and assistance.*³

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Assist client to learn social skills as needed. *Enhancing problem-solving, communication, social skills, and learning skills to manage activities of daily living will improve sense of self-esteem.*⁴
-  Encourage and assist client to enroll in classes as appropriate. *Assertiveness, vocational, and sex education classes may provide skills to improve ability to engage more effectively in social situations.*⁵

-  Involve children and adolescents in age-appropriate programs or activities, as indicated. *Promotes socialization skills and peer contact to enable young person to learn by interacting with others.*⁵
- Help client differentiate between isolation and loneliness or aloneness and discuss how to avoid slipping into an undesired state. *Time for the individual to be alone is important to the maintenance of mental health, but the sadness created by isolation and loneliness needs different interventions.*^{2,11}
- Involve client in programs directed to correction and prevention of identified causes of problem. *Activities such as senior citizen services, daily telephone contact, house sharing, pets, day-care centers, and church resources can help individual move out of isolation and become involved in life.*^{5,10}
-  Discuss use of medications, as indicated. *Prescribed medications, such as selective serotonin reuptake inhibitors, can be very effective in treating social disorders.*^{3,7}
-  Refer to counselor or therapist, as appropriate. *Facilitates grief work, promotes relationship building, and provides opportunity to work toward improvement of individual issues affecting social interactions.*¹

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including precipitating factors, effect on lifestyle, relationships, and functioning.
- Client's perception of situation.
- Cultural or religious factors.
- Availability and use of resources and support systems.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to intervention, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Available resources, specific referrals made.

chronic Sorrow

Taxonomy II: Coping/Stress Tolerance—Class 2 Coping Responses (00137) [**Diagnostic Division:** Ego Integrity], Approved 1998; Revised 2017

DEFINITION: Cyclical, recurring, and potentially progressive pattern of pervasive sadness experienced (by a parent, caregiver, individual with chronic illness or disability) in response to continual loss, throughout the trajectory of an illness or disability.

RELATED FACTORS

Crises in illness or disability management
Missed opportunities or milestones

DEFINING CHARACTERISTICS

Subjective

Overwhelming negative feelings

Sadness

Feelings that interfere with well-being

Sample Clinical Applications: Cancer, multiple sclerosis (MS), Parkinson's disease, AIDS, amyotrophic lateral sclerosis (ALS), prematurity, genetic or congenital defects, infertility, dementia, Alzheimer's disease, bipolar disorder, schizophrenia, developmental delay

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Depression Level: Severity of melancholic mood and loss of interest in life events

Depression Self-Control: Personal actions to minimize melancholy and maintain interest in life events

Hope: Optimism that is personally satisfying and life supporting

Client Will (Include Specific Time Frame)

- Acknowledge presence and impact of sorrow.
- Demonstrate progress in dealing with loss(es) as evidenced by recognizing positive aspects of situation.
- Participate in work and/or self-care activities of daily living (ADLs) as able.
- Verbalize a sense of progress toward resolution of sorrow and hope for the future.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Mood Management: Providing for safety, stabilization, recovery, and maintenance of a patient who is experiencing depressed or elevated mood

Grief Work Facilitation: Assistance with the resolution of a significant loss

Hope Inspiration: Enhancing the belief in one's capacity to initiate and sustain actions

NURSING PRIORITY NO. 1 To assess causative/contributing factors and effect on life:

- Determine current or recent events or conditions contributing to client's state of mind (e.g., death of loved one, chronic physical or mental illness or disability). *Individual information is necessary when formulating a plan of care to address appropriate issues.*

-  Note cues of sadness. *Expressions of feelings of loss, such as sighing, faraway looks, unkempt appearance, inattention to conversation, and refusing food, can be indicators of sorrow that is not being dealt with. Note: Chronic sorrow may be cyclical—at times deepening versus times of feeling somewhat better.*^{4,5}
-  Be aware of use of avoidance behaviors. *Anger, withdrawal, and denial are part of the grieving process and may be used to avoid dealing with the reality of what has happened. However, in a situation that is unchangeable, such as a developmentally disabled child or a child with diabetes, sorrow is seen as a normal response and will continue to be a factor even as the family copes with the condition.*^{5,7}
-  Identify cultural values or religious beliefs and possible conflicts. *Expressions of sorrow are influenced by these beliefs and may result in conflicts. For instance, the Hispanic culture believes genetic defects are the will of God, but individual may be angry at God because of occurrence. Or, individual/family may have difficulty living up to the expectations of others (e.g., “God does not give us more than we can handle”).*⁶
-   Ascertain response of family/SOs to client’s situation and support provided. *Parents who have chronically ill children or premature babies, adults who have multiple sclerosis, and elderly caregivers of spouses with dementia may continue to have feelings of sorrow even though they seem to be managing fairly well; due to cyclic nature of sorrow, they will require ongoing support/assistance from others to cope.*^{4,7,11}
- Determine level of functioning and ability to care for self/others. Assess needs of family/SO. *Individual who is coping with chronic illness (e.g., Parkinson’s disease, MS, HIV/AIDS) may exhibit chronic sorrow related to the illness, fear of death, poverty, and isolation associated with these conditions, which may lead to difficulty managing ADLs for self or meeting needs of family.*^{2,3,11}
- Refer to NDs caregiver Role Strain, ineffective Coping, and complicated Grieving, as appropriate.

NURSING PRIORITY NO. 2 To assist client to move through sorrow:

- Encourage verbalization about situation. Active-listen feelings and be available for support and assistance. *Helpful in beginning resolution and acceptance. Individuals involved, client, and caregivers benefit from being able to talk freely about the situation. Active listening conveys a message of acceptance and helps individual come to own resolution.*^{1,5}
- Encourage expression of anger, fear, or anxiety. (Refer to appropriate NDs.) *Individual needs to deal with these feelings before she or he can move forward.*¹
-  Acknowledge reality of feelings of guilt or blame, including hostility toward spiritual power. (Refer to ND Spiritual Distress.) *It was once believed that grief had an end stage, but research has shown that individuals with chronic conditions, such as diabetes mellitus, MS, and disabling conditions, continue to experience chronic sorrow and lifelong recurring sadness. Understanding this can help individual accept that these feelings are real, and when they are validated, they can be dealt with.*^{4,5,10}
- Provide comfort and availability as well as caring for physical needs. *The way healthcare professionals respond to families is important to helping them cope with the situation as physical care is given.*^{5,9,11}
- Discuss ways individual has dealt with past losses and reinforce use of previously effective coping skills. *As client begins to look at how they have handled previous situations, effective coping skills can be recalled and applied to current situation.*^{2,9}
- Instruct in and encourage use of visualization and relaxation skills. *Learning these stress-management skills can help the individual relax, enhancing ability to deal with feelings of sorrow regarding the long-term situation.*^{5,8}
-  Discuss use of medication when depression is interfering with ability to manage life. *Client may benefit from the short-term use of an antidepressant medication to help deal with situation.*¹
- Assist SOs to cope with client response. *Family/SO may not be dysfunctional, but may be intolerant and lack understanding of individual responses to long-term illness. Grief is unique to each individual and may not always follow a particular course to resolution that is understood by all.*^{4,5,11}
- Include family/SO in setting realistic goals for meeting individual needs. *Inclusion of all family members ensures they all have the same information and are all working toward effective coping strategies.*^{4,5}

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Discuss healthy ways of dealing with difficult situations. *Providing information about effective communication skills, understanding condition they are dealing with, and expectations of the course of the illness or condition can promote personal growth and lead to a positive outcome for the family.*^{7,8}
-  Have client identify familial, religious, and cultural factors that have meaning for him or her. *May help bring loss or distressing situation into perspective and promote grief or sorrow resolution.*⁶
- Encourage involvement in usual activities, exercise, and socialization within limits of physical and psychological state. *Energy is restored and individuals can go on with their lives when they are willing and able to continue activities.*^{5,7}
- Introduce concept of mindfulness (living in the moment) and encourage client to recognize and embrace moments of joy in own life. *Promotes feelings of capability and belief that this moment can be dealt with or enjoyed.*^{4,8}
-  Refer to other resources (e.g., pastoral care, counseling, psychotherapy, respite care providers, support groups). *Provides additional help when needed to resolve situation, continue grief work, and move on with life.*¹¹

DOCUMENTATION FOCUS**Assessment/Reassessment**

- Individual findings, including nature of sorrow, effects on participation in treatment regimen.
- Physical and emotional response to conflict, expressions of sadness.
- Cultural or religious issues and conflicts.
- Reactions of family/SO.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Available resources, specific referrals made.

Spiritual Distress

Taxonomy II: Life Principles—Class 3 Value/Belief/Action Congruence (00066) [**Diagnostic Division:** Ego Integrity], Approved 1978; Revised 2002, 2013, 2017

DEFINITION: A state of suffering related to the impaired ability to experience and integrate meaning in life through connections with self, others, the world, or a superior being.

RELATED FACTORS

Anxiety; depression
 Barrier to experiencing love; ineffective relationships; loneliness; low self-esteem
 Change in religious ritual or spiritual practice; cultural conflict
 Environmental change
 Inability to forgive; perception of having unfinished business
 Increasing dependence on another; self-alienation; separation from support system
 Pain
 Social alienation; sociocultural deprivation
 Substance misuse/[abuse]

DEFINING CHARACTERISTICS

Subjective

Anxiety, fear
 Fatigue; insomnia
 Questioning identity; questioning meaning of suffering or life
Connections to self:
 Anger; guilt; insufficient courage
 Decrease in serenity
 Feeling of being unloved; inadequate acceptance
Connections with others:
 Alienation
Connections with art, music, literature, nature:
 Disinterest in nature or reading spiritual literature
Connections with power greater than self:
 Anger toward power greater than self
 Feeling abandoned; hopelessness; perceived suffering
 Inability to pray or participate in religious activities, or to experience the transcendent

Objective

Crying
Connections to self:
 Ineffective coping strategies; perceived insufficient meaning in life
Connections with others:
 Refuses to interact with significant others or spiritual leader
 Separation from support system
Connections with art, music, literature, nature:
 Decrease in expression of previous pattern of creativity
Connections with power greater than self:
 Inability for introspection; sudden change in spiritual practice; request for a spiritual leader
At Risk Population: Aging; birth of a child
 Death of a significant other; exposure to death; loss

Life transition; unexpected life event; receiving bad news

Exposure to natural disaster

Increasing dependence on another

Associated Condition: Actively dying; imminent death

Illness; physical illness; chronic illness

Loss of a body part, or function of a body part

Treatment regimen

Sample Clinical Applications: Chronic conditions (e.g., cancer, AIDS, traumatic brain injury vegetative state, infertility); fetal demise, risk for Sudden Infant Death (SIDS); death of child; traumatic event with fatal outcome or severe disabilities

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Spiritual Health: Connectedness with self, others, higher power, all life, nature, and the universe that transcends and empowers the self

Hope: Optimism that is personally satisfying and life supporting

Psychosocial Adjustment: Life Change: Adaptive psychosocial response of an individual to a significant life circumstance

Client Will (Include Specific Time Frame)

- Verbalize increased sense of connectedness and hope for future.
- Demonstrate ability to help self and participate in care.
- Participate in activities with others, actively seek relationships.
- Discuss beliefs and values about spiritual issues.
- Verbalize acceptance of self as not deserving illness or situation: “No one is to blame.”

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Spiritual Support: Assisting the patient to feel balance and connection with a greater power

Hope Inspiration: Enhancing the belief in one’s capacity to initiate and sustain actions

Grief Work Facilitation: Assistance with the resolution of a significant loss

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Determine client’s religious and spiritual orientation, current involvement, and presence of conflicts. *Identification of individual spiritual beliefs and practices that may affect client care, or create conflict between beliefs and treatment, provides for more accurate interventions.*¹
- Listen to client’s/SO’s reports or expressions of concern, anger, alienation from God, belief that illness or situation is a punishment for wrongdoing, etc. *Indicates depth of grieving process and possible need for spiritual advisor or other resource to address client’s belief system if desired.*²
-   Assess for influence of cultural beliefs and spiritual values that affect individual in this situation. *Circumstances of illness or situation may conflict with client’s view of self, cultural background, and distress over values. For instance, many Hispanics are Catholic with strong beliefs in the relationship between illness and religious practices.*⁵
- Note recent changes in behavior (e.g., withdrawal from others and creative or religious activities, dependence on alcohol or medications). *Helpful in determining severity and duration of situation and possible need for additional referrals such as substance withdrawal.*^{7,11}

- Assess sense of self-concept and worth and ability to enter into loving relationships. *Lack of connectedness with self or others impairs client's ability to trust others or feel worthy of trust from others, leading to difficulties in relationships with others.*^{1,7}
- Observe behavior indicative of poor relationships with others (e.g., manipulative, nontrusting, demanding). *Manipulation is used for management of client's sense of powerlessness because of distrust of others, interfering with relationships with others.*^{3,6}
- Determine support systems available to client/SO(s) and how they are used. *Provides insight to client's willingness to pursue outside resources.*⁴
- Determine sense of futility, feelings of hopelessness and helplessness, and lack of motivation to help self. *Indicators that client may see no, or only limited, options, alternatives, or personal choices available; that client lacks energy to deal with situation; and that further evaluation is needed.*
-  Note expressions of inability to find meaning in life and/or reason for living. Evaluate suicidal ideation to refer for mental health evaluation and intervention as indicated. *Crisis of the spirit or loss of will to live places client at increased risk for inattention to personal well-being and possible harm to self.*^{1,7}

NURSING PRIORITY NO. 2 To assist client/SO(s) to deal with feelings/situation:

- Develop therapeutic nurse-client relationship. Ascertain client's views as to how care provider(s) can be most helpful. Convey acceptance of client's spiritual beliefs and concerns. *Promotes trust and comfort, encouraging client to be open about sensitive matters.*⁶
- Establish environment that promotes free expression of feelings and concerns. *Provides opportunity for client to explore own thoughts and make appropriate decisions regarding spiritual issues.*⁴
- Provide calm, peaceful setting when possible. *Promotes relaxation and enhances opportunity for reflection on situation/discussions with others and meditation.*³
- Encourage life review by client. Support client in finding a reason for living. *Promotes sense of hope and willingness to continue efforts to improve situation.*³
- Be aware of influence of care provider's own belief system. *It is still possible to be helpful to client while remaining neutral and not espousing own beliefs because client's beliefs and needs are what is important.*⁶
- Identify inappropriate coping behaviors currently being used and associated consequences and discuss with client. *Recognizing negative consequences of actions may enhance desire to change.*²
- Set limits on acting-out behavior that is inappropriate/destructive. *Promotes safety for client/others and helps prevent loss of self-esteem.*^{2,7}
- Ascertain past successes and coping behaviors. *Helps to determine approaches used previously that may be effective in dealing with current situation, providing encouragement.*⁶
- Problem-solve solutions and identify areas for compromise. *May be useful in resolving conflicts that arise from feelings of anxiety regarding questioning of beliefs and current illness or situation.*³
- Assist in developing coping skills to deal with stressors of illness and necessary changes in lifestyle.^{7,9}

NURSING PRIORITY NO. 3 To facilitate setting goals and moving forward:

- Use therapeutic communication skills of reflection and active-listening. *Conveys message of competence and helps client find own solutions to concerns.*⁷
- Involve client in refining healthcare goals and therapeutic regimen as appropriate. *Promotes feelings of control over what is happening, enhancing commitment to plan and optimizing outcomes.*³
- Encourage client/family to ask questions. *Demonstrates support for individual's willingness to learn.*
- Discuss difference between grief and guilt and help client to identify and deal with each. Point out consequences of actions based on guilt. *Aids client in assuming responsibility for own actions and avoids acting out of false guilt.*⁶
- Identify role models (e.g., individual experiencing similar situation). *Provides opportunities for sharing of experiences and hope and identifying new options to deal with situation.*⁷

- Assist client to learn use of meditation, mindfulness, and prayer, if desired. *Provides avenue for learning forgiveness to heal past hurts and developing a sense of peace.*^{3,8}
- Provide information that anger with God is a normal part of the grieving process. *Realizing these feelings are not unusual can reduce sense of guilt, encourage open expression, and facilitate resolution of grief.*^{3,7,11}
- Provide time and privacy to engage in spiritual growth or religious activities as desired (e.g., prayer, meditation, scripture reading, listening to music). *Allows client to focus on self and seek connectedness with spiritual beliefs and values.*⁶
-  Encourage and facilitate outings to neighborhood park or nature walks. *Sunshine, fresh air, and activity can stimulate release of endorphins, promoting sense of well-being and encouraging connection with nature.*⁶
-   Provide play therapy for child that encompasses spiritual data. *Interactive pleasurable activity promotes open discussion and enhances retention of information. Child will act out feelings in play therapy easier than talking. Provides opportunity for child to practice what has been learned and for therapist to evaluate child's progress.*³
-  Abide by parents' wishes in discussing and implementing child's spiritual support. *Limits confusion for child and prevents conflict of values and beliefs.*³
-  Refer to appropriate resources (e.g., pastoral or parish nurse or religious counselor, crisis counselor, hospice; psychotherapy; Alcoholics or Narcotics Anonymous). *Useful in dealing with immediate situation and identifying long-term resources for support to help foster sense of connectedness.*^{7,8}
- Refer to NDs ineffective Coping, Powerlessness, Self-Esteem (specify), Social Isolation, and risk for Suicide for additional interventions as indicated.

NURSING PRIORITY NO. 4 To promote spiritual well-being (Teaching/Discharge Considerations):

-  Make time for nonjudgmental discussion of philosophical issues or questions about spiritual impact of illness or situation and/or treatment regimen. *Open communication can assist client in reality checks of perceptions and help to identify personal options.*⁶
- Assist client to develop long-term goals for dealing with future and illness situation. *Involvement in planning for desired outcomes enhances commitment to goal, optimizing outcomes.*⁷
- Suggest use of journaling. *Provides opportunity to write feelings and happenings; reviewing them over time can assist in clarifying values and ideas, recognizing and resolving feelings or situation.*^{6,10}
- Assist client to identify SO(s)/others who could provide support as needed. *Ongoing support is important to enhance sense of connectedness and continue progress toward goals.*⁶
- Identify spiritual resources that could be helpful (e.g., contact spiritual advisor who has qualifications or experience in dealing with specific problems such as death/dying, relationship problems, substance abuse, suicide). *Provides answers to spiritual questions, assists in the journey of self-discovery, and can help client learn to accept and forgive self.*⁶

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including nature of spiritual conflict, and effects of participation in treatment regimen.
- Physical and emotional responses to conflict.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Available resources, specific referrals made.

risk for Spiritual Distress

Taxonomy II: Life Principles—Class 3 Value/Belief/Action Congruence (00067) [Diagnostic Division: Ego Integrity], Approved 1998; Revised 2013, 2017

DEFINITION: Susceptible to an impaired ability to experience and integrate meaning and purpose in life through connectedness within self, others, literature, nature, and/or a power greater than oneself, which may compromise health.

RISK FACTORS

Anxiety; depression
 Barrier to experiencing love; ineffective relationships; loneliness; low self-esteem
 Change in religious ritual or spiritual practice; cultural conflict
 Environmental change
 Inability to forgive; perception of having unfinished business
 Increasing dependence on another; self-alienation; separation from support system
 Pain
 Social alienation; sociocultural deprivation
 Substance misuse/[abuse]

At Risk Population: Aging; birth of a child
 Death of a significant other; exposure to death; loss
 Life transition; unexpected life event; receiving bad news
 Exposure to natural disaster

Increasing dependence on another
Associated Condition: Actively dying; imminent death
 Illness; physical illness; chronic illness

Loss of a body part, or function of a body part

Treatment regimen

Sample Clinical Applications: Chronic conditions (e.g., cancer, AIDS, traumatic brain injury vegetative state) infertility; terminal conditions (e.g., end-stage renal disease, lung cancer); fetal demise, risk for Sudden Infant Death (SIDS); death of spouse or child; traumatic event with fatal outcome or severe disabilities

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Spiritual Health: Connectedness with self, others, higher power, all life, nature, and the universe that transcends and empowers the self

Hope: Optimism that is personally satisfying and life supporting

Psychosocial Adjustment: Life Change: Adaptive psychosocial response of an individual to a significant life circumstance

Client Will (Include Specific Time Frame)

- Identify meaning and purpose in own life that reinforces hope, peace, and contentment.
- Verbalize acceptance of self as being worthy, not deserving of illness or situation, and so forth.
- Identify and use resources appropriately.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Spiritual Support: Assisting the patient to feel balance and connection with a greater power

Coping Enhancement: Facilitation of cognitive and behavioral efforts to manage perceived stressors, changes, or threats that interfere with meeting life demands and roles

Grief Work Facilitation: Assistance with the resolution of a significant loss

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Ascertain current situation (e.g., natural disaster, death of a spouse, personal injustice). *Identification of circumstances that put the individual at risk for loss of connectedness with spiritual beliefs is essential to plan for appropriate interventions.*
- Listen to client's/significant other's (SO's) expressions of anger or concern, belief that illness or situation is a punishment for wrongdoing, etc. *Identifies need for client to talk about and be listened to in regard to concerns about potential loss of control over his or her life.*^{3,6}
- Note reason for living and whether it is directly related to situation. *Tragic occurrences, such as home and business washed away in a flood or lost in a fire, parent whose only child is terminally ill, or loss of a spouse, can cause individual to question previous beliefs.*^{1,3}
- Determine client's religious or spiritual orientation, current involvement, and presence of conflicts, especially in current circumstances. *Client may be a member of a religious organization, and whether he or she is active or whether conflicts have risen in relation to current illness or situation will indicate need for assistance from spiritual advisor, pastor, or other resource client would accept.*^{1,8,11}
- Assess sense of self-concept, worth, and ability to enter into loving relationships. *Lack of connectedness with self and others impairs client's ability to trust others or feel worthy of trust from others.*^{1,7}
- Observe behavior indicative of poor relationships with others. *Client may be manipulative, nontrusting, and demanding because of distrust of self and others, which can interfere with relationships with others, indicating a need for learning positive ways to interact with others.*^{2,4}

- Determine support systems available to, and used by, client/SO(s). *Provides insight into individual's willingness to pursue outside resources.*^{6,10}
-  Ascertain substance use or abuse. *Complicates situation, affects ability to deal with problems in a positive manner, and identifies need for referral to appropriate treatment programs.*^{4,9,11}
-  Assess for influence of cultural beliefs and spiritual values that affect individual in this situation. *Circumstances of illness or situation may conflict with client's view of self, cultural background, and distress over values. For instance, many Hispanics are Catholic with strong beliefs in the relationship of illness and religious practices.*⁵

NURSING PRIORITY NO. 2 To assist client/SO(s) to deal with feelings/situation:

- Establish environment that promotes free expression of feelings and concerns. *Provides opportunity for client to explore own thoughts and make appropriate decisions regarding spiritual issues and conflicts.*^{6,7,10,12}
- Use therapeutic communication skills of reflection and Active listening. *Communicates confidence in client's ability to find own solutions to concerns.*⁷
- Have client identify and prioritize current or immediate needs. *Helps client focus on what needs to be done and identifies manageable steps to take to achieve goals.*
- Make time for nonjudgmental discussion of philosophical issues or questions about spiritual impact of illness or situation and/or treatment regimen. *Open communication can assist client to make reality checks of perceptions and begin to identify personal options.*^{6,12}
- Discuss difference between grief and guilt and help client to identify and deal with each. *Helps client to assume responsibility for own actions, become aware of the consequences of acting out of false guilt.*
- Review coping skills used and their effectiveness in current situation. *Identifies strengths to incorporate into plan and techniques needing revision.*
- Identify role model (e.g., individual experiencing similar situation or disease). *Sharing of experiences and hope provides opportunity for client to look at options as modeled by others and to begin to deal with reality.*⁷
-   Provide play therapy for child that encompasses spiritual data. *Interactive pleasurable activity promotes open discussion and enhances retention of information. Child will act out feelings in play therapy easier than talking. Provides opportunity for child to practice what has been learned and for therapist to evaluate child's progress.*³
-  Abide by parents' wishes in discussing and implementing child's spiritual support. *Limits confusion for child and prevents conflict of values and beliefs.*³
-  Refer to appropriate resources (e.g., crisis counselor, governmental agencies; pastoral or parish nurse or spiritual advisor who has qualifications or experience dealing with specific problems such as death/dying, relationship problems, substance abuse, suicide; hospice; psychotherapy; Alcoholics or Narcotics Anonymous). *Useful in dealing with immediate situation and identifying long-term resources for support to help foster sense of connectedness.*^{7,8,12}

NURSING PRIORITY NO. 3 To promote spiritual well-being (Teaching/Discharge Considerations):

-  Role-play new coping techniques. *Provides opportunity to practice and enhances integration of new skills or necessary lifestyle changes.*⁴
- Assist client to learn use of meditation, mindfulness, and prayer, if desired. *Provides avenue for learning forgiveness to heal past hurts and developing a sense of peace.*^{3,8}
- Suggest use of journaling. *Provides opportunity to write feelings and happenings; reviewing them over time can assist in clarifying values and ideas and recognizing and resolving feelings or situation.*^{6,9}
-  Encourage individual to become involved in cultural activities of his or her choosing. *Art, music, plays, and other cultural activities provide a means of connecting with self and others.*
- Discuss possibilities of taking classes and becoming involved in discussion groups or community programs.
- Assist client to identify SO(s) and individuals/support groups who could provide ongoing support. *Having sufficient support can help client maintain spiritual resolve.*⁶

-  Discuss benefit of family counseling as appropriate. *Issues of this nature (e.g., situational losses, natural disasters, difficult relationships) affect family dynamics, and family may find it useful to discuss and resolve problems they are experiencing.*⁷

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including risk factors, nature of current distress.
- Physical and emotional responses to distress.
- Access to and use of resources.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Available resources, specific referrals made.

readiness for enhanced Spiritual Well-Being

Taxonomy II: Life Principles—Class 2 Beliefs (00068) [Diagnostic Division: Ego Integrity], Approved 1994; Revised 2002, 2013

DEFINITION: A pattern of experiencing and integrating meaning and purpose in life through connectedness with self, others, art, music, literature, nature, and/or a power greater than oneself, which can be strengthened.

DEFINING CHARACTERISTICS

Subjective

Connections to self:

Expresses desire to enhance: acceptance, surrender, coping, courage, self-forgiveness, hope, joy, love, serenity (e.g., peace), meaning or purpose in life, satisfaction with philosophy of life

Expresses desire to enhance meditative practice

Connections with others:

Expresses desire to enhance interaction with significant other/spiritual leaders, service to others

Expresses desire to enhance forgiveness from others

Connections with art, music, literature, and nature:

Expresses desire to enhance creative energy (e.g., writing, poetry, music), spiritual reading, time outdoors

Connections with powers greater than self:

Expresses desire to enhance participation in religious activity, prayerfulness, reverence, mystical experiences

Sample Clinical Applications: As a health-seeking behavior, the client may be healthy or this diagnosis can occur in any clinical condition

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Spiritual Health: Connectedness with self, others, higher power, all life, nature, and the universe that transcends and empowers the self

Hope: Optimism that is personally satisfying and life supporting

Quality of Life: Extent of positive perception of current life circumstances

Client Will (Include Specific Time Frame)

- Acknowledge the stabilizing and strengthening forces in own life needed for balance and well-being of the whole person.
- Identify meaning and purpose in own life, which reinforces hope, peace, and contentment.
- Verbalize a sense of peace or contentment and comfort of spirit.
- Demonstrate behavior congruent with verbalizations that lend support and strength for daily living.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Spiritual Growth Facilitation: Facilitation of growth in patients' capacity to identify, connect with, and call upon the source of meaning, purpose, comfort, strength, and hope in their lives

Religious Ritual Enhancement: Facilitating participation in religious practices

Meditation Facilitation: Facilitating a relaxed internal state of expanded awareness in the present moment by concentrating focus on a sound, object, visual image, the breath, or moment

NURSING PRIORITY NO. 1 To determine spiritual state/motivation for growth:

- Ascertain client's perception of current state or degree of connectedness and expectations. *Provides insight as to where client is currently and specific hopes for the future.*¹
- Ascertain motivation and expectations for change. *Motivation to improve and high expectations can encourage client to make changes that will improve his or her life. However, unrealistic expectations may hamper efforts.*
- Review spiritual or religious history, activities, rituals, and frequency of participation. *Determines basis to build on for growth or change.*¹
-  Determine influence of cultural beliefs or values. *Most individuals are strongly influenced by the spiritual or religious orientation of their family of origin, which can be a major determinate for client's choice of activities and receptiveness to various options.*⁵
- Determine relational values of support systems to client's spiritual centeredness. *The client's family may have differing beliefs from those espoused by the individual, which may be a source of conflict for the client. Comfort can be gained when family and friends share client's beliefs and support the search for spiritual knowledge.*²
- Explore meaning or interpretation and relationship of spirituality, life and death, and illness to life's journey. *This information helps client strengthen personal belief system, enabling him or her to move forward and live life to the fullest.*^{2,3}
- Clarify the meaning of client's spiritual beliefs or religious practice and rituals to daily living. *Discussing these issues allows client to explore spiritual needs and decide what fits own view of the world to enhance life.*⁶
- Explore ways that spirituality or religious practices have affected client's life and given meaning and value to daily living. Note consequences as well as benefits. *Promotes understanding and appreciation of the difference between spirituality and religion and how each can be used to enhance client's journey of self-discovery.*³
- Discuss life's or God's plan (when this is the person's belief) for the individual. *Helpful in determining individual goals and choosing specific options.*²

NURSING PRIORITY NO. 2 To assist client to integrate values and beliefs to achieve a sense of wholeness and optimum balance in daily living:

- Explore ways beliefs give meaning and value to daily living. *As client develops understanding of these issues, he or she will provide support for dealing with current and future concerns.*⁴
- Clarify reality and appropriateness of client's self-perceptions and expectations. *Necessary to provide firm foundation for growth. Unrealistic ideas can impede desired improvement.*²
- Discuss the importance and value of connections to client's daily life. *The contacts that one has with others sustain the feeling of belonging and connection and promote feelings of wholeness and well-being.*^{4,6}
-  Identify ways to achieve connectedness or harmony with self, others, nature, and/or a higher power (e.g., meditation, prayer, talking or sharing self with others; being out in nature, gardening, walking; attending religious activities). *This is a highly individual and personal decision, and no action is too trivial to be considered.*⁴

NURSING PRIORITY NO. 3 To enhance optimum spirituality:

-  Encourage client to take time to be introspective in the search for peace and harmony. *Finding peace within oneself will carry over to relationships with others and own outlook on life.*¹
- Discuss use of relaxation or meditative activities (e.g., yoga, tai chi, prayer). *Helpful in promoting general well-being and sense of connectedness with self, nature, and/or spiritual power.*^{4,6}
- Suggest attendance or involvement in dream-sharing group to develop and enhance learning of the characteristics of spiritual awareness and facilitate the individual's growth.¹
- Identify ways for spiritual or religious expression. *There are multiple options for enhancing spirituality through connectedness with self/others (e.g., volunteering time to community projects, mentoring, singing in the choir, painting, spiritual writings).*^{3,4}
- Encourage participation in desired religious activities and contact with minister or spiritual advisor. *Validating one's beliefs in an external way can provide support and strengthen the inner self.*^{1,3}

- Discuss and role-play, as necessary, ways to deal with alternative view or conflict that may occur with family/SO(s)/society or cultural group. *Provides opportunity to try out different behaviors in a safe environment and be prepared for potentialities.*³
- Provide bibliotherapy, list of relevant resources (e.g., study groups, parish nurse, poetry society), and reliable Web sites for later reference, self-paced learning, and ongoing support.³

DOCUMENTATION FOCUS

Assessment/Reassessment

- Assessment findings, including client perception of needs and desire for growth.
- Cultural values or religious beliefs.
- Motivation and expectations for change.

Planning

- Plan for growth and who is involved in planning.

Implementation/Evaluation

- Response to activities, learning, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan.

Discharge Planning

- Long-term needs, expectations, and plan of action.
- Specific referrals made.

impaired Standing

Taxonomy II: Safety/Protection—Class 2 Activity/Exercise (00238) [**Diagnostic Division:** Safety], Approved 2013; Revised 2017

DEFINITION: Limitation of ability to independently and purposefully attain and/or maintain the body in an upright position from feet to head.

RELATED FACTORS

Emotional disturbance
 Malnutrition; obesity
 Insufficient endurance or energy; insufficient muscle strength
 Pain
 Self-imposed relief posture

DEFINING CHARACTERISTICS

Objective

Impaired ability to adjust position of one or both lower limbs on uneven surface

Impaired ability to attain or maintain a balanced position of the torso; impaired ability to stress torso with body weight

Impaired ability to flex or extend one or both hips

Inability to flex or extend one or both knees

Associated Condition: Circulatory perfusion disorder; impaired metabolic functioning; neurological disorder; sarcopenia

Injury to lower extremity; surgical procedure

Prescribed posture

Sample Clinical Applications: Neuromuscular disorders (e.g., multiple sclerosis [MS], amyotrophic lateral sclerosis [ALS], Parkinson's disease), traumatic injuries (e.g., lower extremity fractures, spinal cord or brain injuries), osteoarthritis, rheumatoid arthritis, hip or knee joint replacement; severe depression, dementia

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Knowledge: Body Mechanics: Extent of understanding conveyed about proper body alignment, balance and coordinated movement

Balance: Ability to maintain body equilibrium

Body Mechanics Performance: Personal actions to maintain proper body alignment and to prevent musculoskeletal strain

Client Will (Include Specific Time Frame)

- Verbalize understanding of individual treatment regimen and safety measures.
- Attain and maintain position of standing function that enables activities and prevents complications.
- Participate in activities of daily living (ADLs) and desired activities.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Exercise Therapy: Muscle Control: Use of specific activity or exercise protocols to enhance or restore controlled body movement

Body Mechanics Promotion: Facilitating the use of posture and movement in daily activities to prevent fatigue and musculoskeletal strain or injury

NURSING PRIORITY NO. 1 To identify causative/contributing factors:

-  Determine diagnosis that contributes to difficulty with standing balance (e.g., stroke, other neurological disorders [e.g., MS, Parkinson's disease; traumatic brain injury, spinal cord injury with hemi/paraplegia]; vestibular disorders/vertigo; osteoarthritis, rheumatoid arthritis, degenerative joint disease; back pain conditions; lower-limb amputations; psychiatric conditions including severe depression, dementias). *Impaired standing balance has a detrimental effect on a person's functional ability and increases the risk of falling. These conditions can cause postural and balance impairments, muscular weakness, and inadequate range of motion. Sensory deficits may also be involved (e.g., impaired proprioception and/or visual processing, cognitive impairments). For example, sitting and standing balance are major concerns in an amputee's ability to*

maintain the center of gravity over the base of support. Both balance and coordination are required for weight shifting from one limb to another, thus improving the potential for an optimal gait.¹ In persons with chronic neck pain, one study suggested that lack of proprioceptive inhibition of nociceptors at the dorsal horn of the spinal cord would result in suboccipital muscle atrophy and a loss of standing balance.² Dizziness and/or unsteadiness and episodes of loss of balance are not infrequent complaints of persons with persistent whiplash-associated disorders.³

-   Assess client's mental status, noting age, developmental stage, and presence or potential for cognitive dysfunction (e.g., traumatic brain injury, stroke, dementia, extremes of age). Several studies have suggested that seemingly automatic postural tasks (such as standing balance and walking) require some attention and cognitive processing.^{4,5}
- Determine fall risk, noting factors that may be present. Fall risk is high in clients with certain conditions (e.g., advanced age or debilitating disease; vision and hearing loss, diminished depth perception; decreased sensation in feet, artificial joints; trauma to lower extremity; amputation, other surgery or immobilizer; presence of severe vertigo with postural sway; generalized or specific leg weakness; reaching upward, forward, or laterally outside of standing balance position).
-  Encourage sitting before attempting standing, when indicated (e.g., supine client with low blood pressure or dehydration, vertigo, first attempt to get up after long period on bedrest). Longer sitting pause times might improve postural stability after rising from a supine position. One study suggested that longer sitting pause times may also provide improved adaptability to dimly lit environments.⁶

NURSING PRIORITY NO. 2 To assess functional ability:

- Determine functional status using a 0–4 scale, noting muscle strength and tone, joint mobility, cardiovascular status, balance, and endurance. *Identifies strengths and deficits (e.g., unable to stand without assistance, but can maintain standing position once attained; standing balance improved as vertigo diminishes; standing improves with pain management and nutrition measures, etc.) and may provide information regarding potential for recovery (e.g., client with severe brain injury may have permanent limitations because of impaired cognition affecting memory, judgment, problem-solving, and motor planning).*^{7,8}
- Determine degree of perceptual or cognitive impairment and ability to follow directions. *Impairments, which may be related to age, chronic or acute disease condition, trauma, surgery, or medications, can necessitate alternative interventions or changes in plan of care.*
-   Refer to physician and/or physical therapy specialists, as indicated, to determine potential for improvement and direction for therapies. May include many different functional and lab tests (e.g., sitting to standing, tolerance, muscle strength and movement, posture and balance monitor, American Spinal Injury Association Impairment Scale, Berger Balance Scale, Functional Independence Measure, electrophysiological and clinical measures of neuropathy).^{9,10}
- Note: Studies have shown that people with the earliest stage of impaired glucose tolerance exhibit deficits in standing balance and trunk position sense, highlighting the importance of early screening for diabetes.¹¹

NURSING PRIORITY NO. 3 To promote optimal level of function and prevent complications:

-  Assist with treatment of underlying condition(s) to maximize potential for optimal function.
-   Assist with/refer for rehabilitation therapies and techniques for implementing standing activities. Various modalities may be used to gain physiological benefits from standing or modified standing therapy. For example, “standing” can be accomplished in a variety of positions with proper support (e.g., a prone-position with blanket under the abdomen), which helps preserve joint range of motion and improves muscle flexibility, weight-bearing ability, and bowel and bladder function even when person is not upright.¹² Note: Research found that a “Standing Strong” program was effective at improving strength, balance, and function, as well as at reducing falls in older adults. This program combines strength training with balance-specific exercises to target the muscular system as well as the three major sensory control systems that control balance.¹³

- Provide for safety measures as indicated by individual situation, including environmental management and fall prevention. (Refer to ND risk for Falls.)
- Encourage client's participation in self-care activities and in physical or occupational therapies. *Improves body strength and function and enhances self-concept and sense of independence.*
-  Administer pain medications before activity as needed to *permit maximal effort and involvement in activity.*
-  Collaborate with nutritionist in providing nutritious foods and needed feeding assistance, maximizing client's abilities in ingesting and swallowing (upright position) to *optimize available energy for activities.*
- Demonstrate and assist with use of assistive devices (e.g., siderails, overhead trapeze, roller pads, safety belt, hydraulic lifts, chairs) for *position changes and safe transfers.*
- Refer to NDs Activity Intolerance, impaired bed Mobility, impaired physical Mobility, impaired wheelchair Mobility, impaired Transfer Ability, impaired Sitting, and impaired Walking for additional interventions.

NURSING PRIORITY NO. 4 To promote wellness (Teaching/Discharge Considerations):

-  Encourage client's/significant other's involvement in decision making as much as possible. *Enhances commitment to plan, optimizing outcomes.*
-  Demonstrate use of mobility devices (e.g., walkers, strollers, scooters, braces, prosthetics) and have client/caregiver demonstrate knowledge about and safe use of device. Identify appropriate resources for obtaining and maintaining appliances or equipment. *Safe use of mobility aides promotes client's independence and enhances quality of life and safety for client and caregiver.*
-  Refer to support and community services as indicated to *provide care, supervision, companionship, respite services, nutritional and ADL assistance, adaptive devices or changes to living environment, financial assistance, etc.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including level of function and ability to participate in specific or desired activities.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Discharge and long-term needs, noting who is responsible for each action to be taken.
- Specific referrals made.
- Sources of and maintenance for assistive devices.

Stress Overload

Taxonomy II: Coping/Stress Tolerance—Class 2 Coping Responses (00177) [Diagnostic Division: Ego Integrity], Approved 2006

DEFINITION: Excessive amounts and types of demands that require action.

RELATED FACTORS

Insufficient resources (e.g., financial, social, knowledge)
Stressors; repeated stressors

DEFINING CHARACTERISTICS

Subjective

Impaired functioning, decision making
Feeling of pressure; increase in impatience or anger
Negative impact from stress [e.g., physical symptoms, psychological distress, feeling sick]
Excessive stress; tension

Objective

Increase in anger behavior
Sample Clinical Applications: Chronic illness (e.g., multiple sclerosis [MS], diabetes, Parkinson's disease), terminal illness (e.g., ovarian cancer, amyotrophic lateral sclerosis [ALS]), abusive situations, bipolar disorder, depression, social phobia

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Stress Level: Severity of manifested physical or mental tension resulting from factors that alter an existing equilibrium

Anxiety Self-Control: Personal actions to eliminate or reduce feelings of apprehension, tension, or uneasiness from an unidentifiable source

Leisure Participation: Use of relaxing, interesting, and enjoyable activities to promote well-being

Client Will (Include Specific Time Frame)

- Assess current situation accurately.
- Identify ineffective stress-management behaviors and consequences.

- Meet psychological needs as evidenced by appropriate expression of feelings, identification of options, and use of resources.
- Verbalize or demonstrate reduced stress reaction.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Emotional Support: Provision of reassurance, acceptance, and encouragement during times of stress

Coping Enhancement: Facilitation of cognitive and behavioral efforts to manage perceived stressors, changes, or threats that interfere with meeting life demands and roles

Resiliency Promotion: Assisting individuals, families, and communities in development, use, and strengthening of protective factors to be used in coping with environmental and societal stressors

NURSING PRIORITY NO. 1 To identify causative/precipitating factors and degree of impairment:

- Ascertain what tragic or difficult events have occurred (e.g., family violence, death of loved one; separation from living partner/parent; change in financial status or living conditions; chronic or terminal illness, work-place stress, loss of job or retirement; major trauma; catastrophic natural or human-caused event) over remote and recent past to *assist in determining number, duration, and intensity of difficult events causing perception of overwhelming stress.*
- ∞ Ascertain other life events (e.g., job promotion, moving to different home, change such as getting married, having a new baby or adding other new family member, child leaving home, adult children returning home, elder parent requiring care, traveling, spending holidays with relatives) that have occurred over recent months. *All such changes, even when desired, can be stressful and can evoke stress reactions.*²
- Evaluate client's report of physical or emotional problems (e.g., fatigue, aches and pains, irritable bowel, skin rashes, frequent colds, sleeplessness, crying spells, anger, feeling overwhelmed or numb, compulsive behaviors) *that can be representing body's response to stress.*¹
- Determine client's/significant other's (SO's) understanding of events, noting differences in viewpoints.
- ∞ Note client's gender, age, and developmental level of functioning. *Although everyone experiences stress and stressors, women, children, young adults, divorced or separated persons, and people in roles or occupations requiring constant multitasking tend to have higher stress-related symptoms. Multiple stressors can weaken immune system and tax physical and emotional coping mechanisms of persons of any age, but particularly the elderly.*^{1-3,9}
- 🌐 Note cultural values or religious beliefs *that may affect client's expectation for self in dealing with situation, ability to ask for help from others, and expectations placed on client by SO/family.*⁷
- Identify client locus of control: internal (expressions of responsibility for self and ability to control outcomes—"I didn't quit smoking") or external (expressions of lack of control over self and environment—"Nothing ever works out"). *Knowing client's locus of control will help in developing a plan of care reflecting client's ability to realistically make changes that will help to manage stress better.*
- Assess emotional responses and coping mechanisms being used.
- Determine stress feelings and self-talk client is engaging in. *Negative self-talk, all-or-nothing or pessimistic thinking, exaggeration, and unrealistic expectations will contribute to stress overload.*²
- Assess degree of mastery client has exhibited in life. *Passive individual may have more difficulty being assertive and standing up for rights.*
- Determine presence or absence and nature of resources (e.g., whether family/SO are supportive, lack money, problems with relationship or social functioning).
- Note change in relationships with SO(s). *Conflict in the family, loss of a family member, divorce can result in a change in support client is accustomed to and impair ability to manage situation.*

-  Evaluate stress level using appropriate tool (e.g., Stress & Depression, Self-Assessment Tool) to help identify areas of most distress. *While most stress seems to come from disastrous events in individual's life, positive events can also be stressful.*
-  Review lab results to identify physiological conditions (e.g., thyroid or other hormone imbalance, anemia, unstable glucose levels, kidney or liver disease) *that may be causing or exacerbating stress.*¹

NURSING PRIORITY NO. 2 To assist client to deal with current situation:

- Discuss situation or condition in simple, concise manner. *May help client to express emotions, grasp situation, and feel more in control.*
- Active-listen concerns and provide empathetic presence, using talk and silence as needed.
-  Deal with the immediate issues first (e.g., treatment of physical injury, meet safety needs, removal from traumatic or violent environment).
-  Collaborate in treatment of underlying conditions (e.g., traumatic injury, chronic or terminal illness, hormone imbalance, depression and other psychiatric disorders).¹
- Provide or encourage restful environment where possible.
- Assist client in determining whether or not he or she can change stressor or response. *May help client to sort out things over which he or she has control and determine responses that can be modified in order to view life through a more holistic lens.*
- Allow client to react in own way without judgment. Provide support and diversion as indicated.
- Help client to focus on strengths, to set limits on acting-out behaviors, and to learn ways to express emotions in an acceptable manner. *Promotes internal locus of control, enabling client to maintain self-concept and feel more positive about self.*
- Discuss benefits of a “Stop Doing” in place of a “To Do” list. *May help client identify and take action regarding energy drainers (e.g., internalizing others' criticism, fragmented boundaries, power struggles, unprotected personal time) in order to make room for what energizes and brings him/her closer to achieving goals.*⁹
-  Address use of ineffective or dangerous coping mechanisms (e.g., substance use or abuse, self-/other-directed violence) and refer for counseling as indicated.

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Use client's locus of control to develop individual plan of care (e.g., for client with internal control, encourage client to take control of own care; for those with external control, begin with small tasks and add as tolerated).⁴
- Incorporate strengths, assets, and past coping strategies that were successful for client. *Reinforces that client is able to deal with difficult situations.*
- Encourage strengthening of positive SO/family routines and interactions *that support and provide assistance in managing stress.*⁵
- Provide information about stress and exhaustion phase, which occurs when person is experiencing chronic or unresolved stress. *Release of cortisol can contribute to reduction in immune function, resulting in physical illness, mental disability, and life dysfunction.*
- Review stress management and coping skills that client can use:^{1,2,4-6}
Practice behaviors that may help *reduce negative consequences*—change thinking by focusing on positives, reframing thoughts, and changing lifestyle.
Learn to read own body signs (e.g., shakiness, irritability, sleep disturbances, fatigue).
Take a step back and reduce obligations, simplify life, and learn to say no *to reduce sense of being overwhelmed.*
Practice exchanging stresses (i.e., when a new stress comes into play, eliminate or postpone another stress) *to keep total stress level below overstress level.*
Seek help or assistance in meeting obligations and delegate tasks as appropriate.
Learn to control and redirect anger.
Develop and practice positive self-esteem skills.

 Rest, sleep, and exercise on regular schedule or set times *to recuperate and rejuvenate self*. Note: A recent study found that physically fit women in their mid-60s had essentially the same response to stress as a group of unfit women in their late 20s.⁸

Postpone changes in living situation (e.g., moving, remodeling) if possible.

Participate in self-help actions (e.g., deep breathing and other relaxation exercises, spend time alone, get involved in recreation or desired activity, plan something fun, develop humor) *to actively relax*.

Eliminate possible food or environmental allergens and toxins.

Eat nutritious meals; avoid junk food and excessive sugars.

Avoid excessive caffeine, alcohol or other drugs, and nicotine *to balance body chemicals and support general health*.

Take a multivitamin, mineral, and/or trace element preparation.

Develop spiritual self (e.g., meditate or pray; block negative thoughts; learn to give and take, speak and listen, forgive and move on).

Interact socially, reach out, and nurture self and others *to reduce loneliness or sense of isolation*.

-  Review proper medication use *to manage exacerbating conditions (e.g., depression, mood disorders)*.
-  Identify community resources (e.g., vocational counseling; educational programs; child or elder care; Women, Infants, and Children program or food stamps; home or respite care) *that can help client manage life-style and environmental stress*.
-  Refer for therapy, as indicated (e.g., medical treatment, psychological counseling; hypnosis, massage, biofeedback).

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, noting specific stressors, individual's perception of the situation, locus of control.
- Specific cultural or religious factors.
- Availability and use of support systems and resources.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

risk for Sudden infant Death

Taxonomy II: Safety/Protection—Class 2 Physical Injury (00156) [**Diagnostic Division:** Safety], Approved 2002; Revised 2013, 2017

DEFINITION: Susceptible to unpredicted death of an infant.

RISK FACTORS

Delay in or insufficient prenatal care

Infant placed in the prone or side-lying position to sleep

Infant less than 4 months placed in sitting devices for routine sleep

Soft sleep surface; soft, loose items placed near infant

Infant overheating or overwrapping

Exposure to second hand smoke

At Risk Population: African American or Native American ethnicity; male gender

Age 2–4 months

Infant not breast-fed exclusively or fed with expressed breast milk

Low birth weight; prematurity

Maternal smoking during pregnancy; prenatal or postnatal exposure to alcohol or illicit drug

Young parental age

Associated Condition: Cold weather

Sample Clinical Applications: Any child during first year of life

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Risk Control: Personal actions to understand, prevent, eliminate, or reduce modifiable health threats

Knowledge: Infant Care: Extent of understanding conveyed about caring for a baby from birth to first birthday

Parent/Caregiver Will (Include Specific Time Frame)

- Verbalize knowledge of modifiable factors.
- Make changes in environment to prevent death occurring from other factors.
- Follow medically recommended regimen for prenatal and postnatal care.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Risk Identification: Analysis of potential risk factors, determination of health risks, and prioritization of risk-reduction strategies for an individual or group

Teaching: Infant Safety [specify age 0–12 months]: Instruction on safety during first year of life

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

-  Identify individual risk factors pertaining to situation, noting presence of Risk Factors, as listed above. *Determines modifiable or potentially modifiable factors that can be addressed. Note: According to the Centers for Disease Control and Prevention (CDC, 2018), “(1) risk for Sudden Infant Death (SIDS), (2) accidental suffocation in a sleeping environment, and (3) other deaths from unknown causes fall under the umbrella of sudden unexpected infant deaths (SUIDs). In 2016, there were about 1,500 deaths due to SIDS, 1,200 deaths due to unknown causes, and about 900 deaths due to accidental suffocation and strangulation in bed.”^{1,7,9–11}*

-  Determine ethnicity and cultural background of family. *Although the overall rate of SUIDS in the United States declined between 1990 and 2015, disparities in risk factors and SUIDS rates remain. The CDC/National Vital statistics system reports (2017) that SUID rates for American Indian/Alaska Native and non-Hispanic black infants were more than twice those of non-Hispanic white infants. SUIDS rates were lowest among Hispanic and Asian/Pacific Islander infants.*^{7-9,12}
-  Note whether mother smoked during pregnancy or is currently smoking. *Many risk factors for SIDS also apply to non-SIDS deaths as well, and smoking is known to negatively affect the fetus prenatally as well as the infant after birth. It has been reported that if both parents smoke, baby's SIDS risk is 3.5 times greater than if neither parent smokes. If mother smokes, but father doesn't, baby's risk is 2 times greater. If father smokes, but mother doesn't, baby's risk is 1.5 times greater.*^{1,2,12}
- Assess extent of prenatal care, how early it was begun, and extent to which mother followed recommended care measures. *Prenatal care is important for all pregnancies to afford the optimal opportunity for all infants to have a healthy start to life.*²⁻⁴
- Determine client's knowledge of premature labor and actions to be taken in the event they occur. *Prompt action can prevent early delivery and the complications of prematurity.*⁴
-  Note use of tobacco, alcohol or other drugs (including prescribed medications) during and after pregnancy. *"Alcohol is one of the most widely abused substances during pregnancy, and its effects on fetal development and infant outcomes have been well studied. Illicit drug use during pregnancy has been associated with a variety of adverse effects, though more research is needed to draw causal connections."*^{5,12}

NURSING PRIORITY NO. 2 To promote use of activities to minimize risk of SIDS:

-  Emphasize importance of placing infant on his or her back to sleep, both at nighttime and naptime. *Research confirms that fewer babies die of SIDS when they sleep on their backs, not on their tummies or sides.*^{6,8,15}
-  Advise all formal child-care providers, as well as grandparents, babysitters, neighbors, or anyone who will have responsibility for the care of the child during sleep, to maintain safe sleeping position in own sleeping place with head and face uncovered. *The recommendation is to always place the infant on the back until he or she can roll over; then repositioning is not required.*^{1,2,4,6,7,15}
- Encourage parents to schedule "tummy time" only while infant is awake. *This activity promotes strengthening of back and neck muscles while parents are close and baby is not sleeping.*¹
-  Encourage well-baby checkups and immunizations. *Keeping babies healthy prevents problems that could put the infant at risk for SIDS. Immunizing infants prevents many illnesses that can be life-threatening.*^{1,4,10}
-  Encourage breastfeeding, if possible. *Breastfeeding has many advantages (immunological, nutritional, psychosocial), promoting a healthy infant. While this does not preclude the occurrence of SIDS, healthy babies are less prone to many illnesses and health problems. Note: One meta-analysis of 18 studies shows that breastfeeding to any extent and of any duration is protective against SIDS.*^{1,4,13,15}
-  Suggest providing pacifier at nap time and bedtime, refraining from placing around neck or attaching to clothing due to risk of strangulation. *Specific mechanism of action is unclear but studies demonstrate decreased incidence of SIDS with pacifier use.*¹⁵
-  Discuss issues of bed-sharing. *Some of the many concerns include accidental entrapment under a sleeping adult or suffocation by becoming wedged in a couch or cushioned chair. There are also concerns about accidental death from suffocation when the mother smokes, has recently consumed alcohol, is fatigued, the infant is covered by a blanket or quilt, or there are multiple bed-sharers. Also, studies show that the odds of SIDS is 16 times greater if babies who bed-share are also exposed to secondhand smoke. Research suggests that infants in this setting have more difficulty rousing from sleep, perhaps because smoke exposure changes serotonin pathways of the brain.*^{6,13,14}
-  Note cultural beliefs about bed-sharing. *Studies show that bed-sharing is growing across all populations in the United States. Bed-sharing is more common among breastfed infants, young unmarried mothers,*

low-income families where multiple people share a bed, or those from a minority group. Additional study is needed to better understand bed-sharing practices and associated risks and benefits.^{6,14}

-  Recommend infant share room with parents for at least first 6 months. Studies suggest that sleeping in parents' room but on a separate surface can reduce incidence of SIDS by up to 50%.¹⁵

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-   Discuss known facts about SIDS with parents. *SIDS is not preventable, although research indicates that SIDS deaths have reduced since back-sleeping position policy was implemented. The cause is determined only after autopsy and can only be determined after ruling out other causes. SIDS is not the same as suffocation, is not caused by vomiting or choking, is not caused by immunizations, is not contagious, is not the cause of every unexpected infant death, and is not the result of child neglect or abuse.*^{1,2,7}
-   Recommend attention to factors below that may help in reducing risk:
 Avoid overdressing or overheating infants during sleep. *Baby should be kept warm, but not too warm. Too many layers of clothing or blankets can overheat the infant. Room temperature that is comfortable for an adult will be comfortable for the baby. Note: Infants who were dressed in two or more layers of clothes as they slept had six times the risk of SIDS as those dressed in fewer layers.*^{1,4,15}
 Place infant on a firm mattress in an approved crib. *Avoiding soft mattresses, sofas, cushions, waterbeds, and other soft surfaces, while not known to prevent SIDS, will minimize chance of suffocation.*^{1,2,15}
 Remove crib bumper pads, stuffed toys, fluffy and loose bedding from sleep area, making sure baby's head and face are not covered during sleep. *Minimizes possibility of entrapment and suffocation.*^{1,2,15}
 Verify that day-care center/provider(s) are trained in observation and modifying risk factors (e.g., sleeping position) to reduce risk of death while infant in their care.
 Discourage excessive checking of the infant. *Since there is nothing that can currently be done (beyond proper sleep positioning) to reduce the occurrence of SIDS, excessive checking only tires the parents and creates an atmosphere of tension and anxiety.*^{1,2}
-   Discuss the use of apnea monitors, if appropriate. *Apnea monitors are not recommended to prevent SIDS but may be used to monitor other medical problems. Only a small percentage of infants who died of SIDS were known to have prolonged apnea episodes, and monitors are also not medically recommended for subsequent siblings.*^{1,2,15}
-   Recommend contacting public health nurse for visit to new mother at least once or twice following discharge. *These early visitation programs have demonstrated an improvement in infant safety outcomes.*⁴
-  Refer parents to local SIDS programs and resources for learning (e.g., National SIDS/Infant Death Resource Center and similar Web sites). *Provides reassurance and information for self-paced learning.*¹
-  Encourage consultation with primary care provider if baby shows any signs of illness or behaviors that concern parent. *Promotes timely evaluation and intervention for treatable problems.*¹

DOCUMENTATION FOCUS

Assessment/Reassessment

- Baseline findings, degree of parental anxiety or concern.
- History of infant deaths within family.

Planning

- Plan of care, specific interventions, and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Parent's responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and actions to be taken.
- Support systems available, specific referrals made, and who is responsible for actions to be taken.

risk for Suffocation

Taxonomy II: Safety/Protection—Class 2 Physical Injury (00036) [**Diagnostic Division:** Safety], Approved 1980; Revised 2013, 2017

DEFINITION: Susceptible to inadequate air availability for inhalation, which may compromise health.

RISK FACTORS

Access to empty refrigerator/freezer; low strung clothesline
 Eating large mouthfuls [or pieces] of food; small object in airway
 Gas leak; unvented fuel-burning heater; vehicle running in closed garage; smoking in bed
 Pacifier around infant's neck; propped bottle in infant's crib
 Playing with plastic bag; soft underlayment [loose items placed near infant]
 Unattended in water

Associated Condition: Alteration in cognitive functioning; impaired motor functioning
 Face/neck disease or injury; alteration in olfactory function
 Emotional disturbance
 Insufficient knowledge of safety precautions

(continues on page 854)

risk for Suffocation (continued)

Sample Clinical Applications: Substance use or abuse, spinal cord injury, crushing chest injury, obesity, near-drowning, burn or inhalation injury, sleep apnea, seizure disorder

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Risk Control: Aspiration: Personal actions to understand and prevent the passage of fluid and solid particles into the lung

Client/Caregiver Will (Include Specific Time Frame)

- Verbalize knowledge of hazards in the environment.
- Identify interventions appropriate to situation.
- Correct hazardous situations to prevent or reduce risk of suffocation.
- Demonstrate cardiopulmonary resuscitation (CPR) skills and how to access emergency assistance.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Airway Management: Facilitation of patency of air passages

Aspiration Precautions: Prevention or minimization of risk factors in the patient at risk for aspiration

Teaching: Infant Safety [specify months of age]: Instruction on safety during first year of life

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Determine client's/significant other's (SO's) knowledge of individual safety concerns and environmental hazards present *to identify misconceptions and educational needs. Suffocation can be caused by (1) spasm of airway (e.g., food or water going down wrong way, irritant gases, asthma); (2) airway obstruction (e.g., foreign body, tongue falling back in unconscious person, swelling of tissues from burn injury or allergic reaction); (3) airway compression (e.g., tying rope or band tightly around neck, hanging, throttling, smothering); (4) conditions affecting the respiratory mechanism (e.g., epilepsy, tetanus, rabies, nerve diseases causing paralysis of chest wall or diaphragm); (5) conditions affecting respiratory center in brain (e.g., electric shock; stroke or other brain trauma; medications such as morphine, barbiturates); and (6) compression of the chest (e.g., crushing as might occur with cave-in, motor vehicle crash, pressure in a massive crowd).*^{1,5,6}
- Identify level of concern or awareness and motivation of client/SOs to correct safety hazards and improve individual situation. *Lack of commitment may limit willingness to make changes, placing dependent individuals at risk.*
- ∞ Determine age, developmental level, and mentation (e.g., infant/young child, frail elder, person with developmental delay, altered level of consciousness, or cognitive impairments or dementia) *to identify individuals unable to be responsible for or protect self.*
- Assess neurological status and note history of conditions, such as stroke, cerebral palsy, multiple sclerosis, and amyotrophic lateral sclerosis, *that have potential to compromise airway or affect ability to swallow.*
- 🧠 Determine presence of seizure disorder, noting use of antiepileptics and how well condition is controlled. *Seizure activity (and especially status epilepticus) is a major risk factor for respiratory inhibition or arrest, particularly when consciousness is impaired.*¹⁰
- Note reports of sleep disturbance and daytime fatigue. *May be indicative of sleep apnea (airway obstruction), requiring referral for evaluation. Refer to NDs Insomnia and Sleep Deprivation.*

-  Review medication regimen to note potential for oversedation and respiratory failure (e.g., central nervous system depressants, analgesics, sedatives, antidepressants).
- Assess for allergies to medications, foods, and environmental factors that could result in severe reaction or anaphylaxis resulting in respiratory arrest.
-  Be alert to and carefully monitor those individuals who are severely depressed, mentally ill, or aggressive and in restraints. *These individuals could be at risk for suicide by suffocation (e.g., inhaled carbon monoxide or death by strangling or hanging).*² Refer to ND risk for Suicide.
- Note signs of respiratory distress (e.g., cough, stridor, wheezing, increased work of breathing) that could indicate swelling or obstruction of airways.³ Refer to NDs ineffective Airway Clearance, risk for Aspiration, ineffective Breathing Pattern, and impaired spontaneous Ventilation, as appropriate, for additional interventions.

NURSING PRIORITY NO. 2 To reverse/correct contributing factors:

-  Discuss with client/SO(s) identified environmental or work-related safety hazards and problem-solve methods for resolution (e.g., need for smoke and carbon monoxide alarms, vents for household heater, clean chimney, properly strung clothesline, proper venting of machinery exhaust, monitoring of stored chemicals, bracing trench walls when digging).
- Protect airway at all times, especially if client unable to protect self:^{2,5,8}
Use proper positioning, suctioning, and use of airway adjuncts, as indicated, *for comatose or cognitively impaired individual or client with swallowing impairment or obstructive sleep apnea.*
Provide seizure precautions and antiseizure medication, as indicated.
-  Administer medications when client is sitting or standing upright and can swallow without difficulty.
Emphasize importance of chewing carefully, taking small amounts of food, and using caution *to prevent aspiration when talking or drinking while eating.*
Provide diet modifications as indicated by specific needs (e.g., developmental level; presence/degree of swallowing disability, impaired cognition) *to reduce risk of aspiration.*
Avoid physical and mechanical restraints, including vest or waist restraint, siderails, and choke holds. *Can increase client's agitation, causing struggle to escape and resulting in entrapment of head and hanging.*
- Emphasize with client/SO the importance of getting help when beginning to choke or feel respiratory distress (e.g., staying with people instead of leaving table, making gestures across throat, making sure someone recognizes the emergency) *in order to provide timely intervention such as abdominal thrusts and calling 911.*
- Avoid idling automobile (or using fuel-burning heaters) in closed or unvented spaces.
- Emphasize importance of periodic evaluation and repair of gas appliances, furnace, and automobile exhaust system *to prevent exposure to carbon monoxide.*
-  Review child protective measures:^{2,4,7,8}
Place infant in supine position for sleep. Refer to ND risk for Sudden Infant Death.
Do not prop baby bottles in infant crib.
Attach pacifier to clothing—not around neck; remove bib before putting baby in bed.
Store or dispose of plastic bags (e.g., shopping, garbage, dry cleaning, shipping) out of reach of infants/young children.
Avoid use of plastic mattress or crib covers.
Avoid placing infant to sleep on soft surfaces (e.g., beanbag chair, basket with soft sides, soft pillow or comforter, waterbed) *that baby can sink into or be unable to free face.*
Use a crib with slats that are no more than 2 3/8 in. apart *so that baby cannot get head trapped or slip body through slats.*
Refrain from bedsharing with infant/young child *to prevent accidental smothering.*
Provide constant supervision of young children in bathtub, swimming pool, other bodies of water.
Make certain that blind and curtain cords, drawstrings on clothing, etc., are out of reach of small children *to prevent accidental hanging.*

Prevent young child/impaired individual from putting objects in mouth (e.g., food such as chunks of raw vegetables, nuts and seeds, popcorn, hot dogs; toy parts; buttons; balloons; small balls/marbles; button-type batteries; refrigerator magnets; coins) *that can get lodged in airway and cause choking.*
 Lock or remove lid or door of chests, trunks, old refrigerators or freezers *to prevent child from being trapped in airless environment.*

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Review safety factors identified in individual situation and methods for remediation.
- Develop plan with client/caregiver for long-range management of situation to avoid risks. *Enhances commitment to plan, optimizing outcomes.*
- Discuss possibility of choking resulting from relaxation of throat muscle and impaired judgment *when combining drinking alcohol with eating.*
- Involve family members in learning and practicing rescue techniques (e.g., treating of choking or breathing problems, CPR) *to deal with emergency situations (especially when at-home client is at risk on a regular basis).*
- Encourage individuals to read package labels and identify and remove safety hazards, such as toys with small parts, and monitor Web sites for product recalls.
- Promote water and swimming pool safety, vigilance, and use of approved flotation equipment, fencing and locked gates, alarm system, etc.
- Discuss fire safety and concerns regarding use of heaters; household gas appliances; and old, discarded appliances. Encourage home fire safety drills yearly.
- Promote public education in techniques for clearing blocked airways (e.g., Heimlich maneuver, CPR).
-   Collaborate in community public health education regarding hazards for children (e.g., appropriate toy size for young child; discussing dangers of “huffing” [inhalants] and playing choking or hanging games with preteens; how to spot potential for depression and risk of suicidal gestures in adolescent) *to reduce potential for accidental or intentional suffocation.*⁹

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual risk factors, including individual’s cognitive status and level of knowledge.
- Level of concern and motivation for change.
- Equipment or airway adjunct needs.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs, appropriate preventive measures, and who is responsible for actions to be taken.
- Specific referrals made.

risk for Suicide

Taxonomy II: Safety/Protection—Class 3 Violence (00150) [**Diagnostic Division:** Safety]. Approved 2000; Revised 2013, 2017

DEFINITION: Susceptible to self-inflicted, life-threatening injury.

RISK FACTORS

Behavioral

Purchase of a gun; stockpiling medication
 Making or changing a will; giving away possessions
 Sudden euphoric recovery from major depression
 Marked changes in behavior, attitude, or school performance

Psychological

Substance misuse/[abuse]
 Guilt

Situational

Access to weapon
 Loss of autonomy or independence

Social

Loss of significant relationship; disruptive family life; insufficient social support; social isolation
 Grieving, loneliness
 Hopelessness; helplessness
 Disciplinary problems; legal difficulty
 Cluster suicides

Verbal

Threat of killing self; reports desire to die

Other

Chronic pain

At Risk Population: Family history of suicide; history of suicide attempt

Adolescence; adolescents living in nontraditional settings; relocation
 Caucasian or Native American ethnicity; male gender; homosexual youth
 Older adults; retired; divorced status; widowed
 Economically disadvantaged
 Living alone; institutionalization
 History of childhood abuse

(continues on page 858)

risk for Suicide (continued)

Associated Condition: Physical illness; terminal illness

Psychiatric disorder

Sample Clinical Applications: Acute or chronic brain syndrome, hormonal imbalances (e.g., premenstrual syndrome [PMS], postpartum psychosis), substance use or abuse, chronic or terminal illness (e.g., amyotrophic lateral sclerosis [ALS], cancer), major depression, schizophrenia, bipolar disorder, panic state

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Suicide Self-Restraint: Personal actions to refrain from gestures and attempts at killing self

Coping: Personal actions to manage stressors that tax an individual's resources

Hope: Optimism that is personally satisfying and life supporting

Client Will (Include Specific Time Frame)

- Acknowledge difficulties perceived in current situation.
- Identify current factors that can be dealt with.
- Be involved in planning course of action to correct existing problems.
- Make decision that suicide is not the answer to perceived or real problems.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Suicide Prevention: Reducing the risk for self-inflicted harm with intent to end life

Behavior Management: Self-Harm: Assisting the patient to decrease or eliminate self-mutilating or self-abusive behaviors

Patient Contracting: Negotiating an agreement with an individual that reinforces a specific behavior change

NURSING PRIORITY NO. 1 To assess causative/contributing factors and degree of risk:

-  Note behaviors indicative of intent. *Individual may not make statements of intent, but gestures (e.g., threats, giving away possessions), presence of means (e.g., guns), previous attempts, and presence of hallucinations or delusions may provide clues to intent.*^{3,6,11}
- Ask directly if person is thinking of acting on thoughts or feelings to determine intent. *Most individuals want someone to see what desperate straits they are in, and by bringing the issue into the open, discussion can begin and plans made to keep the person safe.*^{3,7}
-  Identify degree of risk or potential for suicide and seriousness of threat. *Information may be obtained from client or SO interviews, or over time in the course of care. Most people who are contemplating suicide send a variety of signals indicating their intent, and recognizing these warning signs allows for immediate intervention. Note: The Centers of Disease Control and Prevention (CDC) reported in 2013 that suicide remains a significant threat in the U.S. population with over 41,000 deaths and over 494,000 self-inflicted injuries treated in emergency departments that year. A 2013 Veterans Administration report estimated that 18–22 veterans died each day based on 2010 data.*^{4,14–16}
-  Use a risk scale (where available) to prioritize client risk according to severity of threat and availability of means. *Several risk scales may be used (e.g., Beck's Scale for Suicide Ideation, Linehan's Reasons for Living Inventory, Cole's self-administered adaptation of Linehan's structured interview called the Suicidal Behaviors Questionnaire) to assist in evaluating the severity of risk. Note: In recent years there have been "several*

significant changes in how mental health professionals think about, and work with patients who are suicidal. Major modifications include (not a complete listing) (1) acknowledgment that ‘traditional’ suicide risk factors contribute little to clinicians’ suicide prediction and prevention efforts; (2) ongoing clinical encounters and monitoring, including use of comprehensive suicide assessment interviewing protocols; and (3) asking client direct questions about suicide ideation when interviewing.”^{4,14}

- Note withdrawal from usual activities and lack of social interactions. *These are classic behaviors of the individual who is feeling depressed and sad and may be having negative thoughts of worthlessness.*⁶
- Identify what losses client has experienced, and meaning of those losses. *Unresolved issues may be contributing to thoughts of hopelessness, feelings of despair, and suicidal ideation.*^{3,6}
-  Note age and gender. *While women may attempt suicide more frequently, men usually succeed more often. Risk of suicide is greater in teens and the elderly, but there is a rising awareness of risk in early childhood. Note: The CDC reported in 2013 that suicide was the second leading cause of death for young people ages 15 to 34 in the United States.*^{4,8,10,15}
-  Determine cultural or religious beliefs that may be affecting client’s thinking about life and death. *Family of origin and culture in which individual grew up influence attitudes toward taking one’s own life. Note: A recent study showed that after other factors were controlled, greater moral objections to suicide and lower aggression level in religiously affiliated subjects seemed to function as protective factors against suicide attempts.*^{2,4,10}
- Identify conditions such as acute or chronic brain syndrome, epilepsy, panic state, and hormonal imbalance (e.g., PMS, mental illness, postpartum or drug-induced psychosis). *These conditions may interfere with ability to control own behavior leading to impulsive actions that may put client at risk.*^{1,4,10,13}
-  Review lab results (e.g., blood alcohol, serum glucose, arterial blood gases, electrolytes, renal function tests). *Identifies factors that may affect reasoning ability, interfering with ability to think clearly about issues that are leading to thoughts of suicide.*^{1,3,5}
- Assess physical complaints. *Sleeping difficulties and lack of appetite can be indicators of depression and suicidal ideation, requiring further evaluation.*^{3,4}
-  Review family history for suicidal behavior. *Individual risk is increased when other family members have committed suicide or exhibited symptoms of depression. Studies have shown a possible genetic link toward suicidal behavior.*¹²
- Assess coping behaviors presently used. *Client’s current negative thinking may preclude looking at positive behaviors that have been used in the past that would help in the current situation. Client may believe there is no alternative except suicide.*^{6,7}
- Ascertain presence of significant others (SOs)/friends available for support. *Individuals who have positive support systems on whom they can rely during a crisis situation are less likely to commit suicide and are more apt to return to a successful life.*³
-  Determine drug use or “self-medication.” *The use of drugs and alcohol, especially the combination of alcohol and barbiturates, increases the risk of suicide.*⁴
- Note history of disciplinary problems or involvement with judicial system. *Feelings of despair over problems with the legal system and lack of hope about outcome can lead to belief that the only solution is suicide.*^{3,10}

NURSING PRIORITY NO. 2 To assist client to accept responsibility for own behavior and prevent suicide:

- Develop therapeutic nurse-client relationship, providing a consistent care provider. *Promotes sense of trust, allowing individual to discuss feelings openly. Collaborating with the client to better understand the problem affirms the client’s ability to solve the current situation.*^{3,6}
- Maintain straightforward communication. *By being direct and honest and acknowledging need for attention, care provider can avoid reinforcing manipulative behavior.*⁶
- Explain concern for safety and willingness to help client stay safe. *Clients often believe their concerns will not be taken seriously, and stating clearly that they will be listened to sends a clear message of support and caring.*⁶

- Encourage expression of feelings and make time to listen to concerns. *Acknowledges reality of feelings and that they are okay. Helps individual sort out thinking and begin to develop understanding of situation.*^{3,6}
- Give permission to express angry feelings in acceptable ways and let client know someone will be available to assist in maintaining control. *Promotes acceptance and sense of safety while client is regaining own control.*^{3,4}
- Acknowledge reality of suicide as an option. Discuss consequences of actions if they follow through on intent. Ask how it will help individual to resolve problems. *Can help client to focus on consequences of actions and begin to discuss the possibility of other options.*^{5,7}
- Help client identify more appropriate solutions/behaviors. *Alternative activities, such as exercise, can lessen sense of anxiety and associated physical manifestations.*³
- Maintain observation of client and check environment for hazards that could be used to commit suicide. Do not leave client alone if expressing “I’m going to kill myself.” Do not promise to keep client’s suicidal thoughts a secret. *Increases client safety and may reduce risk of impulsive behavior.*¹¹
-  Discuss medication regimen in general and note use of antidepressant medications, especially when there may be a significant organic component to the suicidal ideation. *Certain medications have been shown to increase risk of suicidal ideation or suicide, including (and not limited to) antidepressants, anticonvulsants, pain medications, and smoking-cessation medications. While the use of medications may be helpful in the short term, there are some drawbacks, namely, the length of time it takes for most medications to take effect and the potential for giving a client a means of suicide because of the possibility of a lethal overdose.*^{4,6,9,10}
- Reevaluate potential for suicide periodically at key times (e.g., mood changes, increasing withdrawal), as well as when client is feeling better and planning for discharge becomes active. *The highest risk is when the client has both suicidal ideation and sufficient energy with which to act.*^{5,6}

NURSING PRIORITY NO. 3 To assist client to plan course of action to correct/deal with existing situation:

- Gear interventions to individual involved. *Age, relationships, and current situation determine what is needed to help client deal with feelings of despair and hopelessness.*^{6,10}
- Negotiate contract with client regarding willingness not to do anything lethal for a stated period of time. Specify what care provider will be responsible for and what client responsibilities are. *Making a contract in which the individual agrees to stay alive for a specified period of time, from Day 1 through the entire course of treatment, and which is written and signed by each party may help the client to follow through with therapy to find reason for living. Although there is little research on the effectiveness of these contracts, they are frequently used.*⁶
- Specify alternative actions necessary if client is unwilling to negotiate contract. *Client may be willing to agree to other actions (i.e., calling therapist if feelings are overwhelming) even though he or she is not willing to commit to a contract.*⁶
- Provide directions for actions client can take, avoiding negative statements such as “do nots.” *Providing opportunity for client to have control over circumstances can promote a positive attitude and give client some hope for the future.*^{3,5}

NURSING PRIORITY NO. 4 To promote wellness (Teaching/Discharge Considerations):

-  Promote development of internal control. *Helping the client look at new ways to deal with problems can provide a sense of own ability to solve problems, improve situation, and hope for the future.*³
- Assist with learning problem-solving, assertiveness training, and social skills. *By learning these new skills, client can begin to feel more confidence in own ability to handle problems that arise and deal with the current situation.*^{3,5}
- Engage in physical activity programs. *Promotes release of endorphins and feelings of self-worth, improving sense of well-being and giving client hope.*³
- Determine nutritional needs and help client to plan for meeting them. *Enhances general well-being and energy level.*^{1,10}

-  Review use of antidepressants, noting that it takes 4 to 8 weeks for effects of medication to be observed, and different medications may need to be tried to obtain maximum benefit. Stress importance of continuing medication after symptoms of depression resolve to reduce risk of relapse. *Antidepressants can be effective in quick relief of suffering in severe cases of depression. Studies have shown that cognitive behavior therapy has prevented relapse in 70% more cases than have drugs. In a sample of older adults with depression, the combination of medication and interpersonal psychotherapy was more effective than either alone.*^{10,17}
- Involve family/SO in planning. *Improves understanding and support when family knows the facts and has a part in planning for rehabilitation efforts for the client.*^{1,5}
-  Refer to formal resources as indicated. *May need assistance with referrals to individual, group, or marital psychotherapy; substance abuse treatment program; or social services when situation involves mental illness or family disorganization.*^{5,10,11}

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including nature of concern (e.g., suicidal or behavioral risk factors and level of impulse control, plan of action and means to carry out plan).
- Client's perception of situation, motivation for change.
- Cultural or religious beliefs influencing attitudes about life and suicide.
- Availability of family and other support systems.

Planning

- Plan of care and who is involved in the planning.
- Details of contract regarding suicidal ideation or plans.
- Teaching plan.

Implementation/Evaluation

- Actions taken to promote safety.
- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Available resources, specific referrals made.

delayed Surgical Recovery

Taxonomy II: Safety/Protection—Class 2 Physical Injury (00100) [Diagnostic Division: Safety], Approved 1998; Revised 2006, 2013, 2017

DEFINITION: Extension of the number of postoperative days required to initiate and perform activities that maintain life, health, and well-being.

RELATED FACTORS

Malnutrition; obesity
Pain
Postoperative emotional response

DEFINING CHARACTERISTICS

Subjective

Discomfort
Loss of appetite
Postpones resumption of work

Objective

Evidence of interrupted healing of surgical area
Excessive time required for recuperation; inability to resume employment
Impaired mobility; requires assistance for self-care

At Risk Population: Extremes of age

History of delayed wound healing

Associated Condition: American Society of Anesthesiologists (ASA) Physical Status classification score ≥ 2

Diabetes mellitus
Edema or trauma at surgical site
Extensive or prolonged surgical procedure; surgical site contamination
History of delayed wound healing; perioperative surgical site infection
Impaired immobility
Persistent vomiting

Pharmaceutical agent

Psychological disorder in perioperative period

Sample Clinical Applications: Major surgical procedures, traumatic injuries with surgical intervention, chronic conditions (e.g., diabetes mellitus, cancer, HIV/AIDS, chronic obstructive pulmonary disease [COPD])

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Self-Care: Activities of Daily Living (ADL): Personal actions to perform the most basic physical tasks and personal care activities independently with or without assistive device

Endurance: Capacity to sustain activity

Wound Healing: Primary Intention: Extent of regeneration of cells and tissues following intentional closure

Client Will (Include Specific Time Frame)

- Perform desired self-care activities.
- Report increased energy and be able to participate in usual (work or employment) activities in a timely manner.
- Display complete healing of surgical area.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Self-Care Assistance: Assisting another to perform activities of daily living

Energy Management: Regulating energy use to treat or prevent fatigue and optimize function

Wound Care: Prevention of wound complications and promotion of wound healing

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Identify vulnerable client (e.g., low socioeconomic status or poverty; lack of insurance; inadequate transportation; lack of family or support system; severe trauma or prolonged hospitalization with multiple complicating factors; client with severe anxiety about diagnosis or outcome) *who is at higher risk for adverse outcomes.*⁶
-  Determine age, developmental level, and general state of health *to help determine time that may be required for client to resume ADLs and other activities or expectation of time needed for healing. Note: The older adult undergoing surgical treatment is at greater risk for delayed recovery because of age-related changes in numerous systems and protective mechanisms that increase the potential for complications.*^{1,7,16}
-  Note underlying condition or pathology (e.g., cancer, burns, diabetes, hypothyroidism, obesity, steroid therapy, major trauma, infections, radiation therapy, cardiopulmonary disorders, debilitating illness) *that can adversely affect healing and prolong recuperation time. Note: One study found the incidence of surgical-site infection to be more than five times higher in obese patients and eight times higher in morbidly obese patients than in patients of normal weight. In this population, impaired pulmonary function, hyperglycemia, immobility, and nutritional deficits can compromise wound healing.*^{3,8,12}
-  Determine the length of operative procedure or time under anesthesia (e.g., typical or lengthy), type and severity of perioperative complications (e.g., trauma, other conditions requiring multiple surgeries; heavy bleeding during procedure), type of surgical wound (e.g., clean; clean-contaminated; grossly contaminated, acutely infected), and development of postoperative complications (e.g., surgical site infection, suture reactions, dehiscence, ventilator-associated pneumonia, deep vein thrombosis) *that can affect the pace of healing or prolong recovery.*^{2,3,9}

-  Evaluate circulation and sensation in surgical area, noting location of incision. *Lack of blood supply at the wound site can slow healing. Note: Some areas of the body, such as the face and neck, receive the most blood supply and heal the fastest, whereas other areas, such as extremities, take longer to heal. Poor circulation and impaired sensation in extremities, such as in the diabetic person, cause even longer healing times.*¹⁴
-  Determine nutritional status and current intake to ascertain if nutrition is adequate to support healing. *Client may have preexisting nutritional concerns (e.g., elderly person, client with anorexia or morbid obesity) or may have been fasting perioperatively or experienced nausea, vomiting, and loss of appetite postoperatively, depending on the surgical procedure performed and client's reactions to medications (e.g., pain medications, antibiotics). Note: A lack of carbohydrates, proteins, zinc, and vitamins can cause a delay in healing.*^{2,7,14}
-   Review client's preoperative medications/other drug regimen to ascertain that none could impede healing processes (e.g., aspirin and NSAIDs, chemotherapy agents) or increase bleeding time, (e.g., alcohol and some herbals such as garlic and ginkgo biloba can also be associated with bleeding complications).²
- Perform pain assessment to ascertain whether pain management is adequate to meet client's needs during recovery.
- Evaluate client's cognitive and emotional state, noting presence of postoperative changes, including confusion, depression, apathy, and expressions of helplessness, to determine need for further assessment of possible physical or psychological interferences.
-  Ascertain attitudes and cultural values of individual about condition. *Family beliefs and cultural values, stress and fear related to surgery (and the reason for it), possible stigma about relative condition or disease, or change in body image, as well as motivation to return to usual role and activities, all impact rate and expectations for sick role and recovery.*⁵
-   Review results of laboratory tests (e.g., complete blood count, blood/wound cultures, serum glucose; hormones [e.g., cortisol, glucocorticoid and other hormones associated with inflammation and immune system dysfunction]) to assess for presence and type of infections, immunosuppression, metabolic or endocrine dysfunction, or other conditions affecting body's ability to heal. *Surgical site infections have been found to be tied to hyperglycemia that may impair phagocytosis, negatively affecting the body's normal defense mechanisms. Also, stress-impaired wound healing is mediated primarily through the hypothalamic-pituitary-adrenal hormones, and psychological response-induced unhealthy behaviors.*^{11,16}
-  Note allergies or history of skin reactions. Evaluate use of plastics (e.g., incontinence pads or moisture barriers), tape/adhesives, or latex materials. *Plastics retain heat and can enhance growth of pathogens in wound. Client sensitivity to adhesives and/or latex can cause skin or tissue reactions that delay primary wound healing and cause additional skin/tissue damage.*¹⁵ Refer to NDs impaired Skin Integrity and Latex Allergy Response.
-  Note lifestyle factors (e.g., obesity, cigarette smoking, alcohol abuse, lack of exercise/sedentary lifestyle) that influence circulation and wound healing and can impede recovery.^{4,17}

NURSING PRIORITY NO. 2 To determine impact of delayed recovery:

-  Note length of illness or hospitalization, time of discharge, and progress to date to compare with general expectations for procedure and situation.
-  Determine client's/significant other's (SO's) expectations for recovery and specific stressors related to delay (e.g., return to work or school, home responsibilities, child care, financial difficulties, limited support system).
- Determine energy level and current participation in ADLs to compare with usual level of function.
-  Ascertain whether client usually requires assistance in home setting and who provides it, as well as individual's current availability and capability.
- Note client/SO reports of helplessness or inability to cope with situation.
-  Obtain psychological assessment of client's emotional status, noting potential problems arising from current situation.

NURSING PRIORITY NO. 3 To promote optimal recovery:

-  Inspect incisions or wounds routinely, describing changes (e.g., deepening or healing, wound measurements, presence and type of drainage, development of necrosis).
-  Practice and instruct client/caregiver(s) in proper hand hygiene and aseptic technique for incisional care *to reduce incidence of contamination and infection. Note: A recent study showed that while hand hygiene between patients remains a compliance issue in hospitals, healthcare workers have been found to be more motivated to perform hand hygiene to protect vulnerable patients than they are to protect their own health.*^{4,13}
-  Administer antibiotics as appropriate and medications to manage postoperative discomforts (e.g., pain, nausea, vomiting) and other concurrent or underlying conditions, such as diabetes, osteoporosis, heart failure, and COPD. *Several types of medications may be needed. For example, client may require antibiotics perioperatively, insulin to support tissue repair, and/or management of chronic pain to improve mobility and tissue recovery.*^{10,11}
-  Instruct client/SO in necessary self-care of incisions and specific symptom management. *With short hospital stays, client/SO are usually expected to provide a great deal of postoperative care and monitoring at home.*⁶
-  Provide wound care expectations and instructions in verbal and written forms *to facilitate self-care and reduce likelihood of misinterpretation of information when client/SO is providing care at home.*²
-  Instruct client/SO in routine inspection of incision or wound and to report changes in wound indicative of failure to heal (e.g., deepening wound, local or systemic fever, exudates [noting color, amount, and odor], loss of approximation of wound edges) *to establish comparative baseline and allow for early intervention (e.g., antimicrobial therapy, wound irrigation or packing).*
- Avoid or limit use of plastics or latex materials in wound care, as appropriate. *Can delay healing and cause skin breakdown.*
-  Collaborate in treatment and assist with wound care, as indicated. *May require barrier dressings, skin-protective agents, wound vac for open or draining wounds, or surgical débridement. Refer to/include wound care specialist or stomal therapist, as appropriate, to address treatment interventions to deal with healing difficulties.*
-  Provide optimal nutrition with adequate protein *to provide a positive nitrogen balance, which aids in healing and contributes to general good health.*
- Encourage adequate fluid and electrolyte intake *to avoid dehydration of tissues and to promote optimal cellular and organ function.*
- Encourage early ambulation and regular exercise *to promote circulation, improve muscle strength and overall endurance, and reduce risks associated with immobility.*
- Recommend pacing (alternating activity with adequate rest periods) *to reduce fatigue and allow weakened muscles and tissues to recuperate.*
- Employ nonpharmacological healing measures as indicated (e.g., breathing exercises, listening to music, relaxation tapes, biofeedback, hot or cold applications) *to promote relaxation of muscles and tissue healing, as well as improve coping and outlook for positive healing experience.*
-  Refer for follow-up care, as indicated (e.g., telephone monitoring, home visit, wound care clinic, pain management program).

NURSING PRIORITY NO. 4 To promote wellness (Teaching/Discharge Considerations):

-  Discuss reality of recovery process and client's/SO's expectations. *Individuals are often unrealistic regarding energy and time required for healing and own abilities and responsibilities to facilitate process.*
- Involve client/SO(s) in setting incremental goals. *Enhances commitment to plan and reduces likelihood of frustration, thus blocking progress.*
- Demonstrate self-care skills and provide client/SO with health-related information and psychosocial support *to manage symptoms and pain, thus enhancing well-being.*
-  Refer to physical or occupational therapist and/or wound care specialist, as indicated *to address exercise program and home-care needs and identify assistive devices to facilitate independence in ADLs.*
- Identify suppliers for dressings and wound care items or assistive devices as needed.

-  Consult nutritionist for individual dietary plan *to meet increased nutritional needs that reflect personal situation and resources.*
- Evaluate home situation (e.g., lives alone, bedroom or bathroom on second floor, availability of assistance) where appropriate, *to evaluate for beneficial adjustments, such as moving bed to first floor; arranging for com-mode during recovery; and obtaining an in-home emergency call system.*
-  Discuss alternative placement (e.g., convalescent or rehabilitation center, as appropriate). *Brief stay with concentrated support and therapy may speed recovery and return to home.*
-  Identify community resources (e.g., visiting nurse, home healthcare agency, wound care, Meals on Wheels, respite care). *Facilitates adjustment to home setting.*
-  Refer for counseling or support. *May need additional help to overcome feelings of discouragement, deal with changes in life, weight management, and/or smoking cessation.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Assessment findings, including status of wound healing, individual concerns, family involvement and support factors, availability of resources.
- Cultural expectations.
- Assistive device use or need.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses of client/SO(s) to plan, interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

- Encourage adequate fluid and electrolyte intake *to avoid dehydration of tissues and to promote optimal cellular and organ function.*
- Encourage early ambulation and regular exercise *to promote circulation, improve muscle strength and overall endurance, and reduce risks associated with immobility.*
- Recommend pacing (alternating activity with adequate rest periods) *to reduce fatigue and allow weakened muscles and tissues to recuperate.*
-  Refer for follow-up care, as indicated (e.g., telephone monitoring, home visit, pain management program).

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Discuss reality of recovery process and client's/SO's expectations. *Individuals are often unrealistic regarding energy and time required for healing and own abilities and responsibilities to facilitate process.*
- Demonstrate self-care skills and provide client/SO with health-related information and psychosocial support *to manage healing process.*
-  Refer to physical or occupational therapist as indicated *to address recovery needs and identify assistive devices to facilitate independence.*
-  Consult nutritionist for individual dietary plan *to meet increased nutritional needs that reflect personal situation and resources.*
-  Discuss alternative placement (e.g., convalescent or rehabilitation center, as appropriate). *Brief stay with concentrated support and therapy may speed recovery and return to home.*
-  Identify community resources (e.g., visiting nurse, home healthcare agency, wound care, Meals on Wheels, respite care). *Facilitates adjustment to home setting.*

DOCUMENTATION FOCUS**Assessment/Reassessment**

- Assessment findings, including status of wound healing, individual concerns, family involvement and support factors, availability of resources.
- Cultural expectations.
- Assistive device use or need.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses of client/SO(s) to plan, interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

risk for Surgical Site Infection

Taxonomy II: Safety/Protection—Class 1 Infection (002466) [Diagnostic Division: Safety], Approved 2016

DEFINITION: Susceptible to invasion of pathogenic organisms at surgical site, which may compromise health.

RISK FACTORS

Alcoholism
Obesity
Smoking

At Risk Population: Cold temperature of operating room

Excessive number of personnel present during surgical procedure

Surgical wound contamination; increased environmental exposure to pathogens

Suboptimal American Society of Anesthesiologists (ASA) physical health status score

Associated Condition: Comorbidity; diabetes mellitus; hypertension; post-traumatic osteoarthritis; rheumatoid arthritis

Type of surgical procedure; duration of surgery; type of anesthesia

Immunosuppression; infections at other surgical sites
 Inadequate or ineffective antibiotic prophylaxis
 Invasive procedure; use of implants and/or prostheses

Sample Clinical Applications: Surgical procedures, traumatic injuries with surgical intervention; fractures with surgical reduction

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Infection Severity: Severity of signs and symptoms of infection

Self-Management: Wound: Personal actions to manage a surgical incision, puncture, ulcer, or open wound following tissue injury

Client Will (Include Specific Time Frame)

- Be afebrile and free of signs/symptoms of infection, e.g., purulent drainage.
- Complete antibiotic therapy as directed.
- Engage in proper wound care techniques.
- Display complete healing of surgical incision.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Infection Control: Intraoperative: Preventing nosocomial infection in the operating room

Incision Site Care: Cleansing, monitoring, and promotion of healing in a wound that is closed with sutures, clips, or staples

Wound Care: Prevention of wound complications and promotion of wound healing

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Determine reason for surgical intervention (e.g., trauma, elective joint replacement, traumatic amputation, colon resection) as well as comorbid conditions (e.g., obesity, current smoking, uncontrolled diabetes/hyperglycemia, advanced age, use of immunosuppressive drugs, poor nutritional status (especially low-protein and albumin levels), renal failure, client being carrier of *methicillin-resistant* *Staphylococcus aureus* (MRSA) or other antibiotic-resistant bacterium, *that could be a factor in development of postoperative site infections and identify needed interventions.* Note: As recently as 2011, it was reported that in the United States approximately 157,500 surgical site infections (SSIs) occur after surgery each year.^{2,6}

NURSING PRIORITY NO. 2 To reduce risk of infection (Perioperatively):

-  Prepare operative site according to specific procedure per agency protocol (e.g., scrubbing with liquid antibacterial soap, swabbing with betadine or other appropriate prep). *Minimizes bacterial count at operative site.* Note: New Centers for Disease Control and Prevention (CDC) guidelines recommend skin prep in the OR should be performed using an alcohol-based agent unless contraindicated.²
- Be aware of the type(s) of surgical wound(s). *Helps in predicting client's risk of surgical site infection (SSI).* Note: The Centers of Disease Control and Prevention (CDC) has classified surgical wounds thus: "(1) Clean (Class I) not infected or inflamed at time of surgery; (2) clean-contaminated (Class II) involves entering the respiratory, gastrointestinal, genitourinary systems under controlled conditions; (3) contaminated (Class III) [including] open, fresh, accidental wounds, such as open fractures, or operations with . . . gross spillage from

the gastrointestinal tract, or incisions in which acute, non-purulent inflammation is encountered; (4) dirty-infected (Class IV) . . . is infected prior to surgical intervention, including old traumatic wounds with retained devitalized tissue or those that involve existing clinical infection or perforated viscera. . . .”¹⁻³

-  Adhere to all surgical care policies and procedures to prevent or reduce risks of infections. *Note: The Surgical Care Improvement Project (SCIP) measures focus on reduction of surgically related infections through (1) use and timing of prophylactic antibiotics for selected procedures (e.g., cardiovascular, joint arthroplasty, colon resection); (2) appropriate hair removal and skin prep; (3) serum glucose management; (4) perioperative temperature management; and (5) timely removal of urinary catheters.*^{1,4,5}
-  Review laboratory studies for systemic infections or possible localized infections. *Increased white blood cell (WBC) count may indicate ongoing infection (e.g., appendicitis, abscess) or inflammation (e.g., recent trauma).*
-  Maintain normal client temperature range as much as possible during surgery. *CDC recommends maintaining normothermia in all clients.² One study in 2011 found that patients who experienced mild hypothermia during surgery were three times more likely to have positive cultures from the surgical site.⁵*
- Identify breaks in aseptic technique and resolve immediately upon occurrence. *Contamination by environmental or personnel contact renders the operative field unsterile, thereby increasing the risk of infection.*
-  Insert drain to evacuate wound bed, as necessary, via separate incision distant from the wound; remove the drain as soon as possible.
-  Apply sterile dressings and maintain dressings according to facility protocol. *Prevents environmental contamination of fresh wound.*
-  Administer appropriate antibiotics in timely manner, as indicated. *Antibiotics may be given prophylactically for (1) selected elective surgical procedures; (2) planned in client at high-risk for infection; or (3) when procedures need to be performed in the setting of known or suspected wound contamination. SCIP guidelines require the antibiotic to be administered within 1 hour of cut time (any time skin integrity is disrupted, such as in laparoscopic procedures)² with the belief that it provides opportunity for the medication to travel through the body and be available at the surgical site at the time of incision. Note: The CDC recommends that topical antimicrobial agents not be applied to the surgical incision.²*

NURSING PRIORITY NO. 3 To reduce risk of surgical site infections (**Postoperatively**):

-  Obtain information from operating room staff regarding type of procedure performed (e.g., clean, contaminated, etc). *Different surgical types and sites may contribute to the development of infection. For example, elective procedures carry a lower risk of SSIs than do emergency procedures; cosmetic operations of the head and neck in otherwise healthy person pose a much lower risk of SSI than colon resection for cancer in elderly person with COPD and obesity.⁴*
- Determine presence and severity of comorbid conditions that may increase the incidence of surgical site infections (SSIs).
-  Practice and promote hand washing before and after contact with any client. *Hand hygiene is the single most important factor in the reduction of SSIs. Skin contaminants on the client may be transferred to the caregiver and then passed on to another client if strict adherence to hand washing is not maintained.⁷*
- Perform ongoing assessments: (1) postoperative surgical dressing and surrounding areas immediately; (2) surgical incision when dressings are removed; (3) assessment of skin surrounding the incision *to evaluate any changes and/or to monitor trends in healing.*
-  Protect primary closed incisions with a sterile dressing for 24 to 48 hr (or per surgeon instruction). Use sterile technique for wound dressing change.
- Monitor client's vital signs and skin color and warmth. *Provides information about systemic tissue perfusion, which impacts tissue healing.*
-  Monitor lab values such as hematocrit, white blood cell count, serum glucose, serum albumin. *Provides information about fluid and circulatory status, immune and endocrine systems functioning, and nutrition needs.*

-  Administer blood products and fluids, as indicated *to reduce risk of tissue health problems associated with hypoxemia, hypovolemia, and dehydration.*
-  Administer antibiotics as indicated. *Use of postoperative antibiotics is variable, and may be continued (1) if surgical wound was contaminated (either preoperatively or intraoperatively); (2) a high risk of infection is associated with the procedure (e.g., colon resection); or (3) consequences of infection are unusually severe (e.g., total joint replacement). Note: Postoperative administration of preventive systemic antibiotics beyond 24 hours has not been demonstrated to reduce the risk of SSIs.⁸*
-  Maintain adequate control of serum blood glucose levels (usually less than 180 mg/dl) in all diabetic clients and avoid hyperglycemia perioperatively. *Hyperglycemia reduces the body's natural resistance to infection.⁸*
-  Provide nutrition by appropriate route (e.g., oral, enteral, parenteral) *to promote healing and general well-being.*
- Encourage early ambulation and resumption of activities *to reduce risks associated with immobility and stasis of body fluids.*

NURSING PRIORITY NO. 4 To promote wellness (Teaching/Discharge Considerations):

-  Review client's specific surgical intervention and associated care needs *to promote client's informed self-care and reduce incidence of preventable complications.*
- Instruct client/care provider in incision care and receive return demonstration, as indicated.
- Review reportable symptoms (postdischarge) such as fever (especially if trending upward), increased pain in surgical site, hardness/redness/warmth of incision, development of drainage or change in character of drainage (e.g., from serosanguinous to blood-tinged pus). *Early intervention may prevent development of serious infectious complications.*
- Advise client to eat nutritious foods and snacks and have adequate fluid intake.
- Instruct client to get adequate rest and to increase activities gradually but steadily as tolerated.
- Ask client about home environment, support, and resources. *May reveal areas of concern (e.g., client unable to provide own incision care; has no access to nutritious food; cannot afford antibiotics).*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Assessment findings, including vital signs, pain level, lab results/serum glucose levels,
- Character of wound and status of healing.
- Self-care ability, family support.
- Availability of resources.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses of client/significant others to plan, interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

impaired Swallowing

Taxonomy II: Nutrition—Class 1 Ingestion (00103) [Diagnostic Division: Food/Fluid], Approved 1986; Nursing Diagnosis Extension and Classification Revision 1998, 2017

DEFINITION: Abnormal functioning of the swallowing mechanism associated with deficits in oral, pharyngeal, or esophageal structure or function.

RELATED FACTORS

Behavioral feeding problem
Self-injurious behavior

DEFINING CHARACTERISTICS**Subjective**

Third Stage: Esophageal

Reports “something stuck”; odynophagia [pain in esophagus on swallowing]
Food refusal; volume limiting
Heartburn; epigastric pain
Nighttime coughing or awakening

Objective

First Stage: Oral

Abnormal oral phase of swallow study
Prolonged bolus formation; tongue action ineffective in forming bolus; premature entry of bolus
Incomplete lip closure; insufficient chewing; piecemeal deglutition; food pushed out of or falls from mouth
Coughing, choking, or gagging prior to swallowing
Inability to clear oral cavity; pooling of bolus in lateral sulci; nasal reflux; drooling
Inefficient suck or nipping
Prolonged meal time with insufficient consumption

Second Stage: Pharyngeal

Abnormal pharyngeal phase of swallow study
Alteration in head position; inadequate laryngeal elevation
Choking; coughing; gagging sensation; nasal reflux; gurgly voice quality
Delayed or repetitive swallowing

Food refusal

Fevers of unknown etiology; recurrent pulmonary infection

Third Stage: Esophageal

Abnormal esophageal phase of swallow study

Difficulty swallowing

Hyperextension of head [e.g., arching during or after meals]

Repetitive swallowing; bruxism

Unexplained irritability surrounding mealtimes

Acidic-smelling breath; regurgitation; vomitus on pillow; vomiting; hematemesis

At Risk Population: Behavioral feeding problem; self-injurious behavior

Failure to thrive; developmental delay

History of enteral feeding

Prematurity

Associated Condition: Achalasia; laryngeal abnormality or defect; esophageal reflux disease

Acquired anatomic defect; oropharynx abnormality; nasopharyngeal cavity defect; tracheal or nasal defect; upper airway anomaly; congenital heart disease

Brain injury; cerebral palsy; cranial nerve involvement; conditions with significant hypotonia

Trauma; neurological problems; neuromuscular impairment

Mechanical obstruction

Sample Clinical Applications:

Brain injury/stroke, neuromuscular conditions (e.g., muscular dystrophy, cerebral palsy, Parkinson's disease, amyotrophic lateral sclerosis [ALS], Guillain-Barré syndrome), facial trauma, head/neck cancer, radical neck surgery/laryngectomy, cleft lip/palate, tracheoesophageal fistula, gastroesophageal reflux disease (GERD), dementia

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Swallowing Status: Safe passage of fluids and/or solids from the mouth to the stomach

Self-Care: Eating: Personal actions to prepare and ingest food and fluid independently with or without assistive device

Client Will (Include Specific Time Frame)

- Pass food and fluid from mouth to stomach safely.
- Maintain adequate hydration as evidenced by good skin turgor, moist mucous membranes, and individually appropriate urine output.
- Achieve or maintain desired body weight.

Sample NOC linkage:

Risk Control: Personal actions to understand, prevent, eliminate, or reduce modifiable health threats

Client/Caregiver Will (Include Specific Time Frame)

- Verbalize understanding of causative/contributing factors.
- Identify individually appropriate interventions/actions to promote intake and prevent aspiration.
- Demonstrate feeding methods appropriate to the individual situation.
- Demonstrate emergency measures in the event of choking.

(continues on page 876)

impaired Swallowing (continued)

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Swallowing Therapy: Facilitating swallowing and preventing complications of impaired swallowing

Aspiration Precautions: Prevention or minimization of risk factors in the patient at risk for aspiration

Airway Suctioning: Removal of secretions by inserting a suction catheter into the patient's oral, nasopharyngeal, or tracheal airway

NURSING PRIORITY NO. 1 To assess causative/contributing factors and degree of impairment:

-  Evaluate client's potential for swallowing problems, noting age and medical conditions (e.g., Parkinson's disease, multiple sclerosis, myasthenia gravis, other neuromuscular conditions). *Swallowing disorders are especially common in the elderly, possibly due to coexistence of variety of neurological, neuromuscular, and/or other conditions. Infants at risk include those born prematurely or born with tracheoesophageal fistula or lip and palate malformation. Persons with traumatic brain injuries often exhibit swallowing impairments regardless of gender or age.*^{1,2,13}
-  Determine current situation (e.g., intubation, surgery of head, neck, or jaw; cervical spine injury, vocal cord paralysis, problems with saliva production or management; pain with swallowing; mental or anxiety disorder) that can affect swallowing. *Note: Studies show that dysphagia has a significant impact on hospital stay and is a poor prognostic factor. Consequences include problems with nutrition, hydration, quality of life, and social issues.*^{7,12}
- Assess client's cognitive and sensory-motor functional status. *Sensory awareness, orientation, concentration, and motor coordination affect desire and ability to swallow safely and effectively.*⁴
- Note voice quality and speech. *Abnormal voice (dysphonia) and abnormal speech patterns (dysarthria) are signs of motor dysfunction of structures involved in oral and pharyngeal swallowing.*¹
- Note symmetry of facial structures and muscle tone. Assess strength and excursion of muscles involved in chewing and swallowing.
- Note hyperextension of head or arching of neck during or after meals or repetitive swallowing, *which suggests inability to complete swallowing process.*
-  Determine infant's ability to initiate and sustain effective suck. *Weak suck results in inefficient nipple, suggesting ineffective movement of tongue and mouth muscles, impairing ability to swallow.*² Refer to ND ineffective infant Feeding Pattern.
- Ascertain presence and strength of cough and gag reflex. *Although absence of gag reflex is not necessarily predictive of client's eventual ability to swallow safely, it does increase client's potential for aspiration (overt or silent).*¹ *Coughing, drooling, double swallowing, decreased ability to move food in mouth, and throat clearing with or after swallowing is indicative of swallowing dysfunction and increases risk for aspiration.*¹
- Auscultate breath sounds to evaluate the presence of aspiration, especially if client is coughing with intake or has a "gurgly" or "gargly" voice.
- Inspect oropharyngeal cavity for edema, inflammation, and altered integrity of oral mucosa or structures (e.g., lesions or tumors of the mouth or oral cavity and throat).^{1,3}
- Evaluate state of dentition (e.g., poor or missing teeth, ill-fitting dentures) and adequacy of oral hygiene.
-  Review medications that may affect (1) oropharyngeal function (e.g., benzodiazepines, neuroleptics, anti-convulsants, certain sedatives), (2) esophageal function (e.g., NSAIDs, iron preparations, tetracycline, calcium channel blockers), or (3) medications that can cause xerostomia (e.g., anticholinergics, opioids, antidepressants, antineoplastics, diuretics), thus impairing swallowing by means of sedation, pharyngeal weakness, inflammation, dry mouth, etc.¹

-  Review laboratory test results for underlying problems (e.g., complete blood count) *to screen for infectious or inflammatory conditions* or other metabolic and nutritional studies *that can affect swallowing*.⁷
-  Prepare for or assist with diagnostic testing of swallowing activity (e.g., reflex cough test, swallowing electromyography, transnasal or esophageal endoscopy, videofluorographic swallow studies; fiber-optic endoscopic examination of swallowing) *to identify the pathophysiology of swallowing disorder*.^{1,3,7}

NURSING PRIORITY NO. 2 To prevent aspiration and maintain airway patency:

-  Withhold oral feedings until appropriate diagnostic workup is completed *to determine client's individual factors causing impaired swallowing and identify specific needs*.
-  Consult with physician or dietitian regarding meeting current nutritional needs. *May need enteral (preferably by peripheral endoscopic gastrostomy tube) or parenteral feedings in order to obtain nutrition, while reducing risk of aspiration that could accompany nasogastric feedings*.⁵
- Move client to chair for meals, snacks, and drinks when possible; if client must be in bed, raise head of bed as upright as possible with head in anatomic alignment and slightly flexed forward during feeding. Keep client seated upright, or head of bed elevated for 30 to 45 min after feeding, if possible, *to reduce risk of regurgitation and aspiration*.^{7,9}
- Instruct client to cough and expectorate *when secretion management is of concern*.
- Have suction equipment available during initial feeding attempts and as indicated. Suction oral cavity if client cannot clear secretions *to prevent aspiration*.
- Instruct client in self-suctioning techniques, when appropriate (e.g., for drooling, frequent choking, structural changes in mouth or throat). *Promotes independence and sense of control*.

NURSING PRIORITY NO. 3 To enhance swallowing ability to meet fluid and caloric body requirements:

-  Consult with physician, speech pathologist, dysphagia specialist, gastroenterologist, or rehabilitation team, as indicated. *Therapies may consist of dietary modification, compensatory movements, medical or surgical procedures, etc. For example, medications may help with underlying condition (e.g., swallowing problem associated with Parkinson's disease), surgery (e.g., reconstructive facial surgery following trauma or to correct structural defect in infant), or esophageal dilatation when impaired sphincter function or esophageal strictures impede swallowing. Client/significant other (SO) may learn specific retraining or compensatory techniques (e.g., modifying head and neck posture, strengthening of swallowing muscles, techniques of food placement in mouth)*.^{1,3,8–10}
-  Encourage a rest period before meals *if fatigue is interfering with efforts*.
-  Provide analgesics (with caution) before feeding, as indicated, *to enhance comfort, but avoid decreasing awareness or sensory perception*.
- Implement dietary modifications as indicated:^{1,3,8–11}

Provide proper consistency of food and fluids. *Foods that can be formed into a bolus before swallowing, such as gelatin desserts prepared with less water than usual, pudding, and custard; thickened liquids (addition of thickening agent or yogurt, cream soups prepared with less water); thinned purees (hot cereal with water added) or thick drinks, such as nectars or fruit juices that have been frozen into “slush” consistency; and medium-soft boiled or scrambled eggs, canned fruit, and soft-cooked vegetables are most easily swallowed. Feed one consistency or texture of food at a time. Single-textured foods (e.g., pudding, hot cereal, pureed food) should be tolerated well before advancing to soft table foods*.⁵

Avoid milk products and chocolate, *which may thicken oral secretions and impair swallowing*, and sticky foods (e.g., peanut butter, white bread) *that are difficult to swallow or need fluids to completely swallow*.⁵

Ensure temperature (hot or cold versus tepid) of foods and fluids, *which will stimulate sensory receptors*.

Avoid pouring liquid into the mouth or “washing food down” with liquid. *May cause client to lose control of food bolus, increasing risk of aspiration. Note: To avoid posterior head tilting while drinking, some people find drinking from a straw easier than sipping from a cup (if a straw is easier, consider using a flexible*

one-way straw); if a cup is easier, consider using a “nosey” cup that is double handled and made of durable plastic.

Feed smaller, more frequent meals *to limit fatigue associated with eating efforts and to promote adequate nutritional intake.*

Determine food preferences of client and present foods in an appealing, attractive manner. *Client may make effort to overcome swallowing problems when food is appealing and desired.*

- Provide or encourage use of proper food placement, chewing, and swallowing techniques.^{1,3,8–10}

Provide cognitive cues and specific directions (e.g., remind client to open mouth, chew, or swallow), as indicated, *to enhance concentration and performance of swallowing sequence.*

Focus attention on feeding and swallowing activity by decreasing environmental stimuli, *which may be distracting during feeding. Also, if client is talking or laughing while eating, risk of aspiration is increased.*⁶

Position client on the unaffected side when appropriate, placing food in this side of mouth and having client use the tongue *to assist with managing the food when one side of the mouth is affected (e.g., hemiplegia).*

Manage size of bites—use a small spoon or cut all solid foods into small pieces (e.g., *small bites 1/2 tsp or less are usually easier to swallow*).

Place food midway in oral cavity *to adequately trigger the swallowing reflex.*

-  Massage the laryngopharyngeal musculature (sides of trachea and neck) gently (when prescribed) *to stimulate swallowing.*

Observe oral cavity after each bite and have client check around cheeks with tongue for remaining or unswallowed food *to prevent overloading mouth with food and reduce risk of aspiration.*

Allow ample time for eating (feeding). Incorporate client's eating style and pace when feeding *to avoid fatigue and frustration with process.*

Remain with client during meal *to reduce anxiety and provide assistance if needed.*

Provide positive feedback for client's efforts. *Encourages continuation of efforts and attainment of goals.*

Discontinue feeding and remove any food from mouth if client choking or unable to swallow *to reduce potential for aspiration.*

- Provide oral hygiene following each feeding *to clear mouth of retained food particles and reduce risk of infection and dental carries.*
- Monitor intake, output, and body weight *to evaluate adequacy of fluid and caloric intake and need for changes to therapeutic regimen.*
-  Discuss use of tube feedings or parenteral solutions as indicated *for the client unable to achieve adequate nutritional intake.*
-  Refer to lactation counselor or support group (e.g., La Leche League) *for breastfeeding guidance and problem-solving.* Refer to NDs ineffective Breastfeeding and ineffective infant Feeding Pattern for additional interventions for infants.

NURSING PRIORITY NO. 4 To promote safe swallowing (Teaching/Discharge Considerations):

-   Consult with nutritionist *to establish optimum dietary plan considering specific pathology, nutritional needs, and available resources.* Refer to ND risk for imbalanced Nutrition: less than body requirements.
- Establish routine schedule for obtaining weight (same time of day and same clothes) and specific weight loss or gain to be reported to primary care provider. *Facilitates timely intervention to change regimen as needed.*
-  Consult with pharmacist *to determine if pills may be crushed or if liquids or capsules are available.* Administer medication in gelatin, jelly, or puddings as appropriate.
- Instruct client and/or SO in specific feeding and swallowing techniques. *Enhances client safety and independence.*
- Instruct client/SO in emergency measures in event of choking *to prevent aspiration or more serious complications.*
- Encourage continuation of facial exercise program *to maintain or improve muscle strength.*

- Recommend avoiding food intake within 3 hr of bedtime, eliminating alcohol and caffeine intake, reducing weight if needed, using stress-reduction techniques, and elevating head of bed during sleep *to limit potential for gastric reflux and aspiration.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including degree and characteristics of impairment, current weight and recent changes, and nutritional status.
- Effects on lifestyle and socialization.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Available resources and specific referrals made.

risk for Thermal Injury

Taxonomy II: Safety/Protection—Class 5 Physical Injury (00220) [**Diagnostic Division:** Safety], Approved 2010; Revised 2013, 2017

DEFINITION: Susceptible to extreme temperature damage to skin and mucous membranes, which may compromise health.

RISK FACTORS

Inadequate supervision

Inadequate protective clothing [e.g., flame-retardant sleepwear, gloves, ear coverings]

Fatigue; inattentiveness

Insufficient knowledge of safety precautions; unsafe environment

Smoking

At Risk Population: Extremes of age

Extremes of environmental temperature

Associated Condition: Alcohol or drug intoxication

Alteration in cognitive functioning

Neuromuscular impairment; neuropathy

Treatment regimen

Sample Clinical Applications: Burns, face and head trauma, surgical procedure, radiation therapy, neonatal jaundice, frostbite, dementia/Alzheimer's, attempted suicide

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Tissue Integrity: Skin & Mucous Membrane: Structural intactness and normal physiological function of skin and mucous membranes

Risk Control: Personal actions to understand, prevent, eliminate, or reduce modifiable health threats

Client/Caregivers Will (Include Specific Time Frame)

- Be free of damage to skin or mucous membranes associated with extreme temperatures.
- Demonstrate behaviors and lifestyle changes to reduce risk factors and protect from injury.

ACTIONS/INTERVENTIONS

[This ND is a compilation of a number of situations that can result in injury. Refer to specific NDs, such as Hypothermia, risk for Injury; impaired Skin Integrity; impaired Tissue Integrity; and risk for physical Trauma, as appropriate, for more specific interventions.]

Sample NIC linkages:

Skin Surveillance: Collection and analysis of patient data to maintain skin and mucous membrane integrity

Risk Identification: Analysis of potential risk factors, determination of health risks, and prioritization of risk reduction strategies for an individual or group

NURSING PRIORITY NO. 1 To identify causative/precipitating factors related to risk:

- Identify client at risk (e.g., chronic illness conditions with weakness, prolonged immobility; acute or chronic confusion, mental illness, dementia, head injury; cultural, familial, and socioeconomic factors adversely affecting lifestyle and home; exposure to environmental chemicals).

-   Note chronological and developmental age of client. *Infants, young children, disabled, and debilitated aged or impaired individuals are not able to protect themselves and may not recognize and/or react appropriately in dangerous situations. Safe Kids Worldwide reported that in the United States in 2013, more than 126,000 children across the country (including more than 67,000 children age 4 and under) were injured due to a fire or burn.*^{1,14}
- Evaluate client's/significant other's (SO's) level of cognition, competence, decision-making ability, and independence. *Determines ability to attend to safety issues.*
-  Ascertain if client is using alcohol/other drugs or medications *that could impair ability to act in best interest of self or others.*
- Evaluate client's lifestyle practices, noting reports of risk-prone behavior (e.g., smoking in bed, failure to use safety equipment when working with chemicals, allowing child to play with matches, unprotected exposure to sun or cold environment) *that can place client or others at high risk for injury.*
- Ascertain knowledge of safety needs and injury prevention, as well as motivation to prevent injury. *Information may reveal areas of misinformation, lack of knowledge, and need for teaching.*

NURSING PRIORITY NO. 2 To assist client/caregiver to reduce or correct individual risk factors:

- Provide client/SO information regarding client's specific situation and consequences of continuing unsafe behaviors *to enhance decision making, clarify expectations and individual needs.*
- Review client's physical and psychological abilities or limitations *to determine adaptations that may be required by current situation.*
-  Provide for client's safety while in facility care (e.g., apply hot and cold treatments judiciously, prevent/monitor smoking, supervise bath temperature in confused individuals, young children or elder adults, etc.) *to reduce risk of dermal injury.*
- Ensure client safety during **surgical procedures**:
 -  Conduct a fire risk assessment at beginning of each surgical procedure, and continuously monitor for changes in risk during procedure. *The highest risks involve an ignition source (such as electrocautery device), delivery of supplemental oxygen, and the operation of the ignition source near the oxygen (e.g., head, neck, or upper chest surgery).*^{2,4}
 -  Provide supplemental oxygen safely, using the lowest concentration possible. Use a closed oxygen delivery system (e.g., endotracheal tube) when higher concentrations of oxygen are needed *to reduce amount of oxygen flowing into surgical field.*^{2,4}
 -  Verify electrical safety of equipment, including intact cords, grounds, and medical engineering verification labels. *Malfunction of equipment can occur during the operative procedure, causing burn injury or death. Note: Ignition sources include, but are not limited to, electrosurgery or electrocautery units and lasers.*^{3,4}
 -  Place dispersive electrode (electrocautery pad) over largest available muscle mass closest to surgical site, ensuring its contact. *Provides for shortest distance and maximum conductivity to ground to prevent electrical burns.*⁴
 -  Ascertain that alcohol-containing skin prep solutions are not pooled under client or in surgical drapes and had sufficient drying time *to prevent sparking with electrocautery equipment activated.*^{2,3}
 -  Protect surrounding skin and anatomy appropriately when laser equipment is used in surgical procedures, utilizing wet towels, sponges, dams, and cottonoids *to prevent inadvertent skin integrity disruption, hair ignition, and adjacent anatomy injury. Surgical drapes should be configured to minimize the accumulation of oxidizers (oxygen and nitrous oxide) under the drapes and from flowing into the surgical site.*⁴

Apply eye protection before laser activation. *Eye protection for specific laser wavelength must be used to prevent injury.*⁴
-  Implement skin care protocol for client receiving **radiation therapy**:
Assess skin frequently for side effects of therapy; note breakdown and delayed wound healing. Emphasize importance of reporting open areas to caregiver. *A reddening and/or tanning effect (radiation dermatitis) may develop within the field of radiation.*⁵

Avoid rubbing the skin or use of soap, lotions, creams, ointments, powders, or deodorants on area; avoid applying heat or attempting to wash off marks/tattoos placed on skin to pinpoint location for radiation therapy. *These factors can potentiate or otherwise interfere with radiation delivery and may increase dermal reaction.*⁵

-   Avoid application of lotion or oils to skin of infants receiving **phototherapy** for hyperbilirubinemia to prevent dermal injury, and cover male groin with small pad to protect testes from heat-related injury.⁶
-   Provide or instruct in proper care of skin surfaces during exposure to very cold or hot weather. *Although everyone is at risk for frostbite or sunburn, individuals with impaired sensation or cognition and infants/young children require special attention to deal with extremes in weather (e.g., wearing gloves, boots, a face mask, and goggles when out in very cold weather to avoid frostbite; using sunscreen, limiting time in sun, and wearing light clothing to protect from dermal injury in summer).*⁷
-  Discuss importance of self-monitoring of factors that can contribute to occurrence of injury (e.g., fatigue, anger). *Client/significant other (SO) may be able to modify risk through monitoring of actions or postponement of certain actions, especially during times when client is likely to be highly stressed.*
-  Perform home assessment, if indicated to address safety issues. *Concerns vary widely and may include evaluation of fire alarms or extinguisher function, safe use of oxygen, checking hot water temperature, or obtaining medical alert device or home health services.*
-  Review specific employment concerns or worksite issues and needs (e.g., properly fitting safety equipment, regular use of safety glasses or goggles, safe storage of hazardous substances).
-   Discuss need for and refer to sources of supervision (e.g., before- and after-school programs for children, elder day programs, home-care assistance) *when client or care provider is unable or unwilling to attend to safety concerns.*

NURSING PRIORITY NO. 3. To promote wellness (Teaching/Discharge Criteria):

-  Identify individual needs and resources for safety education.
-  Prevent **burn injuries** (flame, scalding, chemical, electrical, sunburn).⁸⁻¹²
 Install smoke alarms in kitchen, in every sleeping area, and on every floor of home.
 Keep space heaters away from flammable materials and from at-risk persons.
 Check all fuel-burning appliances, including fireplaces, for proper functioning.
 Store combustibles away from all heat-producing appliances.
 Prepare and practice an emergency escape plan.
-  Avoid smoking in bed. Get rid of used cigarettes carefully. *Fires caused by smoking materials are the leading cause of deaths in house fires.*⁹
 Prevent small children from playing with matches or near open flame or stove.
 Turn handles of pots and pans toward side of stove or use back burners.
 Set the temperature on water heater to 120°F or use the “low-medium” setting.
 Test water temperature before allowing child/impaired person into tub or shower.
 Use cool-water humidifiers instead of hot-steam vaporizers.
 Store cleaning supplies and other chemicals out of the reach of children to prevent chemical burns.
 Avoid storing chemicals in food or drink containers; store in original containers with intact labels.
 Wear gloves, safety glasses, and other protective clothing when handling chemicals.
-  Check electrical appliances for proper function and follow manufacturer’s safety instructions. Discard frayed or damaged electrical cords to reduce risk of electrical burn. *Note: Most electrical injuries that occur in the home are low-voltage burns and almost exclusively involve either the hands or oral cavity.*¹⁰
 Use child safety plugs in all outlets.
 Avoid using electrical appliances while showering or when in other wet environmental conditions.
 Stay out of midday sun. Avoid lengthy sun exposure/ultraviolet tanning, especially with specific disease conditions or treatments (e.g., systemic lupus, tetracycline or psychotropic drug use, radiation therapy) to reduce risk of sunburn.

-  Start protecting child from the sun when he or she is a baby, dressing infants in lightweight long pants, long-sleeved shirts, and brimmed hats that shade the neck to prevent sunburn. Sunscreen is often not used in babies under the age of 6 months. *Because children spend a lot of time outdoors playing, they get most of their lifetime sun exposure in their first 18 years.*^{11,13}
- Provide telephone numbers and other contact numbers as individually indicated (e.g., fire, police, physician).
-  Refer to resources as indicated (e.g., substance recovery, anger management, or parenting classes) to address conditions that could exacerbate risk of injury to self or others.
-  Recommend community education programs to increase awareness of safety measures and available resources.
- Identify emergency escape plans and routes for home and community to be prepared in the event of natural or human-caused disaster (e.g., fire, toxic chemical release).

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual risk factors identified.
- Client concerns or difficulty making and following through with plan.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward outcomes.

Discharge Planning

- Referrals to other resources.
- Long-term need and who is responsible for actions.

ineffective Thermoregulation

Taxonomy II: Safety/Protection—Class 6 Thermoregulation (00008) [**Diagnostic Division:** Safety], Approved 1986; Revised 2017

DEFINITION: Temperature fluctuation between hypothermia and hyperthermia.

RELATED FACTORS

Dehydration

Fluctuating environmental temperature; inappropriate clothing for environmental temperature

Inactivity or vigorous activity

DEFINING CHARACTERISTICS

Objective

Increase in body temperature above normal range; skin warm to touch; flushed skin; seizures

Reduction in body temperature below normal range; skin cool to touch; moderate pallor; mild shivering; piloerection; cyanotic nailbeds; slow capillary refill

Tachycardia; hypertension; increase in respiratory rate

At Risk Population: Extremes of age

Extremes of weight; increased body surface area-to-weight ratio; insufficient supply of subcutaneous fat

Extremes of environmental temperature

Associated Condition: Alteration in metabolic rate

Brain injury; sepsis; trauma

Condition affecting temperature regulation; decrease in sweat response; inefficient nonshivering thermogenesis

Pharmaceutical agent; sedation

Sample Clinical Applications: Prematurity, CNS trauma or diseases (e.g., stroke, brain or spinal cord injury, intracranial bleeding or surgery, Parkinson's disease, multiple sclerosis); lengthy anesthesia or sedation; prolonged cardiac arrest; infection or sepsis, major surgical procedures

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Thermoregulation: Balance among heat production, heat gain, and heat loss

Thermoregulation: Newborn: Balance among heat production, heat gain, and heat loss during the first 28 days of life

Client/Caregiver Will (Include Specific Time Frame)

- Verbalize understanding of individual factors and appropriate interventions.
- Demonstrate techniques or behaviors to correct underlying condition or situation.
- Maintain body temperature within normal limits.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Temperature Regulation: Attaining and/or maintaining body temperature within a normal range

Temperature Regulation: Perioperative: Attaining and maintaining desired body temperature throughout the surgical event

Fever Treatment: Management of symptoms and related conditions associated with an increase in body temperature mediated by endogenous pyrogens

NURSING PRIORITY NO. 1 To identify causative/contributing factors:

-  Note client's age (e.g., premature neonate, young child, aging individual), *as it can directly impact ability to maintain or regulate body temperature and respond to changes in environment.*^{1,8}
- Obtain history concerning present symptoms and correlate with previous episodes or family history and diagnostic studies. *Thermoregulation is a controlled process that maintains the body's core temperature in the range at which most biochemical processes work best (97.7°F–99.5°F [36.5°C–37°C]).*⁹
- Determine specific factors involved in current temperature fluctuation (e.g., environmental factors [such as extreme heat or cold], surgery, infectious process, effects of drugs or toxins, brain or spinal cord injury; behaviors that can increase risk of exposure such as alcoholism, illicit drug use; homelessness). *Thermoregulation is affected in two ways: (1) endogenous factors (via diseases or conditions of body/organ systems that affect temperature homeostasis) and (2) exogenous factors (via environmental exposures, medications, and nutrition).*^{6,10}
Note: Understanding the current situation helps to determine the scope of interventions that may be needed (e.g., simple addition of warm blankets during or after surgery, hypothermia therapy following brain trauma).
-  Review lab results (e.g., tests indicative of infection, thyroid or other endocrine tests, drug screens) to identify potential internal causes of temperature imbalances.

NURSING PRIORITY NO. 2 To assist with measures to correct/treat underlying cause:

-   Monitor temperature by appropriate route (e.g., tympanic, rectal, oral), using the same site and device over time and noting variation from client's usual or normal temperature. *Oral temperature measurement has been shown to be more accurate than tympanic, axillary, or chemical dot thermometers. Rectal and tympanic temperatures most closely approximate core temperature; however, shell temperatures (oral, axillary, touch) are often measured at home and are predictive of fever or subnormal temperatures. Rectal temperature measurement may be the most accurate but is not always expedient (e.g., client declines, is agitated, has rectal lesions or surgery, parent is unskilled or uncomfortable with using rectal thermometer on child). Abdominal temperature monitoring may be done in the premature neonate.*^{3,6,7}
-  Collaborate in treatment of underlying conditions (e.g., sepsis, spinal cord injury, hormonal imbalances, severe malnourishment, dehydration) *that can cause or contribute to body temperature disturbances.*
- Ensure that cooling and warming equipment and supplies are readily available during childbirth and following procedures or surgery *to maintain or restore body temperature within normal range.*
-   Initiate emergent or immediate interventions, such as cooling or warming measures, fluids, electrolytes, supplemental oral or enteral nutrition, medications (e.g., antipyretics, antibiotics), as indicated, *to restore body temperature within client's usual range, and to optimize organ function.*^{1–4}
-   Place newborn infant under radiant warmer, cover infant's head with cap, and use layers of lightweight blankets. *Newborns/infants have temperature instability, especially premature or very low-birth-weight infants. Heat loss is greatest through the head and by evaporation and convection.*⁵
- Maintain and instruct care providers to environmental temperature in comfortable range *to prevent or compensate for client's heat production or heat loss (e.g., may need to add or remove clothing or blankets, avoid drafts, reduce or increase room temperature and humidity).*
-   Ensure that elderly or fragile, high-risk, and debilitated client is evaluated for nutritional deficits, environmental safety, need for social or psychiatric interventions (e.g., need for home health assistance, referral for social services or substance abuse treatment). *Client needs may extend beyond what can be immediately met and require referral for long-term interventions and follow-up.*
- Refer to NDs risk for ineffective Thermoregulation, Hypothermia, or Hyperthermia for additional interventions.

NURSING PRIORITY NO. 3 To promote optimal body temperature (Teaching/Discharge Considerations):

-  Review causative or related factors with client/significant others (SOs). *Provides information about what, if any, measures can be implemented to protect client from harm or limit potential for problems associated with ineffective thermoregulation.*

- ∞ Review home management of temperature fluctuations in special population (e.g., newborn infant, person with spinal cord injury, frail elder). *Measures could include use of heating pads or ice bags, radiant heaters or fans, adding or removing clothing or blankets, cool or warm liquids and bath water, occlusive wrap in the delivery room, skin-to-skin contact in newborn, etc.*²⁻⁴
- Discuss with client/caregivers appropriate dressing for environment or weather conditions, as indicated, such as:
Wearing layers of clothing that can be removed or added as needed;
Donning hat and gloves in cold weather;
Using water-resistant outer gear to protect from wet weather chill; and
Dressing in light, loose protective clothing in hot weather.
- Provide oral and written information concerning client's disease processes, current therapies, and postdischarge precautions regarding hypothermia or hyperthermia, as appropriate to situation. *Allows for review of instructions for early intervention and implementation of preventive or corrective measures.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including nature of problem, degree of impairment, or fluctuations in temperature.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

risk for ineffective Thermoregulation

Taxonomy II: Safety/Protection—Class 6 Physical Injury (00274) [**Diagnostic Division:** Safety], Approved 2016

DEFINITION: Susceptible to temperature fluctuation between hypothermia and hyperthermia, which may compromise health.

RISK FACTORS

Dehydration

Fluctuating environmental temperature; inappropriate clothing for environmental temperature

Inactivity or vigorous activity

Increase in oxygen demand

At Risk Population: Extremes of age

Extremes of weight; increased body surface area-to-weight ratio; insufficient supply of subcutaneous fat

Extremes of environmental temperature

Associated Condition: Alteration in metabolic rate

Brain injury; sepsis; trauma

Condition affecting temperature regulation; decrease in sweat response; inefficient nonshivering thermogenesis

Pharmaceutical agent; sedation

Sample Clinical Applications: Prematurity, brain injury, CVA, intracranial surgery (cerebral edema), infection or sepsis, major surgical procedures

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Thermoregulation: Balance among heat production, heat gain, and heat loss

Thermoregulation: Newborn: Balance among heat production, heat gain, and heat loss during the first 28 days of life

Client Will (Include Specific Time Frame)

- Maintain body temperature within normal limits.
- Verbalize understanding of risk factors and appropriate interventions.
- Demonstrate techniques or behaviors to correct underlying conditions or prevent hyperthermia or hypothermia.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Risk Identification: Analysis of potential risk factors, determination of health risks, and prioritization of risk reduction strategies for an individual or group

Temperature Regulation: Attaining or maintaining body temperature within a normal range

NURSING PRIORITY NO. 1 To identify causative/risk factors present:

- Note presence of condition that can affect body's heat production and heat dissipation (e.g., brain or spinal cord injury; burns or skin diseases; cardiac or endocrine disorders; neurological disorders, such as Parkinson's disease; kidney disease; being significantly overweight or underweight).^{2,3}
- ∞ Note client's age (e.g., premature neonate, young child, aging individual), *as it can directly impact ability to maintain or regulate body temperature and respond to changes in environment.*^{1,4,5}

- Determine specific factors involved in current temperature fluctuation (e.g., environmental factors, surgery, infectious process, effects of drugs or toxins, brain or spinal cord injury). *Thermoregulation is affected in two ways: (1) endogenous factors (via diseases or conditions of body/organ systems that affect temperature homeostasis) and (2) exogenous factors (via environmental exposures, medications, and nutrition).*
-  Review lab results (e.g., tests indicative of infection, thyroid, or other endocrine tests, drug screens) to identify potential internal causes of temperature imbalances.
- Assess nutritional status to determine metabolism effect on body temperature and to identify foods or nutrient deficits that affect metabolism.

NURSING PRIORITY NO. 2 To prevent occurrence of temperature alteration:

-  Monitor temperature regularly, measuring core body temperature whenever needed to observe this vital sign. Exercise care in selecting appropriate thermometer for client's age and clinical condition, and observe for inconsistencies in readings obtained with various instruments. Observe temperature reading for trends, and avoid basing therapeutic decisions solely on thermometer readings. *Traditionally, temperature measurements have been taken orally (good in alert, oriented adults), rectally (accurate, but not always easy to obtain), or axillary (readings may be lower than core temperature), with each site offering advantages and disadvantages in terms of accuracy and safety. Newer technologies allow temperatures to be instantly measured. Tympanic temperature measurement is a noninvasive way to measure core temperature, as blood is supplied to the tympanic membrane by the carotid artery.*^{3,5-8}
- Maintain comfortable ambient environment to reduce effect on body temperature alterations: Provide environmental heating or cooling measures, as needed, such as space heater or air conditioner or fans.
-  Ascertain that cooling and warming equipment and supplies are available during or following procedures and surgery.
- Dress or discuss with client/caregivers appropriate dressing for client's condition:^{2,6} Wear layers of clothing that can be removed or added as needed. Wear hat and gloves in cold weather; wear light, loose protective clothing in hot weather; and wear water-resistant outer gear to protect from changes in weather or wet weather chill.
-  Cover infant's head with knit cap, use layers of lightweight blankets, and provide for skin-to-skin contact with mother. Place newborn infant under a radiant warmer. Teach parents to dress infant appropriately for weather and home environment. *Newborns/infants, especially very low-weight neonates, can have temperature instability, with heat loss greatest through head and by evaporation and convection.*⁷
-  Limit clothing or remove blanket from premature infant placed in incubator to prevent overheating in climate-controlled environment.
- Maintain adequate fluid intake. Offer cool or warm liquids, as appropriate. *Hydration assists in maintaining normal body temperature. Note: Ambient temperature affects how much heat is lost through the skin and airways.*^{2,3,4}
-  Maintain core temperature within client's normal range. (If temperature is below or above normal range, or parameters defined by physician, refer to NDs Hypothermia or Hyperthermia for additional interventions.)
-  Recommend lifestyle changes, such as cessation of substance use, normalization of body weight, nutritious meals, or regular exercise to maximize metabolism and general health.⁴
-  Refer at-risk persons to appropriate community resources (e.g., home care, social services, Foster Adult Care, housing agencies) to provide assistance to meet individual needs.⁵

NURSING PRIORITY NO. 3 To promote optimal body temperature (Teaching/Discharge Considerations):

-  Review potential problem or individual risk factors with client/significant others (SOs). *Provides information about what, if any, measures can be implemented to protect client from harm or limit potential for problems associated with ineffective thermoregulation.*
-  Discuss effects of age and gender with client/caregiver, as appropriate. *Older or debilitated persons, infants, and young children typically feel more comfortable in higher ambient temperatures. Women notice*

feeling cool quicker than men, which may be related to body size or to differences in metabolism and the rate that blood flows to extremities to regulate body temperature.^{4,5}

- Instruct in measures to protect from identified risk factors. *Provides understanding for ways in managing life-style and environment (e.g., adding or removing clothing, adding or removing heat sources, evaluating home or shelter for ability to manage heat and cold, addressing nutritional and hydration status) and enhances self-care abilities.*
-  Review client's medications for possible thermoregulatory side effects (e.g., diuretics, certain sedatives and antipsychotic agents, anticholinergics, anticonvulsants, some heart and blood pressure medications, anesthesia).⁹
-  Review home management of temperature fluctuations in special population (e.g., newborn infant, person with spinal cord injury, frail elder). *Measures could include use of heating pads or ice bags, radiant heaters or fans, adding or removing clothing or blankets, cool or warm liquids and bath water, etc.*^{1,6-8}
- Provide oral and written information concerning client's disease processes, current therapies, and postdischarge precautions regarding hypothermia or hyperthermia, as appropriate to situation. *Allows for review of instructions for early intervention and implementation of preventive or corrective measures.*
- Refer to teaching section in NDs ineffective Thermoregulation, Hypothermia, or Hyperthermia for related interventions as appropriate.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Identified individual risk factors.
- Record of core temperature, initially and prn.

Planning

- Plan of care and who is involved in planning.
- Teaching plan, including best ambient temperature and ways to prevent hypothermia or hyperthermia.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions.
- Specific referrals made.

risk for venous Thromboembolism

Taxonomy II: Safety/Protection—Class 2 Physical Injury (00268) [**Diagnostic Division:** Safety], Approved 2016

DEFINITION: Susceptible to the development of a blood clot in a deep vein, commonly in the thigh, calf, or other extremity, which can break off and lodge in another vessel, which may compromise health.

RISK FACTORS

Dehydration

Impaired mobility

Obesity

At Risk Population: Age >60 years

Critical care admission

Current smoker

First-degree relative with history of venous thromboembolism; history of previous venous thromboembolism; history of cerebral vascular accident (CVA)

Less than 5 weeks postpartum

Associated Condition: Cerebral vascular accident (CVA); current cancer diagnosis; significant medical comorbidity; thrombophilia

Trauma below the waist or upper extremity; varicose veins

Postoperative for major or orthopedic surgery; surgery and total anesthesia time >90 minutes

Use of estrogen-containing contraceptive or hormone replacement therapy

Sample Clinical Applications: Cerebral vascular accident (CVA); current cancer diagnosis; pelvic trauma; upper or lower extremity crush injuries; orthopedic surgery; varicose veins.

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Knowledge: Thrombus Threat Reduction: Extent of understanding conveyed about causes, prevention, and early detection of blood clots within the circulatory system

Tissue Perfusion: Peripheral: Adequacy of blood flow through the small vessels of the extremities to maintain tissue function

Client Will (Include Specific Time Frame)

- Identify individual risk factors.
- Develop plan to reduce risk factors.
- Engage in activities/lifestyle changes to prevent thrombus/thromboembolism.
- Be free of signs/symptoms of thrombosis, e.g., extremity pulses/capillary refill equal bilaterally, free of erythema, edema, pain.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Embolus Precautions: Reduction of the risk of an embolus in a patient with thrombi or at risk for thrombus formation

NURSING PRIORITY NO. 1 To identify causative/risk factors

- Identify client at risk. *Conditions may include (1) past history of venous thromboembolism (VTE) or cessation of recent anticoagulant therapy or (2) predisposing factors (e.g., major surgery [especially orthopedic],*

trauma, extended travel; prolonged immobilization for any cause; spinal cord injury; pregnancy [especially when pregnant client has several conditions, including gestational hypertension, preeclampsia and eclampsia, cardiomyopathy, amniotic fluid embolism (not a complete listing)] use of oral contraceptives; valvular heart disease, heart failure, stroke; certain cancers or ongoing cancer treatments; clients requiring critical care for extended periods, indwelling central venous catheter use).^{2,3}

- Evaluate client reports of calf pain or chest pain *symptoms that can be associated with VTE event.*
- Examine extremities in at-risk client *for signs potentially associated with development of deep vein thrombosis (DVT), such as asymmetry of calves, edema, changes in skin color, obvious tissue injury, prominent veins.*
- Note client reports of shortness of breath.
-  Review results of laboratory studies (such as hematocrit, coagulation profile, d-dimer assay). *Abnormalities in these tests (and others) point toward conditions associated with VTE, such as dehydration or clotting defects or other thrombotic processes.*¹

NURSING PRIORITY NO. 2 To reduce risk/prevent VTE

-  Initiate active or passive exercises while in bed or chair; for example, flex, extend, and rotate feet periodically.
- Promote early ambulation after any acute illness, surgery, or trauma
- Elevate legs when in bed or chair as indicated *to reduce edema*
- Caution client to avoid crossing legs or hyperflexing knee, such as when seated position with legs dangling, or lying in jackknife position.
- Increase fluid intake to at least 1500 to 2000 mL/day, within cardiac tolerance.
-  Apply elastic support hose, compression stockings, or sequential compression devices, if indicated.
-  Collaborate in treatment of underlying conditions *to manage/treat conditions that can cause or exacerbate risk of thromboembolism.*
-  Provide DVT prophylaxis protocol, if indicated, and progressive mobility protocol where available. *While a prophylactic regimen of intermittent compression devices and chemical DVT prophylaxis is often standard practice in trauma intensive care units, studies suggest an additional benefit in VTE reduction with a focused progressive mobility protocol for this patient population.*²

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Instruct client/SO about client's particular condition and risk factors.
- Recommend continuation of prescribed treatments, exercises, and other measures to prevent immobility and stasis of body fluids.
- Review position recommendations, such as sitting with feet touching the floor, avoiding crossing of legs. *Prevents excess pressure on the popliteal space and enhances venous return.*
- Problem-solve solutions to predisposing factors that may be present, such as employment that requires prolonged standing or sitting, wearing restrictive clothing, use of oral contraceptives, obesity, prolonged immobility, smoking, and dehydration. *Actively involves client in identifying and initiating lifestyle and behavior changes to promote health and prevent recurrence of condition or development of complications.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual risk factors identified.
- Client concerns or difficulty making and following through with plan.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward outcomes.

Discharge Planning

- Referrals to other resources.
- Long-term need and who is responsible for actions.

impaired Tissue Integrity

Taxonomy II: Safety/Protection—Physical Injury 00044 [**Diagnostic Division:** Safety], Approved 1986; Revised 1998, 2013, 2017

DEFINITION: Damage to the mucous membrane, cornea, integumentary system, muscular fascia, muscle, tendon, bone cartilage, joint capsule, and/or ligament.

RELATED FACTORS

Imbalanced nutritional state [e.g., obesity, emaciation]
 Chemical injury agent; high-voltage power supply; mechanical factor
 Excessive or insufficient fluid volume; impaired circulation
 Humidity
 Insufficient knowledge about maintaining or protecting tissue integrity

DEFINING CHARACTERISTICS**Subjective**

Acute pain

Objective

Bleeding; hematoma
 Destroyed or damaged tissue
 Localized area hot to touch; redness

At Risk Population: Extremes of age
 Extremes of environmental temperature
 Exposure to high-voltage power supply

Associated Condition: Alteration in metabolism
 Alteration in sensation; peripheral neuropathy; impaired mobility
 Arterial puncture; impaired circulation; vascular trauma
 Radiation therapy; surgical procedure
 Pharmaceutical agent

Sample Clinical Applications: Abscess, abuse (physical); traumatic injuries, amputation, anemias, burns, cataracts, deep vein thrombosis; diabetes; falls, frostbite; glaucoma, Parkinson's disease, poisoning; substance abuse, malnutrition; vascular occlusive disease

[Note: In reviewing this ND, it is apparent there is much overlap with other diagnoses. We have chosen to present generalized interventions. Although there are commonalities to injury situations, we suggest that the reader refer to other primary diagnoses as indicated, such as risk for Bleeding; risk for Contamination; risk for corneal Injury; risk for Dry Eye; risk for Falls; ineffective Health Maintenance; impaired Home Maintenance; risk for Infection; risk for Injury; impaired physical Mobility; risk for impaired oral Mucous Membrane Integrity; impaired/risk for impaired Parenting; ineffective Protection; risk for Poisoning; impaired/risk for impaired Skin/Tissue Integrity; risk for Surgical Site Infection; delayed/risk for delayed Surgical Recovery; risk for Perioperative Positioning Injury; risk for Pressure Ulcer; ineffective Tissue Perfusion; risk for Thermal Injury; risk for physical Trauma; risk for self- and other-directed Violence; risk for vascular Trauma for additional interventions.]

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Tissue Integrity: Skin & Mucous Membranes: Structural intactness and normal physiological function of skin and mucous membranes

Tissue Perfusion: Peripheral: Adequacy of blood flow through the small vessels of the extremities to maintain tissue function

Client/Caregiver Will (Include Specific Time Frame)

- Verbalize understanding of condition and causative factors.
- Identify interventions appropriate for specific condition.
- Demonstrate behaviors or lifestyle changes to promote healing and prevent complications.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Wound Care: Prevention of wound complications and promotion of wound healing

Incision Site Care: Cleansing, monitoring, and promotion of healing in a wound that is closed with sutures, clips, or staples

NURSING PRIORITY NO. 1 To identify causative/contributing factors:

-  Identify underlying conditions or pathology. Assess for individual factors *that can result in tissue damage or can impede healing, such as (1) trauma that causes internal tissue damage* (e.g., burns, high-velocity and penetrating trauma) and fractures (especially long-bone fractures) with hemorrhage, (2) **external pressures** (e.g., from tight dressings, splints or casting, burn eschar), (3) **immobility** (e.g., long-term bedrest, traction/cast), (4) presence of **conditions affecting peripheral circulation and sensation** (e.g., atherosclerosis, diabetes, venous insufficiency), (5) **lifestyle factors** (e.g., smoking, obesity, sedentary lifestyle), (6) **use of medications** (e.g., anticoagulants, corticosteroids, immunosuppressives, antineoplastics) that adversely affect healing, (7) **malnutrition** (deprives the body of protein and calories required for cell growth and repair), and (8) **dehydration** (impairs transport of oxygen and nutrients).^{1-4,11,13,26}

-  Note age, developmental stage, and gender. *Children, young adults, elderly persons, and men are at greater risk for injury, which may reflect client's ability or desire to protect self and influences choice of interventions or teaching.*^{21,22}
-  Determine mechanism of traumatic injury where indicated (e.g., chemical burn affecting skin, mucous membranes; electrical/high-voltage injury, car crash, gunshot wound; environmental exposure to toxins or extreme temperatures). *Suggests initial treatment options and potential for tissue damage. Note: Information should include type of injuring agent (e.g., acid or base with route and length of exposure to offending agent; fire; penetration of contaminated object; possibility of coexisting injuries).*²⁶
- Assess skin and mucous membranes for color, temperature, and sensation for *adequacy of blood supply and innervation.*
- Evaluate skin and mucous membranes for hydration status; note presence and degree of edema (1+ to 4+) and urine characteristics and output. *Determines presence of circulatory or metabolic imbalances resulting in fluid deficit or overload that can adversely affect cell or tissue health and organ function. Note: Edematous tissues are prone to breakdown.* Refer to NDs risk for imbalanced Fluid Volume, impaired Skin Integrity, and risk for Pressure Ulcer.
- Examine eyes for conjunctivitis, hemorrhage, burns, abrasions, or lacerations as indicated. Note reports of dry, scratchy eye, and vision impairment or pain. *May indicate injury to eye tissues, requiring more intensive evaluation and interventions.*¹⁸ Refer to NDs risk for Dry Eye and risk for Corneal Injury for related interventions.
-  Evaluate pulses and calculate ankle-brachial index *to evaluate actual or potential for impairment of circulation to lower extremities. Result less than 0.9 indicates need for close monitoring or more aggressive intervention (e.g., tighter blood glucose and weight control in diabetic client).* Refer to NDs risk for peripheral Neurovascular Dysfunction and ineffective peripheral Tissue Perfusion.^{6,11,13}
-  Determine race and ethnic background and family history for genetic factors *that may make individual vulnerable to particular conditions (e.g., sickle cell disease impairs circulation; systemic lupus erythematosus, Marfan syndrome)* and cultural or religious beliefs and practices regarding use of folk remedies or customs *that may damage tissues or impact choice of treatment options.*
- Determine nutritional status and impact of malnutrition on situation (e.g., pressure points on emaciated or elderly client, obesity, lack of activity, slow healing or failure to heal).
- Evaluate client's health and safety practices, noting lack of cleanliness, poor oral care, lack of foot and toenail care, unsafe sexual practices, failure to use safety equipment for occupational or sports-related activities, and unprotected exposure to sun or toxic substances, *that can place client at risk for injury to tissues or impaired function.*
- Note use of prosthetic, diagnostic, or external devices (e.g., artificial limbs, contacts, dentures, endotracheal airways, indwelling catheters, esophageal dilators), *which can cause pressure on/injure delicate tissues or provide entry point for infectious agents.*¹⁰

NURSING PRIORITY NO. 2 To assess degree of impairment:

- Obtain history of condition (e.g., pressure, venous, or diabetic wound; eye or oral lesions), including whether condition is acute or recurrent, original site and characteristics of wound, and duration of problem and changes that have occurred over time.
- Assess skin and tissues, bony prominences, and pressure areas, noting color, texture, and turgor. Assess areas of least pigmentation for color changes (e.g., sclera, conjunctiva, nailbeds, buccal mucosa, tongue, palms, and soles of feet).
- Assess wound/lesion, documenting (1) location; (2) dimensions and depth in centimeters; (3) exudates—color, odor, and amount; (4) margins—fixed or unfixed; (5) tunneling/tracts (*full extent of lesions of mucous membranes or subcutaneous tissue may not be visually discernible*); and (6) evidence of necrosis (e.g., color gray to black) or healing (e.g., pink or red granulation tissue) *in order to clarify treatment needs and establish a comparative baseline.*^{3,4}

-  Classify/stage pressure ulcer(s) using an ulcer classification system, such as the Braden (or similar) scale. (See ND risk for Pressure Ulcer.) *Provides consistent terminology for risk assessment and documentation of pressure ulcers. Note: The National Pressure Ulcer Advisory Panel has updated the definition of a pressure ulcer and the stages of pressure ulcers based on current research and expert opinion. New definitions have been drafted to achieve accuracy, clarity, succinctness, clinical utility, and discrimination between and among the definitions of other pressure ulcer stages and other types of wounds. Deep tissue injury was also added as a distinct pressure ulcer in this updated system.*^{5,16,19,20}
- Remeasure and photograph wound(s) periodically to evaluate progress, development of complications, or delayed healing.¹⁷
-  Review diagnostic studies (e.g., x-rays, imaging scans, biopsies). *May be necessary to determine cause for and extent of impairment.*
-  Obtain specimens of wound exudate or lesions for culture and sensitivity, when appropriate, to identify effective antimicrobial therapies.
-  Monitor lab studies (e.g., complete blood count, electrolytes, glucose, cultures) for systemic changes indicative of infection or other systemic complications.
- Determine psychological effects of condition on the client and family. *Can be devastating for client's body or self-image and esteem—especially if condition is severe, disfiguring, or chronic—as well as costly and burdensome for SO/caregiver.*

NURSING PRIORITY NO. 3 To facilitate healing:

General^{9-11,23-25}

-  Modify or eliminate factors contributing to condition, if possible. Assist with treatment of underlying condition(s), as appropriate.
-  Provide or encourage optimum nutrition (including protein, lipids, calories, trace minerals, and multivitamins) to promote tissue health/healing. *Nutrients should include adequate protein for tissue/organ maintenance, growth and repair, good immune function, and hormone production. High-quality fats improve energy production and reduction of inflammation. Good-quality carbohydrates provide immediate energy, stable blood sugar and insulin levels.*
- Provide/encourage adequate hydration to reduce and replenish cellular water loss and enhance circulation. *Note: Dehydration can reduce tissue perfusion at a wound site by reducing the blood volume, limiting the supply of oxygen and nutrients.*
- Provide or assist with oral care (e.g., teaching oral and dental hygiene, avoiding extremes of hot or cold, changing position of endotracheal and nasogastric tubes, lubricating lips) to prevent damage to mucous membranes. Refer to ND impaired oral Mucous Membranes for related interventions.
- Encourage adequate periods of rest and sleep to promote healing and meet comfort needs.
- Promote early and ongoing mobility. Assist with or encourage position changes and active or passive and assistive exercises to promote circulation and prevent excessive tissue pressure.

Incisions/wounds^{9-12,20}

- Inspect lesions or wounds daily for changes (e.g., signs of infection, complications, or healing). *Promotes timely intervention and revision of plan of care.*
- Keep surgical area(s) clean and dry and change dressings or drainage appliances frequently, as indicated, to prevent accumulation of secretions or excretions that can cause skin and tissue excoriation.
- Practice aseptic technique for cleansing, dressing, and medicating wounds or lesions. *Reduces risk of infection and/or failure to heal.*
- Protect incision or wound approximation (e.g., use of Steri-Strips, splinting when coughing) and stimulate circulation to surrounding areas to assist body's natural process of repair.
-   Collaborate with other healthcare providers (e.g., physician, burn specialist, ophthalmologist, infection or wound specialist, ostomy nurse), as indicated, to assist with developing plan of care for problematic or potentially serious wounds. *Note: A general surgeon or burn specialist/burn center may be needed for burns*

(especially burns to hands, face, or perineum). Ophthalmological consultation is recommended for client with ocular burns from acids or bases if there is any significant degree of corneal or scleral injury. Caustic ingestions may require multiple specialties, including gastroenterology; gastrointestinal surgery; ear, nose, and throat; and surgery.²⁶

-  Apply appropriate barrier dressings or wound coverings (e.g., semipermeable, occlusive, wet-to-dry, hydrocolloid, hydrogel, polyacrylate moist wound dressing), drainage appliances, and skin-protective agents for open or draining wounds and stomas to protect the wound and surrounding tissues from excoriating secretions or drainage and to enhance healing. *Note: Recent studies are reporting that wet-to-dry dressings are beneficial only for mechanical débridement of wounds, can damage healthy granulation tissue, and can increase risk of infection.*^{11,13–15}
-  Assist with débridement or enzymatic therapy, as indicated (e.g., burns, severe pressure ulcer).
-  Provide appropriate protective and healing devices (e.g., eye pads or goggles; heel protectors, padding, cushions, gel pads; therapeutic beds and mattresses; splints, chronic ulcer dressings, compression wrap).
- Refer to NDs dependent on individual situation (e.g., risk for Peripheral Neurovascular Dysfunction, risk for Perioperative Positioning Injury, risk for Pressure Ulcer, impaired physical/bed Mobility, impaired Skin Integrity, delayed Surgical Recovery; ineffective peripheral Tissue Perfusion, risk for Trauma, risk for Infection) for related interventions.

NURSING PRIORITY NO. 4 To correct hazards/minimize impairment:^{3–5,7–10}

-  Assess IV sites on regular basis for erythema, edema, tenderness, burning, etc., which indicate infiltration or phlebitis, requiring immediate discontinuation of site use or interventions to heal the area.
- Use appropriate catheter (e.g., peripheral or central venous) when infusing anticancer or other toxic drugs, and ascertain that IV is patent and infusing well to prevent infiltration and extravasation with resulting tissue damage.
- Inspect skin and tissues routinely around incisions and cast edges and traction devices to ensure proper application and function; note possible development of pressure points.
- Remove adhesive products with care, removing on horizontal plane and using mineral oil or Vaseline for softening, if needed, to prevent abrasions or tearing of skin and damage to underlying tissues.
- Monitor for correct placement of tubes, catheters, and other devices and assess skin tissues around these devices for effects of tape or fasteners or pressure from the devices to prevent damage to skin and tissues as a result of pressure, friction, or shear forces.
- Develop regularly timed repositioning schedule for client with mobility and sensation impairments, using adequate personnel and assistive devices as needed; encourage and assist with periodic weight shifts for client in chair to reduce stress on pressure points and encourage circulation to tissues.
- Use or demonstrate proper turning and transfer techniques to avoid movements that cause friction or shearing (e.g., pulling client with parallel force, dragging movements).
- Provide appropriate mattress (e.g., foam, flotation, alternating-pressure or air mattress) and appropriate padding devices (e.g., foam boots, heel protectors, ankle rolls), when indicated, to reduce tissue pressure and enhance circulation to compromised tissues.^{13,20}
- Limit use of plastic material (e.g., rubber sheet, plastic-backed linen savers) and remove wet or wrinkled linens promptly. *Moisture potentiates skin and underlying tissues, increasing risk of breakdown and infection.*
- Avoid or restrict use of restraints; use adequate padding and evaluate circulation, movement, and sensation of extremity frequently when restraints are required. *Reduces risk of impaired circulation and tissue ischemia.*
- Elevate linens over affected extremity with bed cradle to reduce pressure on and irritation of compromised tissues.
- Encourage physical activity and exercise to stimulate circulation, enhance organ function, and prevent/limit potential complications of immobility.
- Provide or assist with oral care (e.g., oral and dental hygiene, avoiding extremes of hot or cold, change position of endotracheal/nasogastric tubes, lubricate lips) to prevent damage to oral mucous membranes. Refer to NDs impaired oral Mucous Membrane and risk for Pressure Ulcer for additional interventions.

- Encourage use of adequate clothing or covers; protect from drafts and cold environment *to prevent vasoconstriction that can compromise circulation.*
- ∞ Provide or instruct in proper care of extremities during cold or hot weather. *Individuals with impaired sensation or young children/individuals unable to verbalize discomfort require special attention to deal with extremes in weather (e.g., dressing in layers and wearing gloves, clean dry socks, properly fitting shoes or boots, and a face mask in winter; using sunscreen and wearing light clothing to protect from dermal injury in summer).*
- ☑ Advise smoking cessation and refer for resources, if indicated. *Smoking causes vasoconstriction/interferes with healing.*

NURSING PRIORITY NO. 5 To promote wellness (Teaching/Discharge Considerations):

- 🏠 Encourage verbalizations of feelings and expectations regarding condition and potential for recovery of structure and function.
- Help client and family to identify and implement successful coping skills *to reduce pain or discomforts and to improve quality of life.*
- Discuss importance of follow-up care (e.g., diabetic foot care clinic, wound care specialist, enterostomal therapist) as appropriate, self-monitoring, and reporting of changes in condition or pain characteristics. *Promotes early intervention and reduces potential for complications.*
- ∞ Educate the client/caregivers on proper safety precautions regarding hazardous materials, as indicated:²⁶ Inform client/caregivers of various substances in the home that are potentially dangerous. Counsel parents on how to keep chemicals out of the reach of children and cognitively impaired persons.
- ☑ Consult with local social services agency to evaluate child's home situation.
- ☑ Refer client to appropriate agencies for adequate training and protective equipment to protect against hazardous materials/agents in the community or employment setting.
- Review medical regimen (e.g., proper use of topical sprays, creams, ointments, soaks, or irrigations) with client/caregiver *to facilitate tissue healing and prevent complications associated with lack of knowledge about maintaining tissue integrity.*
- Identify required changes in lifestyle, occupation, or environment *necessitated by limitations imposed by condition or to avoid causative factors.*
- ☑ Refer to community or governmental resources as indicated (e.g., Public Health Department, Occupational Safety and Health Administration) *for information regarding specific conditions and to report hazards.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including history of condition, characteristics of wound or lesion, evidence of other organ or tissue involvement.
- Impact on functioning and lifestyle.
- Availability and use of resources.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

risk for impaired Tissue Integrity

Taxonomy II: Safety/Protection—Physical Injury 000248 [Diagnostic Division: Safety], Approved 2013; Revised 2017

DEFINITION: Susceptible to damage to the mucous membrane, cornea, integumentary system, muscular fascia, muscle, tendon, bone, cartilage, joint capsule, and/or ligament, which may compromise health.

RISK FACTORS

Imbalanced nutritional state [e.g., obesity, emaciation]

Chemical injury agent; high-voltage power supply; mechanical factor

Excessive or insufficient fluid volume; impaired circulation

Humidity

Insufficient knowledge about maintaining or protecting tissue integrity

At Risk Population: Extremes of age

Extremes of environmental temperature

Exposure to high-voltage power supply

Associated Condition: Alteration in metabolism

Alteration in sensation; peripheral neuropathy; impaired mobility

Arterial puncture; impaired circulation; vascular trauma

Radiation therapy; surgical procedure

Pharmaceutical agent

Sample Clinical Applications: Abscess, abuse (physical); traumatic injury, amputation, anemias, burns, cataracts, deep vein thrombosis; diabetes; falls, frostbite; glaucoma, Parkinson's disease, poisoning; substance abuse, malnutrition; vascular occlusive disease

[Note: In reviewing this ND, it is apparent there is much overlap with other diagnoses. We have chosen to present generalized interventions. Although there are commonalities to injury situations, we suggest that the reader refer to other primary diagnoses as indicated, such as risk for Bleeding; risk for Contamination; risk for corneal Injury; risk for Dry Eye; risk for Falls; ineffective Health Maintenance; impaired Home Maintenance; risk for Infection; risk for Injury; impaired physical Mobility; risk for impaired oral Mucous Membrane Integrity; impaired/risk for impaired Parenting; ineffective Protection; risk for Poisoning; impaired/risk for impaired Skin/Tissue Integrity; risk for Surgical Site Infection; delayed/risk for delayed Surgical Recovery; risk for Perioperative Positioning Injury; risk for Pressure Ulcer; ineffective Tissue Perfusion; risk for Thermal Injury; risk for physical Trauma; risk for self- and other-directed Violence; risk for Vascular Trauma for additional interventions.]

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Tissue Integrity: Skin & Mucous Membranes: Structural intactness and normal physiological function of skin and mucous membranes

Tissue Perfusion: Peripheral: Adequacy of blood flow through the small vessels of the extremities to maintain tissue function

Client/Caregiver Will (Include Specific Time Frame)

- Verbalize understanding of condition and causative factors.
- Identify interventions appropriate for specific condition.
- Demonstrate behaviors or lifestyle changes to promote healing and prevent complications or recurrence.

Sample NOC linkage:

Wound Healing: Secondary Intention: Extent of regeneration of cells and tissues in an open wound

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Wound Care: Prevention of wound complications and promotion of wound healing

Incision Site Care: Cleansing, monitoring, and promotion of healing in a wound that is closed with sutures, clips, or staples

NURSING PRIORITY NO. 1 To identify risk factors:

-  Identify underlying conditions or pathology. Assess for individual factors *that can result in tissue damage or can impede healing, such as (1) trauma that causes internal tissue damage* (e.g., burns, high-velocity and penetrating trauma) and fractures (especially long-bone fractures) with hemorrhage, (2) **external pressures** (e.g., from tight dressings, splints or casting, burn eschar), (3) **immobility** (e.g., long-term bedrest, traction/cast), (4) presence of **conditions affecting peripheral circulation and sensation** (e.g., atherosclerosis, diabetes, venous insufficiency), (5) **lifestyle factors** (e.g., smoking, obesity, sedentary lifestyle), (6) **use of medications** (e.g., anticoagulants, corticosteroids, immunosuppressives, antineoplastics) that adversely affect healing, (7) **malnutrition** (deprives the body of protein and calories required for cell growth and repair); and (8) **dehydration** (impairs transport of oxygen and nutrients).¹⁻⁷
-  Note age, developmental stage, and gender. *Children, young adults, elderly persons, and men are at greater risk for injury, which may reflect client's ability or desire to protect self, and influences choice of interventions or teaching.*^{8,9}
- Assess skin and mucous membranes for color, temperature, and sensation *for adequacy of blood supply and innervation.*
- Evaluate skin and mucous membranes for hydration status; note presence and degree of edema (1+ to 4+) and urine characteristics and output. *Determines presence of circulatory or metabolic imbalances resulting in fluid deficit or overload that can adversely affect cell or tissue health and organ function. Note: Edematous tissues are prone to breakdown.* Refer to NDs risk for imbalanced Fluid Volume, impaired Skin Integrity, and risk for Pressure Ulcer.
- Assess skin over bony prominence and pressure areas, noting color, texture, and turgor. Assess areas of least pigmentation for color changes (e.g., nailbeds, buccal mucosa, tongue, palms, soles of feet).
-  Evaluate pulses and calculate ankle-brachial index *to evaluate potential for impairment of circulation to lower extremities. Result less than 0.9 indicates need for close monitoring or more aggressive intervention (e.g., tighter blood glucose and weight control in diabetic client).*^{5,6,10} Refer to NDs risk for Peripheral Neurovascular Dysfunction and ineffective peripheral Tissue Perfusion.
- Determine nutritional status and potential impact on situation (e.g., pressure points on emaciated or elderly client, obesity, lack of activity, history of slow healing or failure to heal).
- Evaluate client's health and safety practices, noting lack of cleanliness, poor oral care, lack of foot and toenail care, unsafe sexual practices, failure to use safety equipment for occupational or sports-related activities, and unprotected exposure to sun or toxic substances, *that can place client at risk for injury to tissues.*

NURSING PRIORITY NO. 2 To facilitate healing: General^{5,11-13}

-  Assist with treatment of underlying condition(s), as appropriate.
-  Provide or encourage optimum nutrition (including protein, lipids, calories, trace minerals, multivitamins) *to promote tissue health/healing and adequate hydration to reduce and replenish cellular water loss and enhance circulation.*
- Assess IV sites on regular basis for erythema, edema, tenderness, burning, etc., *which indicate infiltration or phlebitis, requiring immediate discontinuation of site use or interventions to heal the area.*
- Use appropriate catheter (e.g., peripheral or central venous) when infusing anticancer or other toxic drugs and ascertain that IV is patent and infusing well *to prevent infiltration and extravasation with resulting tissue damage.*
- Provide or assist with oral care (e.g., teaching oral and dental hygiene, avoiding extremes of hot or cold, changing position of endotracheal and nasogastric tubes, lubricating lips) *to prevent damage to mucous membranes.* Refer to ND impaired oral Mucous Membranes for related interventions.
- Inspect skin and tissues routinely around incisions and cast edges and traction devices *to ensure proper application and function; note possible development of pressure points.*

- Remove adhesive products with care, removing on horizontal plane and using mineral oil or Vaseline for softening, if needed, *to prevent abrasions or tearing of skin and damage to underlying tissues.*
- Monitor for correct placement of tubes, catheters, and other devices and assess skin tissues around these devices for effects of tape or fasteners or pressure from the devices *to prevent damage to skin and tissues as a result of pressure, friction, or shear forces.*
- Develop regularly timed repositioning schedule for client with mobility and sensation impairments, using adequate personnel and assistive devices as needed; encourage and assist with periodic weight shifts for client in chair *to reduce stress on pressure points and encourage circulation to tissues.*
- Use or demonstrate proper turning and transfer techniques *to avoid movements that cause friction or shearing (e.g., pulling client with parallel force, dragging movements).*
- Avoid or restrict use of restraints; use adequate padding and evaluate circulation, movement, and sensation of extremity frequently, when restraints are required. *Reduces risk of impaired circulation and tissue ischemia.*
- Encourage adequate periods of rest and sleep *to promote healing and meet comfort needs.*
- Promote early and ongoing mobility. Assist with or encourage position changes and active or passive and assistive exercises *to promote circulation and prevent excessive tissue pressure.*

Incisions/Wounds^{9–15}

Inspect lesions or wounds daily for changes (e.g., signs of infection, complications, or healing). *Promotes timely intervention and revision of plan of care.*

Keep surgical area(s) clean and dry and change dressings or drainage appliances frequently, as indicated, *to prevent accumulation of secretions or excretions that can cause skin and tissue excoriation.*

Practice aseptic technique for cleansing, dressing, and medicating wounds or lesions. *Reduces risk of infection and/or failure to heal.*

Protect incision or wound approximation (e.g., use of Steri-Strips, splinting when coughing) and stimulate circulation to surrounding areas *to assist body's natural process of repair.*

 Apply appropriate barrier dressings or wound coverings (e.g., semipermeable, occlusive, wet-to-dry, hydrocolloid, hydrogel, polyacrylate moist wound dressing), drainage appliances, and skin-protective agents for open or draining wounds and stomas *to protect the wound and surrounding tissues from excoriating secretions or drainage and to enhance healing.*

Refer to NDs dependent on individual situation (e.g., risk for peripheral Neurovascular Dysfunction, risk for Perioperative Positioning Injury, risk for Pressure Ulcer, impaired physical/bed Mobility, impaired Skin Integrity, delayed Surgical Recovery, ineffective peripheral Tissue Perfusion, risk for physical Trauma, risk for Infection) *for related interventions.*

NURSING PRIORITY NO. 3 To promote wellness (Teaching/Discharge Considerations):

-  Review medical regimen (e.g., proper use of topical sprays, creams, ointments, soaks, or irrigations) with client/caregiver *to prevent complications associated with lack of knowledge about maintaining tissue integrity.*
- Discuss importance of follow-up care (e.g., diabetic foot care clinic, wound care specialist, enterostomal therapist) as appropriate, self-monitoring, and reporting of changes in condition or pain characteristics. *Reduces potential for complications.*
- Advise smoking cessation and refer for resources, if indicated. *Smoking causes vasoconstriction/interferes with healing.*
- Educate client/caregivers on proper safety precautions regarding hazardous materials, as indicated.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, characteristics of wound/incisions, etc.
- Impact on functioning and lifestyle.
- Availability and use of resources.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

ineffective peripheral Tissue Perfusion

Taxonomy II: Activity/Rest—Class 4 Cardiovascular/Pulmonary Responses (00204) [**Diagnostic Division:** Circulation], Approved 2008; Revised 2010,2017

DEFINITION: Decrease in blood circulation to the periphery which may compromise health.

RELATED FACTORS

Excessive sodium intake

Insufficient knowledge of disease process or aggravating factors

Sedentary lifestyle; smoking

DEFINING CHARACTERISTICS

Subjective

Extremity pain; intermittent claudication
Paresthesia

Objective

Decrease in or absence of peripheral pulses; ankle-brachial index <0.90 ; decrease in blood pressure in extremities; femoral bruit

Alteration in skin characteristics [e.g., color, elasticity, hair, moisture, nails, sensation, temperature]

Skin color pales with limb elevation; capillary refill time >3 sec; color does not return to lowered limb after 1 min leg elevation

Decrease in pain-free distances achieved in the 6-minute walk test; distance in the 6-minute walk test below normal range

Edema

Alteration in motor function

Delay in peripheral wound healing;

Associated Condition: Diabetes mellitus; hypertension

Endovascular procedure; trauma

Sample Clinical Applications: Atherosclerosis, anemias; arthritis; coronary artery disease; amputation; Buerger's disease, burns; CVA; COPD; CHF; diabetes mellitus, obesity; peripheral vascular disease, Raynaud's disease, thrombophlebitis

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Tissue Perfusion: Peripheral: Adequacy of blood flow through the small vessels of the extremities to maintain tissue function

Knowledge: Disease Process: Extent of understanding conveyed about a specific disease process and prevention of complications

Client Will (Include Specific Time Frame)

- Demonstrate increased perfusion as individually appropriate (e.g., skin warm and dry, peripheral pulses present and strong, absence of edema, free of pain or discomfort).
- Verbalize understanding of condition, therapy regimen, side effects of medications, and when to contact healthcare provider.
- Demonstrate behaviors or lifestyle changes to improve circulation (e.g., engage in regular exercise, cessation of smoking, weight reduction, disease management).

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Circulatory Care: Arterial Insufficiency: Promotion of arterial circulation

Circulatory Care: Venous Insufficiency: Promotion of venous circulation

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Note current situation or presence of conditions that can affect perfusion to all body systems (e.g., congestive heart failure, lung disorders, major trauma, septic or hypovolemic shock, coagulopathies, sickle cell anemia) *affecting systemic circulation and perfusion.*
-  Determine history of conditions associated with thrombus or emboli (e.g., problems with coronary or cerebral circulation, stroke; high-velocity trauma with fractures, abdominal or orthopedic surgery, long periods of immobility; inflammatory diseases; chronic lung disease; diabetes with coexisting peripheral vascular disease; estrogen therapy; cancer and cancer therapies; presence of central venous catheters) *to identify client at higher risk for venous stasis, vessel wall injury, and hypercoagulability.*^{1,2,14,15}
- Identify presence of high-risk factors or conditions (e.g., smoking, uncontrolled hypertension, obesity, pregnancy, pelvic tumor, paralysis, hypercholesterolemia, varicose veins, arthritis, sepsis). *Places client at greater risk for developing peripheral vascular disease (PVD), including arterial blockage and chronic venous insufficiency, with associated complications.*^{3,4,14}
- Note location of restrictive clothing, pressure dressings, circular wraps, and cast or traction device *that may restrict circulation to limb.*
- Ascertain impact on functioning and lifestyle. *For example, leg pain may restrict ambulation or person may develop skin ulceration and healing problems that seriously impact quality of life.*

NURSING PRIORITY NO. 2 To evaluate degree of impairment:

- Assess skin color, temperature, moisture, and whether changes are widespread or localized. *Helps in determining location and type of perfusion problem.*
- Compare skin temperature and color with other limb when assessing extremity circulation. *Helps differentiate type of problem (e.g., deep redness in both hands triggered by vibrating machinery is associated with functional PVD, such as Raynaud's disease; edema, redness, swelling in calf of one leg is associated with localized thrombophlebitis).*^{1,5,14-16}
- Assess presence, location, and degree of swelling or edema formation. Measure circumference of extremities, noting differences in size. *Useful in identifying or quantifying edema in involved extremity.*
- Measure capillary refill to determine adequacy of systemic circulation.
- Note client's nutritional and fluid status. *Protein-energy malnutrition and weight loss make ischemic tissues more prone to breakdown. Dehydration reduces blood volume and compromises peripheral circulation.*¹⁴
- Inspect lower extremities for skin texture (e.g., atrophic; shiny appearance; lack of hair; dry, scaly, reddened skin) and skin breaks or ulcerations *that often accompany diminished peripheral circulation.*^{2,3,6,14}
-  Palpate arterial pulses (bilateral femoral, popliteal, dorsalis pedis, posterior tibial), using handheld Doppler if indicated *to determine level of circulatory problem (e.g., client with intermittent claudication may have palpable pulses that disappear after ambulation).*^{2,5}
- Determine pulse equality as well as intensity (e.g., bounding, normal, diminished, absent) and compare with unaffected extremity *to evaluate distribution and quality of blood flow and success or failure of therapy.*²
- Evaluate extremity pain reports, noting associated symptoms (e.g., cramping or heaviness, discomfort with walking, progressive temperature or color changes, paresthesia). Determine time (day or night) that symptoms are worse, precipitating or aggravating events (e.g., walking), and relieving factors (e.g., rest, sitting down with legs in dependent position, oral analgesics) *to help isolate and differentiate problems such as intermittent chronic claudication versus loss of function and pain due to acute sustained ischemia related to loss of arterial blood flow.*^{2,3}
- Assess motor and sensory function. *Problems with ambulation, hypersensitivity or loss of sensation, numbness and tingling are changes that can indicate neurovascular dysfunction or limb ischemia, requiring more evaluation for differentiation of problem.*^{2,6}
-  Check for calf tenderness or pain on dorsiflexion of foot (Homans' sign) and swelling and redness. *Indicators of deep vein thrombosis (DVT), although DVT is often present without a positive Homans' sign.*^{1,15,18}
-  Review lab studies (e.g., lipid profile, coagulation studies, hemoglobin/hematocrit, renal/cardiac function tests, inflammatory markers [e.g., D dimer, C-reactive protein]) and diagnostic studies (e.g., Doppler

ultrasound, magnetic resonance angiography, venogram, contrast angiography, resting ankle-brachial index, leg segmental arterial pressure measurements) *to determine probability, location, and degree of impairment.*^{1-3,6}

NURSING PRIORITY NO. 3 To maximize tissue perfusion:

-  Collaborate in treatment of underlying conditions, such as diabetes, hypertension, cardiopulmonary conditions, blood disorders, traumatic injury, hypovolemia, and hypoxemia *to maximize systemic circulation and organ perfusion.*
-  Administer medications such as antiplatelet agents, thrombolytics, and antibiotics *to improve tissue perfusion and organ function.*^{1,2,4,6,15,16}
-  Administer fluids, electrolytes, nutrients, and oxygen as indicated *to promote optimal blood flow, organ perfusion, and function.*
-  Assist with or prepare for medical procedures such as endovascular stent placement, surgical revascularization procedures, thrombectomy, and sympathectomy *to improve peripheral circulation.*
-  Assist with application of elasticized tubular support bandages, adhesive elastic or Velcro wraps (e.g., Circ-Aid), paste bandages (Unna's boot), multilayer bandage regimens, sequential pneumatic compression devices, and custom-fitted compression stockings as indicated *to provide graduated compression of lower extremity in presence of venous stasis ulcer.*^{13,15}
-  Collaborate with wound care specialist if arterial or venous ulcerations are present. *In-depth wound care may include débridement and various specialized dressings that provide optimal moisture for healing, prevention of infection and further injury.*^{14,15}
- Provide interventions to promote peripheral circulation and limit complications:^{1-3,7}
 -  Encourage early ambulation when possible and recommend regular exercise. *Enhances venous return. Studies indicate exercise training may be an effective early treatment for intermittent claudication.*⁸
 - Recommend or provide foot and ankle exercises when client unable to ambulate freely *to reduce venous pooling and increase venous return.*¹⁵
 - Provide pressure-relieving devices for immobilized client (e.g., air mattress, foam or sheepskin padding, bed or foot cradle) *to reduce excessive tissue pressure that could lead to skin breakdown.*
 -  Apply intermittent compression devices or graduated compression stockings to lower extremities *to limit venous stasis, improve venous return, and reduce risk of DVT or tissue ulceration in client who is limited in activity or otherwise at risk.*^{9,14-16}
 - Assist with or cue client to change position at timed intervals rather than using presence of pain as signal to change positions *because sensation may be impaired.*⁶
 - Elevate the legs when sitting, but avoid sharp angulation of the hips or knees *to enhance venous return and minimize edema formation.*
 - Avoid massaging the leg in presence of thrombosis *to reduce risk for embolus.*
 - Avoid, or carefully monitor, use of heat or cold, such as hot water bottle, heating pad, or ice pack. *Tissues may have decreased sensitivity due to ischemia, increasing risk of dermal injury.*
- Refer to NDs risk for peripheral Neurovascular Dysfunction, risk for impaired Skin Integrity, impaired Tissue Integrity, and [disturbed Sensory Perception] for additional interventions as appropriate.

NURSING PRIORITY NO. 4 To promote wellness (Teaching/Discharge Considerations):

-  Discuss relevant risk factors (e.g., family history, obesity, age, smoking, hypertension, diabetes, clotting disorders) and potential outcomes of atherosclerosis (e.g., systemic and peripheral vascular disease conditions). *Information necessary for client to make informed decisions concerning risk factors and to commit to lifestyle changes necessary to prevent onset of complications or manage symptoms when condition present.*^{10,11}
- Identify necessary changes in lifestyle and assist client to incorporate disease management into activities of daily living. *Promotes independence and enhances self-concept regarding ability to deal with change and manage own needs.*

- Emphasize need for regular exercise program *to enhance circulation and promote general well-being*.¹²
-  Refer to nutritionist for well-balanced, low-saturated-fat, low-cholesterol diet or other modifications as indicated *to promote weight loss and/or lower cholesterol levels*.
- Discuss care of dependent limbs and foot care as appropriate. *When circulation is impaired, changes in sensation place client at risk for development of lesions or ulcerations that are often slow to heal.*
- Discourage sitting or standing for long periods, wearing constrictive clothing, and crossing legs, *which can restrict circulation and lead to edema*.
-  Provide education about relationship between smoking and peripheral vascular circulation, as indicated. *Smoking contributes to development and progression of PVD and is associated with higher rate of amputation in presence of Buerger's disease.*^{10,17}
-  Educate client/significant other (SO) in reportable symptoms, including any changes in pain level, difficulty walking, and nonhealing wounds, *to provide opportunity for timely evaluation and intervention*.
-  Emphasize need for regular medical and laboratory follow-up *to evaluate disease progression and response to therapies, including medications for desired and untoward effects*.
-  Review medication regimen with client/SO. *Client may be on various drugs (e.g., antiplatelet agents, blood viscosity-reducing agents, vasodilators, anticoagulants, cholesterol-lowering agents) for treatment of the particular vascular disorder. Any of these medications have harmful side effects and require client teaching and medical monitoring.*^{5,14–16}
-  Emphasize importance of avoiding use of aspirin, some over-the-counter drugs and supplements, and alcohol when taking anticoagulants.
-  Refer to community resources such as smoking-cessation assistance, weight control program, and exercise group *to provide support for lifestyle changes*.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, noting nature, extent, and duration of problem, effect on independence and lifestyle.
- Characteristics of pain, precipitators, and what relieves pain.
- Pulses and blood pressure, including above and below suspected lesion as appropriate.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions/teaching, actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Available resources, specific referrals made.

risk for decreased cardiac Tissue Perfusion

Taxonomy II: Activity/Rest—Class 4 Cardiovascular/Pulmonary Responses (00200) [Diagnostic Division: Circulation], Approved 2008; Revised 2013, 2017

DEFINITION: Susceptible to a decrease in cardiac (coronary) circulation, which may compromise health.

RISK FACTORS

Insufficient knowledge of modifiable risk factors [e.g., smoking, sedentary lifestyle, obesity]

Substance misuse/abuse

At Risk Population: Family history of cardiovascular disease

Associated Condition: Coronary artery spasm; cardiovascular surgery; cardiac tamponade

Diabetes mellitus; hypertension

Hypovolemia; hypoxia/hypoxemia

Hyperlipidemia; increase in C-reactive protein

Pharmaceutical agent

Sample Clinical Applications: Angina, coronary artery disease, hypertension, congestive heart failure, diabetes, cardiac surgery, pericarditis, sepsis, anemia, hemorrhagic shock, cocaine use

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Tissue Perfusion: Cardiac: Adequacy of blood flow through the coronary vasculature to maintain heart function

Self-Management: Coronary Artery Disease: Personal actions to manage coronary artery disease, its treatment, and to prevent disease progression and complications

Client Will (Include Specific Time Frame)

- Demonstrate adequate coronary perfusion as individually appropriate (e.g., vital signs within client's normal range, free of chest pain or discomfort).
- Identify individual risk factors.
- Verbalize understanding of treatment regimen.
- Demonstrate behaviors or lifestyle changes to maintain or maximize circulation (e.g., cessation of smoking, relaxation techniques, exercise program, dietary plan).

(continues on page 908)

risk for decreased cardiac Tissue Perfusion (continued)**ACTIONS/INTERVENTIONS****Sample NIC linkages:**

Cardiac Risk Management: Prevention of an acute episode of impaired cardiac function by minimizing contributing events and risk behaviors

Hemodynamic Regulation: Optimization of heart rate, preload, afterload, and contractility

NURSING PRIORITY NO. 1 To identify individual risk factors:

- Note presence of conditions such as heart failure, major trauma with blood loss, recent coronary artery bypass graft (CABG) surgery, use of intra-aortic balloon pump, chronic anemia, sepsis, etc. *Conditions such as these can affect systemic circulation, tissue oxygenation, and organ function.*^{1,14}
-  Note client's age and gender when assessing risk for coronary artery spasm or myocardial infarction. *Risk for heart disorders increases with age, and men are still considered at higher risk for myocardial infarction, and experience it earlier in life. Note: Although studies show that men have experienced a decline in coronary heart disease mortality in the last 2 decades, only 54% of women recognize that heart disease is their number one killer (based on 2010 data).³ Studies continue to report the death rate from acute MI to be three times higher in men than in women until age 75.²² And the American Heart Association (AHA) reported (2016) that "at older ages, women who have heart attacks are more likely than men are to die from them within a few weeks."²*
-  Identify lifestyle issues such as obesity, smoking, high cholesterol, excessive alcohol intake, use of drugs such as cocaine, and physical inactivity *that can raise client's risk for coronary artery disease and impaired cardiac tissue perfusion.*²
-  Determine presence of breathing problems, such as obstructive sleep apnea (OSA) with oxygen desaturation. *Can produce alveolar hypoventilation, respiratory acidosis, and hypoxia, which can result in cardiac dysrhythmias and cardiac dysfunction. Note: A recent study (2014) reported that "the strongest OSA-related predictor of cardiovascular events . . . was total sleep time spent with oxygen saturation below 90%, which increased the risk of a cardiovascular event or death by 50%."*⁸
- Determine if client is experiencing unusual long-term stress or may have underlying psychiatric disorder (e.g., anxiety or panic) *that may cause or exacerbate coronary artery disease and affect cardiac function.*⁵
-  Review client's medications, noting current use of any vasoactive drugs such as amiodarone, dopamine, dobutamine, esmolol, lidocaine, nitroglycerin, and vasopressin. *These medications may be used in emergent situations or to manage blood pressure over time and can exert undesirable and potentially dangerous secondary effects in addition to their intended primary effects.*⁹
-  Review diagnostic studies and lab tests (e.g., electrocardiogram; exercise tolerance tests, myocardial perfusion scan; echocardiogram, bubble echocardiogram; angiography, Doppler ultrasound, chest radiography; oxygen saturation, capnometry, or arterial blood gases; electrolytes, lipid profile; blood urea nitrogen/creatinine, cardiac enzymes) *to identify conditions requiring treatment, and response to therapies.*^{7,10,11}

NURSING PRIORITY NO. 2 To determine changes in cardiac status:

-  Investigate reports of chest pain, noting changes in characteristics of pain *to evaluate for potential myocardial ischemia or inadequate systemic oxygenation or perfusion of organs. Note: Chest pain is often difficult to diagnose due to variability in symptoms. Leading causes of chest pain (other than heart) include musculoskeletal, gastrointestinal, and pulmonary systems, as well as psychiatric disorders such as panic disorders.*⁴⁻⁶

- Monitor vital signs, especially noting blood pressure changes, including hypertension or hypotension, *reflecting systemic vascular resistance problems that alter oxygen consumption and cardiac perfusion.*¹
- Assess heart sounds and pulses for dysrhythmias. *Can be caused by inadequate myocardial or systemic tissue perfusion, electrolyte or acid-base imbalances.*¹³
- Assess for restlessness, fatigue, changes in level of consciousness; increased capillary refill time; diminished peripheral pulses; and pale, cool skin. *Signs and symptoms of inadequate systemic perfusion, which can cause or affect cardiac function.*¹
- Inspect for pallor, mottling, cool and clammy skin, and diminished pulses. *Systemic vasoconstriction resulting from reduced cardiac output may be evidenced by poor skin or tissue perfusion and diminished pulses.*¹³
- Investigate reports of difficulty breathing; note respiratory rate outside of acceptable parameters, *which can be indicative of oxygen exchange problems with potential for cardiac dysfunction.*⁷

NURSING PRIORITY NO. 3 To maintain/maximize cardiac perfusion:

-  Collaborate in treatment of underlying conditions such as hypovolemia, chronic obstructive pulmonary disease, diabetes, and chronic atrial fibrillation, *to correct or treat disorders that could influence cardiac perfusion or organ function.*
-   Maintain hemodynamic stability when client is in postoperative phase of CABG surgery *to keep vital organs adequately perfused. Risk factors in this time frame include dysrhythmias, hypotension or hypertension, cardiac tamponade, and pulmonary dysfunction.*¹²
-  Provide supplemental oxygen as indicated *to improve or maintain cardiac and systemic tissue perfusion.*
-   Administer fluids and electrolytes as indicated *to maintain systemic circulation and optimal cardiac function.*
-  Administer medications (e.g., antihypertensive agents, analgesics, antidysrhythmics, bronchodilators, fibrinolytic agents) *to treat underlying conditions, to prevent thromboembolic phenomena, and to maintain cardiac tissue perfusion and organ function.*^{12,13,15}
-  Collaborate with dietician or nutritionist to provide easily digestible diet sufficient in nutrients, low in cholesterol and fat, and high in complex carbohydrates *to provide energy and reduce substances harmful to coronary arteries.*^{2,16}
- Provide periods of undisturbed rest and calming environment *to reduce myocardial workload.*

NURSING PRIORITY NO. 4 To promote heart health (Teaching/Discharge Considerations):

-   Discuss the risk factors (e.g., family history, obesity, age, smoking, hypertension, diabetes, clotting disorders) and potential outcomes of atherosclerosis (e.g., systemic and cardiac disease conditions). *Information necessary for client to make informed decisions concerning risk factors and to commit to lifestyle changes necessary to prevent onset of complications or manage symptoms when condition present.*²
 - Review difference between modifiable and nonmodifiable risk factors *to assist client/significant other (SO) in understanding those areas in which he/she can take action or make healthy choices:*
 -  Recommend maintenance of normal weight or weight loss if client is obese *to decrease risk associated with overweight and obesity.*²
- Review specific dietary concerns with client, such as reducing animal and dairy fats and increasing plant foods—fruits, vegetables, olive oil, and nuts.¹⁶
- Encourage smoking cessation, when indicated, offering information about stop-smoking aids and programs. *Smoking cessation is important in the medical management of many contributors to heart attack (e.g., vasoconstriction [which can reduce coronary perfusion], atherosclerosis, thrombosis, coronary artery spasm, and cardiac dysrhythmias).*¹⁷
- Encourage client to engage in regular exercise *to enhance circulation and promote general well-being.*¹⁸
-  Review medications on regular basis *to manage those that affect cardiac function or those given to prevent blood pressure or thromboembolic problems.*

 Discuss drug use where indicated (including cocaine, methamphetamines, alcohol) *to educate client regarding effect of drug on the heart. Note: Studies have found a substantial association between self-reported cocaine use and physician-diagnosed myocardial infarction. Another study indicates that when methamphetamine is used with alcohol, increased psychological and cardiac effects are observed.*^{19–21}

Discuss coping and stress tolerance. Demonstrate and encourage use of relaxation or stress management techniques *to decrease tension level, thereby improving heart health.*

Encourage client in high-risk categories (e.g., strong family history, diabetic, prior history of cardiac event) to have regular medical examinations *to provide timely intervention, when needed.*

-  Refer to educational or community resources, as indicated. *Client/SO may benefit from instruction and support provided by agencies to engage in healthier heart activities (e.g., weight loss, smoking cessation, exercise).*
-  Instruct in blood pressure monitoring at home if indicated; advise purchase of home monitoring equipment; refer to community resources as indicated. *Facilitates management of hypertension, which is a major risk factor for damage to blood vessels or organ function.*¹³

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, noting specific risk factors.
- Vital signs, cardiac rhythm, presence of dysrhythmias.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Available resources, specific referrals made.

risk for ineffective cerebral Tissue Perfusion

Taxonomy II: Activity/Rest—Class 4 Cardiovascular/Pulmonary Responses (00201) [**Diagnostic Division:** Circulation], Approved 2008; Revised 2013, 2018

DEFINITION: Susceptible to a decrease in cerebral tissue circulation, which may compromise health.

RISK FACTORS

Substance misuse [abuse]

At Risk Population: Recent myocardial infarction; [cerebral vascular accident (CVA)/stroke]

Associated Conditions: Abnormal partial thromboplastin time (PTT); abnormal prothrombin time (PT); coagulopathy; disseminated intravascular coagulopathy; hypercholesterolemia

Akinetic left ventricular wall segment; dilated cardiomyopathy; atrial myxoma; infective endocarditis; aortic atherosclerosis

Arterial dissection; carotid stenosis; cerebral aneurysm; brain injury, brain neoplasm; embolism

Hypertension

Pharmaceutical agent; treatment regimen

Sample Clinical Applications: Traumatic brain injury, stroke; atherosclerosis, hypertension, atrial fibrillation, mitral valve stenosis or replacement, transient ischemic attack, cerebral vascular accident (CVA)/stroke; sickle cell anemia, cocaine use

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Tissue Perfusion: Cerebral: Adequacy of blood flow through the cerebral vasculature to maintain brain function

Risk Control: Personal actions to understand, prevent, eliminate, or reduce modifiable health threats

Client Will (Include Specific Time Frame)

- Display neurological signs within client's normal range.
- Verbalize understanding of condition, therapy regimen, side effects of medications, and when to contact healthcare provider.
- Demonstrate behaviors or lifestyle changes to improve circulation (e.g., cessation of smoking, relaxation techniques, exercise program, dietary plan).

(continues on page 912)

risk for ineffective cerebral Tissue Perfusion (continued)

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Cerebral Perfusion Promotion: Promotion of adequate perfusion and limitation of complications for a patient experiencing or at risk for inadequate cerebral perfusion

Surveillance: Purposeful and ongoing acquisition, interpretation, and synthesis of patient data for clinical decision making

Cerebral Edema Management: Limitation of secondary cerebral injury resulting from swelling of brain tissue

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Determine history of conditions associated with thrombus or emboli such as stroke, complicated pregnancy, sickle cell disease, fractures (especially long bones or pelvis) *to identify client at higher risk for decreased cerebral perfusion related to bleeding and/or coagulation problems.*
- Note current situation or presence of conditions (e.g., congestive heart failure, major trauma, sepsis, hypertension) *that can affect all body systems and systemic circulation and perfusion.*
- Ascertain potential for presence of acute neurological conditions, such as traumatic brain injury, tumors, hemorrhage, anoxic brain injury associated with cardiac arrest, and toxic or viral encephalopathies. *These conditions alter the relationship between intracranial volume and pressure, potentially increasing intracranial pressure and decreasing cerebral perfusion.*¹
- Investigate client reports of headache, particularly when accompanied by loss of coordination, confusion, visual disturbances, difficulty understanding or using language, or a range of progressive neurological deficits. *These symptoms may accompany cerebral perfusion deficits associated with conditions such as stroke, transient ischemic attack, brain trauma, or cerebral arteriovenous malformations.*^{2,5}
- Ascertain if client has history of cardiac problems (e.g., recent myocardial infarction, heart failure, heart valve dysfunction or replacement, chronic atrial fibrillation), *which can impair systemic and cerebral blood flow or cause thromboembolic events to brain.*³
- Determine presence of cardiac dysrhythmias (e.g., chronic atrial fibrillation, bradycardia). *Can be caused by inadequate myocardial perfusion, electrolyte imbalances, or be associated with brain injury (e.g., bradycardia can accompany traumatic injury; stroke can be precipitated by dysrhythmias).*³
- Assess level of consciousness, mental status, speech, and behavior. *Clinical symptoms of decreased cerebral perfusion include fluctuations in consciousness and cognitive functions.*¹¹
- Evaluate blood pressure. *Chronic or severe acute hypertension can precipitate cerebrovascular spasm and stroke. Low blood pressure or severe hypotension causes inadequate perfusion of brain, with adverse changes in consciousness/mentation.*⁴
-  Verify proper use of antihypertensive medications. *Individuals may stop medication because of lack of symptoms, presence of undesired side effects, and/or cost of drug, potentiating risk of stroke.*
-  Review medication regimen noting use of anticoagulants or antiplatelet agents and other drugs *that could cause intracranial bleeding.*
-   Review pulse oximetry or arterial blood gases, noting oxygenation level and saturation. *Hypoxia (PaO₂ level less than 60 mg Hg, or O₂ saturation level less than 90%) is associated with reduced cerebral perfusion and increased morbidity and mortality from severe brain injury.*^{3,4}
-  Review lab studies (e.g., coagulation profiles, complete blood count, electrolytes, lipids, B-type natriuretic peptide) *to identify disorders that increase risk of clotting or bleeding or other conditions contributing to causing decreased cerebral perfusion.*

-  Review results of diagnostic studies (e.g., ultrasound or other imaging scans such as echocardiography, computed tomography [CT], or magnetic resonance angiography [MRA]; diffusion and perfusion magnetic resonance imaging) *to determine location and severity of disorder that can cause or exacerbate cerebral perfusion problems.*¹⁰

NURSING PRIORITY NO. 2 To maximize tissue perfusion:

-  Collaborate in treatment of underlying conditions (e.g., carotid stent placement, medical or surgical reperfusion procedures, treatment of infections) as indicated *to improve systemic perfusion and organ function.*^{1,16}
- Restore or maintain fluid balance *to maximize cardiac output and prevent decreased cerebral perfusion associated with hypovolemia.*^{1,2}
- Assist with treatment/management of cardiac dysrhythmias (such as with medication administration, pacemaker insertion). *Reduces risk of diminished cerebral perfusion due to blood clots or low cardiac output.*^{1,2}
- Restrict fluids and administer diuretics as indicated *to prevent diminished cerebral perfusion associated with hypertension, and cerebral edema.*^{1,2}
- Keep head in midline position, when indicated, *to promote venous drainage, preventing or reducing risk of elevated intracranial pressure.*^{1,2}
-  Maintain optimal head of bed (HOB) placement (e.g., 0, 15, 30 degrees). *Various studies demonstrate different perfusion responses to HOB placement but indicate that cerebral perfusion is reduced when HOB elevated greater than 30 degrees. Note: A recent study showed that routine nursing of patients with severe head injury at 30 degrees of head elevation within 24 hr after trauma leads to a consistent reduction of intracranial pressure (statistically significant) and an improvement in cerebral perfusion (although not statistically significant) without concomitant deleterious changes in cerebral oxygenation.*^{6,12}
- Control fever, monitor hypothermia therapy, and provide supplemental oxygen, as indicated, *to decrease cerebral metabolism and cerebral edema.*^{1,2}
-  Administer vasoactive medications, as indicated, *to increase cardiac output and/or adequate mean arterial pressure to maintain cerebral perfusion.*^{1,2}
-  Administer other medications as indicated. *Corticosteroids may be used to reduce cerebral edema, antihypertensives may be used to manage high blood pressure, and anticoagulants may be used to prevent cerebral embolus.*^{1,2}
- Prepare client for surgery as indicated (e.g., carotid endarterectomy, evacuation of hematoma or space-occupying lesion; thrombectomy following stroke) *to improve cerebral perfusion.*^{1,16}
- Refer to NDs decreased Cardiac Output and decreased Intracranial Adaptive Capacity for additional interventions.

NURSING PRIORITY NO. 3 To promote optimal perfusion (Teaching/Discharge Considerations):

-  Review modifiable risk factors, as indicated: *Information can help client make informed choices about remedial actions to reduce risk factors and to commit to lifestyle changes as appropriate.*^{2,7}

Uncontrolled hypertension: *Incidence of stroke increases with systolic blood pressure greater than 140/90 mmHg. Client at risk can learn to self-monitor blood pressure, take prescribed antihypertensive agents consistently, and identify symptoms to report to physician.*

 **Smoking:** *Smoking causes vasoconstriction and increased arterial wall stiffness, increasing fibrinogen levels and platelet aggregation, and abnormal blood lipids. Numerous recent studies have confirmed a relationship between active and passive smoking, with the maximum risk period being middle life. Smoking cessation immediately lowers risk of stroke.⁸ Note: A report of a clinical trial (2012) reported that “50% of stroke patients in this trial who claimed to be motivated to quit at the time of discharge [after stroke] relapsed in three weeks. If a patient resumed smoking within 10 days of discharge, their risk of death in the following year was five times greater than those who managed to abstain.”¹⁵*

 **Obesity and unhealthy diet:** *Abdominal obesity has been associated with increased risk for ischemic stroke.⁸ Diet high in cholesterol contributes to development of cerebral atherosclerosis. High intake of sodium can contribute to hypertension.*

Physical inactivity: *Contributes to obesity and hypertension.*

 **Excessive alcohol intake:** *Linked to higher risk of stroke because it can cause hypertension, which is a major risk factor. Note: Alcohol intake consumption at higher amounts is associated with increased risk of atrial fibrillation, ventricular fibrillation, dilated cardiomyopathy, hypertension, dyslipidemia, and a systemic anticoagulant effect, all of which increase the risk of stroke.*^{7,14}

 **Illicit drug use:** *Can significantly boost the risk of a deadly or debilitating stroke. Note: Many illicit drugs have been linked to increased stroke risk (i.e., cocaine, amphetamines, opiates, phencyclidine, marijuana).*⁹

- Discuss impact of unmodifiable risk factors such as family history, age, and race. *Understanding effects and interrelationship of all risk factors may encourage client to address what can be changed to improve general well-being and reduce individual risk.*
- Assist client to incorporate disease management into activities of daily living, including regular exercise. *Promotes independence and enhances self-concept regarding ability to deal with change and manage own needs.*
-  Emphasize necessity of routine follow-up and laboratory monitoring as indicated. *Important for effective disease management and possible changes in therapeutic regimen.*
-  Refer to educational or community resources as indicated. *Client/SO may benefit from instruction and support provided by agencies to engage in healthy activities (e.g., weight loss, smoking cessation, exercise).*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, noting specific risk factors.
- Vital signs, blood pressure, cardiac rhythm.
- Medication regimen.
- Diagnostic studies, laboratory results.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Available resources, specific referrals made.

risk for ineffective peripheral Tissue Perfusion

Taxonomy II: Activity/Rest—Class 4 Cardiovascular/Pulmonary Responses (00228) [**Diagnostic Division:** Circulation], Approved 2010; Revised 2013, 2017

DEFINITION: Susceptible to a decrease in blood circulation to the periphery, which may compromise health.

RISK FACTORS

Sedentary lifestyle; smoking

Endovascular procedure; trauma

Excessive sodium intake

Insufficient knowledge of disease process, risk factors, or aggravating factors (e.g., smoking, sedentary lifestyle, trauma, obesity, salt intake, immobility)

Associated Condition: Diabetes mellitus; hypertension

Endovascular procedure; trauma

Sample Clinical Applications: Atherosclerosis, coronary artery disease, Raynaud's disease, peripheral vascular disease, Buerger's disease, thrombophlebitis, diabetes mellitus, sickle cell anemia

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Tissue Perfusion; Peripheral: Adequacy of blood flow through the small vessels of the extremities to maintain tissue perfusion

Knowledge: Disease Process: Extent of understanding conveyed about a specific disease process and prevention of complications

Client Will (Include Specific Time Frame)

- Demonstrate adequate perfusion as individually appropriate (e.g., peripheral pulses present and strong, absence of edema, free of pain or discomfort).
- Verbalize understanding of risk factors and when to contact healthcare provider.
- Demonstrate behaviors or lifestyle changes to improve circulation (e.g., engage in regular exercise, cessation of smoking, weight reduction, disease management).

(continues on page 916)

risk for ineffective peripheral Tissue Perfusion (continued)

Sample NIC linkages:

Circulatory Care: Arterial Insufficiency: Promotion of arterial circulation

Circulatory Care: Venous Insufficiency: Promotion of venous circulation

Teaching: Disease Process: Assisting the patient to understand information related to a specific disease process

NURSING PRIORITY NO. 1 To identify causative/precipitating factors related to risk:

- Note current situation or presence of conditions that can affect perfusion to all body systems (e.g., client admitted for endovascular procedure such as angiography or placement of stent, history or presence of congestive heart failure, lung disorders, major trauma, septic or hypovolemic shock, coagulopathies, sickle cell anemia) *affecting systemic circulation and perfusion.*
- Determine history of conditions associated with thrombus or emboli (e.g., problems with coronary or cerebral circulation, stroke; high-velocity trauma with fractures, abdominal or orthopedic surgery, long periods of immobility; inflammatory diseases; chronic lung disease; diabetes with coexisting peripheral vascular disease (PVD); estrogen therapy; cancer and cancer therapies; presence of central venous catheters) *to identify client at higher risk for venous stasis, vessel wall injury, and hypercoagulability.*¹⁻⁴
- Identify presence of high-risk factors or conditions (e.g., smoking, uncontrolled hypertension, obesity, pregnancy, pelvic tumor, paralysis, hypercholesterolemia, varicose veins, arthritis, sepsis). *Places client at greater risk for developing PVD (including arterial blockage and chronic venous insufficiency) with associated complications.*^{3,5,6}

NURSING PRIORITY NO. 2 To assess for and reduce risk of perfusion complications:

- Evaluate reports of extremity pain promptly, noting any associated symptoms (e.g., cramping or heaviness, discomfort with walking, progressive temperature or color changes, paresthesia) *to help isolate and differentiate problems.*
- Note presence and location of restrictive pressure dressings, circular wraps, cast or traction device *that may impede circulation to limb.*
- Assess skin color and temperature in all extremities *for changes that might indicate circulation problem.*
- Compare skin temperature and color with other limb *if developing problem is suspected (e.g., edema, redness, swelling in calf of one leg is associated with localized thrombophlebitis).*^{1,3,7}
- Palpate arterial pulses—bilateral radial, femoral, popliteal, dorsalis pedis, and posterior tibial—comparing equality as well as intensity (e.g., bounding, normal, diminished, absent). *Assesses distribution and quality of blood flow.*²
- Inspect lower extremities for skin texture (e.g., atrophic; shiny appearance; lack of hair; dry, scaly, reddened skin) and skin breaks or ulcerations *that often accompany diminished peripheral circulation.*^{3,5,8}
- Note client's nutritional and fluid status. *Protein-energy malnutrition and weight loss make ischemic tissues more prone to breakdown. Dehydration reduces blood volume and compromises peripheral circulation.*^{3,5,8}
-  Review lab studies such as lipid profile, coagulation studies, hemoglobin/hematocrit, renal/cardiac function tests, inflammatory markers (e.g., D dimer, C-reactive protein) *to determine potential for circulatory impairment.*

NURSING PRIORITY NO. 3 To maximize tissue perfusion or reduce risk of perfusion complications:

-    Collaborate in treatment of underlying conditions, such as diabetes, hypertension, cardiopulmonary conditions, blood disorders, traumatic injury, hypovolemia, and hypoxemia *to maximize systemic circulation and organ perfusion.*

-  Administer fluids, electrolytes, nutrients, and oxygen as indicated *to promote optimal blood flow and organ and peripheral tissue perfusion and function.*
- Provide interventions to promote peripheral circulation and limit complications:^{1,2,4,5,9}
Encourage early ambulation when possible. *Enhances venous return.*
Recommend or provide foot and ankle exercises when client unable to ambulate freely *to reduce venous pooling and increase venous return.*
Provide pressure-relieving/reducing devices for immobilized client (e.g., air mattress, gel or foam padding, bed or foot cradle) *to reduce excessive tissue pressure that could lead to skin breakdown.*
-   Apply intermittent compression devices or graduated compression stockings to lower extremities *to limit venous stasis, improve venous return, and reduce risk of deep vein thrombosis or tissue ulceration in client who is limited in activity or otherwise at risk.*^{4,10,11}
Assist with or cue client to change position at timed intervals rather than using presence of pain as signal to change positions, *if sensation is/could be impaired.*
Elevate the legs when sitting, but avoid sharp angulation of the hips or knees *to enhance venous return and minimize edema formation.*
Discuss/monitor use of heat or cold, such as hot water bottle, heating pad, or ice pack. *Reduces risk of dermal injury if client has condition associated with decreased sensation or neuropathy.*
-  Refer to dietitian or nutritionist to discuss dietary needs such as a well-balanced, low-saturated-fat, low-cholesterol diet or other modifications as indicated *to promote weight loss and/or lower cholesterol levels to improve tissue perfusion.*
- Refer to NDs ineffective peripheral Tissue Perfusion, risk for peripheral Neurovascular Dysfunction, risk for impaired Skin Integrity, impaired Tissue Integrity, and [disturbed Sensory Perception] for additional interventions as appropriate.

NURSING PRIORITY NO. 4 To promote and maintain optimal perfusion (Teaching/discharge Considerations):

-  Discuss relevant risk factors (e.g., family history, obesity, age, smoking, hypertension, diabetes, clotting disorders) and potential outcomes of atherosclerosis (e.g., systemic and peripheral vascular disease conditions). *Information necessary for client to make informed choices about risk factors and commit to lifestyle changes as appropriate to prevent onset of complications or manage symptoms when condition is present.*^{2,12}
- Identify necessary changes in lifestyle and assist client to incorporate disease management into activities of daily living. *Promotes independence and enhances self-concept regarding ability to deal with change and manage own needs.*
- Emphasize need for regular exercise program *to enhance circulation and promote general well-being.*¹³
- Discourage sitting or standing for long periods, wearing constrictive clothing and crossing legs, *which can restrict circulation and lead to edema.*
-   Provide education about relationship between smoking and peripheral vascular circulation, as indicated. *Smoking contributes to development and progression of PVD.*^{2,14}
- Educate client/significant other in reportable symptoms, including any changes in pain level, difficulty walking, and nonhealing wounds *to provide opportunity for timely evaluation and intervention.*
-  Refer to community resources such as smoking-cessation assistance, weight control program, diabetic educator, and/or exercise group *to provide support for lifestyle changes.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual risk factors identified.
- Client concerns or difficulty making and following through with plan.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Response to interventions, teaching, and actions performed.
- Attainment or progress toward outcomes.

Discharge Planning

- Referrals to other resources.
- Long term need and who is responsible for actions.

impaired Transfer Ability

Taxonomy II: Activity/Rest—Class 2 Activity/Exercise (00090) [**Diagnostic Division:** Activity/Rest], Approved 1998; Revised 2006, 2017

DEFINITION: Limitation of independent movement between two nearby surfaces.

RELATED FACTORS

Insufficient muscle strength; physical deconditioning

Pain

Obesity

Insufficient knowledge of transfer techniques

Environmental barrier [e.g., bed height, inadequate space, wheelchair type, treatment equipment, restraints]

DEFINING CHARACTERISTICS

Subjective or Objective

Impaired ability to transfer between bed and chair, bed and standing position; between chair and car, chair and floor, or chair and standing; on or off a toilet or commode; in or out of bathtub or shower; between uneven levels

Associated Condition: Alteration in cognitive function

Impaired vision

Musculoskeletal, neuromuscular impairment

Note: Specify level of independence using a standardized functional scale—[refer to ND impaired physical Mobility for suggested functional level classification]

Sample Clinical Applications: Arthritis, fractures, amputation, neuromuscular diseases (e.g., multiple sclerosis [MS], amyotrophic lateral sclerosis [ALS], Guillain-Barré syndrome), paralysis, glaucoma, macular degeneration, dementias

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample NOC linkages:

Transfer Performance: Ability to change body location independently with or without assistive device

Balance: Ability to maintain body equilibrium

Body Positioning: Self-Initiated: Personal actions to change own body position independently with or without assistive device

Client/Caregiver Will (Include Specific Time Frame)

- Verbalize understanding of situation and appropriate safety measures.
- Master techniques of transfer successfully.
- Make desired transfer safely.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Self-Care Assistance: Transfer: Assisting a patient with limitation of independent movement to learn to change body location

Body Mechanics Promotion: Facilitating the use of posture and movement in daily activities to prevent fatigue and musculoskeletal strain or injury

Exercise Promotion: Strength Training: Facilitating regular resistive muscle training to maintain or increase muscle strength

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Determine presence of conditions that contribute to transfer problems. *Neuromuscular and musculoskeletal problems (such as MS, fractures with splints or casts, back injuries, knee/hip replacement surgery, amputation, quadriplegia or paraplegia, contractures or spastic muscles); agedness (diminished faculties; multiple medications; painful conditions; decreased balance, muscle mass, tone, or strength), and effects of dementias, brain injury, etc., can seriously impact balance and physical and psychological well-being.*³
- Evaluate perceptual and cognitive impairments and ability to follow directions. *Plan of care and choice of interventions is dependent upon nature of condition—acute, chronic, or progressive; for example, client with severe brain injury may have permanent limitations because of impaired cognition affecting memory, judgment, problem-solving, and motor coordination, requiring more intensive inpatient and long-term care.*
- Note factors complicating current situation. *Recent surgery or traction apparatus, debilitating illness or weakness, and mechanical ventilation or multiple IV/indwelling tubings can restrict movement.*
-  Review medication regimen and schedule to determine possible side effects or drug interactions impairing balance and/or muscle tone.

NURSING PRIORITY NO. 2 To assess functional ability:

-  Perform the “Timed Up and Go” (TUG) test, as indicated, *to assess client’s basic ability to transfer and ambulate safely, and risks of falling. In this test, the client is asked to get up from a seated position in a chair, stand still momentarily, walk forward 10 feet, turn around, walk back to the chair, turn, and sit down. Factors assessed include sitting balance, ability to transfer from sitting to standing and back to sitting, the pace and stability of ambulation, and the ability to turn without staggering. If the client is not safe with ambulation, assistance may also be required with transfers.*^{1,7} *Note: Client may perform this test adequately and still have difficulty with some transfers, such as in or out of a car or bathtub or from floor to chair.*
- Determine degree of impairment using a 0–4 scale, noting muscle strength and tone, joint mobility, cardiovascular status, balance, and endurance. *Identifies strengths and deficits (e.g., ability to ambulate with assistive devices or problems with balance, failure to attend to one side, inability to bear weight [client is non-weight-bearing or partial weight-bearing]) and may provide information regarding potential for recovery.*^{3,8}
- Observe movement when client is unaware of observations *to note any incongruence with reported abilities.*
- Note emotional and behavioral responses of client/significant other to problems of immobility. *Restrictions or limitations imposed by immobility can cause physical, social, emotional, and financial difficulties for everyone.*

NURSING PRIORITY NO. 3 To promote optimal level of movement:

-  Assist with treatment of underlying condition causing dysfunction. *Treatment of condition (e.g., surgery for hip replacement, therapy for unilateral neglect following stroke) can alleviate or improve difficulties with transfer activity.*
-  Consult with physical and occupational therapists or rehabilitation team *to develop general and specific muscle strengthening and range-of-motion exercises and transfer training and techniques, as well as recommendations and provision of balance, gait, and mobility aids or adjunctive devices.*¹
- Position devices (e.g., call light, bed-positioning switch) in easy reach on the bed or chair. *Facilitates transfer and allows client to obtain assistance for transfer as needed.*
- Use appropriate number of people to assist with transfers and correct equipment (e.g., mechanical lift/sling, gait belt, sitting or standing disk pivot) *to safely transfer the client in a particular situation (e.g., chair to bed, chair to car, in or out of shower or tub).*^{4–6,8}
- Demonstrate and assist with use of side rails or stand pole, overhead trapeze, and transfer or sit-to-stand hoist; specialty slings; and/or cane, walker, wheelchair, or crutches, as necessary, *to protect client or care providers from injury during transfers and movements.*^{4,5,8}
- Provide instruction and reinforce information for client and caregivers regarding body and equipment positioning *to improve or maintain balance during transfers.*
- Monitor body alignment, posture, and balance and encourage wide base of support *when standing to transfer.*
- Use full-length mirror, as needed, *to facilitate client’s view of own postural alignment.*

NURSING PRIORITY NO. 4 To maintain safety (Teaching/Discharge Considerations):

-  Instruct client/caregiver in appropriate safety measures. *Actions (e.g., proper use of transfer board; locking wheels on bed or chair; correct placement of equipment for optimal body mechanics of client and caregivers(s); use of gait belt, supportive nonslip footwear; good lighting; clearing floor of clutter) are important to facilitating transfers and reducing the possibility of fall and subsequent injury to client and caregiver.*²
- Discuss need for and sources of care or supervision. *Home-care agency, before- and after-school programs, senior day care, personal companions, etc., may be required to assist with or monitor activity.*
-  Refer to appropriate community resources for evaluation and modification of environment (e.g., roll-in-shower or tub, correction of uneven floor surfaces and steps, installation of ramps, use of standing tables or lifts).
- Refer also to NDs impaired bed/physical/wheelchair Mobility, Unilateral Neglect, risk for Falls, impaired Sitting; impaired Standing; impaired Walking for additional interventions.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including level of function and ability to participate in desired transfers.
- Mobility aides and transfer devices used.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Discharge and long-term needs, noting who is responsible for each action to be taken.
- Specific referrals made.
- Sources of and maintenance for assistive devices.

risk for physical Trauma

Taxonomy II: Safety/Protection—Class 2 Physical Injury (00038) [**Diagnostic Division:** Safety], Submitted 1980; Revised 2013, 2017

DEFINITION: Susceptible to physical injury of sudden onset and severity, which requires immediate attention.

RISK FACTORS

Internal

Emotional disturbance
Impaired balance; weakness; insufficient vision
Insufficient knowledge of safety precautions

(continues on page 922)

risk for Physical Trauma (continued)

External:

Absent or dysfunctional call-for-aid device; bed in high position; struggling with restraints
 Absence of stairway gate or window guard; inadequate stair rails; slippery floor; insufficient anti-slip material in bathroom; use or throw rugs; obstructed passageway; insufficient lighting; unstable chair or ladder
 Access to weapon; high crime neighborhood
 Insufficient protection from heat source; bathing in very hot water; pot handle facing front of stove; use of cracked dishware; flammable object; wearing loose clothing around open flame; inadequately stored combustible
 Children riding in front seat of car; nonuse or misuse of seat restraint; misuse of headgear [e.g., hard hat, motorcycle helmet]
 Defective appliance; delay in ignition of gas appliance; grease on stove; electrical hazard;
 Exposure to corrosive product or toxic chemical; inadequately stored corrosive; exposure to radiation
 Icicles hanging from roof
 Playing with dangerous object or explosive
 Proximity to vehicle pathway [e.g., driveway, railroad track]; unsafe road or walkway; unsafe operation of heavy equipment
 Smoking in bed or near oxygen

At Risk Population: Economically disadvantaged

Extremes of environmental temperature

Gas leak

High crime neighborhood

History of trauma

Associated Condition: Alteration in cognitive function; alteration in sensation

Decrease in eye-hand coordination; decrease in muscle coordination

Sample Clinical Applications: Substance intoxication or abuse, peripheral neuropathy, cataracts, glaucoma, macular degeneration, Parkinson's disease, seizure disorder, dementia, major depression, developmental delay

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Physical Injury Severity: Severity of signs and symptoms of injuries to the body

Personal Safety Behavior: Personal actions to prevent unintentional physical injury to self

Knowledge: Personal Safety: Extent of understanding conveyed about risk reduction and prevention of unintentional injuries to self

Client/Caregiver Will (Include Specific Time Frame)

- Identify and correct potential risk factors in the environment.
- Demonstrate appropriate lifestyle changes to reduce risk of injury.
- Identify resources to assist in promoting a safe environment.
- Recognize need for and seek assistance to prevent accidents/injuries.

ACTIONS/INTERVENTIONS

[This ND is a compilation of a number of situations that can result in injury. Refer to specific NDs, such as risk for imbalanced Body Temperature; risk for Contamination; risk for Falls; impaired Home Maintenance; Hyperthermia; Hypothermia; risk for Injury; impaired physical Mobility; risk for impaired Parenting; risk for Poisoning; risk for Thermal Injury, [disturbed Sensory Perception]; impaired Skin Integrity;

risk for Suffocation; impaired Tissue Integrity; risk for self-/other-directed Violence; impaired Walking, as appropriate, for more specific interventions.]

Sample NIC linkages:

Environmental Management: Safety: Monitoring and manipulation of the physical environment to promote safety

Environmental Management: Worker Safety: Monitoring and manipulation of the worksite environment to promote safety and health of workers

Teaching: Infant [or] Toddler Safety [specify age]: Instruction on safety during first or second and third years of life

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Determine factors related to individual situation and extent of risk for trauma. *Influences scope and intensity of interventions to manage threats to safety, which are dynamic and constants in every life and situation. Clients interfacing with the healthcare system are at higher risk for trauma for any number of reasons (e.g., illness state, cognitive function, family structure, information and training) and require protection in numerous ways.*¹
-  Note client's age, gender, developmental stage, decision-making ability, level of cognition and competence to determine client's ability to recognize danger and to protect self. *Note: Children, young adults, older persons, and men are at greater risk for injury, which may reflect client's ability or desire to protect self, and influences choice of interventions or teaching.*^{12,13}
- Ascertain client's/significant other's (SO's) knowledge of safety needs, injury prevention, and ways of looking at and improving own environment. *Lack of appreciation of significance of individual hazards increases risk of traumatic injury.*¹
- Assess influence of stressors (e.g., physical, mental, peer related, work related, financial) *that can impair judgment and greatly increase client's potential for injury.*
-  Assess mood, coping abilities, and personality styles (i.e., temperament, aggression, impulsive behavior, level of self-esteem). *May result in carelessness or increased risk-taking without consideration of consequences.*^{10,11}
- Evaluate individual's emotional and behavioral response to violence in surroundings (e.g., neighborhood, television, peer group). *May affect client's view of and regard for own/others' safety.*¹⁰⁻¹²
-  Evaluate environment (home, neighborhood, work, transportation) *for obvious safety hazards, as well as situations that can exacerbate injury or adversely affect client's well-being. Unsafe factors include a vast array of possibilities (e.g., unsafe heating appliances, smoking and unattended smoking materials, toxic substances and chemicals, open flames, knives, improperly stored weapons, overloaded electrical outlets, dangerous neighborhoods, unsupervised children).*¹
-  Review potential occupational risk factors (e.g., works with dangerous tools and machinery, electricity, explosives; police, fire, emergency medical service officers; working with hazardous chemicals, various inhalants, or radiation).
- Note history of accidents during specific period of time, noting circumstances of the accident (e.g., time of day that falls occur, activities going on, who was present). *Investigation of such events can provide clues for client's risk for subsequent events and potential for enhanced safety by a change in the people or environment involved (e.g., client may need assistance when getting up at night, increased playground supervision may be required).*
-  Determine potential for abusive behavior by family members/SO(s)/peers. Be prepared for assessment of persons in abusive/violent situations and reporting and referral to appropriate social and law enforcement services. *Anyone, but especially child/frail elder, may require placement if incurring repeated injuries in family/community setting.*

- Note socioeconomic status and availability and use of resources. *Lack of resources, including financial, may limit ability to meet safety needs (e.g., proper child safety seat, appliance repairs, window grates).*
-  Review diagnostic studies and laboratory results, noting impairments or imbalances that may result in or exacerbate conditions, such as confusion, tetany, pathological fractures, etc.

NURSING PRIORITY NO. 2 To enhance safety in healthcare environment:

-  Screen client for safety concerns (e.g., risk for falls, cognitive, developmental, vision/other sensory impairments upon admission and during stay in healthcare facility). Assess for and report changes in client's functional status. Perform thorough assessments regarding safety issues when planning for client discharge. *Failure to accurately assess and intervene or refer regarding these issues can place the client at needless risk and creates negligence issues for the healthcare practitioner.*^{8,9,14}
-  Monitor client's therapeutic regimen on a continual basis when under direct care (e.g., client's vital signs, medications, treatment modalities, infusions, nutrition, physical environment) to prevent healthcare-related complications.^{9,14}
-  Collaborate in treatment of underlying medical, surgical, or psychiatric conditions to improve cognition and thinking processes, musculoskeletal function, awareness of own safety needs, and general well-being.
-  Refer to physical or occupational therapist as appropriate to identify high-risk tasks, conduct site visits, select, create, or modify equipment; and provide education about body mechanics and musculoskeletal injuries, as well as provide needed therapies.²
- Emphasize with client importance of obtaining assistance when weak or sedated and when problems of balance, coordination, or postural hypotension are present to reduce risk of syncope and falls.
- Provide quiet environment and reduced stimulation as indicated. *Helps limit confusion or overstimulation for clients at risk for such conditions as seizures, tetany, and autonomic hyperreflexia.*
- Demonstrate and encourage use of techniques to reduce or manage stress and vent emotions such as anger and hostility to reduce risk of violence to self/others.
- Provide for routine safety needs:²⁻⁷
 Provide adequate supervision and frequent observation.
 Place young children and confused client/person with dementia near nurses' station.
 Provide for appropriate communication tools (e.g., call light, cell phone; writing implements and paper; computer/tablet, alphabet picture board).
 Demonstrate use and place call bell/light or phone within client's reach.
 Orient or reorient client to environment as needed.
 Encourage client's use of corrective vision and hearing aids.
 Keep bed in low position or place mattress on floor as appropriate.
 Maintain correct body alignment and mechanics.
 Provide positioning as required by situation (e.g., immobilization of fractures).
 Implement appropriate measures to maintain skin and tissue health.
 Protect client (with sensory impairments) from injury due to heat and cold.
 Provide seizure precautions when indicated.
 Lock wheels on bed, wheelchair, and movable furniture.
 Assist with activities and transfers as needed.
 Provide well-fitting, nonskid footwear.
 Demonstrate and monitor use of assistive devices, such as cane, walker, crutches, wheelchair, and safety bars.
 Clear travel paths, pick up small items from floor; keep furniture in one place and door in one position (completely open or closed).
 Provide adequate area lighting.
 Follow facility protocol and closely monitor use of restraints when required (e.g., vest, limb, belt, mitten).
- Administer treatments, medications, and therapies in a therapeutic manner.
- Dispose of sharp implements in appropriate container.

NURSING PRIORITY NO. 3 To enhance safety for client in community care setting:

-  Provide information to caregivers regarding client's specific disease or condition(s) and associated risks. *For example, postural hypotension, muscle weakness (e.g., multiple sclerosis), dementia, osteoporosis, and head injury can impair function or cognition, impacting client's ability to protect self.*
- Identify interventions and safety devices to promote safe physical environment and individual safety:^{5,6,8-11}
Recommend wearing visual or hearing aids *to maximize sensory input.*
Ensure availability of communication devices (e.g., telephone, computer, alarm system, or medical emergency alert device).
Install and maintain electrical and fire safety devices, extinguishers, and alarms. Participate in fire drills and planning for fire evacuation routes.
Review smoking safety rules, as indicated, especially as relates to unsafe places to smoke, including while in bed or when oxygen is in use.
Identify environmental needs (e.g., decals on glass doors *to show when they are closed*; adequate lighting of stairways, handrails, ramps, bathtub safety tapes *to reduce risk of falls*; lowering temperature on hot water heater *to prevent accidental burns*; creation of ergonomic workstation).
Obtain seat raisers for chairs; ergonomic beds or chairs.
-  Encourage participation in back-safety classes, injury-prevention exercises, and/or mobility or transfer device training.
-  Install locked cabinets for medications and toxic household substances and use tamper-proof medication containers.
Review proper storage and disposal of volatile liquids, installation of proper ventilation for use when mixing or using toxic substances, and use of safety glasses or goggles.
Emphasize importance of appropriate use of car restraints and bicycle, skating, or skiing helmets.
Discuss swimming pool fencing and supervision; attending first-aid and cardiopulmonary resuscitation classes.
Obtain trigger locks or gun safes for firearms.
-  Initiate appropriate teaching and referrals, *if reckless behavior is occurring or likely to occur (e.g., smoking in bed, driving without safety belts, working with chemicals without safety goggles).*
- Encourage participation in self-help programs *to address individual risks (e.g., assertiveness training, positive self-image to enhance self-esteem, smoking cessation, weight management).*
-  Refer to counseling or psychotherapy, as needed, *especially when individual is "accident-prone" or violent or self-destructive behavior is noted.* Refer to NDs risk for self-directed/other-directed Violence.

NURSING PRIORITY NO. 4 To promote optimal safety (Teaching/Discharge Considerations):

-  Discuss importance of self-monitoring of conditions or emotions that can contribute to occurrence of injury to self/others (e.g., fatigue, anger, irritability). *Client/SO may be able to modify risk through monitoring of actions or postponement of certain actions, especially during times when client is likely to be highly stressed.*
-  Review expectations caregivers have of children, cognitively impaired, or older family members *to identify needed information, required assistance with care, and follow-up that may be needed to provide safe environment for client.*
-  Problem-solve with client/parent *to provide adequate child supervision after school, during working hours, and on school holidays.*
-  Discuss need for and sources of adult supervision (e.g., senior day care, home health aide, or companion).
- Encourage client's family to identify neighbors or friends *willing to assist elderly/individuals with disabilities in providing such things as checking on client who lives alone, removing snow and ice from walks and steps, assisting with structural maintenance, etc.*

-  Explore behaviors related to use of alcohol, tobacco, and recreational drugs and other substances. *Provides opportunity to review consequences of previously determined risk factors (e.g., increase in oral cancer among teenagers using smokeless tobacco, potential consequences of illegal activities, effects of smoking on health of family members as well as fire danger; occurrence of spontaneous abortion, fetal alcohol syndrome or neonatal addiction in prenatal women using tobacco, alcohol, and other drugs).*^{10–12}
- Encourage development of fire safety program. *Participation in family fire drills, use of smoke detectors, yearly chimney cleaning, purchase of fire-retardant clothing (especially children's nightwear), fireworks safety, safe use of in-home oxygen or propane sources, etc., enhances home safety.*
- Recommend use of seat belts and approved infant seat in appropriate position in vehicle; fitted helmets for cyclists, motorcyclists, and skateboarders; wearing necessary visual aids; driver training course for new and mature drivers; avoidance of hitchhiking; and substance-abuse program as indicated *to promote transportation safety.*
-  Identify community resources (e.g., financial, volunteer) *to assist with necessary home improvements or equipment purchases.*
-  Refer to other resources as indicated (e.g., counseling/psychotherapy, parenting classes, budget counseling).
- Provide client/caregiver with emergency contact numbers as individually indicated (e.g., doctor, 911, poison control, police).
- Provide client/caregiver with bibliotherapy and written resources *for later review and self-paced learning.*
- Encourage involvement in community awareness programs and problem-solving of identified community needs:
 Participate in self-help programs (e.g., Neighborhood Watch, Helping Hand, after-school activities). *Programs based on identified needs enhance support of community members and potential funding sources.*
 Promote educational opportunities *geared toward increasing awareness of safety measures (e.g., firearms safety) and resources available to the individual.*
 Seek out and involve businesses in volunteer outreach activities such as building safe playgrounds, community or street cleanup, home repair or improvement for frail elders, etc.
 Advocate for and promote solutions for problems of design of buildings, equipment, transportation, and workplace practices *that contribute to accidents.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual risk factors, past and recent history of injuries, awareness of safety needs.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Available resources, specific referrals made.

risk for vascular Trauma

Taxonomy II: Safety/Protection—Class 2 Physical Injury [Diagnostic Division: Safety], Approved 2008; Revised 2013, 2017

DEFINITION: Susceptible to damage to vein and its surrounding tissues related to the presence of a catheter and/or infused solutions, which may compromise health.

RISK FACTORS

Inadequate available insertion site
Prolonged period of time catheter is in place
Irritating solution
Rapid infusion rate

Sample Clinical Applications: Surgery, trauma, cancer/chemotherapy, pneumonia, sepsis, dehydration, heat stroke

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Risk Control: Personal actions to understand, prevent, eliminate, or reduce modifiable health threats

Knowledge: Treatment Procedure: Extent of understanding conveyed about a procedure required as part of a treatment regimen

Self-Care: Parenteral Medication: Personal actions to administer parenteral medications to meet therapeutic goals independently with or without assistive device

Client Will (Include Specific Time Frame)

- Identify sign/symptoms to report to healthcare provider.
- Be free of signs/symptoms associated with venipuncture, infusion solution, or local infection.
- Develop plan for home therapy where indicated and demonstrate appropriate procedures.

(continues on page 928)

risk for vascular Trauma (continued)

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Intravenous (IV) Insertion: Insertion of a cannulated needle into a peripheral vein for the purpose of administering fluids, blood, or medications

Intravenous (IV) Therapy: Administration and monitoring of intravenous fluids and medications

Medication Administration: Intravenous: Preparing and giving medications via the intravenous route

NURSING PRIORITY NO. 1 To assess risk factors:

- Determine presence of medical condition(s) requiring IV therapy, such as dehydration, trauma, and surgery; long-term antibiotic treatment of severe infections; cancer therapies; and pain management when oral drugs not effective or practical.
- ∞ Note client's age, body size, and weight. *Very young and elderly clients are at risk because of lack of subcutaneous tissue surrounding veins, and veins may be fragile or ropy, causing difficulties with insertion. Forearm veins may be difficult to see in obese, edematous, or dark-skinned individuals.*^{3,4}
- Identify particular issues, such as client's emotional state (including fear of needles) and mental or developmental status, *that might interfere with client's ability to cooperate with procedures*, and IV site choices that interfere with client's mobility *to prevent or limit potential for vascular damage.*³
- ☞ Determine type(s) of solutions being used or planned. *Certain infusates are associated with greater risk of vein irritation and pain (e.g., potassium, contrast media); others are associated with tissue injury, especially upon infiltration into surrounding tissues, including certain antibiotics (e.g., nafcillin, cloxacillin, vancomycin). Hyperosmolar solutions such as total parenteral nutrition can cause tissue damage by altering osmotic pressure. Most cancer chemotherapeutic agents cause direct cellular toxicity after extravasation, and some have potential for causing substantial tissue necrosis (e.g., doxorubicin, vincristine).*⁵ *Note: Therapies not appropriate for peripheral short catheters include continuous vesicant therapy, parenteral nutrition, infusates with a pH less than 5 or greater than 9, and solutions with an osmolarity greater than 600 mOsm/L.*^{6,7}
- Assess peripheral IV site when one is already in place to determine potential for complications. *Reddened, blanched, tight, translucent, or cool skin; swelling; pain; numbness; streak formation; and a palpable venous cord or purulent drainage are indicative of problem with IV requiring immediate intervention.*¹
- Assess central venous access device (CVAD), if present, to determine potential for complications. *Inability to aspirate; slowed or absent solution flow; site pain; and engorged veins or swelling in upper arm, chest wall, neck, or jaw on side of catheter insertion may indicate vein or catheter-related thrombus, requiring immediate intervention.*^{1,2}

NURSING PRIORITY NO. 2 To reduce potential complications:

- Determine appropriate site choice:
 - ☞ Identify extremities and sites that have impaired circulation or injury, such as lymphedema, postoperative swelling, recent trauma, hematoma, axillary lymph node dissection, open wounds, etc.⁴ *Leg veins should be avoided in adults due to potential for thrombophlebitis. Antecubital veins should be avoided for peripheral catheters where possible because they limit client's movement and are easily dislodged.*⁶
 - ☞ Inspect and palpate chosen veins to determine size and condition. *Vein that is scarred, lumpy, or small and fragile can not only cause problems upon cannulation but also can impede effectiveness of infusion.*^{1,6}
- Avoid inserting needle in vein valve site. *Damage to this area can cause blood pooling and increase risk of thrombosis.*³

- Use a best-practice approach to IV insertion and therapies:

 Determine best type of access when IV therapy is to be initiated. *Peripheral catheter in forearm is recommended for short-duration, nonirritating solutions of less than 7 days. CVAD placed so that tip is in or near the superior vena cava is appropriate for infusing many kinds of solutions over long periods of time.*^{4,8,9}

 Choose appropriate needle or catheter for situation considering planned length and type of therapy, avoiding steel butterfly needles when possible to reduce risk of vein injury and infiltration.^{1,2,4} *Over-the-needle catheter for hand or forearm may be ideal for most solutions over a short length of time, while midline catheter may be chosen for chemotherapy or when antibiotic therapy is planned for 1 to 4 weeks; a central venous catheter is used for infusates and other substances that are too irritating to peripheral veins, when client has suffered multiple peripheral sticks, or when one extremity is not available (e.g., amputation, dialysis shunt in one arm).*^{4,8}

 Use appropriate needle gauge. *Size should be smallest diameter possible for chosen vein and solution to be infused to deliver solution at appropriate rate, to promote hemodilution of fluid(s) at the catheter tip, and to reduce mechanical and chemical irritation to vein wall.*^{1,3,4}

 Make use of equipment (e.g., ultrasound, near-infrared technology, transillumination), as indicated/available, when venous access is difficult and/or after failed venous access attempts to reduce client's trauma (both physical and emotional), and potential for excess vein damage affiliated with multiple attempts (2016 Infusion Nurses Society [INS] Standards of Practice, Standard 22).⁶

 Clean site and follow agency policy for the use of a local anesthetic (e.g., buffered 1% lidocaine) before venipuncture to reduce risk of infection and pain with needle or cannula insertion. *Note: Nursing research is being conducted on the use of lidocaine or normal saline injection for the reduction of the discomfort of venipuncture. One recent small study found intradermal lidocaine superior to bacteriostatic normal saline as an anesthetic pretreatment; however, this study demonstrated that normal saline can provide reasonable pain relief and is thus a practical alternative when intradermal lidocaine is not available or the patient has an allergy to lidocaine.*¹⁰

Stretch and immobilize skin and tissues to stabilize vein and prevent rolling, requiring multiple sticks.

*Insert needle bevel up and hold at a 3- to 10-degree angle to prevent “blowing” the vein by piercing the back wall.*²

*Release tourniquet immediately when insertion is complete to prevent intravascular pressure from causing bleeding into surrounding tissues.*¹

*Observe for hematoma development and/or reports of pain and discomfort during insertion, indicating vein damage with bleeding into tissues.*⁴

*Secure needle or cannula with tape or other securement device to prevent dislodging and extend catheter dwell time.*⁶

*Avoid placing tape entirely around arm to anchor catheter. This may impede venous return and cause venous stasis, pooling of fluid, and infiltration or extravasation into surrounding tissues.*⁴

Utilize transparent dressing over insertion site to protect from external contaminants and to easily observe for potential complications.

 Adhere to recommended infusions, dilutions, and administration rates for medications or irritating substances such as potassium to reduce incidence of tissue irritation and sloughing.^{2,4,6}

-  Consult with IV nurse or other medical provider to problem-solve issues that arise with IVs and/or when different access should be considered (e.g., midline catheter for continuous infusion of irritating solutions, peripheral intravenous central catheter [PICC] for parenteral nutrition) or for evaluation and interventions for complications such as thrombus development in central catheter tip or in the vein around the catheter.^{4,9}

NURSING PRIORITY NO. 3 To promote optimum therapeutic effect:

-  Observe IV site on a regular basis and instruct client/caregiver to report any discomfort, bruising, redness, swelling, bleeding, or other fluid leaking from site to allow for prompt intervention and limit serious complications.

- Replace peripheral catheters every 72 to 96 hr (or per agency policy) *to prevent thrombophlebitis and catheter-related infections.*⁴
- Apply pressure to site when IV is discontinued for sufficient time *to prevent bleeding, especially in client with coagulopathies or on anticoagulants.*⁴
- Adhere to specific protocols related to infection control *to promote safe infusion of solutions or medications and prevent complications.* Refer to ND risk for Infection.
- 🏠 Identify community resources and suppliers *to support home therapy regimen.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Assessment findings pre/postinsertion, site choice, use of local anesthetic, type and gauge of needle or cannula inserted, number of sticks required, dressing applied.
- Type, amount, and rate of solution administered, presence of additives.
- Client's response to procedure.

Planning

- Plan of care, specific interventions, and who is involved in the planning.
- Teaching plan as appropriate.

Implementation/Evaluation

- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-range needs, identifying who is responsible for actions to be taken.
- Community resources for equipment and supplies for home therapy.
- Specific referrals made.

Unilateral Neglect

Taxonomy II: Perception/Cognition—Class 1 Attention (00123) [**Diagnostic Division:** Neurosensory], Submitted 1986; Revised 2006

DEFINITION: Impairment in sensory and motor response, mental representation, and spatial attention to the body and the corresponding environment, characterized by inattention to one side and overattention to the opposite side. Left-side neglect is more severe and persistent than right-side neglect.

RELATED FACTORS

To Be Developed

DEFINING CHARACTERISTICS

Objective

Left hemiplegia from cerebrovascular accident; unilateral visuospatial neglect
 Hemianopsia; marked deviation of the eyes or trunk to stimuli on the non-neglected side
 Failure to move eyes, head, limbs, or trunk in the neglected hemisphere; failure to notice people approaching from the neglected side
 Disturbance of sound lateralization
 Unaware of positioning of neglected limb
 Alteration in safety behavior on neglected side
 Failure to: eat food from portion of plate on neglected side; dress or groom neglected side
 Use of vertical half of page only when writing; impaired performance on line cancellation, line bisection, and target cancellation tests; substitution of letters to form alternative words when reading
 Omission of drawing on the neglected side; representational neglect [e.g., distortion of drawing on the neglected side]
 Perseveration
 Transfer of pain sensation to the non-neglected side
Associated Condition: Brain injury
Sample Clinical Applications: Traumatic brain injury, CVA/ruptured cerebral aneurysm, brain tumor, glaucoma

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Heedfulness of Affected Side: Personal actions to acknowledge, protect, and cognitively integrate affected body part(s) into self

Self-Care: Activities of Daily Living (ADL): Personal actions to perform the most basic physical tasks and personal care activities independently with or without assistive device

Client/Caregiver Will (Include Specific Time Frame)

- Acknowledge presence of sensory-perceptual impairment.
- Identify adaptive and protective measures for individual situation.
- Demonstrate behaviors and lifestyle changes necessary to promote physical safety.

Client Will (Include Specific Time Frame)

- Verbalize positive realistic perception of self, incorporating the current dysfunction.
- Perform self-care within level of ability.

(continues on page 932)

Unilateral Neglect (continued)

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Unilateral Neglect Management: Protecting and safely reintegrating the affected part of the body while helping the patient adapt to disturbed perceptual abilities

Positioning: Deliberate placement of the patient or a body part to promote physiological and/or psychological well-being

Environmental Management: Safety: Monitoring and manipulation of the physical environment to promote safety

NURSING PRIORITY NO. 1 To assess the extent of altered perception and the related degree of disability:

-  Identify underlying condition or reason for alterations in sensory/motor/behavioral perceptions as noted in Related Factors. *The client with injury to either side of the brain may experience spatial neglect, but more commonly, it occurs when brain injury affects the right cortical hemisphere, causing left hemiparesis.*¹⁰
- Observe client's behaviors (as noted in Defining Characteristics) *to determine the extent of impairment (e.g., failure to respond to stimuli, objects, or people on the contralesional side).*
- Ascertain client's/significant other's (SO's) perception of problem and changes and impact on life and future, noting differences in perceptions. *Client is often not aware of, or able to express, spatial perception problems or understand potential effect on future expectations.*
-  Assist with/review results of early screening tests. *Tests (often performed at the bedside) may include (and are not limited to) observation to determine if client shows evidence of body neglect such as asymmetric shaving/grooming. Reading test might reveal that client begins reading in the middle of the page. Client may not be able to count fingers on both hands or perceive finger snapping at both ears. Paper and pencil testing may reveal hemispatial neglect through line dissection.*^{1,9}
-  Assess ability to distinguish between right and left. *Unilateral spatial neglect is observed in stroke, brain tumor, or accident victims with damage to the right parietal or parietal-occipital lobe, resulting in misperceptions of space opposite to brain damage. The individual with this condition has information from the left hemisphere but no conscious awareness of the information; thus, he/she will pay no attention to the left space.*¹⁻⁴
- Assess sensory awareness (e.g., response to stimulus of hot and cold, dull or sharp); note problems with awareness of motion and proprioception. *Disturbances in these areas may be result of spinal cord injury (where loss of sensation affects body awareness) or brain lesion (where sensation may be intact but awareness is impaired).*
- Note physical signs of neglect (e.g., inability to maintain normal posture; disregard for position of affected limb[s], bumping into objects or walls on the left when ambulating, skin irritation/damage on the left side, indicating lack of awareness of injury).
- Observe ability to function within limits of impairment. Compare with client's perception of own abilities. *Client may or may not be able to learn from mistakes or from observing others depending on the location and severity of the brain lesion.*⁵
-  Explore and encourage verbalization of feelings *to identify meaning of loss, dysfunction, or change to the client and impact it may have on assuming ADLs. Note: Expression of loss may be difficult for the client for a variety of reasons. For example, some emotional disturbances and personality changes are caused by the physical effects of brain damage, or the client may be hyperemotional or depressed or be unable to express feelings in the same manner as prior to brain injury.*⁵

-  Review results of testing (e.g., computed tomography or magnetic resonance imaging scanning, complete neuropsychological tests) *done to determine cause or type of neglect syndrome (e.g., sensory, motor, representational, personal, spatial, behavioral inattention).*⁶⁻⁹

NURSING PRIORITY NO. 2 To promote optimal comfort and safety for the client in the environment:

-  Engage in treatment strategies *focused on training of attention to the neglected hemisphere.*^{1-5,8,9}
Encourage use of vision and hearing aids if condition requires or client usually wears them *to improve sensory input and interpretation.*
Remove excess stimuli from the environment *to decrease confusion and reactive stress.*
Orient or reorient to physical environment and persons interacting with client. *Client with unilateral neglect can also have numerous other cognitive defects affecting ability to think, remember, speak or understand language, and/or interpret environment.*⁵
Approach client and instruct others to approach client from the unaffected side (e.g., right side, side where vision is not impaired) *to enhance client's awareness and potential for communication.*
Encourage client to turn head and eyes in full rotation and “scan” the environment *to compensate for visual field loss or when neglect therapies include scanning.*
Position bedside table and objects (e.g., telephone, call bell, tissues) *within functional field of vision or awareness to facilitate self-care. Note: Therapies may include orienting the client's environment leftward in attempt to help client perceive the neglected space.*
Place nonessential items (e.g., television, pictures, hairbrush) on affected side during postacute phase once client begins to cross midline *to encourage continuation of retraining behaviors.*
Discuss affected side while touching, manipulating, and stroking affected side *to focus client's attention on area and provide objects of various weight, texture, and size for the client to handle to provide tactile stimuli.*
Describe where affected areas of body are *when moving or repositioning client.*
Use descriptive terms to identify body parts rather than “left” and “right”; for example, “Lift this leg” (point to leg) or “Lift your affected leg.”
Encourage client to accept affected limb or side as part of self even when it no longer feels like it belongs.
Have client look at and handle affected side *to stimulate awareness and bring the affected limb across the midline for client to visualize during care.*
Provide visual cues and assist client to position the affected extremity carefully and teach to routinely visualize placement of the extremity.
Use a mirror to help client adjust position *by visualizing both sides of the body.*
-  Provide assistance with ADLs (e.g., feeding, bathing, dressing, grooming, toileting), *which helps client tend to affected side or compensate for client's impairments. Note: Studies show that unilateral neglect is a major factor limiting ADLs and in client being at increased risk for falls.*¹¹
- Monitor neglected body part(s) for positioning and anatomic alignment, pressure points, skin irritation or injury, and dependent edema. *Increased risk of injury and pressure ulcer formation necessitates close observation and timely intervention. (Refer to NDs risk for Peripheral Neurovascular Dysfunction and impaired Tissue Integrity.)*
- Assist with ambulation or movement, using appropriate mobility and assistive devices *to promote safety of client and caregiver.*
- Protect from falls and/or collision with objects:
Position furniture and equipment *so travel path is unobstructed.*
Remove articles that may create a safety hazard (e.g., footstool, throw rug).
Ensure adequate lighting in the environment.
Keep doors wide open or completely closed.
- Refer to NDs impaired Environmental Interpretation Syndrome, risk for Falls/Injury, and Self-Care Deficit (specify) for additional interventions regarding comfort and safety.
-  Collaborate with rehabilitation team in strategies (e.g., sensory stimulation techniques such as tapping or stroking, patching one half of each eye, auditory stimulation, wedge prism adaptation techniques, virtual reality technology) *to assist client to overcome or compensate for deficits.*^{5,12,13}

NURSING PRIORITY NO. 3 To promote optimal functioning (Teaching/Discharge Considerations):

-  Acknowledge and accept feelings of despondency, grief, and anger. *When feelings are openly expressed, client can deal with them and move forward.* (Refer to ND Grieving as appropriate.)
- Encourage family members/SO(s) to treat client normally, to urge client to perform own care as able, and to include client in family activities and outings. *Promotes sense of self-worth and encourages participation in life activities to limit withdrawal and depression.*
- Reinforce to client the reality of the dysfunction and need to compensate. Avoid participating in the client's use of denial. *Delays dealing with reality of situation and limits progress toward goals.*
-  Encourage client to continue rehabilitative services *to maximize recovery and enhance independence.*
Note: Research indicates that most clients with neglect show early recovery, particularly within the first month, and marked improvement within 3 months. In approximately 5% of clients, classic (more severe) symptoms of spatial neglect persist after 6 months or longer. In these individuals, the deficit may be regarded as chronic neglect.⁹
- Discuss and prepare for ongoing safety issues. *Client may continue to have some functional problems after apparent recovery of spatial neglect, including difficulty with navigating in familiar and unfamiliar environments or safe driving.⁹*
-  Identify additional resources to meet individual needs (e.g., Meals on Wheels, home-care rehabilitation services) *to maximize independence and allow client to return to and succeed in community setting.*

DOCUMENTATION FOCUS**Assessment/Reassessment**

- Individual findings, including extent of altered perception, degree of disability, effect on independence and participation in ADLs.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Responses to intervention, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Available resources, specific referrals made.

impaired spontaneous Ventilation

Taxonomy II: Activity/Rest—Class 2 Cardiovascular/Pulmonary Response (00033) [Diagnostic Division: Respiration], Approved 1992; Revised 2017

DEFINITION: Inability to initiate and/or maintain independent breathing that is adequate to support life.

RELATED FACTORS

Respiratory muscle fatigue

DEFINING CHARACTERISTICS

Subjective

Dyspnea

Apprehensiveness

Objective

Alteration in metabolic rate

Increase in heart rate

Restlessness

Increase in accessory muscle use

Decrease in tidal volume

Decrease in partial pressure of oxygen (PO_2), arterial oxygen saturation (SaO_2); increase in partial pressure of carbon dioxide (PCO_2)

Associated Condition: Alteration in metabolism

Sample Clinical Applications: Chronic obstructive pulmonary disease (COPD), asthma, pulmonary embolus, acute respiratory distress syndrome, brain injury, chest trauma or surgery, Guillain-Barré syndrome, amyotrophic lateral sclerosis (ALS)

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Mechanical Ventilation Response: Adult: Alveolar exchange and tissue perfusion are effectively supported by mechanical ventilation

Respiratory Status: Ventilation: Movement of air in and out of the lungs

Endurance: Capacity to sustain activity

Client Will (Include Specific Time Frame)

- Reestablish and maintain effective respiratory pattern via ventilator, with absence of retractions or use of accessory muscles, cyanosis, or other signs of hypoxia, and with arterial blood gases (ABGs)/ SaO_2 within acceptable range.
- Participate in efforts to wean (as appropriate) within individual's ability.

(continues on page 936)

impaired spontaneous Ventilation (continued)

Sample NOC linkage:

Energy Conservation: Personal actions to manage energy for initiating and sustaining activity

Caregiver Will (Include Specific Time Frame)

- Demonstrate behaviors necessary to maintain client's respiratory function.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Ventilation Assistance: Promotion of an optimal spontaneous breathing pattern that maximizes oxygen and carbon dioxide exchange in the lungs

Mechanical Ventilation Management: Invasive: Assisting the patient receiving artificial breathing support through a device inserted into the trachea

Respiratory Monitoring: Collection and analysis of patient data to ensure airway patency and adequate gas exchange

NURSING PRIORITY NO. 1 To determine degree of impairment:

- Identify client with impending respiratory failure (e.g., developing apnea or slow, shallow breathing; declining mentation or obtunded with need for airway protection).⁵
- Determine presence of conditions that could be associated with hypoventilation. *Causes include (1) central alveolar hypoventilation as a result of congenital defects, drugs, and central nervous system disorders (e.g., stroke, trauma, neoplasms); (2) obesity hypoventilation syndrome is another well-known cause of hypoventilation; (3) chest wall deformities (e.g., kyphoscoliosis, changes after thoracic surgery) can be associated with alveolar hypoventilation, leading to respiratory insufficiency and failure; and (4) neuromuscular diseases that can cause alveolar hypoventilation include myasthenia gravis, ALS, Guillain-Barré, and muscular dystrophy.*⁵
-  Assess spontaneous respiratory pattern, noting rate, depth, rhythm, symmetry of chest movement, and use of accessory muscles. *Tachypnea, shallow breathing, and demonstrated or reports of dyspnea (using a numeric or similar scale); increased heart rate and dysrhythmias; pallor or cyanosis; and intercostal retractions and use of accessory muscles indicate increased work of breathing or impaired gas exchange. Note: Studies to date show that no one specific scale has been developed to cover all aspects of breathlessness, but asking the client to rate it some way may be helpful in differentiating this episode from others.*^{5,8}
- Auscultate breath sounds, noting presence or absence and equality of breath sounds and adventitious breath sounds (e.g., wheezing) to evaluate presence and degree of ventilatory impairment.
-  Evaluate ABGs or pulse oximetry and capnography to determine presence and degree of arterial hypoxemia (PaO_2 less than 55%) and hypercapnia (PaCO_2 greater than 45%), resulting in impaired ventilation requiring support.^{6,7}
-  Obtain or review results of pulmonary function studies (e.g., lung volumes, inspiratory and expiratory pressures, forced vital capacity), as appropriate, to assess presence and degree of respiratory insufficiency. *Note: Pulmonary function tests revealing (1) $\text{PaO}_2 < 55$ mmHg; (2) vital capacity less than 10 mL/kg; (3) negative inspiratory force < 25 cm H_2O ; and (4) FEV_1 less than 10 mL/kg are standard indicators for intubation and ventilatory management.*⁷
-  Investigate etiology of current respiratory failure (e.g., exacerbation of COPD, pneumonia, pulmonary embolus, heart failure, trauma) to determine client's ventilation needs and most appropriate type of ventilatory support.

-  Review serial chest x-rays and imaging scans (e.g., magnetic resonance imaging, computed tomography) that may be performed *to diagnose underlying disorder and monitor response to treatment.*
- Note response to current measures and respiratory therapy (e.g., bronchodilators, supplemental oxygen, intermittent positive pressure breathing treatments). *Client may already be receiving treatments to maintain airway patency and enhance gas exchange or may have respiratory failure associated with sudden event (e.g., severe trauma, sudden onset respiratory illness, surgery with complications).*
- Ascertain desires of client/significant others (SOs) regarding plan for treatment of respiratory failure, as indicated. *Client may have advance directives and/or prior stated decisions about the level of therapy aggressiveness that he or she desires if situation is chronic or long term. Family members may help in decision-making processes if client is a minor or is incapacitated.*

NURSING PRIORITY NO. 2 To provide/maintain ventilatory support:

-  Collaborate with physician and respiratory care practitioners regarding effective mode of ventilation (e.g., noninvasive oxygenation via continuous positive airway pressure [CPAP] and biphasic positive airway pressure [BIPAP]) or intubation and mechanical ventilation (e.g., continuous mandatory, assist control, intermittent mandatory [IMV], pressure support). *Specific mode is determined by client's respiratory requirements, presence of underlying disease process, and the extent to which client can participate in ventilatory efforts. Goals of therapy depend on the reason for mechanical ventilation (e.g., to improve oxygenation, permit sedation, reverse respiratory muscle fatigue).⁹*
-  Ensure effective ventilation:^{1,7,9}
 Ensure that ventilator settings and parameters are correct as ordered by client situation, including respiratory rate and fraction of inspired oxygen (FIO₂, expressed as a percentage; tidal volume); peak inspiratory pressure.
 Observe overall breathing pattern, distinguishing between spontaneous respirations and ventilator breaths. *Client may be completely dependent on the ventilator or able to take breaths but have poor oxygen saturation without the ventilator. The client on assist-control ventilation mode can still experience hyper/hypoventilation or "air hunger" and attempt to correct deficiency by overbreathing.⁷*
 Verify that client's respirations are in phase with the ventilator. *Decreases work of breathing, maximizes O₂ delivery when client is not fighting the ventilator.*
 Inflate tracheal or endotracheal tube cuff properly using minimal leak or occlusive technique *to ensure adequate ventilation and delivery of desired tidal volume.*
 Check cuff inflation periodically per facility protocol, and whenever cuff is deflated then reinflated *to prevent risks associated with under/overinflation.*
 Check tubings for obstruction (e.g., kinking or accumulation of water) *that can impede flow of oxygen.* Drain tubing, as indicated; refrain from draining toward the client or back into the reservoir, *which can result in contamination and provide medium for growth of bacteria.*
 Check ventilator alarms for proper functioning. Do not turn off alarms, even for suctioning. Verify that alarms can be heard in the nurses' station by care providers *to ensure care provider is alerted to emergent situation or ventilator disconnect.*
 Suction only as needed, using lowest pressure possible, *to clear secretions if client is coughing excessively, has visible secretions, or is tripping high-pressure alarm on ventilator.*
 Remove from ventilator and ventilate manually *if source of ventilator alarm cannot be quickly identified and rectified.*
 Verify that oxygen line is in proper outlet or tank; monitor in-line oxygen analyzer or perform periodic oxygen analysis *to deliver an acceptable oxygen percentage and saturation for client's specific needs.*
 Assess ventilator settings routinely and readjust, as indicated, *according to client's primary disease and results of diagnostic testing.*
 Verify tidal volume set to volume needed for individual situation and proper functioning of spirometer, bellows, or computer readout of delivered volume *to reduce risk of complications associated with alteration in lung compliance or leakage through machine or around tube cuff.*

Monitor airway pressure for developing complications or equipment problems (e.g., increased airway resistance, retained secretions, decreased lung compliance, client out of phase or off ventilator).

Promote periodic maximal ventilation of alveoli; check sigh rate intervals (usually 1 1/2 to 2 times tidal volume). *Reduces risk of atelectasis and helps mobilize secretions.*

Note inspired humidity and temperature; maintain hydration *to prevent excessive drying of mucosa and secretions.*

- Auscultate breath sounds periodically. Note frequent crackles or rhonchi that do not clear with coughing or suctioning. *May indicate developing complications (e.g., atelectasis, pneumonia, acute bronchospasm, pulmonary edema).*
- Note changes in chest symmetry. *May indicate improper placement of endotracheal tube or development of barotrauma.*
- Keep resuscitation bag at bedside *to allow for manual ventilation whenever indicated (e.g., if client is removed from ventilator or troubleshooting equipment problems).*
-  Administer and monitor response to medications that promote airway patency and gas exchange *to determine efficacy and need for change.*
-  Administer sedation, as required, *to synchronize respirations and reduce work of breathing and energy expenditure.*
- Refer to NDs ineffective Airway Clearance, ineffective Breathing Pattern, and impaired Gas Exchange for related interventions.

NURSING PRIORITY NO. 3 To prepare for/assist with weaning process if appropriate:

- Determine client's physical and psychological readiness to wean soon after intubation, whenever possible, *to limit complications associated with long-term mechanical ventilation. Successful weaning is based on parameters such as (1) evidence for some reversal of the underlying cause of respiratory failure, (2) adequate oxygenation and normal pH, (3) hemodynamic stability, (4) capability and willingness to initiate inspiratory effort, (5) absence of excessive secretions, and (6) nutritional status sufficient to maintain work of breathing.*^{1-4,5,7,9}
-  Determine mode for weaning. *Recent studies indicate that pressure support mode or multiple daily T-piece trials may be superior to IMV, low-level pressure support may be beneficial for spontaneous breathing trials, and early extubation and institution of noninvasive positive pressure ventilation may have substantial benefits in alert, cooperative client.*^{2,4,5}
- Explain to client/SO weaning activities and techniques, individual plan, and expectations. *Reduces fear of unknown, provides opportunities to deal with concerns, clarifies reality of fears, and helps reduce anxiety to a more manageable level.*^{3,7}
-  Engage client in specialized exercise program *to enhance respiratory muscle strength and general endurance.*
- Maximize weaning effort:
Elevate head of bed/place in orthopedic chair, if possible, or position *to alleviate dyspnea and to facilitate oxygenation.*
Coach client in “taking control” of breathing during weaning periods (e.g., to take slower, deeper breaths; practice abdominal or pursed-lip breathing; assume position of comfort) *to maximize respiratory function and reduce anxiety.*
Instruct in or assist client to perform effective coughing techniques. *Necessary for secretion management after extubation.*
Provide quiet environment, calm approach, and undivided attention of nurse. *Promotes relaxation, decreasing energy and oxygen requirements.*
Involve family/SO(s) as appropriate. Provide diversionary activity. *Helps client focus on something other than breathing.*
Instruct client in use of energy-saving techniques during care activities *to limit oxygen consumption and fatigue associated with work of breathing.*

- Acknowledge and provide ongoing encouragement for client's efforts. Communicate hope for successful weaning response (even partial). *Emotional support can enhance client's commitment to continue weaning activity, maximizing outcomes.*

NURSING PRIORITY NO. 4 To prepare for discharge on ventilator when indicated:

-  Ascertain plan for discharge placement (e.g., return home, short-term admission to subacute or rehabilitation center, permanent placement in extended-care facility). *Helps to determine care needs and fiscal impact of home care versus extended-care facility.*
- Review layout of home, noting size of rooms, doorways, placement of furniture, and number and type of electrical outlets *to identify necessary modifications and safety needs.*
- Determine specific equipment needs and resources for equipment and maintenance. Arrange for delivery before client discharge *to allow SO/caregivers to prepare for transfer.*
- Allow sufficient opportunity for SO(s)/family to practice new skills. Role-play potential crisis situations *to enhance confidence in ability to handle client's needs.*
- Demonstrate airway management techniques and proper equipment cleaning practices *to reduce risk of infection.*
-  Instruct SO(s)/caregivers in pulmonary physiotherapy measures, as indicated. Refer for home respiratory therapy support, as needed.
- Provide positive feedback and encouragement for efforts of SO(s)/caregivers. *Promotes continuation of desired behaviors.*
- List names and phone numbers for identified contact persons and resources. *Can reduce sense of isolation and enhance likelihood of obtaining assistance and support when needed.*
- Review and provide written or audiovisual materials regarding proper ventilator management, maintenance, and safety for reference in home setting. *Provides information to enhance client's/SO's level of comfort with challenging tasks.*
- Identify signs/symptoms requiring prompt medical evaluation or intervention. *Timely treatment may prevent progression of problem or untoward complications.*
- Obtain no-smoking signs to be posted in home, and remind family members to refrain from smoking *to reduce risk of fire.*
- Have family/SO(s) notify utility company and fire department of presence of ventilator in home. *Client will be placed in high-risk list for follow-up in case of power outage or fire.*

NURSING PRIORITY NO. 5 To promote wellness (Teaching/Discharge Considerations):

-  Discuss impact of specific activities on respiratory status and problem-solve solutions *to maximize weaning effort or to reduce incidence of respiratory distress or failure.*
- Monitor health of visitors and persons involved in care *to protect client from sources of infection.*
- Encourage time-out or respite for caregivers *so they may attend to personal needs, wellness, and growth.* Refer to ND risk for caregiver Role Strain.
- Provide opportunities for client/SO(s) to discuss advance directives. *Clarifies parameters for termination of therapy or other end-of-life decisions, as desired.*
-  Recommend involvement in support group; introduce to other ventilator-dependent individuals who are successfully managing home ventilation, if desired, *to answer questions, provide role model, assist with problem-solving, and offer encouragement and hope for the future.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Baseline findings, subsequent alterations in respiratory function.
- Results of diagnostic testing.
- Individual risk factors and concerns.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Client's/other's responses to interventions, teaching, and actions performed.
- Skill level and assistance needs of SO(s)/family.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Discharge plan, including appropriate referrals, action taken, and who is responsible for each action.
- Equipment needs and source.
- Resources for support persons or home-care providers.

dysfunctional Ventilatory Weaning Response

Taxonomy II: Activity/Rest—Class 4 Cardiovascular/Pulmonary Responses (00034) [**Diagnostic Division:** Respiration], Approved 1992; Revised 2017

DEFINITION: Inability to adjust to lowered levels of mechanical ventilator support that interrupts and prolongs the weaning process.

RELATED FACTORS*Physiological*

Ineffective airway clearance
Alteration in sleep pattern; [fatigue]
Inadequate nutrition
Pain

Psychological

Insufficient knowledge of the weaning process
Uncertainty about ability to wean; [unprepared for weaning attempt]
Decrease in motivation; low self-esteem
Anxiety; fear; insufficient trust in healthcare professionals
Hopelessness; powerlessness

Situational

Uncontrolled episodic energy demands

Inappropriate pace of weaning process
 Insufficient social support
 Environmental barrier [e.g., distractions, low nurse to patient ratio, unfamiliar healthcare staff]

DEFINING CHARACTERISTICS

Mild

Subjective

Perceived need for increase in oxygen; breathing discomfort; fatigue, warmth
 Fear of machine malfunction

Objective

Restlessness
 Mild increase of respiratory rate from baseline
 Increase in focus on breathing

Moderate

Subjective

Apprehensiveness

Objective

Increase in blood pressure (<20 mmHg)/heart rate (<20 beats/min) from baseline
 Moderate increase in respiratory rate over baseline; minimal use of respiratory accessory muscles;
 decrease in air entry on auscultation
 Hyperfocused on activities; facial expression of fear
 Impaired ability to cooperate or respond to coaching
 Diaphoresis
 Abnormal skin color

Severe

Objective

Agitation; decrease in level of consciousness
 Deterioration in arterial blood gases from baseline
 Increase in blood pressure (≥ 20 mmHg)/heart rate (≥ 20 beats/min) from baseline
 Significant increase in respiratory rate above baseline; use of significant respiratory accessory muscles;
 shallow breathing; gasping breaths; paradoxical abdominal breathing
 Adventitious breath sounds
 Asynchronized breathing with the ventilator
 Profuse diaphoresis
 Abnormal skin color

Associated Condition: History of unsuccessful weaning attempt

History of ventilator dependence >4 days

Sample Clinical Applications: Traumatic brain injury, stroke, substance overdose, chronic obstructive pulmonary disease (COPD), crushing chest trauma, respiratory or cardiac arrest

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Mechanical Ventilation Weaning Response: Adult: Respiratory and psychological adjustment to progressive removal of mechanical ventilation

Respiratory Status: Ventilation: Movement of air in and out of the lungs

(continues on page 942)

dysfunctional Ventilatory Weaning Response (continued)

Respiratory Status: Gas Exchange: Alveolar exchange of carbon dioxide and oxygen to maintain arterial blood gas concentrations

Client Will (Include Specific Time Frame)

- Actively participate in the weaning process.
- Reestablish independent respiration with arterial blood gases (ABGs) within client's normal range and be free of signs of respiratory failure.
- Demonstrate increased tolerance for activity and participate in self-care within level of ability.

ACTIONS/INTERVENTIONS

Sample NIC linkages:

Mechanical Ventilation Management: Invasive: Assisting the patient receiving artificial breathing support through a device inserted into the trachea

Mechanical Ventilatory Weaning: Assisting the patient to breathe without the aid of a mechanical ventilator

Energy Management: Regulating energy use to treat or prevent fatigue and optimize function

NURSING PRIORITY NO. 1 To identify contributing factors/degree of dysfunction:

-  Determine extent and nature of underlying disorders or factors (e.g., respiratory pump insufficiency [control of breathing, respiratory muscles, lung/chest wall mechanics or, rarely, gas exchange], cardiovascular dysfunction, neuromuscular disorders, psychological factors [such as depressive disorders or delirium] as well as metabolic/endocrine diseases, alone or combined) *that contribute to client's reliance on mechanical support, thus affecting weaning efforts.*⁷ *Note: Recent studies have reported on various predictors of weaning outcome, which included maximal inspiratory pressure, rapid shallow breathing index, fluid balance, comorbidity burden, severity of illness, emphysematous changes, and low serum albumin. Age, in and of itself, was not a predictor of weaning from mechanical ventilation in six studies.*⁴
-  Note length of time client has been on ventilator. Review previous episodes of extubation and reintubation. *Previous unsuccessful weaning attempts (e.g., due to inability to protect airway or clear secretions; oxygen saturation less than 50% on room air) can influence weaning interventions. Although most individuals remain on the ventilator for 7 days or less, some require support for several weeks or more. Note studies have shown that if client fails to wean from ventilator dependence within 60 days, he/she will probably not do so later.*^{1,8,15}
-  Complete Burns Weaning Assessment Program (BWAP) or similar checklist (e.g., stability of vital signs, factors that increase metabolic rate [e.g., sepsis, fever]; hydration status; need for or recent use of analgesia or sedation; nutritional state, muscle strength, and activity level) *to assess systemic parameters that may affect readiness for weaning. Note: A recent study of the use of BWAP score in five adult critical care units found that a score of 50 or higher was linked to successful weaning outcomes.*^{1,2,9-11,13}
- Ascertain client's awareness and understanding of weaning process, expectations, and concerns. *Client/significant other (SO) may need specific and repeated instructions during process to allay fears and enhance cooperation. Unrealistic expectations or unvoiced concerns can impair weaning process or willingness to participate.*
- Determine psychological readiness and presence/degree of anxiety. *Weaning provokes anxiety regarding ability to breathe on own and likelihood of ventilator dependence. The client must be highly motivated, be able to actively participate in the weaning process, and be physically comfortable enough to work at weaning.*³
-  Review lab studies, such as complete blood count, *to determine number and integrity of red blood cells for oxygen transport; electrolytes; and nutritional markers, such as serum protein and albumin, to determine if client has sufficient nutritional stores to meet demands of spontaneous breathing and weaning.*^{13,10}

-  Review chest radiograph, pulse oximetry or ABGs, and/or capnometry. *Before weaning attempts, chest radiograph should show clear lungs or marked improvement in pulmonary congestion. ABGs should document satisfactory oxygenation on an FIO_2 of 40% or less. Capnometry measures end-tidal carbon dioxide values and can be used to confirm correct placement of endotracheal tube and monitor integrity of ventilation equipment.*^{3,8}

NURSING PRIORITY NO. 2 To support weaning process:

- Discuss with client/SO individual plan and expectations. *May reduce client's anxiety about process and ultimate outcome and support willingness to work at spontaneous breathing trials.*
-  Consult with dietitian and nutritional support team for adjustments in composition of diet prior to weaning to support respiratory muscle strength and work of breathing and to prevent excessive production of CO_2 , which could alter respiratory drive. *Individuals on long-term ventilation may require enteral feedings with high intake of carbohydrates, protein, and calories to improve respiratory muscle function.*^{3,8}
-  Collaborate in implementing weaning protocols and mode (e.g., spontaneous breathing trials, automatic tube compensation, partial client support by means of synchronized intermittent mandatory ventilation, pressure support ventilation during client's spontaneous breathing) to optimize the work of breathing and to provide support for spontaneous ventilation.^{4,7,10–12}
- Note response to activity or client care during weaning and limit, as indicated. Provide undisturbed rest or sleep periods. Avoid stressful procedures or situations and nonessential activities to prevent excessive oxygen consumption or demand with increased possibility of weaning failure.
- Discuss impact of specific activities on respiratory status, and problem-solve solutions to maximize weaning effort.
-  Time medications during weaning efforts to minimize sedative effects.
- Provide quiet room, calm approach, and undivided attention. *Enhances relaxation, thereby conserving energy.*
- Involve SO(s)/family, as appropriate (e.g., sit at bedside, provide encouragement, help monitor client status).
- Provide diversionary activity (e.g., watching TV, listening to audiobooks, music) to focus attention away from breathing when not actively working at breathing exercises.
- Acknowledge and provide ongoing encouragement for client's efforts.
- Minimize setbacks and focus client attention on gains and progress to date to reduce frustration that may further impair progress.

NURSING PRIORITY NO. 3 To prepare for discharge on ventilator when indicated:

-  Prepare client/SO for alternative actions when client is unable to resume spontaneous ventilation (e.g., tracheostomy with long-term ventilation support in alternate care setting or home, palliative care or end-of-life procedures). *Numerous studies report that despite meeting all weaning criteria and succeeding in a weaning trial, failure of planned extubation occurs in about 10% to 20% of cases.¹⁵ Therefore long-term strategies may be required. Client discharged from intensive care unit may sent to specialized units (so-called long-term acute care), extended care facilities, or home. Customized discharge planning for people new to home ventilation is essential. This must include assessment of the environment, assessment of resources, assessment of caregivers, education and training, and a plan of care.*^{5,7,14}
- Ascertain that all needed equipment is in place, caregivers are trained, and safety concerns have been addressed (e.g., alternative power source, backup equipment, client call or alarm system, established means of client/caregiver communication) to ease the transfer when client is going home on ventilator.
- Evaluate caregiver capabilities and burden when client requires long-term ventilator in the home to determine potential or presence of skill-related problems or emotional issues (e.g., caregiver overload, burnout, or depression). *Note: All home caregivers (professionals, family, friends) should receive a comprehensive orientation before caring for someone using a home ventilator. This includes familiarization with the ventilator; alarms and the subsequent actions that must be taken; tracheostomy care; safe transfer of the ventilator user; suctioning techniques; and bag-valve-mask ventilation (use of an Ambu bag) in the case of an emergency, such as accidental disconnection of the ventilator circuit.*^{6,14}
- Refer to ND impaired spontaneous Ventilation for additional interventions.

NURSING PRIORITY NO. 4 To promote optimal ventilation (Teaching/Discharge Considerations):

-   Encourage client/SO(s) to evaluate impact of ventilatory dependence on their lifestyle and what changes they are willing or unwilling to make when client is discharged on ventilator. *Quality-of-life issues must be examined, including issues of privacy and intimacy, and resolved by the ventilator-dependent client and SO(s). All parties need to understand that ventilatory support is a 24-hr job that ultimately affects everyone.*¹⁴ *A recent study of 160 caregivers (age, 50–53 years) of clients receiving home mechanical ventilation reported insufficient sleep, physical exhaustion, back pain, and significantly higher physical burden levels than respiratory care ward caregivers. Findings may dictate alternative placement is desirable or needed.*¹⁶
- Discuss importance of time for self and identify appropriate sources for respite care. *Initially, caregivers have limited understanding of the magnitude of the demands on their time and energy. Knowing support is available enhances coping abilities.* Refer to ND risk for caregiver Role Strain.
- Emphasize to client/SO(s) importance of monitoring health of visitors and persons involved in care, avoiding crowds during flu season, obtaining immunizations, etc., *to protect client from sources of infection.*
-  Engage in rehabilitation program *to enhance respiratory muscle strength and general endurance or to compensate for deficits.*
- Encourage client/SO(s) to discuss advance directives and ascertain that all care providers are aware of the plan of care. *Clarifies parameters for emergency situations, termination of therapy, or other end-of-life decisions, as desired.*
- Recommend involvement in support group (may be online) and introduce to other ventilator-dependent individuals who are successfully managing home ventilation, if desired, *to answer questions, provide role models, assist with problem-solving, and offer encouragement and hope for the future.*
-  Identify conditions requiring immediate medical intervention *to treat developing complications and potentially prevent respiratory failure.*

DOCUMENTATION FOCUS**Assessment/Reassessment**

- Baseline findings and subsequent alterations.
- Results of diagnostic testing and procedures.
- Individual risk factors.

Planning

- Plan of care, specific interventions, and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Client response to interventions.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Status at discharge, long-term needs and referrals, indicating who is to be responsible for each action.
- Equipment needs and supplier.

risk for other-directed Violence

Taxonomy II: Safety/Protection—Class 3 Violence (00138) [Diagnostic Division: Safety], Approved 1980; Revised 1996, 2013, 2017

DEFINITION: Susceptible to behaviors in which an individual demonstrates that he or she can be physically, emotionally, or sexually harmful to others.

RISK FACTORS

Suicidal behavior; impulsiveness; access to weapon

Negative body language [e.g., rigid posture, clenching of fists/jaw, pacing, threatening stances]; suicidal behavior

Pattern of violent anti-social behavior

Pattern of indirect violence [e.g., tearing objects off walls, urinating/defecating on floor, temper tantrum] or other-directed violence [e.g., hitting/kicking/spitting/scratching others, throwing objects, sexual molestation]; threatening violence [e.g., verbal threats against property/people, threatening notes/gestures]

At Risk Population: History of childhood abuse; witnessing family violence

History of cruelty to animals; fire-setting; motor vehicle offense

History of substance misuse [abuse]

Associated Condition: Alteration in cognitive functioning; neurological impairment; psychotic disorder [panic states; rage reactions; manic excitement]

Pathological intoxication [toxic reaction to pharmaceutical agent]

Prenatal or perinatal complications

Sample Clinical Applications: Psychotic conditions (e.g., schizophrenia, paranoia), antisocial personality disorder, dementia, substance abuse (e.g., phencyclidine [PCP], delirium tremens), postpartum psychosis, premenstrual syndrome [PMS], brain injured

[****Note: NANDA has separated the diagnosis of Violence with its two elements—other-directed and self-directed. However, the interventions in general address both situations and have been left in one block following the Desired Outcomes section of risk for self-directed Violence.]

risk for self-directed Violence

Taxonomy II: Safety/Protection—Class 3 Violence (00140) [**Diagnostic Division:** Safety], Approved 1994; Revised 2013, 2017

DEFINITION: Susceptible to behaviors in which an individual demonstrates that he or she can be physically, emotionally, or sexually harmful to self.

RISK FACTORS

Behavioral clues [e.g., writing forlorn love notes, giving away personal items, taking out a large life insurance policy]

Conflict about sexual orientation; engagement in autoerotic sexual acts

Conflict in interpersonal relationship(s); employment concern

Insufficient personal resources [e.g., achievement, insight, affect unavailable and poorly controlled]; social isolation

Suicidal ideation; verbal cues of suicidal intent [e.g., talking about death, “better off without me,” asking about lethal dosages of medication]; suicidal plan

At Risk Population: Age 15 to 19, ≥45

Marital status; pattern of difficulties in family background; occupation [e.g., executive, professional, semi-skilled worker]

History of multiple suicide attempts

Associated Condition: Mental health issue [e.g., substance abuse]; psychological disorder [e.g., depression, psychosis, severe personality disorder]; physical disorder

Sample Clinical Applications: Major depression, postpartum depression/psychosis, Munchausen syndrome, psychosis, substance abuse (e.g., phencyclidine [PCP]), abuse or neglect

DESIRED OUTCOMES/EVALUATION CRITERIA (FOR OTHER-/SELF-DIRECTED VIOLENCE)

Sample **NOC** linkages:

Aggression Self-Restraint: Personal actions to refrain from assaultive, combative, or destructive behaviors toward others

Abusive Behavior Self-Restraint: Personal actions to refrain from abusive and neglectful behaviors toward others

Impulse Self-Control: Self-restraint of compulsive or impulsive behaviors

Depression Self-Control: Personal actions to minimize melancholy and maintain interest in life events

Client Will (Include Specific Time Frame)

- Acknowledge realities of the situation.
- Verbalize understanding of why behavior occurs.
- Identify precipitating factors in individual situation.
- Express realistic self-evaluation and increased sense of self-esteem.
- Participate in care and meet own needs in an assertive manner.
- Demonstrate self-control as evidenced by relaxed posture, nonviolent behavior or verbalizations.
- Use resources and support systems in an effective manner.

ACTIONS/INTERVENTIONS (ADDRESSES BOTH OTHER- AND SELF-DIRECTED)

Sample NIC linkages:

Anger Control Assistance: Facilitation of the expression of anger in an adaptive, nonviolent manner

Environmental Management: Violence Prevention: Monitoring and manipulation of the physical environment to decrease the potential for violent behavior directed toward self, others, or environment

Behavior Management: Self-Harm: Assisting the patient to decrease or eliminate self-mutilating or self-abusive behaviors

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Determine underlying dynamics as listed in Risk Factors.
- Identify conditions, such as acute or chronic brain syndrome, panic state, hormonal imbalance, premenstrual syndrome, postpartum psychosis, drug-induced psychotic states, and postanesthesia or postseizure confusion, *that may interfere with ability to control own behavior and lead to violent episodes.*^{1,12}
-  Review lab findings (e.g., blood alcohol, drug/tox screen, blood glucose, arterial blood gases, electrolytes, renal function tests). *Provides information about possible treatable sources of behavior.*^{2,6}
- Ascertain client's perception of self and situation. Note use of defense mechanisms. *Individuals who are prone to violent behavior may see themselves as victims (denial), may blame others (projection), may not follow social norms, and may be impulsive.*¹
- Observe and listen for early cues of distress or increasing anxiety. *Behaviors, such as irritability, lack of cooperation, and demanding behavior, and body posture or expression may signal escalating potential for violent behavior and need for immediate intervention.*^{1,6}
- Observe for signs of suicidal or homicidal intent. *Perceived morbid or anxious feelings while with the client; warning from the client, "It doesn't matter," "I'd/They'd be better off dead"; mood swings; "accident-prone" or self-destructive behavior; and possession of alcohol or other drug(s) by known substance abuser needs to be noted, taken seriously, and treated appropriately.*^{1,6} Refer to ND risk for Suicide.
- Note family history of suicidal or homicidal behavior. *Dynamics in family of origin and current family and parental deprivation or abuse in the early years of an individual's life may contribute to violent behavior in current situation as individual uses violence as a means of solving problems.*^{1,10}
- Ask directly if the person is thinking of acting on thoughts or feelings. *Can determine reality and urgency of violent intent and importance of immediate intervention.*⁶
- Determine availability of suicidal means. *Identifies urgency of situation and need to intervene by removing lethal means, possibly hospitalizing client, or instituting other measures to ensure safety of client and others.*^{1,6,8}
- Assess client coping behaviors. *Client believes there are no alternatives other than violence and has been dealing with frustration and anger in unacceptable ways (yelling, hitting, other violent behaviors) and needs to learn alternative coping skills.*^{1,9}
- Identify risk factors and assess for indicators of child abuse or neglect (e.g., unexplained or frequent injuries, failure to thrive). *Visible evidence of physical abuse or neglect makes it more easily recognized; however, behaviors of withdrawal and acting out may also signal the presence of abuse.*^{6,9,12}
-  Determine presence, extent, and acceptance of violence in the client's culture. *Youth violence has become a national concern with widely publicized school shootings and an increase in arrests of both boys and girls for violent crimes and weapons violations. Young people who are at risk for violence need to be identified, and positive programs aimed at promoting emotional wellness need to be instituted in schools, parent education meetings, churches, and community centers.*^{3,7,11}

NURSING PRIORITY NO. 2 To assist client to accept responsibility for impulsive behavior and potential for violence:

- Develop therapeutic nurse-client relationship. Provide consistent caregiver when possible. *Promotes sense of trust, allowing client to discuss feelings openly and to begin to identify sources of anger and more acceptable ways of dealing with it.*^{1,6}
- Maintain straightforward communication. *Avoids reinforcing manipulative behavior. Manipulation is used for management of powerlessness because of distrust of others, fear of loss of power or control, fear of intimacy, and search for approval.*^{4,6}
- Discuss motivation for change (e.g., failing relationships, job loss, involvement with judicial system). *Crisis situation can provide impetus for change but requires timely therapeutic intervention to sustain efforts.*^{7,8}
- Make time to listen to expressions of feelings. Acknowledge reality of client's feelings and that feelings are okay. (Refer to ND Self-Esteem, specify.) *Promotes understanding of how feelings lead to actions and that individual is responsible for controlling behavior in acceptable ways.*⁶
- Help client recognize that client's actions may be in response to his/her fear (may be afraid of own behavior, loss of control), dependency, and feeling of powerlessness. *Promotes understanding of self and ability to deal with feelings in acceptable ways.*^{6,13}
- Confront client's tendency to minimize situation or behavior. *Individuals often want to say that things "are not as bad" as portrayed. By confronting this minimization, the reality of the situation can be brought out and discussed, leading to better understanding of the situation and changes in behavior.*^{1,6}
- Identify feelings or events (e.g., individual's view of self, hallucinations, individual/family or peer conflict, aggressive behavior) involved in precipitating violent behavior. *By identifying the factors involved in current situation, an appropriate plan can be made to change actions to prevent future violent behavior.*^{1,7}
- Discuss impact of behavior on others and consequences of actions. *Discussing these issues openly can help client to develop empathy and understand other person's reactions and begin to change behaviors that can lead to violence.*^{5,8}
- Acknowledge reality of suicide or homicide as an option. Discuss consequences of actions if they were to follow through on intent. Ask how it will help client to resolve problems. *Acknowledging the reality of individual's thoughts provides opportunity to look at how actions would affect others, ability to control own behavior, and make choices to live and make a better life for self.*^{6,11}
- Accept client's anger without reacting on emotional basis. Give permission to express angry feelings in acceptable ways and let client know that staff will be available to assist in maintaining control. *Promotes acceptance and sense of safety. Client's anger is usually directed at the situation and not at the caregiver, and by remaining separate, the therapist can be more helpful for resolution of the anger.*^{6,9}
- Help client identify more appropriate solutions/behaviors. *Motor activities or exercise can lessen sense of anxiety and associated physical manifestations, thus diminishing feelings of anger.*⁸
- Provide directions for actions client can take, avoiding negatives, such as "do nots." *Discussing positive ideas to help client begin to look toward a better future can provide hope that violent behaviors can be changed, promoting feelings of self-worth and belief in control of own self.*^{5,13}

NURSING PRIORITY NO. 3 To assist client in controlling behavior:

-  Contract with client regarding safety of self/others. *Making a contract in which the individual agrees to refrain from any violent behavior for a specified period of time, from Day 1 through the entire course of treatment, and that is written and signed by each party may help the client to follow through with therapy to find more effective ways of resolving conflict. Although there is little research on the effectiveness of these contracts, they are frequently used.*^{6,7}
- Give client as much control as possible within constraints of individual situation. *Because control issues are a factor in violent behavior, giving client control in appropriate ways can enhance self-esteem and promote confidence in ability to change behavior.*⁷

- Be truthful when giving information and dealing with individual. *Builds trust, enhancing therapeutic relationship, and prevents manipulative behavior.*⁵
- Identify current and past successes and strengths. Discuss effectiveness of coping techniques used and possible changes. Refer to ND ineffective Coping. *Client is often not aware of positive aspects of life, and once recognized, they can be used as a basis for change.*⁸
- Give positive reinforcement for client's efforts. *Encourages continuation of desired behaviors.*¹
- Assist client to distinguish between reality and hallucinations or delusions. *Violent behavior in clients with major mental disorders (schizophrenia, mania) may be in response to command hallucinations and may require more aggressive treatment or hospitalization until behavior is under control.*^{1,6}
- Approach in positive manner, acting as if the client has control and is responsible for own behavior. Be aware, though, that the client may not have control, especially if under the influence of drugs (including alcohol). *Individuals will often respond to a positive expectation, reducing threatening actions. Staff needs to be trained in management of this behavior and be prepared to take control of the situation if client is out of control.*^{1,6}
- Maintain distance and do not touch client when situation indicates client does not tolerate such closeness. *Individuals who have experienced traumatic events, such as rape, or suffer from posttrauma response may fear close contact even with trusted persons.*^{1,6}
- Remain calm and state limits on inappropriate behavior (including consequences) in a firm manner. *Calm manner enables client to de-escalate anger, and knowing what the consequences will be gives an opportunity to choose to change behavior and deal appropriately with situation. Consequences need to be decided beforehand and agreed to by client or they may sound like punishment and be counterproductive.*^{1,6,12}
- Direct client to stay in view of staff, when indicated. *Intervention may be needed to maintain safety of client and others.*^{1,6} Refer to ND risk for Suicide.
-  Administer prescribed medications (e.g., anti-anxiety or antipsychotic), taking care not to oversedate client. *May be least restrictive way to help client control violent behaviors while learning new coping skills to handle anger and impulsive behavior. The chemistry of the brain is changed by early violence and has been shown to respond to serotonin as well as related neurotransmitter systems, which play a role in restraining aggressive impulses.*^{1,6,9}
-  Monitor for possible drug interactions and cumulative effects of drug regimen (e.g., anticonvulsants, antidepressants). *May be contributing factor in violent behavior.*^{1,6}

NURSING PRIORITY NO. 4 To assist client/SO(s) to correct/deal with existing situation:

- Gear interventions to individual(s) involved based on age, relationship, etc. *Conflict-resolution skills can be learned by all age groups when age-appropriate materials are used.*^{5,8}
- Maintain calm, matter-of-fact, nonjudgmental attitude. *Decreases defensive response, allowing individual to think about own responsibility in the conflict and choose positive behaviors instead of usual angry reaction.*^{4,5,8}
-  Notify potential victims in the presence of serious homicidal threat in accordance with legal and ethical guidelines. *Various Tarasoff statutes exist in many states requiring therapists/healthcare providers to report specific threats to both the individual named and law enforcement when client expresses homicidal intent overtly or covertly in addition to helping the client realize that the proposed action is not wise or in his or her own best interest.*¹
- Discuss situation with abused or battered person, providing accurate information about choices and effective actions that can be taken. *Promotes understanding of options, giving hope and support for planning for a violence-free future.*²
- Assist individual to understand that angry, vengeful feelings are appropriate in the situation and need to be expressed but not acted on. (Refer to ND Post-Trauma Syndrome, as psychological responses may be very similar.) *Helps client accept feelings as natural and begin to learn effective coping skills, and promotes sense of control over situation.*²
-  Identify resources available for assistance (e.g., battered women's shelter, social services, financial). *Helps client to manage immediate needs such as food, shelter, and safety with a long-range goal of attaining or maintaining independence and violence-free life.*²

NURSING PRIORITY NO. 5 To promote safety in event of violent behavior:

-  Provide a safe, quiet environment and remove items from the client's environment that could be used to inflict harm to self/others. *Reducing stimuli can help client to calm down, and removing articles provides for safety of client and staff.*^{1,6}
- Maintain distance from client who is striking out or hitting and take evasive or controlling actions, as indicated. *Staff safety is of prime importance, and avoiding physical confrontation until client regains control or take-down team is assembled can prevent injury.*⁶
- Call for additional staff/security personnel. *Having sufficient people available to handle the situation may defuse client's anger, allowing situation to calm down without further action. All personnel need to be trained in take-down techniques.*⁶
- Approach aggressive or attacking client from the front, just out of reach, in a commanding posture with palms down. *Safety is a prime concern, and these actions may defuse the situation.*⁶
- Tell client "Stop" in a firm voice. *This may be sufficient to help client control own actions.*⁶
- Maintain direct and constant eye contact when appropriate. *Assists in identifying client's intentions and conveys sense of caring. Eye contact may be perceived as threatening, so it needs to be used cautiously.*^{2,6}
- Speak in a low, commanding voice. *Tone of voice conveys message of control and concern and can help to calm the client's anger.*⁶
- Provide client with a sense that caregiver is in control of the situation. *Client is feeling out of control, and seeing that staff are in control provides a feeling of safety.*⁶
- Maintain clear route for staff and client and be prepared to move quickly. *Safety for all is of prime importance, and staff may need to leave the room to regroup while continuing to protect the client. Take-down needs to be done quickly to gain control of the individual.*⁶
-  Hold client, using restraints or seclusion when necessary until client regains self-control. *Brief period of physical restraint may be required until client regains control or other therapeutic interventions take effect.*⁶
-  Administer medication, as indicated. *Client may require chemical restraint until control is regained.*^{1,6}
- Discuss event with client after situation is calmed down and control is regained. *Helping client to understand how feelings of anger had gotten out of control and what can be done to prevent a recurrence can provide a learning opportunity for the individual.*^{2,6}

NURSING PRIORITY NO. 6 To promote wellness (Teaching/Discharge Considerations):

-  Promote client involvement in planning care within limits of situation, allowing for meeting own needs for enjoyment. *Individuals often believe they are not entitled to pleasure and good things in their lives and need to learn how to meet these needs in acceptable ways.*^{6,13}
- Assist client to learn assertive behaviors. *Manipulative, nonassertive, or aggressive behaviors lead to anger, which can result in violence. Learning assertiveness skills can facilitate change, increase self-esteem, and promote interpersonal relationships.*^{1,13}
- Provide information about conflict-resolution skills and help client learn how to use them effectively. *Conflict is always present in human relationships, and learning how to manage conflict is one of the most important tools we can use to solve disagreements and improve relationships.*^{4,5,8}
- Discuss reasons for client's behavior with SO(s). Determine desire and commitment of involved parties to sustain current relationships. *Family members may believe individual is purposefully behaving in angry ways, and understanding underlying reasons for behavior can defuse feelings of anger on their part, leading to willingness to resolve problems.*^{1,4}
-  Develop strategies to help parents learn more effective parenting skills. *Participating in parenting classes and learning appropriate ways of dealing with frustrations can improve family relationships and prevent angry interactions and the possibility of violent behavior.*^{4,5}
- Identify support systems. *Presence of family/friends and clergy who can serve as mentors and listen to individual nonjudgmentally can help client defuse angry feelings and learn appropriate ways of dealing with them.*¹

Note: Not just the client needs help; those around them also need to learn how to provide positive role models and display a broader array of skills for resolving problems.

-  Refer to formal resources, as indicated. *May need individual or group psychotherapy, substance-abuse treatment program, anger-management class, social services, and/or safe house to facilitate change.*¹
- Promote violence prevention and emotional literacy programs in the schools and community. *These programs are based on the premise that intelligent management of emotions is critical to successful living. Aggressive youth lack skills in arousal management and nonviolent problem-solving, which can be learned in programs and reinforced by the adults in their lives.*^{7,11,13}
- Refer to NDs impaired Parenting, family Coping [specify], and Post-Trauma Syndrome.

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including nature of concern (e.g., suicidal, homicidal), behavioral risk factors, and level of impulse control, plan of action, and means to carry out plan.
- Client's perception of situation, motivation for change.
- Family history of violence.
- Availability and use of resources.

Planning

- Plan of care and who is involved in the planning.
- Details of contract regarding violence to self/others.
- Teaching plan.

Implementation/Evaluation

- Actions taken to promote safety, including notification of parties at risk.
- Response to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Available resources, specific referrals made.

impaired Walking

Taxonomy II: Activity/Rest—Class 2 Activity/Exercise (00088) [**Diagnostic Division:** Activity/Rest], Approved 1998; Revised 2006, 2017

DEFINITION: Limitation of independent movement within the environment on foot.
[*** Specify level of independence using a standardized functional scale.]

RELATED FACTORS

Insufficient muscle strength
Decrease in endurance; physical deconditioning
Fear of falling
Pain
Obesity
Alteration in mood
Insufficient knowledge of mobility strategies
Environmental barrier

DEFINING CHARACTERISTICS

Subjective or Objective

Impaired ability to walk required distance, walk on incline or decline, walk on uneven surface, navigate curbs, climb stairs

Associated Condition: Alteration in cognitive functioning

Musculoskeletal, neuromuscular functioning

Impaired balance, vision

Sample Clinical Applications: Arthritis, obesity, amputation, brain injury, stroke, traumatic injury, fractures, chronic pain, peripheral vascular disease (PVD), spinal nerve compression, multiple sclerosis (MS), cerebral palsy, Parkinson's disease, macular degeneration, dementia

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkages:

Ambulation: Personal actions to walk from place to place independently with or without assistive device

Mobility: Ability to move purposefully in own environment independently with or without assistive device

Balance: Ability to maintain body equilibrium

Client Will (Include Specific Time Frame)

- Be able to move about within environment as needed or desired within limits of ability or with appropriate adjuncts.
- Verbalize understanding of situation, risk factors, and safety measures.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Exercise Therapy: Ambulation: Promotion and assistance with walking to maintain or restore autonomic and voluntary body functions during treatment and recovery from illness or injury

Body Mechanics Promotion: Facilitating the use of posture and movement in daily activities to prevent fatigue and musculoskeletal strain or injury

Exercise Therapy: Balance: Use of specific activities, postures, and movements to maintain, enhance, or restore balance

NURSING PRIORITY NO. 1 To assess causative/contributing factors:

- Identify conditions or diagnoses (e.g., advanced age, sensory impairments, pain, obesity, chronic fatigue, cognitive dysfunction, acute illness with weakness, chronic illness [e.g., cardiopulmonary disorders, cancer], musculoskeletal injuries or surgery [e.g., sprains, fractures, tendon or ligament injury; total joint replacement, surgical repair of fractured bone; amputation], balance problems [e.g., inner ear infection, brain injury, stroke], nerve disorders [e.g., MS, Parkinson's disease, cerebral palsy], spinal abnormalities [disease, trauma, degeneration], impaired circulation or neuropathies [e.g., peripheral, diabetic, alcoholic], degenerative bone or muscle disorders [e.g., osteoporosis, muscular dystrophy, myositis], foot conditions [e.g., plantar warts, bunions, ingrown toenails, pressure ulcers]) *that contribute to walking impairment and identify specific needs and appropriate interventions.*¹⁻⁶
- Determine ability to follow directions and presence of emotional or behavioral responses *that may be affecting client's ability or desire to engage in activity.*
- Note client's particular symptoms (e.g., unable to bear weight, can't walk usual distance, limping, staggering, stiff leg, leg pain, shuffling, asymmetric or unsteady gait; can walk on certain surfaces, but not on others). *Influences choice of interventions.*^{4-6,8}

NURSING PRIORITY NO. 2 To assess functional ability:

-   Perform "Timed Up and Go" (TUG) test, as indicated, to assess client's basic ability to ambulate safely. *Factors assessed include sitting balance, ability to transfer from sitting to standing and back to sitting, the pace and stability of ambulation, and the ability to turn without staggering. Additional testing is indicated for individuals requiring more than 20 sec to complete the test.*⁷
-   Evaluate components of walking (e.g., gait, distance covered over time). Determine muscle strength and tone, joint mobility, cardiovascular status, balance, endurance, and use of assistive device. *Identifies strengths and deficits (e.g., ability to ambulate with/without assistive devices) and may provide information regarding potential for recovery (e.g., client with severe brain injury may have permanent limitations because of impaired cognition affecting memory, judgment, problem-solving, and motor planning, requiring more intensive inpatient and long-term care).*⁶
-  Note whether impairment is temporary or permanent. *Condition may be caused by reversible condition (e.g., weakness associated with acute illness or fractures/surgery with weight-bearing restrictions), or walking impairment can be permanent (e.g., congenital anomalies, amputation, severe rheumatoid arthritis).*⁶
-   Assist with or review results of mobility testing (e.g., timing of walking over fixed distance, distance walked over set period of time [endurance], limb movement analysis, leg strength and speed of walking, ambulatory activity monitoring with pedometer) *for differential diagnosis and to guide treatment interventions.*^{6,7}
- Note emotional or behavioral responses of client/significant other (SO) to problems of mobility. *Walking impairments can negatively affect self-concept and self-esteem, autonomy, and independence. Social, occupational, and relationship roles can change, leading to isolation, depression, and economic consequences.*

NURSING PRIORITY NO. 3 To promote safe, optimal level of independence in walking:

-  Assist with treatment of underlying condition as needed or indicated by individual situation. *Treatment can often reverse or limit dysfunction.*
-  Consult with physical therapist, occupational therapist, or rehabilitation team *to develop individual program (e.g., to improve general conditioning, coordination and balance, range-of-motion exercises, specific muscle strengthening), to instruct in specific tasks (e.g., stair climbing or gait training), and to identify and develop appropriate adjunctive devices (e.g., shoe insert, leg brace for proper foot alignment; customized cane, crutches, or walker).*¹
- Monitor client's cardiopulmonary tolerance for walking. *Increased pulse rate, chest pain, breathlessness, and irregular heartbeat is indicative of need to reduce level of activity.* Refer to ND Activity Intolerance and decreased Cardiac Output for related interventions.

-  Encourage adequate rest and gradual increase in walking distance *to reduce fatigue or leg pain associated with walking, and to improve stamina.*^{3,4} Refer to NDs Fatigue and risk for peripheral neurovascular Dysfunction.
-  Administer medication, as indicated, *to manage pain and maximize level of functioning.* Refer to NDs acute/chronic Pain; chronic Pain Syndrome.
- Implement fall precautions for high-risk clients (e.g., frail or ill elderly, visually or cognitively impaired, person on multiple medications, presence of balance disorders) *to reduce risk of accidental injury.*³ Refer to NDs risk for Falls and risk for Disuse Syndrome for related interventions.
-  Instruct in proper application of prostheses, immobilizers (e.g., walking cast or boot), and braces before walking *to maintain joint stability or immobilization or to maintain alignment during movement.*²
-  Demonstrate and remind client to properly use assistive devices (e.g., cane, crutches, walker) *individually prescribed and fitted to improve balance, reduce limb pain and dysfunction, and provide support during ambulation.*¹
-  Use adequate personnel and safety devices (e.g., gait belt, properly fitted nonslip shoes, handrail) when ambulating *to prevent injury to client or caregivers.*^{1,3,8}
- Limit distractions and provide safe environment. *Allows client to concentrate on walking activities or learning use of assistive devices.*¹
- Provide cueing as indicated. *Client may need reminders (e.g., lift foot higher, look where going, walk tall) to concentrate on/perform tasks of walking, especially when balance or cognition is impaired.*
- Provide ample time to perform mobility-related tasks *to reduce risk of falling and manage fatigue or pain.*
- Provide positive, constructive feedback *to encourage continuation of efforts and enhance client's self-sufficiency.*³
-  Assist client to obtain needed information, such as handicap placard for close-in parking, sources for mobility scooter, or special public transportation options, when indicated, *to deal with temporary or permanent disability access.*

NURSING PRIORITY NO. 4 To promote wellness (Teaching/Discharge Considerations):

-  Evaluate client's home (or work) environment for barriers to walking (e.g., uneven surfaces, many steps, no ramps, long distances between places client needs to walk) *to determine needed changes and make recommendations for client safety.*
- Involve client/SO in problem solving, assisting them to learn ways of managing deficits, *to enhance safety for client with long-term or permanent impairments.*
- Encourage participation in regular active and passive exercise program. Advance levels of exercise, as able, *to improve muscle tone and strength and increase stamina and endurance.*
- Discuss appropriate use of electric scooter, if indicated. *Enhances mobility, especially over distances, to maintain independence and socialization.*
- Identify appropriate resources for obtaining and maintaining appliances, equipment, and environmental modifications *to promote safe mobility.*
- Instruct client/SO in safety measures in home, as individually indicated (e.g., maintaining safe travel pathway, proper lighting, wearing glasses, handrails on stairs, grab bars in bathroom, using walker instead of cane when tired or walking on uneven surface) *to reduce risk of falls.*
- Discuss need for emergency call/support system (e.g., Lifeline, HealthWatch) *to provide immediate assistance for falls and other home emergencies when client lives alone.*

DOCUMENTATION FOCUS

Assessment/Reassessment

- Individual findings, including level of function and ability to participate in specific or desired activities.
- Equipment and assistive device needs.

Planning

- Plan of care and who is involved in the planning.
- Teaching plan.

Implementation/Evaluation

- Responses to interventions, teaching, and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Discharge and long-term needs, noting who is responsible for each action to be taken.
- Specific referrals made.
- Sources of and maintenance for assistive devices.

Wandering [Specify Level]

Taxonomy II: Activity/Rest—Class 3 Energy Balance (00154) [Diagnostic Division: Safety], [Approved 2000; Revised 2017]

DEFINITION: Meandering, aimless, or repetitive locomotion that exposes the individual to harm; frequently incongruent with boundaries, limits, or obstacles.

RELATED FACTORS

Alteration in sleep-wake cycle; physiological state [e.g., hunger/thirst, cold, pain, need to urinate]
Desire to go home; separation from familiar environment
Overstimulating environment

DEFINING CHARACTERISTICS**Objective**

Frequent or continuous movement from place to place; pacing
Persistent locomotion in search of something; scanning or searching behavior
Haphazard or fretful locomotion; long periods of locomotion without an apparent destination
Locomotion into unauthorized spaces; trespassing
Locomotion resulting in getting lost; eloping behavior
Impaired ability to locate landmarks in a familiar setting
Locomotion that cannot be easily dissuaded; shadowing a caregiver's locomotion

(continues on page 556)

Wandering [Specify Level] (continued)

Hyperactivity

Periods of locomotion interspersed with periods of nonlocomotion (e.g., sitting, standing, sleeping)

At Risk Population: Premorbid behavior

Associated Condition: Alteration in cognitive functioning; cortical atrophy; psychological disorder

Sedation

Sample Clinical Applications: Brain injury, dementias, developmental delays, major depression, substance abuse, amnesia, fugue

DESIRED OUTCOMES/EVALUATION CRITERIA

Sample **NOC** linkage:

Physical Injury Severity: Severity of injuries from accidents and trauma

Client Will (Include Specific Time Frame)

- Be free of injury, or unplanned exits.

Sample **NOC** linkages:

Safe Home Environment: Physical arrangements to minimize environmental factors that might cause physical injury in the home

Safe Wandering: Safe, socially acceptable moving about without apparent purpose in an individual with cognitive impairment

Caregiver(s) Will (Include Specific Time Frame)

- Modify environment, as indicated, to enhance safety.
- Provide for maximal independence of client.

ACTIONS/INTERVENTIONS

Sample **NIC** linkages:

Elopement Precautions: Minimizing the risk of a patient leaving a treatment setting without authorization when departure presents a threat to the safety of patient or others

Area Restriction: Use of least restrictive limitation of patient mobility to a specified area for purposes of safety or behavior management

Environmental Management: Safety: Monitoring and manipulation of the physical environment to promote safety

NURSING PRIORITY NO. 1 To assess degree of impairment/stage of disease process:

- Ascertain history of client's memory loss and cognitive changes.
-  Review responses of collaborative diagnostic examinations (e.g., cognition, functional capacity, behavior, memory impairments, reality orientation, general physical health, and quality of life). *A combination of tests is often needed to complete an evaluation of client's overall condition relating to chronic or irreversible condition. These tests include (but are not limited to) Mini-Mental State Examination, Alzheimer's Disease Assessment Scale cognitive subsection, Functional Assessment Questionnaire, Clinical Global Impression of Change, and Neuropsychiatric Inventory.*^{1,2}
-  Evaluate client's past history (e.g., individual was very active physically and socially or reacted to stress with physical activity rather than emotional reactions) to help identify likelihood of wandering. *Note: One*

study showed that a history of prior wandering incidents is a high predictor (72%) for further wandering incidents.^{2,5}

-   Note client's age. *Results of a study in selected nursing homes revealed that subjects' age was found to have significant negative correlations with the Revised Algase Wandering Scale—Nursing Home Version overall, suggesting that younger persons with dementia were likely to show more wandering behavior than older ones.^{2,6,7}*
-  Determine presence of depression. *Research supports the idea that wandering develops more often in depressed client with Alzheimer's disease.²*
- Evaluate client's mental status during both daytime and nighttime, noting when client's confusion is most pronounced and when and how long client sleeps. *Information about cognition and behavioral habits can reveal circumstances under which client is likely to wander.⁷*
- Identify client's reason for wandering, if possible. *Client may demonstrate searching behavior (e.g., looking for lost item, pursuing certain unattainable activity), inexhaustible drive to do things and remain busy, or be experiencing sensations (e.g., hunger, thirst, discomfort) without ability to express the actual need.²*
- Determine bowel and bladder elimination pattern, timing of incontinence, and presence of constipation for possible correlation to wandering behavior.
- Note timing and pattern of wandering behavior. *Client attempting to leave at 5:00 p.m. every day may believe he is going home from work; client may be goal directed (e.g., searching for person or object, escaping from something) or nongoal directed (wandering aimlessly). Knowledge of patterns can prompt caregivers to anticipate need for personal attention.^{2,5}*
- Ascertain if client has delusions due to shadows, lights, and noises to determine necessary changes to environment.
-  Evaluate usual travel patterns. *Activity may be (1) direct (from one location to another without diversion), (2) random (random direction with no obvious stopping point), (3) pacing (back and forth within limited area), or (4) lapping (circling large areas).^{2,5,6}*
-   Assist with or review results of specific testing (e.g., Revised Algase Wandering Scale, Need-Driven Dementia-Compromised Behavior, similar tool), as indicated. *Researchers are using adjunct tools for clinical assessment that quantify wandering in several domains (as reported by caregivers) to determine individual risks and safety needs.^{2,6}*
- Monitor client's need for and use of assistive devices, such as glasses, hearing aids, cane, safe walking shoes, comfortable clothing, etc. *Wandering client is at high risk for falls due to cognitive impairments and the fatigue related to functional decline or forgetting necessary assistive devices or how to properly use them.*

NURSING PRIORITY NO. 2 To assist client/caregiver to deal with wandering:

-  Provide a structured daily routine:
 -  Encourage participation in family activities and familiar routines, such as folding laundry, listening to music, or shared-walking time outdoors. *Activities and exercises may reduce anxiety, depression, and restlessness. Note: Repetitive activity (e.g., rocking, folding laundry, paperwork) may help client with "lapping"—wandering to reduce energy expenditure and fatigue. In addition, studies reveal that wandering may be an adaptive behavior that reflects continuity of premorbid personality traits and lifelong patterns of coping with stress.^{3,7}*
 - Offer food, fluids, and toileting on a regular schedule when client is unable to verbalize, *as agitation, pacing, or wandering may be associated with these basic needs.³*
 - Sit with client and talk *when client is socially gregarious, enjoys conversation, or reminiscence is calming.*
 - Provide television, radio, or music, *which may be more effective than talking or reading to decrease wandering.¹*
 - Monitor activities, loud conversations, and number of visitors at one time *to prevent overstimulation or increased agitation.*
 - Remove items from immediate environment (e.g., coat, hat, keys) *to reduce stimulus for leaving the site.*

- Provide safe place for client to wander:
Remove environmental safety hazards such as hot water faucets and knobs on kitchen stove, gate or block open stairways, etc.^{1,2}
Keep area free of clutter and place comfortable furniture and other items against the wall or out of travel path *to accommodate safe walking and promote rest periods during times of continual lapping.*¹
Install safety locks or latches on doors and windows (*door latches are complex and less accessible*); equip exits with alarms (always turned on; pressure-sensitive doormats that sound an alarm).¹⁻³
Provide for 24-hr supervision, as indicated. *Client can be awake at any time and fail to recognize day or night routines.*
 Consider use of GPS device. Register client with community and national resources such as SafeReturn Program administered by the Alzheimer's Association. *Program registers persons with dementia and operates a 24-hr helpline to facilitate the return of lost persons (800-272-3900).*^{2,4,5}
-  Ascertain client history of wandering when admitted to facility:
Place in room near monitoring station; check client location on frequent basis.
Assign consistent staff as much as possible.
Create a “wanderer’s lounge” or large safe walking area with inaccessible exits or outside gated area.
Avoid overstimulation from activities or new partner/roommate during rest periods. *Client who is used to wandering in usual living setting may react with increased agitation and emotional outbreaks when admitted to an unfamiliar setting and restricted from wandering. This places both the client and caregivers at risk for injury.*¹⁻³
- Use technology to promote safety:
Provide pressure-sensitive bed or chair alarms *to alert caregivers of movement, especially when client frequently gets up at night or when no one is present.*
Provide client ID bracelet or necklace with updated photograph, client name, and emergency contact *to assist with identification efforts, particularly when progressive dementia produces marked changes in client's appearance.*⁴
Obtain electronic locator devices *to find client when there is the potential for client to get lost or go missing.*⁴
Install verbal door alarm system. *Voice command is more effective at redirecting client and less likely to increase agitation than loud sound.*¹
- Use universal symbols, large-print signs, portrait-like photographs, pictures, and signs *to assist client in finding way, especially when client has diminished ability or has lost ability to read*
- Avoid using physical or chemical restraints (sedatives) to control wandering behavior. *May increase agitation, sensory deprivation, and falls, and can aggravate wandering behavior.*

NURSING PRIORITY NO. 3 To enhance safety (Teaching/Discharge Considerations):

-  Identify problems that are remediable and assist client/significant other (SO) to seek appropriate assistance and access resources. *Encourages problem-solving to improve condition rather than accept the status quo.*
- Notify neighbors about client's condition and request that they contact client's family or local police if they see client outside alone. *Community awareness can prevent or reduce risk of client being lost or hurt.*
- Help client/SO and family members develop plan of care when problem is progressive. *Client may initially need part-time assistance at home, progressing to enrollment in day-care program, and then full-time home care or placement in care facility.*
-  Refer to community resources, such as day-care programs, support groups, respite care, etc. *Caregiver(s) will require access to multiple kinds of assistance and opportunities to promote problem-solving, enhance coping, and obtain necessary respite.*
- Refer to NDs acute/chronic Confusion, risk for Falls, risk for Injury, and [disturbed Sensory Perception (specify)].

DOCUMENTATION FOCUS

Assessment/Reassessment

- Assessment findings, including individual concerns, family involvement, and support factors.
- Availability and use of resources.

Planning

- Plan of care and who is involved in planning.
- Teaching plan.

Implementation/Evaluation

- Responses of client/SO(s) to plan interventions and actions performed.
- Attainment or progress toward desired outcome(s).
- Modifications to plan of care.

Discharge Planning

- Long-term needs and who is responsible for actions to be taken.
- Specific referrals made.

Health Conditions and Client Concerns With Associated Nursing Diagnoses

This chapter presents 850 disorders/health conditions and life situations reflecting all specialty areas, with associated nursing diagnoses written as client problem/need statements that include the “related to” and “evidenced by” components.

This section facilitates and helps validate the assessment and diagnosis steps of the nursing process. Because the nursing process is perpetual and ongoing, other nursing diagnoses may be appropriate based on changing individual situations. Therefore, the nurse must continually assess, identify, and validate new client needs and evaluate subsequent care.

To facilitate access to the health conditions/concerns and nursing diagnoses, the conditions are listed alphabetically and coded to identify nursing specialty areas.

MS: Medical-Surgical

PED: Pediatric

OB/GYN: Obstetric/Gynecological

CH: Community/Home

PSY: Psychiatric/Behavioral

There is no separate category for geriatrics because concerns and conditions in this population are subsumed under the other specialty areas and because elderly persons are susceptible to the majority of these problems.

Abdominal hysterectomy

MS

Refer to Hysterectomy

Abdominal perineal resection

MS

Also refer to Surgery, general

disturbed Body Image may be related to alteration in self-perception, cultural or spiritual incongruence, possibly evidenced by verbalizations of feelings or

perceptions, fear of reaction by others, preoccupation with change.

risk for Constipation possibly evidenced by risk factors of decreased physical activity and gastric motility, abdominal muscle weakness (associated with surgery), insufficient fluid intake, change in usual foods or eating pattern.

risk for Sexual dysfunction possibly evidenced by associated conditions of altered body structure or function (e.g., radical resection or treatment procedures), vulnerability, psychological concern about response of significant other(s), and disruption of sexual response pattern (e.g., erection difficulty).

Abortion, elective termination

OB

risk for Decisional Conflict possibly evidenced by unclear personal values/beliefs, lack of experience or interference with decision making, information from divergent sources, deficient support system.

deficient Knowledge regarding reproduction, contraception, self-care, and Rh factor may be related to lack of exposure or recall, misinterpretation of information, possibly evidenced by request for information, statement reflecting misconception, inaccurate follow-through of instructions, development of preventable complications.

risk for Moral Distress possibly evidenced by conflicting information available for ethical decision making, difficulty reaching treatment decision, [perception of moral or ethical implications of therapeutic procedure], time constraints for decision making.

Anxiety [specify level] may be related to threat to personal status, fear of unspecified consequences, value conflicts or beliefs possibly evidenced by increased tension, apprehension, sympathetic stimulation, focus on self.

impaired Comfort may be related to aftereffects of procedure, drug effect, possibly evidenced by verbal report, distraction behaviors, changes in muscle tone, changes in vital signs.

risk for [maternal] Injury possibly evidenced by surgical procedure, effects of anesthesia or medications.

Abortion, spontaneous termination **OB**

risk for Bleeding possibly evidenced by pregnancy complication.

risk for Spiritual distress possibly evidenced by stressors [e.g., challenged beliefs/values, blame directed at self or higher power]; loss.

deficient Knowledge regarding cause of abortion, self-care, contraception, and future pregnancy may be related to lack of familiarity with new self-healthcare needs, sources for support, possibly evidenced by requests for information and statement of concern or misconceptions, development of preventable complications.

Grieving may be related to loss of significant other [e.g., perinatal loss], possibly evidenced by anger, crying, disorganization, expressions of sorrow/distress, or alteration in sleep patterns.

risk for Sexual dysfunction possibly evidenced by vulnerability [increasing fear of pregnancy or repeat loss, impaired relationship with SO(s), self-doubt regarding own femininity].

Abruptio placentae **OB**

Also refer to Hemorrhage, prenatal

risk for Bleeding possibly evidenced by pregnancy complication—abruptio placentae.

Fear related to [threat of death to fetus/self], possibly evidenced by apprehensiveness, feeling of alarm or dread, avoidance behaviors.

acute Pain may be related to biological injury: collection of blood between uterine wall and placenta, possibly evidenced by verbal reports, abdominal guarding, muscle tension, or alterations in vital signs.

risk for disturbed Maternal-Fetal Dyad possibly evidenced by pregnancy complications, compromised fetal oxygen transport.

Abscess, brain (acute) **MS**

acute Pain may be related to physical injury agent: inflammation, edema of tissues, possibly evidenced by reports of headache, restlessness, irritability, and moaning.

risk for Hyperthermia possibly evidenced by increase in metabolic rate and dehydration.

acute Confusion may be related to (delirium [cerebral edema, altered perfusion, fever]), possibly evidenced by fluctuation in cognition or level of consciousness, increased agitation, restlessness, hallucinations.

risk for Trauma possibly evidenced by (alteration in cognitive functioning, [disease process, seizure activity]).

Abscess, gingival **CH**

impaired Dentition may be related to inadequate oral hygiene, insufficient knowledge of dental health, inadequate dietary habits barrier to self-care or [professional care] possibly evidenced by toothache, dental or root caries, halitosis.

risk for imbalanced Nutrition: less than body requirements possibly evidenced by insufficient dietary intake.

Abscess, skin/tissue **CH/MS**

impaired Skin/Tissue Integrity may be related to [infection], alteration in fluid volume, inadequate nutrition (impaired circulation or vascular trauma, immunodeficiency); possibly evidenced by acute pain, alteration in skin integrity, hematoma/bleeding, redness, localized area hot to touch.

risk for Infection [spread] possibly evidenced by exposure to toxins, alteration in skin integrity, malnutrition, insufficient knowledge to avoid exposure to pathogens.

Abuse, physical **CH/PSY**

Also refer to Battered child syndrome

risk for physical Trauma possibly evidenced by [vulnerable client, recipient of verbal threats], history of physical abuse.

Powerlessness may be related to insufficient interpersonal interactions, ineffective coping strategies, insufficient knowledge to manage a situation, low self-esteem social marginalization, [lifestyle of helplessness] as evidenced by verbal expressions of insufficient control, alienation, dependency, shame, [reluctance to express true feelings, apathy, passivity].

chronic low Self-Esteem may be related to inadequate belonging or affection received, inadequate respect from others [continual negative evaluation of self or capabilities, personal vulnerability, willingness to tolerate possible life-threatening domestic violence] as evidenced by nonassertive behavior, overly conforming, passivity, underestimating ability to deal with situation; [self-negative verbalization, evaluation

of self as unable to deal with events, rejects positive feedback about self].

ineffective Coping may be related to high degree of threat or inadequate threat appraisal, insufficient sense of control, inadequate resources or social support possibly evidenced by change in communication pattern, risk-taking or destructive behaviors toward self/others, inability to ask for help or deal with the situation.

Sexual dysfunction may be related to ineffectual or absent role model, vulnerability, physical abuse possibly evidenced by verbalizations, change in sexual behaviors or activities, inability to achieve desired satisfaction.

Abuse, psychological

CH/PSY

ineffective Coping may be related to high degree of threat or inadequate threat appraisal, insufficient sense of control, inadequate resources or social support possibly evidenced by change in communication pattern, frequent illness, risk-taking or destructive behaviors toward self/others, inability to ask for help or deal with the situation.

Powerlessness may be related to insufficient interpersonal interactions, ineffective coping strategies, insufficient knowledge to manage a situation, low self-esteem social marginalization, [lifestyle of helplessness] as evidenced by verbal expressions of insufficient control, alienation, dependency, shame, [reluctance to express true feelings, apathy, passivity].

Sexual dysfunction may be related to ineffectual or absent role model, vulnerability, [psychological abuse (harmful relationship)], possibly evidenced by alteration in sexual function or satisfaction, seeking confirmation of desirability.

[esophageal] Achalasia (cardiospasm) MS

impaired Swallowing may be related to (neuromuscular impairment, trauma, oropharynx abnormality), possibly evidenced by observed difficulty in swallowing, heartburn/regurgitation.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake; inability/reluctance to ingest food, possibly evidenced by perceived inability to ingest food, food aversion, weight loss, and pale conjunctiva and mucous membranes.

acute Pain may be related to spasm of the lower esophageal sphincter, possibly evidenced by reports of substernal pressure, recurrent heartburn, or gastric fullness (gas pains).

Anxiety [specify level]/Fear may be related to stressors [e.g., recurrent pain, choking sensation, threat to health status], possibly evidenced by verbalizations of distress, apprehension, restlessness, or insomnia.

risk for Aspiration possibly evidenced by incompetent lower esophageal sphincter, [regurgitation or spillover of esophageal contents].

deficient Knowledge regarding condition, prognosis, self-care, and treatment needs may be related to lack of familiarity with pathology and treatment of condition, possibly evidenced by requests for information, statement of concern, or development of preventable complications.

Acidosis, metabolic

MS

Refer to underlying cause/condition, e.g., Diabetic ketoacidosis; Renal failure, Dialysis

Acidosis, respiratory

MS

(Also refer to underlying cause/condition)

impaired Gas Exchange may be related to (ventilation-perfusion imbalance, alveolar-capillary membrane changes), [decreased oxygen-carrying capacity of blood, altered oxygen supply], possibly evidenced by dyspnea, irritability, tachycardia, hypoxia, hypercapnia.

Acne

CH/PED

impaired Skin Integrity may be related to secretions, [infectious process] as evidenced by alteration in skin integrity.

disturbed Body Image may be related to alteration in self-perception, possibly evidenced by verbalizations of feelings or perceptions, fear of reaction by others, preoccupation with change in visual appearance as evidenced by fear of rejection of others, focus on past appearance, negative feelings about body, change in social involvement.

situational low Self-Esteem may be related to adolescence, negative perception of appearance as evidenced by self-negating verbalizations, expressions of helplessness.

Acoustic neuroma

MS

Also refer to Surgery, general

[disturbed auditory Sensory Perception] may be related to altered sensory reception (compression of eighth cranial nerve), possibly evidenced by unilateral sensorineural hearing loss, tinnitus.

risk for Falls possibly evidenced by hearing difficulties, dizziness, sense of unsteadiness.

Acquired immune deficiency syndrome CH
Refer to AIDS

Acromegaly CH
chronic Pain may be related to soft tissue swelling, joint degeneration, peripheral nerve compression, possibly evidenced by verbal reports, altered ability to continue previous activities, changes in sleep pattern, fatigue.

disturbed Body Image may be related to alteration in self-perception, cultural or spiritual incongruence possibly evidenced by verbalizations of feelings or perceptions, fear of rejection or reaction by others.

risk for Sexual dysfunction possibly evidenced by altered body structure, perceived sexual limitation, changes in libido.

Acute respiratory distress syndrome MS
Refer to Respiratory distress syndrome, acute

Adams-Stokes syndrome CH
Refer to Dysrhythmia, cardiac

ADD PED
Refer to Attention deficit disorder

Addiction CH/PSY
Refer to specific substance used; Substance dependence/abuse rehabilitation

Addison's disease MS
deficient Fluid Volume [hypertonic] may be related to vomiting, diarrhea, increased renal losses, possibly evidenced by delayed capillary refill, poor skin turgor, dry mucous membranes, report of thirst.

risk for Electrolyte Imbalance possibly evidenced by vomiting, diarrhea, endocrine dysfunction.

decreased Cardiac Output may be related to hypovolemia and altered electrical conduction (dysrhythmias) or diminished cardiac muscle mass, possibly evidenced by alterations in vital signs, changes in mentation, and irregular pulse or pulse deficit.

Fatigue CH
may be related to decreased metabolic energy production, altered body chemistry (fluid, electrolyte, and glucose imbalance), possibly evidenced by unremitting overwhelming lack of energy, inability to maintain usual routines, decreased performance, impaired ability to concentrate, lethargy, and disinterest in surroundings.

disturbed Body Image may be related to alteration in self-perception, cultural or spiritual incongruence, possibly evidenced by verbalizations of feelings or perceptions, fear of reaction by others, preoccupation with changes (i.e., in skin pigmentation, mucous membranes, loss of axillary and pubic hair), and impaired social involvement.

risk for impaired physical Mobility possibly evidenced by neuromuscular impairment (muscle wasting, weakness) and dizziness, syncope.

imbalanced Nutrition: less than body requirements may be related to inadequate dietary intake, (inability to absorb nutrients [glucocorticoid deficiency; abnormal fat, protein, and carbohydrate metabolism]); possibly evidenced by weight loss, muscle wasting, abdominal cramping, diarrhea, and [hypoglycemia].

risk for impaired Home Maintenance possibly evidenced by effects of disease process, impaired cognitive functioning, and inadequate support systems.

Adenoidectomy PED/MS

Anxiety [specify level]/Fear may be related to threat to current status/unmet needs [e.g., separation from supportive others, unfamiliar surroundings, and perceived threat of injury or abandonment], possibly evidenced by crying, apprehension, trembling, and sympathetic stimulation (pupil dilation, increased heart rate).

risk for ineffective Airway Clearance possibly evidenced by sedation, collection of secretions and blood in oropharynx, and vomiting.

risk for deficient Fluid Volume possibly evidenced by operative trauma to highly vascular site, hemorrhage.

acute Pain may be related to physical trauma to oronasopharynx, presence of packing, possibly evidenced by restlessness, crying, and facial mask of pain.

Adjustment disorder PED/PSY
Refer to Anxiety disorders

Adoption/loss of child custody PSY

risk for complicated Grieving possibly evidenced by emotional disturbance, depression, self-blame, separation distress [due to actual loss of child, expectations for future of child/self, thwarted grieving response to loss].

risk for Powerlessness possibly evidenced by [perceived lack of options, no input into decision process, no control over outcome].

Adrenal crisis, acute

MS

Also refer to Addison's disease; Shock
deficient Fluid Volume [hypertonic] may be related to failure of regulatory mechanism (damage to or suppression of adrenal gland), inability to concentrate urine, possibly evidenced by decreased venous filling, pulse volume and pressure; hypotension, dry mucous membranes, changes in mentation, decreased serum sodium.

acute Pain may be related to effects of disease process and metabolic imbalances, decreased tissue perfusion, possibly evidenced by reports of severe pain in abdomen, lower back, or legs.

impaired physical Mobility may be related to neuromuscular impairment, decreased muscle strength and control, possibly evidenced by generalized weakness, inability to perform desired activities or movements.

risk for Hyperthermia possibly evidenced by increase in metabolic rate [illness or infectious process], dehydration.

risk for ineffective Protection possibly evidenced by hormone deficiency, drug therapy, nutritional or metabolic deficiencies.

Adrenalectomy

MS

ineffective Tissue Perfusion (specify) may be related to hypovolemia and vascular pooling of blood [vasodilation], possibly evidenced by diminished pulse, pallor or cyanosis, hypotension, and changes in mentation.

risk for Infection possibly evidenced by alteration in skin integrity, invasive procedure (incision, traumatized tissues).

deficient Knowledge regarding condition, prognosis, self-care, and treatment needs may be related to unfamiliarity with long-term therapy requirements, possibly evidenced by request for information and statement of concern or misconceptions.

Adrenal insufficiency

CH

Refer to Addison's disease

Affective disorder

PSY

Refer to Bipolar disorder; Depression, major

Affective disorder, seasonal

PSY

Also refer to Depression, major

[intermittent] ineffective Coping may be related to ineffective pattern of tension release strategies, inadequate resources, possibly evidenced by alteration in sleep

pattern (too little or too much), fatigue, insufficient problem resolution, [behavioral changes-irritability, discouragement].

Agoraphobia

PSY

Also refer to Phobia

Anxiety [panic] may be related to threat to current status (i.e., contact with feared situation [public place, crowds]), possibly evidenced by tachycardia, chest pain, dyspnea, gastrointestinal distress, faintness, sense of impending doom.

Agranulocytosis

MS

risk for Infection possibly evidenced by (suppressed inflammatory response).

risk for impaired oral Mucous Membrane Integrity possibly evidenced by (immunodeficiency), [infection].

AIDS (acquired immunodeficiency syndrome)

MS

Also refer to HIV infection

risk for Infection [onset of new opportunistic infection] possibly evidenced by chronic illness, suppressed inflammatory response, malnutrition, insufficient knowledge to avoid exposure to pathogens, use of antimicrobial agents.

risk for deficient Fluid Volume possibly evidenced by risk factors of excessive losses—copious diarrhea, profuse sweating, vomiting, hypermetabolic state or fever; and restricted intake—nausea, anorexia, lethargy.

acute/chronic Pain may be related to tissue inflammation or destruction: infections, internal or external cutaneous lesions, rectal excoriation, malignancies, necrosis, peripheral neuropathies, myalgias and arthralgias, possibly evidenced by verbal reports, narrowed focus, alteration in muscle tone, paresthesias, paralysis, guarding behaviors, changes in vital signs (acute), autonomic responses, and restlessness.

risk for ineffective Breathing Pattern possibly evidenced by (neuromuscular impairment [wasting of respiratory musculature]); fatigue, respiratory muscle fatigue, pain.

CH

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (altered ability to ingest, digest, or absorb nutrients); [increased metabolic rate and nutritional needs (fever, infection)], possibly evidenced by perceived inability

to ingest food/food aversion, body weight 20% or more below ideal weight range, altered taste sensation; abdominal cramping, hyperactive bowel sounds, diarrhea, sore buccal cavity, [abnormal laboratory results—vitamin, mineral, and protein deficiencies; electrolyte imbalances].

Fatigue may be related to decreased metabolic energy production, increased energy requirements (hypermetabolic state), overwhelming psychological or emotional demands, altered body chemistry (side effects of medication, chemotherapy), sleep deprivation, possibly evidenced by unremitting or overwhelming lack of energy, inability to maintain usual routines, decreased performance, impaired ability to concentrate, lethargy, listlessness, and disinterest in surroundings.

ineffective Protection may be related to chronic disease affecting immune and neurological systems, inadequate nutrition, drug therapies, possibly evidenced by deficient immunity, impaired healing, neurosensory alterations, maladaptive stress response, fatigue, anorexia, disorientation.

PSY

Social Isolation may be related to alterations in physical appearance, mental status, state of wellness; perceptions of unacceptable social behavior or values [phobic fear of others (transmission of disease)], possibly evidenced by expressed feelings of aloneness or rejection, absence of supportive SO(s), and withdrawal from usual activities.

chronic Confusion may be related to physiological changes (hypoxemia, central nervous system infection by HIV, brain malignancies, or disseminated systemic opportunistic infection); altered drug metabolism and excretion, accumulation of toxic elements (renal failure, severe electrolyte imbalance, hepatic insufficiency), possibly evidenced by clinical evidence of organic impairment, altered response to stimuli, memory deficit, and altered personality.

AIDS dementia

CH

Also refer to Dementia, HIV

chronic Confusion/impaired Memory related to physiological changes (neuronal degeneration), possibly evidenced by inaccurate interpretation of or response to stimuli, progressive or long-standing cognitive impairment, short-term memory deficit, impaired socialization, altered personality, and clinical evidence of organic impairment.

ineffective Protection may be related to immune disorder, inadequate nutrition, drug therapies, possibly evidenced by deficient immunity, impaired healing, neurosensory alterations, maladaptive stress response, fatigue, anorexia, disorientation.

Alcohol abuse/withdrawal

CH/MS/PSY

Refer to Alcohol intoxication, acute; Delirium tremens; Substance dependence/abuse rehabilitation

Alcohol intoxication, acute

MS

Also refer to Delirium tremens

acute Confusion may be related to alteration in sleep-wake cycle, sensory deprivation, impaired mobility, dehydration, malnutrition, substance misuse/[abuse], inappropriate use of restraints, possibly evidenced by hallucinations, exaggerated emotional response, fluctuation in cognition or level of consciousness, increased agitation.

risk for ineffective Breathing Pattern possibly evidenced by (hypoventilation syndrome, neuromuscular impairment), fatigue.

risk for Aspiration possibly evidenced by ineffective cough (decrease in level of consciousness, depressed gag reflexes, delayed gastric emptying).

Alcoholism

CH

Refer to Substance dependence/abuse rehabilitation

Aldosteronism, primary

MS

deficient Fluid Volume may be related to increased urinary losses, possibly evidenced by dry mucous membranes, poor skin turgor, dilute urine, excessive thirst, weight loss.

impaired physical Mobility may be related to neuromuscular impairment, decreased muscle strength, and pain, possibly evidenced by limited range of motion, slowed movement, limited ability to perform gross/fine motor skills.

risk for decreased Cardiac Output possibly evidenced by risk factors of altered preload and altered heart rhythm.

Alkalosis, metabolic

MS

Refer to underlying cause/condition, e.g., Renal failure, Dialysis

Alkalosis, respiratory

MS

(Also refer to underlying cause/condition.)

impaired Gas Exchange may be related to (ventilation-perfusion imbalance, alveolar-capillary membrane

changes [decreased oxygen-carrying capacity of blood, altered oxygen supply]), possibly evidenced by low respiratory rate, tachypnea, changes in mentation.

Allergies, seasonal

CH

Refer to Hay fever

Alopecia

CH

disturbed Body Image may be related to alteration in self-perception, possibly evidenced by verbalizations of feelings or concerns, fear of reaction by others, preoccupation with change in appearance [e.g., effects of illness, therapy, or aging process]; focus on past appearance, preoccupation with change, feelings of helplessness.

ALS

CH

Refer to Amyotrophic lateral sclerosis

Alzheimer's disease

CH

Also refer to Dementia, presenile/senile

risk for Injury/Trauma possibly evidenced by insufficient knowledge of modifiable factors [inability to recognize or identify danger in environment, disorientation, confusion, impaired judgment, weakness, muscular incoordination, balancing difficulties, altered perception].

chronic Confusion related to physiological changes [neuronal degeneration], possibly evidenced by inaccurate interpretation of or response to stimuli, progressive or long-standing cognitive impairment, short-term memory deficit, impaired socialization, altered personality, and clinical evidence of organic impairment.

[disturbed Sensory Perception (specify)] may be related to altered sensory reception, transmission, or integration (neurological disease, deficit), socially restricted environment (homebound or institutionalized), sleep deprivation, possibly evidenced by changes in usual response to stimuli, change in problem-solving abilities, exaggerated emotional responses (anxiety, paranoia, hallucinations), inability to tell position of body parts, diminished or altered sense of taste.

Sleep deprivation may be related to sensory impairment, changes in activity patterns, psychological stress [neurological impairment], possibly evidenced by wakefulness, disorientation [day/night reversal], increased aimless wandering, inability to identify need or time for sleeping, changes in behavior, lethargy, dark circles under eyes, and frequent yawning.

ineffective Health Maintenance may be related to deterioration affecting ability in all areas, including coordination, communication, and cognition; ineffective individual or family coping, possibly evidenced by reported or observed inability to take responsibility for meeting basic health practices, lack of equipment/financial or other resources, and impairment of personal support system.

PSY

risk for Stress overload possibly evidenced by inadequate resources, chronic illness, physical demands, threats of violence.

compromised family Coping/caregiver Role Strain may be related to disruptive behavior of client, family grief about their helplessness watching loved one deteriorate, prolonged disease or disability progression that exhausts the supportive capacity of SO or family, highly ambivalent family relationships, possibly evidenced by verbalizations of frustrations in dealing with day-to-day care, reports of conflict, feelings of depression, expressed anger/guilt directed toward client, and withdrawal from interaction with client or social contacts.

risk for Relocation Stress Syndrome possibly evidenced by little or no preparation for transfer to a new setting, changes in daily routine, sensory impairment, physical deterioration, separation from support systems.

Amenorrhea (secondary or pathological)

GYN

Also refer to Anorexia nervosa

imbalanced Nutrition: less than body requirements may be related to (inability to ingest food or absorb nutrients), possibly evidenced by body weight 20% or more below ideal weight range, aversion to eating, lack of interest in food, [excessive hair growth or lanugo], pale conjunctiva and mucous membranes, [abnormal lab studies].

risk for Sexual dysfunction possibly evidenced by alteration in body function.

Amphetamine abuse

PSY

Refer to Stimulant abuse

Amputation

MS

risk for ineffective peripheral Tissue Perfusion possibly evidenced by reduced arterial or venous blood flow, tissue edema, hematoma formation, hypovolemia.

acute Pain may be related to physical injury agent (tissue and nerve trauma), [psychological impact

of loss of body part], possibly evidenced by reports of incisional or phantom pain, guarding or protective behavior, narrowed or self-focus, and autonomic responses.

impaired physical Mobility may be related to loss of limb, altered sense of balance, pain or discomfort, possibly evidenced by reluctance to attempt movement, impaired coordination; decreased muscle strength, control, and mass.

disturbed Body Image may be related to alteration in self-perception, (alteration in body function, injury/trauma), possibly evidenced by preoccupation with loss; negative feeling about body; focus on past strength, function, or appearance; fear of reaction by others; avoids looking at or touching one's body.

Amyotrophic lateral sclerosis (ALS) MS

impaired physical Mobility may be related to muscle wasting, weakness, possibly evidenced by impaired coordination, limited range of motion, and impaired purposeful movement.

ineffective Breathing Pattern/impaired spontaneous Ventilation may be related to neuromuscular impairment, decreased energy, fatigue, tracheobronchial obstruction, possibly evidenced by shortness of breath, fremitus, respiratory depth changes, and reduced vital capacity.

impaired Swallowing may be related to (neurological problem), possibly evidenced by delayed/repetitive swallowing, coughing, choking, and recurrent pulmonary infection.

PSY

Powerlessness may be related to anxiety, insufficient knowledge to manage a situation, ineffective coping skills, insufficient social support, pain, [chronic and debilitating nature of illness, lack of control over outcome], possibly evidenced by expressions of frustration about inability to perform previous activities, inadequate participation in care, dependency, and depression.

Grieving may be related to anticipatory loss of significant object [self and physiopsychosocial well-being], possibly evidenced by distress, despair, anger, detachment.

CH

impaired verbal Communication may be related to physical barrier (neuromuscular impairment), possibly evidenced by impaired articulation, inability to speak in sentences, and use of nonverbal cues (changes in facial expression).

risk for caregiver Role Strain possibly evidenced by illness severity of care receiver, complexity and amount of home-care needs, duration of caregiving required, caregiver is spouse, family/caregiver isolation, lack of respite or recreation for caregiver.

Anaphylaxis

CH

Also refer to Shock

ineffective Airway Clearance may be related to airway spasm (bronchial), laryngeal edema, possibly evidenced by diminished or adventitious breath sounds, cough ineffective or absent, difficulty vocalizing, wide-eyed.

decreased Cardiac Output may be related to decreased preload—increased capillary permeability (third spacing) and vasodilation, possibly evidenced by tachycardia/palpitations, changes in blood pressure, anxiety, restlessness.

Anemia

CH

Activity Intolerance may be related to imbalance between oxygen supply and demand, possibly evidenced by reports of fatigue and weakness, abnormal heart rate or blood pressure response to activity, [decreased exercise or activity level, and exertional discomfort] or dyspnea.

imbalanced Nutrition: less than body requirements may be related to inadequate dietary intake, (inability to digest food or absorb nutrients), possibly evidenced by [weight loss or weight below normal for age]; pale oral mucous membranes, sore buccal cavity; insufficient muscle tone, [fatigue].

deficient Knowledge regarding condition, prognosis, self-care, and treatment needs may be related to inadequate understanding or misinterpretation of dietary or physiological needs, possibly evidenced by inadequate dietary intake, request for information, and development of preventable complications.

Anemia, iron-deficiency

CH

Also refer to Anemia

Fatigue may be related to anemia, malnutrition, possibly evidenced by feeling tired, inability to maintain usual routines or level of physical activity.

risk for deficient Fluid Volume possibly evidenced by active or chronic blood loss.

risk for impaired oral Mucous Membrane Integrity possibly evidenced by dehydration, malnutrition, [vitamin deficiency].

Anemia, pernicious

CH

Also refer to Anemia

[disturbed kinesthetic/visual Sensory Perception] may be related to changes in reception or perception, possibly evidenced by paresthesia, inability to tell position of extremities (proprioception), loss of vibratory sensation, changes in sensory acuity (yellow-blue color blindness).

risk for Constipation/Diarrhea possibly evidenced by muscular weakness, changes in gastrointestinal motility, neurological impairment.

risk for Injury/Falls possibly evidenced by malnutrition [with generalized weakness, paresthesia of extremities, loss of proprioception, ataxia].

Anemia, sickle cell

MS

impaired Gas Exchange may be related to ventilation-perfusion imbalance, possibly evidenced by dyspnea, abnormal breathing pattern, signs of hypoxia—abnormal skin color, tachycardia, confusion, and restlessness.

ineffective Tissue Perfusion (specify) may be related to stasis, vaso-occlusive nature of sickling, inflammatory response, atrioventricular shunts in pulmonary and peripheral circulation, myocardial damage (small infarcts, iron deposits, fibrosis), possibly evidenced by signs and symptoms dependent on system involved; for example, renal—decreased specific gravity and pale urine in face of dehydration; cerebral—paralysis and visual disturbances; peripheral—distal ischemia, tissue infarctions, ulcerations, bone pain; cardiac—angina, palpitations.

CH

acute/chronic Pain may be related to physical injury agent [intravascular sickling with localized vascular stasis, occlusion, infarction or necrosis and deprivation of oxygen and nutrients, accumulation of noxious metabolites], possibly evidenced by reports of localized, generalized, or migratory joint or abdominal/back pain; guarding and distraction behaviors (moaning, crying, restlessness); facial grimacing; narrowed focus; and autonomic responses.

deficient Knowledge regarding disease process, genetic factors, prognosis, self-care, and treatment needs may be related to lack of exposure or recall, misinterpretation of information, unfamiliarity with resources, possibly evidenced by questions, statements of concern or misconceptions, exacerbation of condition, inadequate follow-through of therapy instructions, and development of preventable complications.

risk for sedentary Lifestyle possibly evidenced by lack of interest or motivation, resources; lack of training or knowledge of specific exercise needs, safety concerns, fear of injury.

PED

risk for delayed Development possibly evidenced by inadequate nutrition, chronic illness.

compromised family Coping may be related to chronic nature of disease and disability, family disorganization, presence of other crises or situations impacting significant person or parent, lifestyle restrictions, possibly evidenced by SO expressing preoccupation with own reaction and displaying protective behavior disproportionate to client's ability or need for autonomy.

Anencephaly

OB

Also refer to Fetal demise

Anxiety [specify level] may be related to situational crisis, threat of fetal death, interpersonal transmission or contagion, possibly evidenced by increased tension, apprehension, feelings of inadequacy, somatic complaints, difficulty sleeping.

risk for Decisional Conflict possibly evidenced by threat to value/belief system, multiple or divergent sources of information, support system deficit, feelings of guilt (particularly regarding moral/ethical issues such as termination of pregnancy, organ donation).

Aneurysm, abdominal aortic

MS

Refer to Aortic aneurysm, abdominal

Aneurysm, cerebral

MS

Refer to Cerebrovascular accident

Aneurysm, ventricular

MS

decreased Cardiac Output may be related to altered stroke volume (decreased contractility, increased systemic vascular resistance), changes in heart rate or rhythm, possibly evidenced by dyspnea, adventitious breath sounds, S₃/S₄ heart sounds, changes in hemodynamic measurements, dysrhythmias.

ineffective Tissue Perfusion (specify) may be related to decreased arterial blood flow, possibly evidenced by blood pressure changes, diminished pulses, edema, dyspnea, dysrhythmias, altered mental status, decreased renal function.

Activity Intolerance may be related to imbalance between oxygen supply and demand, possibly evidenced by weakness, fatigue, abnormal heart rate/

blood pressure response to activity, electrocardiogram changes (dysrhythmias, ischemia).

Angina pectoris

MS

acute Pain may be related to physical injury agent [decreased myocardial blood flow, increased cardiac workload and oxygen consumption], possibly evidenced by verbal reports, narrowed focus, distraction behavior (restlessness, moaning), and autonomic responses (diaphoresis, changes in vital signs).

risk for decreased Cardiac Output possibly evidenced by transient or prolonged myocardial ischemia and effects of medications, alterations in rate, rhythm, and electrical conduction.

Anxiety [specify level] may be related to stressors, change in health status or threat of death; possibly evidenced by apprehensiveness, expressed concerns, facial tension, extraneous movements, and self-focused.

CH

Activity Intolerance may be related to imbalance between oxygen supply and demand, possibly evidenced by exertional dyspnea, abnormal pulse/blood pressure response to activity, and electrocardiogram changes.

deficient Knowledge regarding condition, prognosis, self-care, and treatment needs may be related to lack of exposure, inaccurate/misinterpretation of information, possibly evidenced by questions, request for information, statement of concern, and inaccurate follow-through of instructions.

risk for sedentary Lifestyle possibly evidenced by lack of training or knowledge of specific exercise needs, safety concerns, fear of myocardial injury.

risk for risk-prone Health Behavior possibly evidenced by condition requiring long-term therapy/change in lifestyle, multiple stressors, assault to self-concept, and altered locus of control.

Anorexia nervosa

MS

imbalanced Nutrition: less than body requirements may be related to (physiological disorder), possibly evidenced by weight loss, insufficient muscle tone, food aversion/intake less than recommended daily allowance, [amenorrhea, electrolyte imbalance, cardiac irregularities, hypotension].

risk for deficient Fluid Volume possibly evidenced by inadequate intake of food and liquids, chronic laxative or diuretic use.

PSY

disturbed Body Image may be related to alteration in self-perception, cultural or spiritual incongruence possibly evidenced by verbalizations of feelings or perceptions (e.g., rejection by others, perceptual developmental changes), perceptions reflecting altered view of body appearance, refusal to verify actual change.

chronic low Self-Esteem may be related to inadequate affection received, inadequate respect from others, receiving insufficient approval from others, possibly evidenced by reports of exaggerated negative feedback about self, overly conforming, passivity, shame.

impaired Parenting may be related to issues of control in family, situational or maturational crises, history of inadequate coping methods, possibly evidenced by enmeshed family; dissonance among family members; focus on “identified patient”; family developmental tasks not being met; family members acting as enablers; ill-defined family rules, functions, and roles.

Anthrax, cutaneous

MS/CH

impaired Skin/Tissue Integrity may be related to [chemical injury agent], possibly evidenced by acute pain, alteration in skin integrity, alteration in sensation, [damage to tissues].

impaired Comfort may be related to local edema, effects of circulating toxins, possibly evidenced by reports of headache, muscle aches, nausea, malaise.

risk for Infection [spread/sepsis] possibly evidenced by alteration in skin integrity, suppression, lack of immunity, [presence of infective agent].

Anthrax, gastrointestinal

MS

Anxiety [moderate to severe]/Fear may be related to threat of death, interpersonal transmission or contagion, possibly evidenced by expressed concerns, apprehension, uncertainty, fear, increased tension, restlessness.

risk for deficient Fluid Volume possibly evidenced by decreased intake (nausea), excessive loss—bloody vomit or diarrhea, hypermetabolic state.

imbalanced Nutrition: less than body requirements may be related to inadequate dietary intake, [inability to ingest food or absorb nutrients], possibly evidenced by [loss of appetite, nausea, vomiting], abdominal pain, diarrhea.

impaired oral Mucous Membrane Integrity may be related to effects of infection, dehydration, possibly evidenced by oropharyngeal ulcerations, oral pain, difficulty swallowing.

Anthrax, inhalation (pulmonary)

MS

Also refer to Ventilator assist/dependence

impaired Comfort may be related to effects of inflammatory response, possibly evidenced by fever, malaise, weakness, fatigue, mild chest pain.

Anxiety [moderate to severe]/Fear may be related to threat of death, interpersonal transmission or contagion, possibly evidenced by expressed concerns, apprehension, uncertainty, fear, increased tension, restlessness, blocking of thought.

impaired Gas Exchange may be related to (alveolar-capillary membrane changes [fluid collection or shifts into interstitial space or alveoli]), possibly evidenced by dyspnea, restlessness, irritability, abnormal breathing and skin color, hypoxia, lethargy, confusion.

risk for impaired spontaneous Ventilation possibly evidenced by decrease in arterial oxygen saturation, respiratory muscle fatigue, decrease in tidal volume [widening of mediastinum].

Antisocial personality disorder

PSY

risk for other-directed Violence possibly evidenced by contempt for authority or rights of others, inability to tolerate frustration, need for immediate gratification, easy agitation, vulnerable self-concept, inability to verbalize feelings, use of maladjusted coping mechanisms, history of substance abuse.

ineffective Coping may be related to ineffective tension release strategies, insufficient sense of control, (situational crisis), possibly evidenced by ineffective coping strategies, insufficient problem-solving skills, risk-taking behavior, destructive behaviors toward self/others.

chronic low Self-Esteem may be related to [lack of positive or repeated negative feedback, unmet dependency needs, retarded ego development, dysfunctional family system], possibly evidenced by acting-out behaviors (e.g., substance abuse, sexual promiscuity, feelings of inadequacy, nonparticipation in therapy)].

compromised/disabled family Coping may be related to family disorganization or role changes, highly ambivalent family relationships, client providing little support in turn for the primary person(s), history of abuse or neglect in the home, possibly evidenced by expressions of concern or complaints, preoccupation of primary person with own reactions to situation, display of protective behaviors disproportionate to client's abilities or need for autonomy.

impaired Social Interaction may be related to inadequate personal resources (shallow feelings),

immature interests, underdeveloped conscience, unaccepted social values, possibly evidenced by difficulty meeting expectations of others, lack of belief that rules pertain to self, sense of emptiness or inadequacy covered by expressions of self-conceit, arrogance, contempt; behavior unaccepted by dominant cultural group.

Anxiety disorder, generalized

PSY

Anxiety [specify level]/Powerlessness may be related to real or perceived threat to physical integrity or self-concept, values or beliefs conflicts; possibly evidenced by sympathetic stimulation, extraneous movements, persistent expression of apprehension and uneasiness, poor eye contact, focus on self, impaired functioning, and nonparticipation in decision making.

ineffective Coping may be related to inaccurate threat appraisal, inadequate resources or social support systems, possibly evidenced by inability to ask for help, attend to information or deal with a situation, ineffective coping strategies, risk-taking behavior, substance misuse.

Insomnia may be related to stress, repetitive thoughts, possibly evidenced by reports of difficulty in falling/staying asleep, dissatisfaction with sleep, nonrestorative sleep, lack of energy.

risk for compromised family Coping possibly evidenced by inadequate or incorrect information or understanding by a support person, temporary family disorganization and role changes, exhaustion of support person.

impaired Social Interaction/Social Isolation may be related to low self-concept, inadequate personal resources, misinterpretation of internal or external stimuli, hypervigilance, possibly evidenced by discomfort in social situations, withdrawal from or reported change in pattern of interactions, dysfunctional interactions; expressed feelings of difference from others; sad, dull affect.

Anxiety disorders

PED/PSY

Anxiety [severe/panic] may be related to [situational or maturational crisis], interpersonal transmission or contagion, threat to current status, unmet needs, possibly evidenced by increase in tension, awareness of physiological symptoms, extraneous movement, diminished ability to learn, apprehensiveness, distress, fear.

ineffective Coping may be related to [maturational crisis], inadequate confidence in ability to deal with situation, insufficient sense of control, possibly evidenced by inability to deal with a situation, inability

to meet role expectation, insufficient access of social support, [panic attacks].

impaired Social Interaction may be related to disturbance in self-concept, disturbance in thought processes possibly evidenced by discomfort in social situations, dissatisfaction with social engagement; impaired social functioning.

risk for Self-Mutilation/self-directed Violence possibly evidenced by panic states, dysfunctional family, history of self-destructive behaviors, emotional disturbance, increasing motor activity.

compromised/disabled family Coping may be related to [situational or developmental crisis], family disorganization, differing coping styles, [high-risk family situations—neglect or abuse, substance abuse], possibly evidenced by protective behavior by support person incongruent with client's abilities/need for autonomy, family behaviors detrimental to well-being.

Anxiolytic abuse

PSY

Refer to Depressant abuse

Aortic aneurysm, abdominal (AAA)

MS

risk for ineffective Tissue Perfusion (Specify: cardiovascular, cerebral, peripheral) possibly evidenced by hypertension, hypovolemia, hypoxia.

risk for Bleeding possibly evidenced by abnormal blood profile; treatment regimen [e.g., surgery, medications, administration of platelet-deficient blood products]

acute Pain may be related to physical injury agent (vascular enlargement-dissection or rupture), possibly evidenced by verbal coded reports, guarding behavior, facial mask, change in vital signs.

Aortic aneurysm repair, abdominal

MS

Also refer to Surgery, general

Anxiety may be related to threat to change in status, threat of death, possibly evidenced by expressed concerns, apprehensiveness, increase in tension, changes in vital signs.

risk for Bleeding possibly evidenced by (aneurysm, treatment regimen [e.g., surgery, failure of vascular repair]).

risk for ineffective Tissue Perfusion (Specify) possibly evidenced by (hypertension, treatment regimen—surgery, hypovolemia, hypoxia).

Aortic insufficiency

MS/CH

Refer to Valvular heart disease

Aortic stenosis

MS

Also refer to Valvular heart disease

decreased Cardiac Output may be related to altered contractility, altered preload or afterload possibly evidenced by fatigue, dyspnea, changes in vital signs, jugular vein distension, increased CVP/PAWP, and syncope.

risk for impaired Gas Exchange possibly evidenced by (alveolar-capillary membrane changes).

CH

risk for acute Pain possibly evidenced by physical injury agent (episodic myocardial ischemia, stretching of left atrium).

Activity Intolerance may be related to imbalance between oxygen supply and demand [decreased or fixed cardiac output], possibly evidenced by exertional dyspnea, fatigue, weakness, and abnormal blood pressure or electrocardiogram changes, dysrhythmias in response to activity.

Aplastic anemia

CH

Also refer to Anemia

risk for ineffective Protection possibly evidenced by (abnormal blood profile, pharmaceutical agent [antineoplastics, antibiotics, NSAIDs, anticonvulsants]).

Fatigue may be related to anemia, disease states, malnutrition, possibly evidenced by verbalization of overwhelming lack of energy, inability to maintain usual routines or level of physical activity, tired, compromised libido, lethargy, increase in physical complaints.

Appendectomy

MS

Also refer to Surgery, general

risk for Infection possibly evidenced by alteration in skin/tissue integrity, [release of pathogenic organisms into peritoneal cavity].

Appendicitis

MS

acute Pain may be related to physical injury agent [distention of intestinal tissues/inflammation], possibly evidenced by verbal reports, guarding behavior, narrowed focus, and autonomic responses (diaphoresis, changes in vital signs).

risk for deficient Fluid Volume possibly evidenced by excessive losses through normal routes (vomiting), deviations affecting intake of fluids (nausea, anorexia), and factors influencing fluid needs [hypermetabolic state].

risk for Infection possibly evidenced by alteration in tissue integrity, (invasive procedure, suppressed

inflammatory response and exposure to pathogens [release of pathogenic organisms into peritoneal cavity]).

ARDS

MS

Refer to Respiratory distress syndrome, acute

Arrhythmia, cardiac

MS/CH

Refer to Dysrhythmia, cardiac

Arterial occlusive disease, peripheral

CH

ineffective peripheral Tissue Perfusion may be related to deficient knowledge of disease process [PAD], hypertension, smoking, sedentary lifestyle, possibly evidenced by skin characteristics, diminished pulses, claudication, delayed peripheral wound healing.

risk for impaired Walking possibly evidenced by decrease in endurance, pain.

risk for impaired Skin/Tissue Integrity possibly evidenced by (impaired circulation, and alteration of sensation).

Arthritis, gouty

CH

Refer to Gout

Arthritis, juvenile rheumatoid

PED/CH

Also refer to Arthritis, rheumatoid

risk for delayed Development possibly evidenced by chronic illness, effects of required therapy.

risk for Social Isolation possibly evidenced by delay in accomplishing developmental task, altered state of wellness, and alterations in physical appearance.

Arthritis, rheumatoid

CH

acute/chronic Pain may be related to accumulation of fluid, inflammatory process, degeneration of joint, and deformity, possibly evidenced by verbal reports, narrowed focus, guarding or protective behavior, and physical and social withdrawal.

impaired physical Mobility may be related to musculoskeletal deformity, pain or discomfort, decreased muscle strength, possibly evidenced by limited range of motion, impaired coordination, reluctance to attempt movement, and decreased muscle strength, control, and mass.

Self-Care deficit [specify] may be related to musculoskeletal impairment, decreased strength and endurance, limited range of motion, pain on movement, possibly evidenced by inability to manage activities of daily living.

disturbed Body Image/ineffective Role Performance may be related to change in body structure and

function, impaired mobility or ability to perform usual tasks, focus on past strength, function, or appearance, possibly evidenced by negative self-talk, feelings of helplessness, change in lifestyle and physical abilities, dependence on others for assistance, decreased social involvement.

Arthritis, septic

CH

acute Pain may be related to physical injury agent (joint inflammation), possibly evidenced by verbal or coded reports, guarding behavior, restlessness, narrowed focus.

impaired physical Mobility may be related to joint stiffness, pain or discomfort, reluctance to initiate movement, possibly evidenced by limited range of motion, slowed movement.

Self-Care deficit [specify] may be related to musculoskeletal impairment, pain or discomfort, decreased strength, impaired coordination, possibly evidenced by inability to perform desired activities of daily living.

risk for Infection, spread possibly evidenced by presence of chronic disease state, suppressed inflammatory response.

Arthroplasty

MS

risk for Surgical Site Infection possibly evidenced by comorbidity (e.g., arthritis), duration/type of surgical procedure, use of implants/prosthesis, [stasis of body fluids at operative site, and altered inflammatory response].

risk for Bleeding possibly evidenced by (surgical procedure, trauma to vascular area).

impaired physical Mobility may be related to decreased strength, pain, musculoskeletal changes, possibly evidenced by impaired coordination and reluctance to attempt movement.

acute Pain may be related to physical injury agent (tissue trauma, local edema), possibly evidenced by verbal reports, narrowed focus, guarded movement, and autonomic responses (diaphoresis, changes in vital signs).

Arthroscopy, knee

MS

deficient Knowledge regarding procedure, outcomes, and self-care needs may be related to unfamiliarity with information or resources, misinterpretations, possibly evidenced by questions and requests for information, misconceptions.

risk for impaired Walking possibly evidenced by (musculoskeletal impairment), pain, physical deconditioning, fear of falling.

Asbestosis

CH

impaired Gas Exchange may be related to (alveolar-capillary membrane changes, ventilation-perfusion imbalance, possibly evidenced by dyspnea, tachypnea, restlessness, abnormal arterial blood gases [clubbing of fingers]).

Activity Intolerance may be related to imbalance between oxygen supply and demand, possibly evidenced by exertional dyspnea, generalized weakness, abnormal vital sign response to activity.

ineffective Airway Clearance may be related to inflammatory response to inhaled foreign body, smoking or secondhand smoke, infection, possibly evidenced by dyspnea, adventitious breath sounds, increased sputum.

risk for Infection possibly evidenced by stasis of body fluids, (decrease in ciliary action, chronic illness), malnutrition, insufficient knowledge to avoid exposure to pathogen.

acute Pain may be related to physical injury agent (inflammation or irritation of the parietal pleura), possibly evidenced by verbal reports, guarding or distraction behavior, self-focused, and autonomic responses (changes in vital signs).

Asperger's disorder (now Autism spectrum disorder)

PED/PSY

impaired Social Interaction may be related to insufficient skills to enhance mutuality, communication barriers, social dissonance, possibly evidenced by discomfort in social situations, dysfunctional interaction with others, impaired social functioning.

risk for delayed Development possibly evidenced by behavior disorder.

risk for Injury possibly evidenced by insufficient knowledge of modifiable factors [rituals, repetitive motor mannerisms, clumsiness, poor coordination, vulnerability to manipulation or peer pressure], (alteration in cognitive functioning).

Aspiration, foreign body

CH

ineffective Airway Clearance may be related to presence of foreign body, possibly evidenced by dyspnea, ineffective cough, diminished or adventitious breath sounds.

Anxiety [specify] may be related to threat of death, possibly evidenced by apprehensiveness, fearfulness, pupil dilation, increase in tension.

risk for Suffocation possibly evidenced by lack of safety education or precautions, eating large mouthfuls or pieces of food.

Asthma

MS

Also refer to Emphysema

ineffective Airway Clearance may be related to (airway spasm, allergic airway/asthma), excessive mucus, retained secretions, possibly evidenced by dyspnea, ineffective cough, difficulty verbalizing, diminished/adventitious breath sounds, alteration in respiratory pattern.

impaired Gas Exchange may be related to (ventilation-perfusion imbalance [e.g., altered delivery of inspired oxygen, air trapping]), possibly evidenced by dyspnea, restlessness, abnormal skin color, [reduced tolerance for activity], abnormal arterial blood gases, changes in vital signs.

Anxiety [specify level] may be related to threat to current status, threat of death, possibly evidenced by apprehensiveness, distress, fear, self-focused, extraneous movement, restlessness.

CH

Activity Intolerance may be related to imbalance between oxygen supply and demand, possibly evidenced by fatigue and exertional dyspnea.

risk for Contamination possibly evidenced by (exposure to atmospheric pollutants), environmental contaminants in the home (e.g., smoking or secondhand smoke).

Atelectasis

MS

impaired Gas Exchange may be related to (alveolar-capillary membrane changes [e.g., inflammatory process, stasis of secretions, hypoventilation], possibly evidenced by restlessness, dyspnea, tachycardia, abnormal skin color (pallor, cyanosis), abnormal arterial blood gases, hypoxia.

Atherosclerosis

CH/MS

Refer to Coronary artery disease: Peripheral vascular disease

Athlete's foot

CH

impaired Skin Integrity may be related to [fungal invasion], humidity, secretions, possibly evidenced by alteration in skin integrity, [painful itching].

risk for Infection [spread] possibly evidenced by alteration in skin integrity [exposure to moist, warm environment].

Atrial fibrillation

CH

Also refer to Dysrhythmia, cardiac

risk for Activity Intolerance may be related to imbalance between oxygen supply and demand, exertional dyspnea, (circulatory problem).

risk for ineffective cerebral Tissue Perfusion possibly evidenced by arterial fibrillation, embolism, thrombolytic therapy.

Atrial flutter

CH

Also refer to Dysrhythmia, cardiac

Anxiety [specify] may be related to threat to change in status, possibly evidenced by expressed concerns, apprehensiveness, awareness of physiological symptoms (palpitations, dizziness, presyncope or syncopal episodes), self-focused.

Atrial tachycardia

CH

Refer to Dysrhythmia, cardiac

Attention deficit disorder

PED/PSY

ineffective Coping may be related to (situational or maturational crisis), ineffective tension release strategies, inadequate confidence in ability to deal with situation, possibly evidenced by alteration in concentration, inability to attend to information, insufficient goal directed behavior.

chronic low Self-Esteem may be related to (psychiatric disorder, repeated negative reinforcement), possibly evidenced by poor eye contact, exaggerates negative feedback about self, rejection of positive feedback, hesitant to try new experiences, indecisive or nonassertive behavior.

deficient Knowledge regarding condition, prognosis, and therapy may be related to misinformation or misinterpretations, unfamiliarity with resources, possibly evidenced by verbalization of problems or misconceptions, poor school performance, unrealistic expectations of medication regimen.

Autism spectrum disorder

PED/PSY

impaired Social Interaction may be related to communication barrier, insufficient skills to enhance mutuality, disturbance in thought processes, disturbance in self-concept, absence of significant other, possibly evidenced by dysfunctional interactions with others, discomfort in social situations.

impaired verbal Communication may be related to alteration in self-concept, low self-esteem, emotional disturbance, absence of significant others, possibly evidenced by difficulty speaking, forming words/sentences, difficulty in use of facial/body expressions, inappropriate verbalizations, stuttering.

risk for Self-Mutilation possibly evidenced by inability to express tension verbally, ineffective coping strategies, requires rapid stress reduction, impaired

self-esteem, perfectionism, (individuals with autism, borderline personality disorder, character disorder, developmental delay).

disturbed Personal Identity may be related to low self-esteem, dysfunctional family processes, cultural incongruence, (developmental transition, organic brain disorder), possibly evidenced by fluctuating feelings about self, delusional description of self, unable to distinguish between internal and external stimuli, ineffective relationships.

compromised family Coping may be related to exhaustion of supportive person's capacity, family disorganization, insufficient understanding of information by a support person, coexisting situations affecting the significant other, possibly evidenced by support person reports insufficient knowledge, or inadequate understanding, that interferes with effective behaviors, support person reports preoccupation with personal reactions to client's needs; protective behavior by support person incongruent with client's abilities.

Bacteremia

MS

Refer to Sepsis

Barbiturate abuse

CH/PSY

Refer to Depressant abuse

Battered child syndrome

PED/CH

Also refer to Abuse, physical

risk for other-directed Violence possibly evidenced by pattern of indirect violence or threatening violence, [vulnerability (e.g., congenital problems/chronic illness)], (history of childhood abuse or neglect).

[risk for disproportionate Growth] and/or delayed Development possibly evidenced by presence of abuse, exposure to violence, inadequate nutrition/malnutrition; caregiver mental health issue, substance abuse, unplanned/unwanted pregnancy.

interrupted Family Processes/impaired Parenting may be related to poor role model, unrealistic expectations, presence of stressors, and lack of support, possibly evidenced by verbalization of negative feelings, inappropriate caretaking behaviors, and evidence of physical or psychological trauma to child.

PSY

chronic low Self-Esteem may be related to inadequate affection received, (repeated negative reinforcement, exposure to traumatic situation), possibly evidenced by poor eye contact, exaggerates negative

feedback about self, guilt/shame, nonassertive, indecisive, or overly conforming behavior.

Post-Trauma Syndrome may be related to sustained or recurrent physical or emotional abuse; possibly evidenced by acting-out behavior, development of phobias, poor impulse control, and emotional numbness.

Bedsores

CH/MS

Refer to Ulcer, pressure

Bed-wetting

PED

Refer to Enuresis

Benign prostatic hyperplasia

CH/MS

[acute/chronic] urinary Retention/overflow urinary Incontinence may be related to blockage in urinary tract [enlarged prostate], decompensation of detrusor musculature, inability of bladder to contract adequately, possibly evidenced by frequent voiding, hesitancy, inability to empty bladder completely, incontinence or dribbling, nocturia, bladder distention, residual urine.

acute Pain may be related to physical injury agent [mucosal irritation, bladder distention, colic, urinary infection, radiation therapy], possibly evidenced by verbal reports, narrowed focus, altered muscle tone, grimacing, distraction behavior, restlessness, and autonomic responses.

risk for deficient Fluid Volume/Electrolyte Imbalance possibly evidenced by active fluid volume loss—postobstructive diuresis, endocrine or renal dysfunction.

Fear/Anxiety [specify level] may be related to threat to current status; embarrassment, concern about sexual ability, and fear of unspecified consequences, possibly evidenced by increase in tension, apprehensiveness, worry, expressed concerns regarding perceived changes.

Besnier-Boeck disease

CH

Refer to Sarcoidosis

Biliary calculus

CH/MS

Refer to Cholelithiasis

Biliary cancer

MS

Also refer to Cancer

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to ingest or absorb nutrients), abdominal discomfort, possibly evidenced by food aversion, food intake less than recommended, insufficient muscle tone, weight

loss with adequate food intake, and [imbalances in nutritional studies].

risk for impaired Skin Integrity possibly evidenced by chemical injury agent (accumulation of bile salts in skin), alteration in fluid volume (poor skin turgor), pressure over bony prominence.

Death Anxiety may be related to lack of successful treatment options, poor prognosis, possibly evidenced by fear of the process of dying, leaving SO/family alone after death, negative death images, concern of overworking caregiver, deep sadness.

Binge-eating disorder

PSY

Refer to Bulimia nervosa

Bipolar disorder

PSY

ineffective Impulse Control may be related to mood disorder, (alteration in cognitive functioning, development; personality disorder), possibly evidenced by acting without thinking, temper outbursts, violent behavior.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (psychological disorder), possibly evidenced by insufficient information, misinformation/misperceptions, insufficient interest in food, food intake less than recommended daily allowance, body weight 20% or more below ideal weight range, [laboratory evidence of nutritional deficits or imbalances].

risk for Poisoning [lithium toxicity] possibly evidenced by [narrow therapeutic range of drug], emotional disturbance, insufficient knowledge of pharmaceutical agent.

Sleep Deprivation may be related to overstimulating environment, sustained circadian asynchrony, sustained inadequate sleep hygiene, possibly evidenced by agitation, irritability, restlessness, decrease in functional ability, alteration in concentration.

[disturbed Sensory Perception (specify)]/Stress overload may be related to psychological stress, [sleep deprivation], biochemical imbalances [e.g., increased norepinephrine levels in the brain], insufficient environmental stimulation, possibly evidenced by restlessness, poor concentration, disorientation, change in usual response to stimuli, sensory distortions, hallucination, change in behavior pattern, motor incoordination.

interrupted Family Processes may be related to shift in family roles, (situational crises, shift in health status of family member, change in family finances), possibly evidenced by change in communication pattern, changes in relationship pattern, decrease in

mutual support, assigned tasks change, changes in participation for problem-solving/decision making.

Bladder cancer

MS

Also refer to Cancer; Urinary diversion

impaired urinary Elimination may be related to presence of tumor, possibly evidenced by frequent voiding burning, dysuria.

acute/chronic urinary Retention may be related to blockage of urethra, possibly evidenced by sensation of fullness, bladder distention, residual urine, dysuria.

Body dysmorphic disorder

PSY

Refer to Hypochondriasis

Bone cancer

MS/CH

Also refer to Myeloma, multiple; Amputation

acute Pain may be related to physical injury agent [bone, tissue, and nerve destruction], possibly evidenced by verbal or coded report, protective behavior, autonomic responses.

impaired Walking may be related to (musculoskeletal impairment [amputation], impaired balance), possibly evidenced by impaired ability to climb stairs, navigate curbs, walk on incline or decline, or uneven surface.

Bone marrow transplantation

MS/CH

Also refer to Transplantation, recipient

risk for Injury possibly evidenced by (immune dysfunction or suppression, abnormal blood profile, [action of donor T cells]).

decreased Diversional Activity Engagement may be related to hospitalization or length of treatment, restriction of visitors, limitation of activities, possibly evidenced by expressions of boredom, restlessness, withdrawal, and requests for something to do.

risk for imbalanced Nutrition: less than body requirements possibly evidenced by (inability to ingest food or absorb nutrients), [increased metabolic needs for healing], nausea, vomiting, insufficient interest in food, alteration in taste sensations, sore buccal cavity.

Borderline personality disorder

PSY

risk for ineffective Impulse Control possibly evidenced by acting without thinking, sexual promiscuity, gambling, irritability, temper outbursts, violent behavior, (alteration in cognitive functioning).

Anxiety [severe to panic] may be related to threat to current status, value conflict, unmet needs, substance misuse, possibly evidenced by self-focused,

poor eye contact, hypervigilance, diminished ability to problem-solve, tendency to blame others, alteration in concentration, increase in tension, cardiac excitation.

chronic low Self-Esteem may be related to receiving insufficient approval from others, (repeated negative reinforcement, psychiatric disorder), possibly evidenced by rejection of positive feedback, excessive seeking of reassurance, underestimates ability to deal with situation, repeatedly unsuccessful in life events.

Social Isolation may be related to developmentally inappropriate interests, social behavior incongruent with norms, insufficient personal resources, and inability to engage in satisfying personal relationships, possibly evidenced by inability to meet expectations of others, feeling difference from others, aloneness imposed by others.

Botulism (foodborne)

MS

deficient Fluid Volume may be related to active losses (vomiting, diarrhea, decreased intake), nausea, dysphagia, possibly evidenced by reports of thirst; dry skin or mucous membranes, decreased blood pressure and urine output, change in mental state, increased hematocrit.

impaired physical Mobility may be related to neuromuscular impairment, possibly evidenced by limited ability to perform gross or fine motor skills.

Anxiety [specify level]/Fear may be related to threat of death, possibly evidenced by expressed concerns, apprehensiveness, awareness of physiological symptoms, self-focused.

risk for impaired spontaneous Ventilation possibly evidenced by [neuromuscular impairment, presence of infectious process].

CH

Contamination may be related to lack of proper precautions in food storage or preparation as evidenced by gastrointestinal and neurological effects of exposure to biological agent.

Bowel obstruction

MS

Refer to Ileus

Bowel resection

CH

Refer to Intestinal surgery (without diversion)

BPH

CH/MS

Refer to Benign prostatic hyperplasia

Brachytherapy (radioactive implants; also called internal radiation therapy) **MS**

risk for Injury [to others] possibly evidenced by risk factors of [radiation emitted by client (depending on type of procedure)].

risk for impaired physical Mobility possibly evidenced by prescribed restrictions [48 hours for low-dose implants], reluctance to move [fear of dislodging implants], decreased strength or endurance, depressed mood.

Bradycardia **CH**

Refer to Dysrhythmia, cardiac

Brain attack **MS**

Refer to Cerebrovascular accident

Brain tumor **MS**

Also refer to Cancer

acute Pain may be related to physical injury agent [pressure on brain tissues], possibly evidenced by verbal/coded reports, facial mask, narrowed focus, and autonomic responses [changes in vital signs].

impaired Memory may be related to (neurological impairment, brain injury), possibly evidenced by persistent forgetfulness, persistent inability to recall events/factual information.

[disturbed Sensory Perception (specify)] may be related to altered sensory reception/integration, possibly evidenced by changes in sensory acuity, change in behavior pattern, poor concentration/problem-solving abilities, disorientation.

risk for deficient Fluid Volume, possibly evidenced by insufficient fluid intake, (active fluid volume loss [recurrent vomiting]).

Self-Care deficit [specify] may be related to pain, weakness, (neuromuscular impairment, alteration in cognitive functioning), possibly evidenced by inability to perform necessary steps for activities of daily living.

Breast cancer **MS/CH**

Also refer to Cancer

Anxiety [specify level] may be related to change in status, threat of death, stressors, interpersonal transmission, possibly evidenced by expressed concerns, apprehensiveness, uncertainty, self-focused, diminished productivity.

deficient Knowledge regarding diagnosis, prognosis, and treatment options may be related to lack of

exposure or unfamiliarity with information resources, information misinterpretation, cognitive limitation, anxiety, possibly evidenced by verbalizations, statements of misconceptions, inappropriate behaviors.

risk for disturbed Body Image possibly evidenced by surgical or other treatment/procedure, alteration in self-perception or role perception.

risk for Sexual dysfunction possibly evidenced by health-related changes, medical treatments, perceived sexual limitation; change in sexual role, activity, or satisfaction; concern about relationship with SO.

Bronchitis **CH**

ineffective Airway Clearance may be related to excessive, thickened mucous secretions, possibly evidenced by presence of rhonchi, tachypnea, and ineffective cough.

Activity Intolerance [specify level] may be related to imbalance between oxygen supply/demand, physical deconditioning, possibly evidenced by fatigue, exertional dyspnea, generalized weakness, and abnormal vital sign response to activity.

Bronchogenic carcinoma **MS/CH**

Also refer to Cancer

impaired Gas Exchange may be related to (ventilation-perfusion imbalance), possibly evidenced by abnormal breathing pattern, [diminished or adventitious breath sounds, decreased chest expansion], abnormal arterial blood gases.

risk for ineffective Airway Clearance possibly evidenced by retained secretions, inflammatory exudate, bronchial narrowing, pain, smoking or second-hand smoke, infection.

risk for Infection [spread] possibly evidenced by stasis of body fluids, malnutrition and (chronic illness), decrease in ciliary action, immunosuppression.

Bronchopneumonia **MS/CH**

Also refer to Bronchitis

ineffective Airway Clearance may be related to tracheal bronchial inflammation, edema formation, increased sputum production, pleuritic pain, decreased energy, fatigue, possibly evidenced by changes in rate and depth of respirations, abnormal breath sounds, use of accessory muscles, dyspnea, cyanosis, cough with or without sputum production.

impaired Gas Exchange may be related to (alveolar-capillary membrane changes, ventilation-perfusion imbalance), possibly evidenced by restlessness,

confusion, abnormal breathing pattern (dyspnea), and skin color, (pallor, cyanosis), and arterial blood gas or hypoxia.

risk for Infection [spread] possibly evidenced by stasis of body fluids, malnutrition and associated condition of chronic illness, decrease in ciliary action, immunosuppression.

Brown-Sequard syndrome

MS/CH

Also refer to Paraplegia; Quadriplegia

impaired physical Mobility may be related to (neuromuscular and sensoriperceptual impairment), possibly evidenced by limited motion, weakness, or paralysis (hemiparaplegia).

[disturbed kinesthetic/tactile Sensory Perception] may be related to altered sensory transmission [e.g., neurological trauma, ischemia, inflammation, infection], possibly evidenced by reported change in sensory acuity—loss of touch, vibration, and position on one side of the body, loss of pain and temperature sensation on opposite side of body (hemianesthesia).

Buck's traction

MS

Refer to Traction

Buerger's disease

CH

Refer to Peripheral vascular disease

Bulimia nervosa

PSY/MS

Also refer to Anorexia nervosa

impaired Dentition may be related to inadequate dietary habits/malnutrition; barrier to self-care, inadequate oral hygiene; and associated condition of chronic vomiting, possibly evidenced by erosion of tooth enamel, multiple caries, abraded teeth.

impaired oral Mucous Membrane Integrity may be related to malnutrition or vitamin deficiency, poor oral hygiene, chronic vomiting, possibly evidenced by sore, inflamed buccal mucosa; swollen salivary glands; ulcerations of mucosa; reports of constant sore mouth or throat.

risk for deficient Fluid Volume possibly evidenced by (fluid loss through abnormal route [consistent self-induced vomiting], pharmaceutical agent [laxative or diuretic use], active fluid volume loss [esophageal erosion or tear]).

deficient Knowledge regarding condition, prognosis, complications, and treatment may be related to lack of exposure or recall, unfamiliarity with information about condition, learned maladaptive coping

skills, possibly evidenced by verbalization of misconception of relationship of current situation and bingeing and purging behaviors, distortion of body image, verbalization of the problem.

Bunion

CH

impaired Walking may be related to inflammation and degeneration of joint, inappropriate footwear, possibly evidenced by inability to walk required distances.

Bunionectomy

MS

Also refer to Surgery, general; Postoperative recovery period

impaired Walking may be related to pain, possibly evidenced by inability to walk required distances, navigate curbs, climb stairs.

Burns (dependent on type, degree, and severity of the injury)

MS/CH

risk for deficient Fluid Volume/Bleeding possibly evidenced by loss of fluids through wounds, capillary damage and evaporation, hypermetabolic state, insufficient intake, hemorrhagic losses.

risk for ineffective Airway Clearance possibly evidenced by tracheobronchial obstruction—mucosal edema and loss of ciliary action with smoke inhalation; circumferential full-thickness burns of the neck, thorax, and chest, with compression of the airway or limited chest excursion, trauma—direct upper airway injury by flame, steam, chemicals or gases; fluid shifts, pulmonary edema, decreased lung compliance.

risk for Infection possibly evidenced by alteration in skin integrity, (decreased hemoglobin, suppressed inflammatory response, invasive procedures).

acute/chronic Pain may be related to destruction of skin, tissue, and nerves; edema formation; and manipulation of injured tissues, possibly evidenced by verbal/coded reports, narrowed focus, distraction and guarding behavior, facial mask, and changes in vital signs.

risk for imbalanced Nutrition: less than body requirements possibly evidenced by (inability to ingest or digest food), [hypermetabolic state as much as 50% to 60% higher than normal proportional to the severity of injury, protein catabolism, anorexia], restricted oral intake.

Post-Trauma Syndrome may be related to life-threatening event, possibly evidenced by reexperiencing the event, repetitive dreams or nightmares, psychic or emotional numbness, and sleep disturbance.

ineffective Protection may be related to extremes of age, inadequate nutrition, anemia, impaired immune system, possibly evidenced by impaired healing, deficient immunity, fatigue, anorexia.

PED

decreased Diversional Activity Engagement may be related to (prolonged hospitalization, therapeutic isolation), impaired mobility, physical discomfort, insufficient energy, possibly evidenced by boredom, discontent with situation.

risk for delayed Development possibly evidenced by [effects of physical disability, separation from SO(s), and environmental deficiencies].

Bursitis

CH

acute/chronic Pain may be related to inflammation of affected joint, possibly evidenced by verbal/coded reports, guarding behavior, and narrowed focus.

impaired physical Mobility may be related to inflammation and swelling of joint and pain, possibly evidenced by diminished range of motion, reluctance to attempt movement, and imposed restriction of movement by medical treatment.

CABG

MS

Refer to Coronary artery bypass surgery

CAD

CH/MS

Refer to Coronary artery disease

Calculi, urinary

CH/MS

acute Pain may be related to physical injury agent [increased frequency or force of ureteral contractions, tissue trauma, edema formation, cellular ischemia], possibly evidenced by verbal/coded reports of pain; guarding and distraction behavior; self-focused; and autonomic responses.

impaired urinary Elimination may be related to multiple causality, (anatomic obstruction), possibly evidenced by urgency and frequent voiding, urinary retention, [hematuria].

risk for deficient Fluid Volume possibly evidenced by stimulation of renal-intestinal reflexes causing nausea, vomiting, and diarrhea; changes in urinary output, postobstructive diuresis.

deficient Knowledge regarding condition, prognosis, self-care, and treatment needs may be related to lack of exposure or recall and information misinterpretation, possibly evidenced by requests for information, statements of concern, and recurrence or development of preventable complications.

Cancer

MS

Also refer to Chemotherapy; Radiation therapy
Fear/Death Anxiety may be related to learned response to threat, uncertainty of prognosis, possibly evidenced by apprehensiveness, feeling of fear/dread, anorexia, increase in tension, fear of pain/suffering related to dying, increase in blood pressure.

Grieving may be related to psychological distress with potential loss of physiological well-being, change in lifestyle, perceived potential death, possibly evidenced by anger, sadness, withdrawal, choked feelings, changes in eating or sleep patterns, activity level, libido, and communication patterns.

acute/chronic Pain may be related to the disease process [compression of nerve tissue, infiltration of nerves or their vascular supply, obstruction of a nerve pathway, inflammation], or side effects of therapeutic agents, possibly evidenced by verbal/coded reports, self-focused or narrowed focus, alteration in muscle tone, facial expression of pain, distraction or guarding behavior, autonomic responses, and restlessness.

Fatigue may be related to decreased metabolic energy production, increased energy requirements—hypermetabolic state; overwhelming psychological or emotional demands, and altered body chemistry—side effects of medications, chemotherapy, radiation therapy, biotherapy, possibly evidenced by unremitting or overwhelming lack of energy, inability to maintain usual routines, decreased performance, impaired ability to concentrate, lethargy, listlessness, and disinterest in surroundings.

impaired Home Maintenance may be related to debilitation, lack of resources, or inadequate support systems, possibly evidenced by verbalization of problem, request for assistance, and lack of necessary equipment or aids.

PED

risk for interrupted Family Processes possibly evidenced by (situational or transitional crises—long-term illness, change in roles or economic status; developmental—anticipated loss of a family member).

readiness for enhanced family Coping possibly evidenced by expresses desire to acknowledge growth impact of crisis.

Candidiasis

CH

Also refer to Thrush

impaired Skin/Tissue Integrity may be related to [infectious lesions], possibly evidenced by alteration in

skin and mucous membrane integrity [rashes, patchy lesions, blisters, pustules].

acute Pain/impaired Comfort may be related to exposure of irritated skin and mucous membranes to excretions (urine, feces), possibly evidenced by verbal or coded reports, restlessness, guarding behaviors.

risk for Sexual dysfunction possibly evidenced by alteration in body function [e.g., presence of infectious process, vaginal discomfort].

Cannabis abuse

CH

Refer to Depressant abuse

Carbon monoxide poisoning

MS

impaired Gas Exchange may be related to [altered oxygen-carrying capacity of blood], possibly evidenced by headache, confusion, somnolence, [elevated carbon monoxide levels].

Activity Intolerance may be related to imbalance between oxygen supply and demand, possibly evidenced by fatigue, exertional dyspnea.

risk for Trauma/Suffocation possibly evidenced by insufficient knowledge of safety precautions.

Cardiac catheterization

MS

Anxiety [specify] may be related to threat to change in status, stressors, possibly evidenced by expressed concerns, apprehensiveness, uncertainty, self-focused.

risk for decreased Cardiac Output possibly evidenced by altered heart rate or rhythm [vasovagal response, ventricular dysrhythmias], decreased myocardial contractility [ischemia].

risk for decreased cardiac Tissue Perfusion (specify) may be related to coronary artery spasm, hypovolemia, hypoxia [thrombosis, emboli].

risk for Adverse Reaction to Iodinated Contrast Media possibly evidenced by heart disease, concurrent use of pharmaceutical agents [e.g., beta blockers, metformin], history of allergies.

Cardiac conditions, prenatal

OB

Also refer to Pregnancy, high-risk

risk for Cardiac Output [decompensation] possibly evidenced by increased circulating volume, dysrhythmias, altered myocardial contractility, inotropic changes in the heart.

risk for excess Fluid Volume possibly evidenced by increasing circulating volume, changes in renal function, dietary indiscretion.

risk for ineffective [uteroplacental] Tissue Perfusion possibly evidenced by changes in circulating volume, right-to-left shunt.

risk for Activity Intolerance possibly evidenced by (circulatory problem), physical deconditioning, previous episodes of intolerance.

Cardiac inflammatory disease

MS

Refer to Endocarditis; Myocarditis; Pericarditis

Cardiac surgery

MS/PED

risk for decreased Cardiac Output possibly evidenced by altered myocardial contractility [ventricular wall surgery, recent myocardial infarction, response to certain medications or drug interactions]; altered preload—hypovolemia, and afterload—systemic vascular resistance; altered heart rate or rhythm—dysrhythmias.

risk for Bleeding/deficient Fluid Volume possibly evidenced by [intraoperative bleeding with inadequate blood replacement; bleeding related to insufficient heparin reversal, fibrinolysis, or platelet destruction]; or volume depletion [effects of intraoperative or postoperative diuretic therapy].

risk for impaired Gas Exchange possibly evidenced by (alveolar-capillary membrane changes [atelectasis, interstitial edema]), abnormal breathing pattern [inadequate function or premature discontinuation of chest tubes], [anemia], hypoxemia.

acute Pain/impaired Comfort may be related to [tissue inflammation or trauma, edema formation, intraoperative nerve trauma, and myocardial ischemia], possibly evidenced by reports of incisional discomfort or pain in chest and donor site; paresthesia or pain in hand, arm, shoulder, anxiety, restlessness, irritability; distraction behaviors, and changes in heart rate and blood pressure.

impaired Skin/Tissue Integrity may be related to [mechanical trauma (surgical incisions, puncture wounds) and edema] possibly evidenced by acute pain, alteration in skin/tissue integrity, hematoma.

Cardiogenic shock

MS

Refer to Shock, cardiogenic

Cardiomyopathy

CH/MS

decreased Cardiac Output may be related to altered contractility, possibly evidenced by dyspnea, fatigue, chest pain, dizziness, syncope.

Activity Intolerance may be related to imbalance between oxygen supply and demand, possibly evidenced by generalized weakness, fatigue, exertional dyspnea, abnormal heart rate or blood pressure response to activity, electrocardiogram changes.

ineffective Role Performance may be related to changes in physical health, stress, demands of job and

life, possibly evidenced by change in usual patterns of responsibility, role strain, change in capacity to resume role.

Carotid endarterectomy

MS

Also refer to Surgery, general

risk for ineffective cerebral Tissue Perfusion possibly evidenced by (carotid stenosis, embolism, treatment regimen [thrombolytic therapy]).

Carpal tunnel syndrome

CH/MS

acute/chronic Pain may be related to pressure on median nerve, possibly evidenced by verbal/coded reports, reluctance to use affected extremity, guarding behavior, expressed fear of reinjury, altered ability to continue previous activities.

impaired physical Mobility may be related to (neuromuscular impairment) and pain, possibly evidenced by decreased hand strength, weakness, limited range of motion, and reluctance to attempt movement.

risk for peripheral Neurovascular Dysfunction possibly evidenced by (mechanical compression [e.g., brace, repetitive tasks or motions], immobilization).

deficient Knowledge regarding condition, prognosis, and treatment and safety needs may be related to lack of exposure or recall, information misinterpretation, possibly evidenced by questions, statements of concern, request for information, inaccurate follow-through of instructions, development of preventable complications.

Casts

CH/MS

Also refer to Fractures

risk for peripheral Neurovascular Dysfunction possibly evidenced by (fracture, mechanical compression [cast], tissue trauma, immobilization, vascular obstruction).

risk for impaired Skin Integrity possibly evidenced by [pressure of cast], humidity, [debris under cast, objects inserted under cast to relieve itching], (altered sensation or circulation, vascular trauma).

Self-Care deficit [specify] may be related to impaired ability to perform self-care tasks, possibly evidenced by statements of need for assistance and difficulty in performing activities of daily living.

Cataract

CH

[disturbed visual Sensory Perception] may be related to altered sensory reception or status of sense organs, possibly evidenced by diminished acuity, visual distortions, and change in usual response to stimuli.

risk for physical Trauma possibly evidenced by insufficient knowledge of safety precautions, insufficient vision.

Anxiety [specify level]/Fear may be related to alteration in visual acuity, threat of loss of vision and independence, possibly evidenced by expressed concerns, apprehension, and feelings of uncertainty.

deficient Knowledge regarding ways of coping with altered abilities, therapy choices, and lifestyle changes may be related to lack of exposure or recall, misinterpretation, or cognitive limitations, possibly evidenced by requests for information, statement of concern, inaccurate follow-through of instructions, development of preventable complications.

Cataract extraction (postoperative care)

MS

risk for Injury possibly evidenced by [increased intraocular pressure, intraocular hemorrhage, vitreous loss].

risk for Infection possibly evidenced by alteration in skin/tissue integrity, invasive procedure.

[disturbed visual Sensory Perception] may be related to altered sensory reception (use of eyedrops, cataract glasses), therapeutically restricted environment (surgical procedure, patching), possibly evidenced by visual distortions or blurring, visual confusion, change in depth perception.

Cat scratch disease

CH

acute Pain may be related to physical injury agent: effects of circulating toxins [fever, headache, and lymphadenitis], possibly evidenced by verbal/coded reports, guarding behavior, and autonomic response (changes in vital signs).

Hyperthermia may be related to inflammatory process, possibly evidenced by increased body temperature, flushed warm skin, tachypnea, and tachycardia.

Celiac disease

CH

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to absorb nutrients, mucosal damage, loss of villi, proliferation of crypt cells, shortened transit time through gastrointestinal tract, possibly evidenced by weight loss, [abdominal distention, steatorrhea, anemia, vitamin deficiencies]).

Diarrhea may be related to irritation, malabsorption, possibly evidenced by abdominal pain, hyperactive bowel sounds, at least three loose stools per day.

risk for deficient Fluid Volume possibly evidenced by mild to massive steatorrhea, diarrhea.

Cellulitis

CH/MS

risk for Infection [abscess, bacteremia] possibly evidenced by alteration in skin integrity, (chronic illness), insufficient knowledge to avoid exposure to pathogens.

acute Pain/impaired Comfort may be related to physical injury agent (inflammatory process, circulating toxins), possibly evidenced by verbal/coded reports of pain, headache, guarding behavior, restlessness, autonomic responses.

impaired Tissue Integrity may be related to [trauma, inflammation, or invasion of tissues by infectious bacterial agent], or (impaired circulation), possibly evidenced by redness, localized area hot to touch, tenderness, or pain.

Cerebral embolism

MS/CH

Refer to Cerebrovascular accident

Cerebral palsy

PED/CH

Refer to Palsy, cerebral

Cerebrovascular accident

MS

ineffective cerebral Tissue Perfusion may be related to (embolism, cerebral aneurysm, brain injury[edema]), possibly evidenced by altered level of consciousness, changes in vital signs, changes in motor or sensory responses, restlessness, memory loss; sensory, language, intellectual, and emotional deficits.

impaired physical Mobility may be related to (neuromuscular impairment, sensory-perceptual impairment, alteration in cognitive functioning), possibly evidenced by decrease in fine/gross motor skills, decrease in range of motion; uncoordinated movement.

impaired verbal [and/or written] Communication may be related to (central nervous system impairment, physical barrier [loss of facial or oral muscle tone and control; generalized weakness]), possibly evidenced by difficulty forming words, difficulty speaking (dysarthria); inappropriate verbalization, difficulty comprehending written/spoken language; [inability to produce written communication].

Self-Care deficit [specify] may be related to (neuromuscular impairment, perceptual disorders, alteration in cognitive functioning), weakness, impaired mobility/ability to transfer, pain, possibly evidenced by inability to perform activities of daily living.

risk for impaired Swallowing possibly evidenced by (neuromuscular impairment).

risk for Unilateral Neglect possibly evidenced by visual field impairment.

CH

situational low Self-Esteem/disturbed Body Image may be related to functional impairment, loss, focus on past function/strength, and (cognitive or perceptual impairment), possibly evidenced by actual change in function, self-negating verbalizations, report of perceptions reflecting altered view of body function.

Grieving may be related to alteration in neuro-endocrine functioning, loss of processes of body, [neuromuscular impairments], and psychological distress, loss of job, role function, status, or independence, possibly evidenced by despair, anger, disorganization.

impaired Home Maintenance may be related to condition of individual family member, insufficient finances, family organization or planning; unfamiliarity with resources, and inadequate support systems, possibly evidenced by members expressing difficulty in managing home in a comfortable manner, requesting assistance with home maintenance, disorderly surroundings, and overtaxed family members.

Cervix, dysfunctional

OB

Refer to Dilation of Cervix, premature

Cesarean birth

OB

Also refer to Cesarean birth, unplanned/postpartal
deficient Knowledge regarding surgical procedure, expectation, postoperative routines and therapy, and self-care needs may be related to insufficient information, insufficient knowledge of resources, misinformation presented by others, possibly evidenced by insufficient knowledge, inappropriate behavior.

risk for deficient Fluid Volume/Bleeding possibly evidenced by restriction of oral intake, blood loss.

risk for impaired Attachment possibly evidenced by parent-child separation, insufficient privacy, (premature infant).

Cesarean birth, postpartal

OB

Also refer to Postpartum periods

risk for impaired Attachment possibly evidenced by anxiety, parent-child separation, [situational crisis (e.g., surgical intervention)].

acute Pain/impaired Comfort may be related to physical agent [e.g., surgical trauma, bladder or abdominal distention], chemical agent [e.g., effects of anesthesia], biological agent [hormonal effects], possibly evidenced by verbal/coded reports of pain, guarding or distraction behavior, irritability, facial expression of pain.

risk for situational low Self-Esteem possibly evidenced by, unrealistic self-expectations; physical condition; decrease in control over current situation.

risk for Injury possibly evidenced by (biochemical dysfunction [e.g., orthostatic hypotension, development of preeclampsia or eclampsia]), tissue hypoxia [e.g., effects of anesthesia, thromboembolism], abnormal blood profile [anemia, excessive blood loss, rubella sensitivity, Rh incompatibility], tissue trauma.

risk for Infection possibly evidenced by [tissue trauma], malnutrition, and associated conditions of decreased hemoglobin, invasive procedures or [increased environmental exposure, prolonged rupture of amniotic membranes], malnutrition.

Self-Care deficit (specify) may be related to effects of anesthesia, decreased strength and endurance, physical discomfort, possibly evidenced by inability to perform desired activities of daily living.

Cesarean birth, unplanned

OB

Also refer to Cesarean birth, postpartal
deficient Knowledge regarding underlying procedure, pathophysiology, and self-care needs may be related to incomplete or inadequate information, possibly evidenced by request for information, verbalization of concerns or misconceptions, and inappropriate or exaggerated behavior.

Anxiety [specify level] may be related to threat to current status—mother/fetus, emotional threat to self-esteem, unmet needs, interpersonal transmission, possibly evidenced by sympathetic stimulation, increase in tension, apprehensiveness, expressions of inadequacy, and restlessness.

Powerlessness may be related to anxiety, insufficient knowledge to manage a situation, insufficient interpersonal interactions, possibly evidenced by verbalization of sufficient sense of control, inadequate participation in care [or decision making].

risk for disturbed Maternal-Fetal Dyad possibly evidenced by (compromised fetal oxygen transport, pregnancy complication).

risk for labor Pain possibly evidenced by risk factors of increased or prolonged contractions, psychological reaction.

risk for Infection possibly evidenced by [tissue trauma], malnutrition, (decreased hemoglobin, invasive procedures or prolonged rupture of amniotic membranes), malnutrition.

Chemical dependence

PSY/CH

Refer to specific agents; Substance dependence/abuse rehabilitation

Chemotherapy

MS/CH

Also refer to Cancer

risk for deficient Fluid Volume possibly evidenced by gastrointestinal losses (vomiting), interference with adequate intake (stomatitis, anorexia), losses through abnormal routes (indwelling tubes, wounds, fistulas), hypermetabolic state.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to ingest food), [hypermetabolic state], possibly evidenced by weight loss (wasting), food aversion, alteration in taste sensation, sore buccal cavity; diarrhea or constipation.

impaired oral Mucous Membrane Integrity may be related to side effects of therapeutic agents or radiation, dehydration, and malnutrition, possibly evidenced by ulcerations, leukoplakia, decreased salivation, and reports of pain.

disturbed Body Image may be related to alteration in self-perception, cultural or spiritual incongruence possibly evidenced by verbalizations of feelings or perceptions, fear of reaction by others, preoccupation with change (e.g., anatomical or structural changes; loss of hair and weight), negative feelings about body, feelings of helplessness, hopelessness, and change in social environment.

ineffective Protection may be related to inadequate nutrition, drug therapy, radiation, abnormal blood profile, disease state (cancer), possibly evidenced by impaired healing, deficient immunity, anorexia, fatigue.

readiness for enhanced Hope possibly evidenced by expressed desire to enhance belief in possibilities or sense of meaning to life.

Chickenpox

CH/PED

Refer to Measles

Chlamydia trachomatis infection

CH

Refer to Sexually transmitted infection

Cholecystectomy

MS

acute Pain may be related to physical injury agent (interruption in skin and tissue layers with mechanical closure [sutures, staples] and invasive procedures including T-tube/nasogastric tube), possibly evidenced

by verbal reports, guarding or distraction behaviors, and autonomic responses—changes in vital signs.

ineffective Breathing Pattern may be related to pain, muscular impairment, decreased energy, fatigue, ineffective cough, possibly evidenced by fremitus, tachypnea, decreased respiratory depth and vital capacity, holding breath, reluctance to cough.

risk for deficient Fluid Volume/Bleeding possibly evidenced by losses from vomiting or nasogastric aspiration, medically restricted intake, altered coagulation.

Cholelithiasis

CH

acute Pain may be related to [obstruction or ductal spasm, inflammatory process, tissue ischemia, necrosis] possibly evidenced by verbal reports, guarding or distraction behavior, narrowed focus, and changes in vital signs.

risk for imbalanced Nutrition: less than body requirements possibly evidenced by [self-imposed or prescribed dietary restrictions, nausea and vomiting], food aversion, indigestion, abdominal pain.

deficient Knowledge regarding pathophysiology, therapy choices, and self-care needs may be related to lack of information or recall, misinterpretation, possibly evidenced by verbalization of concerns, questions, and recurrence of condition.

Cholera

CH/MS

deficient Fluid Volume may be related to active volume loss—profuse watery diarrhea, vomiting, possibly evidenced by intense thirst, marked loss of tissue turgor, decreased urine output (oliguria, anuria), change in mental state, hemoconcentration.

risk for Shock possibly evidenced by hypotension, hypovolemia, sepsis.

Christmas disease

CH

Refer to Hemophilia

Chronic obstructive lung disease

CH/MS

ineffective Airway Clearance may be related to bronchospasm, increased production of tenacious secretions, retained secretions, and decreased energy, fatigue, possibly evidenced by presence of wheezes, crackles, tachypnea, dyspnea, changes in depth of respirations, use of accessory muscles, persistent cough, and chest radiograph findings.

impaired Gas Exchange may be related to (alveolar-capillary membrane changes, altered oxygen delivery—[retained secretions/bronchospasm, air

trapping] and alveoli destruction), possibly evidenced by abnormal breathing pattern, restlessness, confusion, hypoxia, hypercapnia.

Activity Intolerance may be related to imbalance between oxygen supply and demand, and physical deconditioning, possibly evidenced by generalized weakness, fatigue, exertional dyspnea, and abnormal vital sign response.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to ingest food/adequate nutrients), possibly evidenced by weight loss, alteration in taste sensation, food aversion/insufficient interest in food, [decreased muscle mass and subcutaneous fat, poor muscle tone].

risk for Infection possibly evidenced by stasis of body fluid and malnutrition, (chronic illness), and decreased ciliary action.

Circumcision

PED

deficient Knowledge regarding surgical procedure, prognosis, and treatment may be related to lack of exposure, misinterpretation, unfamiliarity with information resources, possibly evidenced by request for information, verbalization of concern or misconceptions, inaccurate follow-through of instructions.

acute Pain may be related to physical injury agent (trauma to and edema of tender tissues), possibly evidenced by crying, changes in sleep pattern, refusal to eat.

impaired urinary Elimination may be related to tissue injury, inflammation, development of urethral fistula, possibly evidenced by edema, difficulty voiding.

risk for Bleeding possibly evidenced by insufficient knowledge of bleeding precautions [related to circumcision, decreased clotting factors immediately after birth, previously undiagnosed problems with bleeding or clotting].

risk for Infection possibly evidenced by [immature immune system], (invasive procedure/tissue trauma).

Cirrhosis

MS

Also refer to Substance dependence/abuse rehabilitation; Hepatitis, acute viral

risk for impaired Liver Function possibly evidenced by (viral infection), substance misuse.

CH

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake,

(inability to ingest food or absorb nutrients), possibly evidenced by food aversion, food intake less than recommended daily allowance, satiety immediately upon ingesting food, [muscle wasting, weight loss, and imbalances in nutritional studies].

excess Fluid Volume may be related to compromised regulatory mechanism [syndrome of inappropriate antidiuretic hormone, decreased plasma proteins, malnutrition] and excess sodium or fluid intake, possibly evidenced by generalized or abdominal edema, weight gain, dyspnea, blood pressure changes, positive hepatojugular reflex, change in mentation, altered electrolytes, changes in urine specific gravity, and pleural effusion.

risk for impaired Skin Integrity possibly evidenced by impaired circulation, alteration in metabolism, alteration in skin turgor, pressure over bony prominence, and [presence of edema, ascites, accumulation of bile salts in skin].

risk for Bleeding possibly evidenced by impaired liver function. inherent coagulopathy, [portal hypertension, development of esophageal varices].

risk for acute Confusion possibly evidenced by substance misuse, malnutrition, impaired metabolic functioning.

Self-Esteem (specify)/disturbed Body Image may be related to alteration in self-perception, cultural or spiritual incongruence possibly evidenced by verbalizations of feelings or perceptions (e.g., fear of rejection or reaction by others), preoccupation with biophysical changes, altered physical appearance, uncertainty of prognosis, changes in role function, personal vulnerability, self-destructive behavior, changes in lifestyle.

Cleft lip/palate

PED/MS

Also refer to Newborn, special needs

ineffective infant Feeding Pattern may be related to anatomic abnormality, possibly evidenced by inability to sustain an effective suck, inability to coordinate sucking, swallowing, and breathing.

risk for Aspiration possibly evidenced by (impaired ability to swallow).

risk for impaired verbal Communication possibly evidenced by (oropharyngeal defect), difficulty forming words.

risk for disturbed Body Image/Social Isolation possibly evidenced by altered appearance, anatomic deficit, significance of body part (face).

Cocaine hydrochloride poisoning, acute MS

Also refer to Stimulant abuse; Substance dependence/abuse rehabilitation

ineffective Breathing Pattern may be related to pharmacological effects on respiratory center of the brain, possibly evidenced by tachypnea, altered depth of respiration, shortness of breath, and abnormal arterial blood gases.

risk for decreased Cardiac Output possibly evidenced by drug effect on myocardium (degree dependent on drug purity/quality used); alterations in electrical rate, rhythm, or conduction; preexisting myocardial pathology.

CH

risk for impaired Liver Function possibly evidenced by cocaine abuse, effect of drug on liver.

Coccidioidomycosis (San Joaquin Valley/Valley Fever)

CH

acute Pain may be related to physical injury agent (inflammation), possibly evidenced by verbal/coded reports of pain, distraction behavior, and narrowed focus.

Fatigue may be related to (illness), stressors, possibly evidenced by insufficient energy, impaired ability to maintain usual routines, lethargy, alteration in concentration, alteration in libido.

deficient Knowledge regarding nature and course of disease, therapy, and self-care needs may be related to lack of information, possibly evidenced by statements of concern and questions.

Colectomy

MS

Refer to Intestinal surgery (without diversion)

Colitis, ulcerative

MS

Diarrhea may be related to inflammation or malabsorption of the bowel, presence of toxins or segmental narrowing of the lumen, possibly evidenced by increased bowel sounds and peristalsis; frequent, watery stools (acute phase); abdominal pain; urgency; cramping.

acute/chronic Pain may be related to physical agent—inflammation of the intestines, hyperperistalsis, prolonged diarrhea, and anal or rectal irritation, fissures, fistulas, possibly evidenced by verbal/coded reports of pain, guarding or distraction behavior, restlessness, self-focused.

risk for deficient Fluid Volume possibly evidenced by continued gastrointestinal losses—severe diarrhea, vomiting; capillary plasma loss, restricted intake—nausea, anorexia, hypermetabolic state (inflammation, fever).

CH

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake,

(inability to ingest food or absorb nutrients), and [hypermetabolic state], possibly evidenced by [weight loss, decreased subcutaneous fat or muscle mass], insufficient muscle tone, hyperactive bowel sounds, pale mucous membranes, and food aversion.

ineffective Coping may be related to [chronic nature and indefinite outcome of disease, multiple stressors (repeated over time), personal vulnerability, severe pain, inadequate sleep], lack of or ineffective support systems, possibly evidenced by verbalization of inability to cope with the situation, frequent illness, insufficient coping strategies, [depression and recurrent exacerbation of symptoms].

risk for Powerlessness possibly evidenced by (progressive illness, unpredictably of illness trajectory, complex treatment regimen).

Collagen disorders

CH

Refer to Arthritis, rheumatoid/juvenile rheumatoid; Lupus erythematosus, systemic; Polyarteritis nodosa; Temporal arteritis

Colorectal cancer

MS

Refer to Cancer; Colostomy

Colostomy

MS

risk for impaired Skin Integrity possibly evidenced by risk factors of chemical injury agent (absence of sphincter at stoma, character and flow of effluent and flatus from stoma, reaction to product or removal of adhesive, and improperly fitting appliance).

risk for Diarrhea/Constipation possibly evidenced by interruption or alteration of normal bowel function (placement of ostomy), changes in dietary or fluid intake, and effects of medication.

CH

deficient Knowledge regarding changes in physiological function and self-care/treatment needs may be related to lack of exposure or recall, information misinterpretation, possibly evidenced by questions, statement of concern, inaccurate follow-through of instruction or performance of ostomy care, development of preventable complications.

disturbed Body Image may be related to alteration in self-perception possibly evidenced by verbalizations of feelings or perceptions, preoccupation with biophysical changes (presence of stoma, loss of control of bowel elimination) and psychosocial factors negative feelings about body, fear of rejection or reaction of others, not touching or looking at stoma, and refusal to participate in care.

impaired Social Interaction may be related to fear of embarrassing situation secondary to altered bowel control with loss of contents, odor, possibly evidenced by reduced participation and verbalized or observed discomfort in social situations.

risk for Sexual dysfunction possibly evidenced by (alteration in body structure and function), vulnerability, [concern about response of SO, and disruption of sexual response pattern (e.g., erection difficulty)].

Coma

MS

risk for Suffocation possibly evidenced by cognitive impairment, loss of protective reflexes and purposeful movement.

risk for deficient Fluid Volume/imbalanced Nutrition: less than body requirements possibly evidenced by inability to ingest food or fluids, increased needs—hypermetabolic state.

[total] Self-Care deficit may be related to cognitive impairment and absence of purposeful activity, evidenced by inability to perform activities of daily living.

risk for ineffective cerebral Tissue Perfusion possibly evidenced by brain injury, substance abuse, embolism, cerebral aneurysm, brain tumor/neoplasm.

risk for Infection possibly evidenced by stasis of body fluids (oral, pulmonary, urinary), malnutrition, and associated condition of invasive procedures.

Coma, diabetic

MS

Refer to Diabetic ketoacidosis

Compartment syndrome, abdominal

MS

acute Pain may be related to physical agent [increasing abdominal distention and edema formation, inflammation], possibly evidenced by reports of pain, guarding behavior, restlessness, narrowed focus.

risk for dysfunctional Gastrointestinal Motility possibly evidenced by (decrease in gastrointestinal circulation).

ineffective Breathing Pattern may be related to abdominal distention, pain possibly evidenced by dyspnea, tachypnea, altered chest excursion.

risk for Shock possibly evidenced by hypotension, hypovolemia.

Compartment syndrome, extremity

MS

acute Pain may be related to physical injury agent (increasing pressure within muscle) possibly evidenced by reports of progressing pain [distal to injury unrelieved by routine analgesics].

ineffective peripheral Tissue Perfusion may be related to interruption of arterial blood flow, elevated tissue pressures, possibly evidenced by absent or diminished distal pulses, erythema, pain.

risk for peripheral Neurovascular Dysfunction possibly evidenced by reduction or interruption of blood flow (direct vascular injury, tissue trauma, excessive edema, elevated tissue pressures, hypovolemia).

Complex regional pain syndrome **CH**

acute/chronic Pain may be related to physical agent (continued nerve stimulation), possibly evidenced by verbal reports, distraction or guarding behavior, narrowed focus, changes in sleep pattern, and altered ability to continue previous activities.

ineffective peripheral Tissue Perfusion may be related to reduction of arterial blood flow (arteriole vasoconstriction), possibly evidenced by extremity pain, altered skin characteristics, diminished pulses, and edema.

[disturbed tactile Sensory Perception] may be related to altered sensory reception (neurological deficit, pain), possibly evidenced by change in usual response to stimuli—abnormal sensitivity of touch, physiological anxiety, and irritability.

risk for ineffective Role Performance possibly evidenced by risk factors of situational crisis, chronic disability, debilitating pain.

risk for compromised family Coping possibly evidenced by family disorganization, (family role change, and prolonged disability that exhausts capacity of support person).

Concussion, brain **CH**

Also refer to Postconcussion syndrome

acute Pain may be related to trauma to/edema of cerebral tissue, possibly evidenced by reports of headache, guarding or distraction behaviors, and narrowed focus.

risk for deficient Fluid Volume possibly evidenced by vomiting, decreased intake, and hypermetabolic state (fever).

risk for impaired Memory possibly evidenced by (brain injury, neurological impairment).

deficient Knowledge regarding condition, treatment, safety needs, and potential complications may be related to lack of recall, misinterpretation, cognitive limitation, possibly evidenced by questions, statement of concerns, development of preventable complications.

Conduct disorder (childhood, adolescence) **PSY/PED**

risk for self-/other-directed Violence: possibly evidenced by conflict in interpersonal relationships, pattern of indirect violence, impulsivity, suicide behavior, (pattern of difficulties in family background, mental health issues, psychological disorder).

defensive Coping may be related to inadequate coping strategies, maturational crisis, multiple life changes/losses, lack of control of impulsive actions, and personal vulnerability, possibly evidenced by inappropriate use of defense mechanisms; inability to meet role expectations; poor self-esteem; failure to assume responsibility for own actions; hypersensitivity to slight or criticism; and excessive smoking, drinking, or drug use.

ineffective Impulse Control may be related to chronic low self-esteem, anger, disorder of development, mood, personality possibly evidenced by acting without thinking, irritability, temper outbursts.

chronic low Self-Esteem may be related to cultural incongruence, inadequate belonging or affection, receiving insufficient approval of others, possibly evidenced by exaggerated negative feedback about self, excessive seeking of reassurance, rejection of positive feedback, underestimates ability to deal with situations.

CH
compromised/disabled family Coping may be related to excessive guilt, anger, or blaming among family members; parental inconsistencies; disagreements regarding discipline, limit setting, and approaches; and exhaustion of parental resources [prolonged coping with disruptive child], possibly evidenced by unrealistic parental expectations; rejection or overprotection of child; and exaggerated expressions of anger, disappointment, or despair regarding child's behavior or ability to improve or change.

impaired Social Interaction may be related to retarded ego development, developmental state (adolescence), lack of social skills, low self-concept, dysfunctional family system, and neurological impairment, possibly evidenced by dysfunctional interaction with others, difficulty playing quietly and maintaining attention to task or play activity, and interrupting or intruding on others.

Congestive heart failure **MS**

Refer to Heart failure, chronic

Conjunctivitis, bacterial **CH**

acute Pain/impaired Comfort may be related to inflammation, ocular irritation, edema, possibly evidenced by verbal reports, irritability, guarding behavior.

risk for Infection [spread] possibly evidenced by insufficient knowledge to avoid spread.

risk for ineffective Health Management possibly evidenced by length of therapy, perceived benefit.

Connective tissue disease **CH**

Refer to Arthritis, rheumatoid/juvenile rheumatoid; Lupus erythematosus, systemic; Polyarteritis nodosa; Temporal arteritis

Conn's syndrome **MS/CH**

Refer to Aldosteronism, primary

Constipation **CH**

Constipation may be related to weak abdominal musculature, gastrointestinal obstructive lesions, pain on defecation, medications, diagnostic procedures, pregnancy, possibly evidenced by change in character and frequency of stools, feeling of abdominal or rectal fullness or pressure, changes in bowel sounds, abdominal distention.

acute Pain may be related to physical agent (abdominal fullness or pressure, straining to defecate, and trauma to delicate tissues), possibly evidenced by verbal reports, reluctance to defecate, and distraction behavior.

deficient Knowledge regarding dietary needs, bowel function, and medication effect may be related to lack of information, misconceptions, possibly evidenced by development of problem and verbalization of concerns, questions.

Conversion disorder **PSY**

Refer to Somatoform disorders

Convulsions **CH**

Refer to Seizure disorder

COPD **CH**

Refer to Chronic obstructive lung disease

Corneal transplantation **MS**

risk for Injury possibly evidenced by intraocular hemorrhage, edema/swelling, changes in visual acuity, increased intraocular pressure, glaucoma.

risk for Infection possibly evidenced by (type of surgical procedure, and use of implants; inadequate or ineffective antibiotic prophylaxis).

[disturbed visual Sensory Perception] may be related to altered sensory reception (use of eyedrops, edema, swelling), therapeutically restricted environment (patching), possibly evidenced by visual distortions, blurring, change in acuity.

Coronary artery bypass surgery **MS**

risk for decreased Cardiac Output possibly evidenced by decreased myocardial contractility, diminished circulating volume (preload), alterations in electrical conduction, and increased systemic vascular resistance (afterload).

acute Pain may be related to physical injury agent [direct chest tissue and bone trauma, invasive tubes and lines, donor site incision, tissue inflammation, edema formation, intraoperative nerve trauma], possibly evidenced by verbal reports, changes in vital signs, distraction behaviors, restlessness, irritability.

[disturbed Sensory Perception (specify)] may be related to restricted environment (postoperative), sleep deprivation, effects of medications, continuous environmental sounds and activities, and psychological stress of procedure, possibly evidenced by disorientation, alterations in behavior, exaggerated emotional responses, and visual or auditory distortions.

CH

ineffective Role Performance may be related to situational crises (dependent role), recuperative process, uncertainty about future, possibly evidenced by delay or alteration in physical capacity to resume role, change in usual role or responsibility, change in self-/others' perception of role.

Coronary artery disease **CH**

Activity Intolerance may be related to imbalance between oxygen supply and demand, sedentary lifestyle, possibly evidenced by exertional discomfort, pain, fatigue, abnormal heart rate response, electrocardiogram changes—dysrhythmias, ischemia.

risk for decreased Cardiac Output possibly evidenced by altered heart rate or rhythm, altered contractility, increased peripheral vascular resistance.

Cor pulmonale **CH/MS**

Also refer to Heart failure, chronic; Chronic obstructive lung disease

Activity Intolerance may be related to imbalance between oxygen supply and demand, generalized weakness, [chest pain], possibly evidenced by exertional discomfort and dyspnea, fatigue.

excess Fluid Volume may be related to compromised regulatory mechanism, possibly evidenced by shortness of breath, dependent edema, jugular vein distention, positive hepatojugular reflux, abnormal breath sounds, change in mental status.

impaired Gas Exchange may be related to (ventilation perfusion imbalance [heart failure]), possibly evidenced by abnormal breathing (dyspnea) and skin color (cyanosis), restlessness, somnolence, abnormal arterial blood gas values (hypoxemia, hypercapnia, acidosis), polycythemia.

Cradle cap

CH

Refer to Dermatitis, seborrheic

Craniotomy

MS

Also refer to Surgery, general

risk for decreased intracranial Adaptive Capacity possibly evidenced by brain injuries, systemic hypotension with intracranial hypertension.

[disturbed Sensory Perception (specify)] may be related to altered sensory reception, transmission or integration (neurological deficit), possibly evidenced by disorientation to time, place, person; motor incoordination, altered communication patterns, restlessness, irritability, change in behavior pattern.

risk for Infection possibly evidenced by [traumatized tissues], alteration in skin integrity and (invasive procedures), and [altered integrity of closed system (cerebrospinal fluid leak)].

Creutzfeldt-Jakob disease

CH

impaired Memory may be related to neurological deficits, possibly evidenced by observed experiences of forgetting, inability to perform previously learned skills, inability to recall factual information or recent or past events.

Fear may be related to [diminished functional abilities, progressive deterioration, lack of treatment options], possibly evidenced by apprehension, irritability, defensiveness, suspiciousness, aggressive behavior, social isolation.

impaired Walking may be related to changes in muscle coordination and balance, visual changes, impaired judgment, myoclonic seizures, possibly evidenced by inability to walk desired distances, climb stairs, navigate uneven surfaces.

[disturbed visual Sensory Perception] may be related to altered sensory reception or integration (neurological disease), possibly evidenced by change in sensory acuity (visual field defects, diplopia, dimness,

blurring, visual agnosia), change in usual response to stimuli.

[total] Self-Care deficit may be related to cognitive decline, physical limitations, frustration over loss of independence, depression, possibly evidenced by impaired ability to perform activities of daily living, unkempt appearance, poor hygiene, apathy.

risk for caregiver Role Strain possibly evidenced by illness severity of care receiver, duration of caregiving required, care receiver exhibiting deviant or bizarre behavior; family/caregiver isolation, lack of respite or recreation, spouse is caregiver.

Crohn's disease

MS/CH

Also refer to Colitis, ulcerative

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake due to [intestinal pain after eating, decreased transit time through bowel, fear that eating may cause diarrhea], possibly evidenced by [weight loss, decreased subcutaneous fat and muscle mass], insufficient muscle tone, food aversion.

Diarrhea may be related to inflammation of small intestines, presence of toxins, irritation—particular dietary intake, malabsorption of the bowel, segmental narrowing of the lumen, possibly evidenced by hyperactive bowel sounds, increased peristalsis, cramping, and frequent loose liquid stools.

deficient Knowledge regarding condition, nutritional needs, and prevention of recurrence may be related to misinterpretation of information, lack of recall, unfamiliarity with resources, possibly evidenced by statements of concern, questions, inaccurate follow-through of instructions, and development of preventable complications or exacerbation of condition.

Croup

PED/CH

ineffective Airway Clearance may be related to presence of thick, tenacious mucus and swelling or spasms of the epiglottis, possibly evidenced by harsh, brassy cough; tachypnea; use of accessory breathing muscles; and presence of wheezes.

deficient Fluid Volume may be related to decreased ability or aversion to swallowing, presence of fever, and increased respiratory losses, possibly evidenced by dry mucous membranes; poor skin turgor; and scanty, concentrated urine.

Croup, membranous

PED/CH

Also refer to Croup

risk for Suffocation possibly evidenced by inflammation of larynx with formation of false membrane.

Anxiety [specify level]/Fear may be related to perceived threat [to self (difficulty breathing), and transmission of anxiety of adults], possibly evidenced by restlessness, facial tension, crying, and sympathetic stimulation.

C-section

Refer to Cesarean birth, unplanned

OB

Cubital tunnel syndrome

CH

acute/chronic Pain may be related to physical agent (pressure on ulnar nerve at elbow), possibly evidenced by verbal reports, reluctance to use affected extremity, guarding behaviors, expressed fear of reinjury, altered ability to continue previous activities.

impaired physical Mobility may be related to (neuromuscular impairment), and pain, possibly evidenced by decreased pinch or grasp strength, hand fatigue, and reluctance to attempt movement.

risk for peripheral Neurovascular Dysfunction possibly evidenced by mechanical compression (e.g., brace, repetitive tasks or motions), immobilization.

Cushing's syndrome

CH/MS

risk for excess Fluid Volume possibly evidenced by compromised regulatory mechanism (fluid and sodium retention).

risk for Infection possibly evidenced by (suppressed inflammatory response), [skin and capillary fragility, and negative nitrogen balance].

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (biological factors [disturbance of carbohydrate metabolism]), possibly evidenced by [decreased muscle mass and laboratory evidence of increased resistance to insulin].

Self-Care deficit [specify] may be related to muscle wasting, generalized weakness, fatigue, and demineralization of bones, possibly evidenced by statements of or observed inability to complete or perform activities of daily living.

disturbed Body Image may be related to alteration in self-perception (e.g., change in structure or appearance [effects of disease process, drug therapy], possibly evidenced by negative feelings about body, feelings of helplessness, and changes in social involvement).

Sexual dysfunction may be related to (altered body function [loss of libido, impotence, and cessation

of menses]), possibly evidenced by verbalization of undesired change in sexual function or desire [alteration in relationship with SO].

risk for physical Trauma [fractures] possibly evidenced by impaired balance and associated conditions of decrease in muscle coordination and [increased protein breakdown and demineralization of bones].

CVA

Refer to Cerebrovascular accident

MS/CH

Cyclothymic disorder

PSY

Refer to Bipolar disorder

Cystic fibrosis

CH/PED

ineffective Airway Clearance may be related to excessive production of thick mucus and decreased ciliary action, possibly evidenced by abnormal breath sounds, ineffective cough, cyanosis, and altered respiratory rate and depth.

risk for Infection possibly evidenced by stasis of body fluids (respiratory secretions), insufficient knowledge to avoid exposure to pathogens.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to digest food/absorb nutrients) possibly evidenced by [failure to gain weight, muscle wasting, and retarded physical growth].

deficient Knowledge regarding pathophysiology of condition, medical management, and available community resources may be related to insufficient information, misconceptions, possibly evidenced by statements of concern, questions; inaccurate follow-through of instructions, development of preventable complications.

compromised family Coping may be related to chronic nature of disease and disability, inadequate or incorrect information or understanding by a primary person, and possibly evidenced by SO attempting assistive or supportive behaviors with less than satisfactory results, protective behavior disproportionate to client's abilities or need for autonomy.

Cystitis

CH

acute Pain may be related to physical injury agent [inflammation and bladder spasms], possibly evidenced by verbal reports, distraction behaviors, and narrowed focus.

impaired urinary Elimination may be related to inflammation or irritation of bladder, possibly evidenced by frequency, nocturia, and dysuria.

deficient Knowledge regarding condition, treatment, and prevention of recurrence may be related to inadequate information, misconceptions, possibly evidenced by statements of concern and questions; recurrent infections.

Cytomegalic inclusion disease **CH**
Refer to Cytomegalovirus infection

Cytomegalovirus (CMV) infection **CH**
[*risk for disturbed visual Sensory Perception*] possibly evidenced by inflammation of the retina.

risk for fetal Infection possibly evidenced by risk factors of transplacental exposure, contact with blood or body fluids.

D&C **OB/GYN**
Refer to Dilation and curettage

Deep vein thrombosis **CH/MS**
Refer to Thrombophlebitis

Degenerative disc disease **CH/MS**
Refer to Herniated nucleus pulposus

Degenerative joint disease **CH**
Refer to Arthritis, rheumatoid
(Although this is a degenerative process versus the inflammatory process of rheumatoid arthritis, nursing concerns are the same.)

Dehiscence, abdominal wound **MS**
impaired Skin Integrity may be related to alteration in fluid volume (circulation), inadequate nutrition (obesity, malnutrition), and [physical stress on incision], possibly evidenced by [poor or delayed wound healing and disruption of skin surface or wound closure].

risk for Infection possibly evidenced by risk factors of alteration in skin/tissue integrity (separation of incision) and associated conditions of invasive procedure [traumatized intestines, environmental exposure].

Fear/Anxiety [severe] may be related to learned response to threat [health crisis, potential threat of death], possibly evidenced by apprehensiveness, feeling of dread, restless behaviors, and sympathetic stimulation.

deficient Knowledge regarding condition, prognosis, and treatment needs may be related to lack of information or recall and misinterpretation of

information, possibly evidenced by development of preventable complications, requests for information, and statement of concern.

Dehydration **PED/CH**

deficient Fluid Volume [specify] may be related to etiology as defined by specific situation, possibly evidenced by dry mucous membranes, poor skin turgor, decreased pulse volume and pressure, and thirst.

risk for impaired oral Mucous Membrane Integrity possibly evidenced by risk factors of dehydration and decreased salivation.

deficient Knowledge regarding fluid needs may be related to lack of information/misinterpretation, possibly evidenced by questions, statement of concern, and inadequate follow-through of instructions, development of preventable complications.

Delirium tremens **MS/PSY**

Also refer to Alcohol intoxication, acute
Anxiety [severe/panic]/Fear may be related to cessation of alcohol intake, physiological withdrawal, threat to self-concept, perceived threat of death, possibly evidenced by increased tension; apprehension; expressions of shame, self-disgust, or remorse; fear of unspecified consequences.

[*disturbed Sensory Perception (specify)*] may be related to exogenous (alcohol consumption and sudden cessation) or endogenous factors (electrolyte imbalance, elevated ammonia and blood urea nitrogen), chemical alterations, sleep deprivation, and psychological stress, possibly evidenced by disorientation, restlessness, irritability, exaggerated emotional responses, bizarre thinking, and visual and auditory distortions or hallucinations.

risk for decreased Cardiac Output possibly evidenced by direct effect of alcohol on heart muscle, altered systemic vascular resistance, presence of dysrhythmias.

risk for Falls possibly evidenced by risk factors of history of falls, (alteration in cognitive functioning, impaired balance, anemia).

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake (inability to digest food, absorb nutrients) possibly evidenced by inadequate food intake, alteration in taste sensation, food aversion, [debilitated state, decreased subcutaneous fat or muscle mass, signs of mineral or electrolyte deficiency].

Delivery, precipitous/out of hospital OB

Also refer to Labor, precipitous; Labor stages I–IV
risk for deficient Fluid Volume/Bleeding possibly evidenced by nausea/vomiting, lack of intake, excessive vascular loss (pregnancy complication [e.g., abruptio placenta], postpartum complication [e.g., lacerations]).

risk for Infection possibly evidenced by alteration in skin integrity, increased environmental exposure, (rupture of amniotic membranes).

risk for fetal Injury possibly evidenced by physical factors (e.g., rapid descent, pressure changes), (tissue hypoxia).

Delusional disorder PSY

risk for self/other-directed Violence possibly evidenced by perceived threats of danger, increased feelings of anxiety, acting out in an irrational manner.

[severe] *Anxiety* may be related to stressors, unmet needs, value conflict, threat to current status, (maturation/situational crisis), possibly evidenced by feeling of inadequacy, facial tension, poor eye contact, preoccupation, rumination, blocking of thoughts.

Powerlessness may be related to insufficient interpersonal interaction, anxiety, (complex treatment regimen), possibly evidenced by insufficient sense of control, alienation.

impaired Social Interaction may be related to disturbance in thought processes, insufficient skills to enhance mutuality, possibly evidenced by discomfort in social situations, dysfunctional interaction with others, dissatisfaction with social engagement.

Dementia, HIV CH/PSY

Also refer to Dementia, presenile/senile
acute/chronic Confusion may be related to alteration in sleep-wake cycle, dehydration, malnutrition, (infection, cerebrovascular accident, impaired metabolic functioning), possibly evidenced by misperception, alteration/progressive impairment in cognitive functioning, agitation, restlessness, alteration in behavior/personality.

[mild to severe] *Anxiety* may be related to unmet needs, threat to change in current status, threat of death, interpersonal transmission/contagion, possibly evidenced by increase in tension, apprehensiveness, distress, increase in wariness, restlessness, extraneous movement, cardiovascular excitation.

compromised family Coping/caregiver Role Strain may be related to increase in care needs/

around-the-clock responsibilities, exhaustion of support person's capacity, family disorganization, isolation/alienation, possibly evidenced by family conflict, emotional vacillation, support person withdraws from client.

Dementia, presenile/senile CH/PSY

Also refer to Alzheimer's disease

impaired Memory may be related to (mild cognitive impairment, neurological impairment), possibly evidenced by persistent forgetfulness, persistent inability to recall if a behavior was performed, persistent inability to perform a previously learned skill, persistent inability to recall factual information or events.

Fear may be related to [diminished functional abilities, public disclosure of disabilities, further mental or physical deterioration], possibly evidenced by social isolation, apprehension, irritability, defensiveness, suspiciousness, aggressive behavior.

Self-Care deficit [specify] may be related to decrease in motivation, anxiety, (alteration in cognitive functioning, fatigue, perceptual disorders), possibly evidenced by impaired ability to perform activities of daily living.

risk for Injury/physical Trauma possibly evidenced by emotional disturbance, impaired balance, weakness, malnutrition, (alteration in cognitive functioning).

risk for caregiver Role Strain possibly evidenced by (care receiver illness severity, cognitive disorder), complexity of care activities, family/caregiver isolation, insufficient respite or recreation.

Grieving may be related to anticipatory loss (e.g., decline in memory, loss of job/status, and independence; family perception of potential loss of loved one, possibly evidenced by psychological distress, anger, despair, and alteration in sleep patterns).

Dementia, vascular CH/PSY

Refer to Alzheimer's disease

Depersonalization disorder PSY

Refer to Dissociative disorders

Depressant abuse CH/PSY

Also refer to Drug overdose, acute (depressants)

ineffective Denial may be related to threat of unpleasant reality, insufficient sense of control, ineffective coping strategies, possibly evidenced by does not admit impact of condition on life, minimizes symptoms, refusal of healthcare.

ineffective Coping may be related to inaccurate threat appraisal, ineffective tension release strategies, possibly evidenced by substance misuse, insufficient goal-directed behavior, insufficient problem-solving skills, destructive behavior toward self.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake [use of substance in place of nutritional food] possibly evidenced by loss of weight, pale mucous membranes, [laboratory evidence of electrolyte imbalances, anemias].

risk for Injury possibly evidenced by exposure to toxic chemical [CNS depressant, CNS agitation], (alteration in cognitive functioning).

Depression, major

PSY

risk for Suicide possibly evidenced by marked changes in attitude/behavior, hopelessness, grieving, sudden euphoric recovery from depression.

[*moderate to severe*] *Anxiety* may be related to stressors, conflict about life goals, value conflict, unmet needs, threat to current status, interpersonal transmission/contagion, possibly evidenced by feeling of inadequacy, fear, increase in tension, hypervigilance, alteration in concentration, decrease in productivity, diminished ability to problem-solve, rumination.

Insomnia may be related to stressors, depression, physical discomfort, average daily physical activity is less than recommended for gender/age, alcohol consumption, possibly evidenced by difficulty initiating/maintaining sleep state, early awakening, nonrestorative sleep pattern, insufficient energy, alteration in concentration, increase in accidents/absenteeism.

Social Isolation/impaired Social Interaction may be related to disturbance in self-concept, disturbance in thought processes [depressed mood], communication barrier, insufficient skills to enhance mutuality, possibly evidenced by discomfort in social situations, dissatisfaction with social engagement, impaired social functioning, and dysfunctional interaction with others.

interrupted Family Processes may be related to (situational/developmental crises, change in family social status), shift in family roles, power shift among family members, shift in health status of a family member, possibly evidenced by decrease in available emotional support, change in communication pattern, changes in participation for decision making, alteration in family satisfaction.

Depression, postpartum

OB/PSY

Also refer to Depressive disorders

risk for impaired Attachment possibly evidenced by anxiety [associated with the parent role], inability to meet personal needs, perceived guilt regarding relationship with infant.

Fatigue may be related to stressors, sleep deprivation, depression as evidenced by insufficient energy, impaired inability to maintain usual routines, increase in physical symptoms.

situational low Self-Esteem may be related to (developmental transition), alteration in body image, possibly evidenced by underestimates ability to deal with situation, self-negating verbalizations, helplessness.

risk for other-directed Violence possibly evidenced by hopelessness, increased anxiety, mood swings, despondency, severe depression, (psychotic disorder).

Depressive disorders

PSY

Refer to Depression, major; Bipolar disorder; Premenstrual dysphoric disorder

de Quervain's syndrome

CH

acute/chronic Pain may be related to physical agent (inflammation of tendon sheath, swelling), possibly evidenced by verbal reports of pain, reluctance to use affected hand, guarding behavior, expressed fear of reinjury, altered ability to continue previous activities.

impaired physical Mobility may be related to (musculoskeletal impairment), swelling, pain, numbness of thumb and index finger, possibly evidenced by decreased grasp or pinch strength, weakness, limited range of motion, and reluctance to attempt movement.

Dermatitis, contact

CH

acute Pain/impaired Comfort may be related to [cutaneous inflammation and irritation] possibly evidenced by verbal reports, irritability, and scratching.

impaired Skin Integrity may be related to chemical injury agent (exposure to chemicals or environmental allergens) possibly evidenced by [inflammation, epidermal edema, development of vesicles or bullae].

risk for Infection possibly evidenced by alteration in skin/tissue and suppressed inflammatory response.

Social Isolation may be related to alterations in physical appearance, possibly evidenced by expressed feelings of rejection and decreased interaction with peers.

Dermatitis, seborrheic

CH

impaired Skin Integrity may be related to chronic inflammatory condition of the skin, possibly evidenced by disruption of skin surface with dry or moist scales, yellowish crusts, erythema, and fissures.

Developmental disorders, pervasive PED/PSY

Refer to Autism spectrum disorder; Rett's syndrome; Asperger's disorder

Diabetes, gestational

OB

Also refer to Diabetes mellitus

risk for unstable Blood Glucose Level possibly evidenced by (pregnancy), insufficient knowledge of diabetes management, inadequate blood glucose monitoring.

risk for disturbed Maternal-Fetal Dyad possibly evidenced by (alteration in glucose metabolism, compromised fetal oxygen transport; treatment regimen).

readiness for enhanced Knowledge regarding diabetic condition, prognosis, and self-care treatment needs possibly evidenced by expresses desire to enhance learning.

Diabetes insipidus

MS/CH

deficient Fluid Volume [hypertonic] may be related to failure of regulatory mechanisms and hormone imbalance (e.g., brain injury, medication, sickle cell anemia, hypothyroidism), possibly evidenced by urinary frequency, thirst, polydipsia, dilute urine, dry skin and mucous membranes, decreased skin turgor, nocturia, increased serum sodium.

risk for ineffective Health Management possibly evidenced by complexity of medication regimen, presence of side effects, economic difficulties, inadequate knowledge, perceived seriousness and benefits.

Diabetes, juvenile

PED

Also refer to Diabetes mellitus

risk-prone Health Behavior may be related to inadequate comprehension, negative attitude toward health-care, multiple stressors and life changes, possibly evidenced by failure to take action that prevents health problems, minimizes health status change, failure to achieve optimal sense of control.

risk for Injury possibly evidenced by ineffective control or swings in serum glucose level, changes in mentation, developmental age, risk-taking behaviors.

ineffective Coping may be related to (maturational crisis), inadequate level of perception of control, gender differences in coping strategies, possibly

evidenced by ineffective coping strategies, insufficient problem-solving skills, risk-taking/destructive behavior toward self [inadequate diabetic control].

compromised family Coping may be related to insufficient information or understanding by support person, (situational or developmental crises faced by support person), possibly evidenced by assistive behaviors by support person produce unsatisfactory results; support person reports inadequate understanding that interferes with effective behaviors; support person reports preoccupation with own reaction to client's need, protective behavior by support person incongruent with client's abilities or need for autonomy.

Diabetes mellitus

CH/PED

deficient Knowledge regarding disease process/treatment and individual care needs may be related to unfamiliarity with information, lack of recall, misinterpretation, possibly evidenced by requests for information, statements of concern, misconceptions, inadequate follow-through of instructions, and development of preventable complications.

risk for unstable Blood Glucose Level possibly evidenced by nonadherence to diabetes management plan, ineffective medication management, inadequate blood glucose monitoring, average daily physical activity is less than recommended for gender/age, health status, stress, rapid growth periods.

risk for ineffective Health Management possibly evidenced by complexity and duration of treatment, perceived excessive demands made on individual, powerlessness, perceived susceptibility to complications.

risk for Infection possibly evidenced by associated conditions of (chronic illness, leukopenia, impaired circulation), and [delayed healing].

[*risk for disturbed Sensory Perception (specify)*] possibly evidenced by endogenous chemical alteration (glucose, insulin, or electrolyte imbalance).

Diabetes mellitus, intrapartum

OB

Also refer to Diabetes mellitus

risk for physical Trauma/impaired fetal Gas Exchange possibly evidenced by inadequate maternal diabetic control, presence of macrosomia, or intrauterine growth retardation.

risk for maternal Injury possibly evidenced by inadequate diabetic control (hypertension, severe edema, ketoacidosis, uterine atony or overdistention, dystocia).

[mild to moderate] Anxiety may be related to (situational “crisis”), threat to health status (maternal/fetus), possibly evidenced by increase in tension, apprehensiveness, fear of unspecified consequences, sympathetic stimulation.

Diabetes mellitus, postpartum

OB

risk for unstable Blood Glucose Level possibly evidenced by insufficient knowledge of disease management, ineffective medication management, [increased metabolic demands (recuperation, lactation)].

risk for Injury possibly evidenced by (biochemical or regulatory dysfunction—uterine atony/hemorrhage, gestational hypertension, hyperglycemia).

risk for impaired Attachment possibly evidenced by interruption in bonding process, physical illness, changes in physical abilities.

Diabetic ketoacidosis

CH/MS

deficient Fluid Volume [specify] may be related to hyperosmolar urinary losses, gastric losses, and inadequate intake, possibly evidenced by increased urinary output, dilute urine; reports of weakness, thirst; sudden weight loss; hypotension; tachycardia; delayed capillary refill; dry mucous membranes; poor skin turgor.

unstable Blood Glucose Level may be related to ineffective medication management, insufficient diabetes management, inadequate blood glucose monitoring, possibly evidenced by elevated serum glucose level, ketones in urine, nausea, weight loss, blurred vision, irritability.

Fatigue may be related to (illness), stressors, possibly evidenced by insufficient energy, impaired ability to maintain usual routines, ineffective role performance, alteration in concentration, lethargy.

risk for Infection possibly evidenced by stasis of body fluids, [high glucose levels], leukopenia, invasive procedures.

Dialysis, general

CH

Also refer to Dialysis, peritoneal; Hemodialysis

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to ingest food or absorb nutrients), possibly evidenced by food intake less than recommended daily allowance, satiety immediately upon ingesting food, food aversion, alteration in taste sensation, insufficient muscle tone, weakness, sore buccal cavity, pale mucous membranes.

Grieving may be related to (loss of significant object—chronic disease; anticipatory loss—potentially

fatal illness, possibly evidenced by distress, despair, alteration in sleep/dream pattern, alteration in activity level, and anger.

disturbed Body Image/situational low Self-Esteem may be related to alteration in self-perception, cultural or spiritual incongruence possibly evidenced by verbalizations of feelings or perceptions [or actions], (e.g., fear of reaction by others), preoccupation with changes in usual roles and body image, negative feelings about body, feelings of helplessness, powerlessness, extension of body boundary to incorporate environmental objects (e.g., dialysis setup), change in social involvement, overdependence on others for care, not taking responsibility for self-care, lack of follow-through, and self-destructive behavior).

Self-Care deficit [specify] may be related to (perceptual disorders, alteration in cognitive functioning [accumulated toxins]); fatigue, pain, discomfort, decrease in motivation, possibly evidenced by reported inability to perform activities of daily living.

ineffective Health Management may be related to difficulty managing complex treatment regimen or navigating complex healthcare systems, excessive demands, powerlessness; perceived seriousness of condition, perceived benefit [of treatment], possibly evidenced by difficulty with prescribed regimen, failure to include treatment regimen in daily living, ineffective choices for meeting health goal.

compromised/disabled family Coping may be related to insufficient or incorrect information or understanding by support person, family disorganization, (family role change), insufficient reciprocal, exhaustion of support person's capacity, possibly evidenced by client concern about support person's response to health problem, neglect of treatment regimen, intolerance or rejection, and protective behavior by support person incongruent with client's abilities or need for autonomy.

Dialysis, peritoneal

MS/CH

Also refer to Dialysis, general

risk for excess Fluid Volume possibly evidenced by inadequate osmotic gradient of dialysate, fluid retention—malpositioned, kinked, or clotted catheter; bowel distention, peritonitis, scarring of peritoneum; excessive PO/IV intake.

risk for physical Trauma possibly evidenced by risk factors of improper placement during insertion or manipulation of catheter.

acute Pain/impaired Comfort may be related to physical injury agent (catheter irritation, improper catheter placement, presence of edema, abdominal distention, inflammation, or infection; rapid infusion or infusion of cold or acidic dialysate) possibly evidenced by verbal reports, guarding or distraction behaviors, and self-focus.

risk for Infection [peritonitis] possibly evidenced by [contamination of catheter or infusion system, skin contaminants].

risk for ineffective Breathing Pattern possibly evidenced by increased abdominal pressure restricting diaphragmatic excursion, rapid infusion of dialysate, pain or discomfort, inflammatory process (e.g., atelectasis/pneumonia).

Diaper rash

PED

Refer to Candidiasis

Diaphragmatic hernia

CH/MS

Refer to Hernia, hiatal

Diarrhea

PED/CH

deficient Knowledge regarding causative or contributing factors and therapeutic needs may be related to lack of information, misconceptions, possibly evidenced by statements of concern, questions, and development of preventable complications.

risk for deficient Fluid Volume possibly evidenced by excessive losses through gastrointestinal tract, altered intake.

impaired Skin Integrity may be related to effects of excretions on delicate tissues, possibly evidenced by reports of acute pain and/or bleeding, and alteration in skin integrity.

DIC

MS

Refer to Disseminated intravascular coagulation

Diffuse axonal (brain) injury

MS

Refer to Traumatic brain injury; Cerebrovascular accident

Digitalis toxicity

MS/CH

decreased Cardiac Output may be related to altered myocardial contractility and electrical conduction, possibly evidenced by changes in rate, rhythm, and conduction (development or worsening of dysrhythmias), changes in mentation, [elevated serum drug levels].

risk for imbalanced Fluid Volume possibly evidenced by excessive losses from vomiting or diarrhea,

decreased intake, nausea, decreased plasma proteins, malnutrition, continued use of diuretics; excess sodium and fluid retention.

risk for Poisoning [drug toxicity] possibly evidenced by access to pharmaceutical agent; insufficient knowledge of pharmacological agent or poisoning prevention.

deficient Knowledge regarding condition, therapy, and self-care needs may be related to information misinterpretation and lack of recall, possibly evidenced by inaccurate follow-through of instructions and development of preventable complications.

Dilation and curettage

OB/GYN

Also refer to Abortion, elective or spontaneous termination

deficient Knowledge regarding surgical procedure, possible postprocedural complications, and therapeutic needs may be related to lack of exposure or unfamiliarity with information, possibly evidenced by requests for information and statements of concern, misconceptions.

Dilation of cervix, premature

OB

Also refer to Preterm labor

Anxiety [specify level] may be related to (situational crisis), threat of death or fetal loss, possibly evidenced by increase in tension, apprehensiveness, feeling of inadequacy, sympathetic stimulation, and repetitive questioning.

risk for disturbed Maternal-Fetal Dyad possibly evidenced by (treatment regimen—surgical intervention, use of tocolytic drugs).

Grieving may be related to (anticipatory potential fetal loss), possibly evidenced by expression of distress, anger, blaming.

Dislocation/subluxation of joint

CH

acute Pain may be related to [lack of continuity of bone/joint, muscle spasms, edema], possibly evidenced by verbal or coded reports, guarded or protective behavior, narrowed focus, autonomic responses.

risk for Injury possibly evidenced by nerve impingement, improper fitting of splint device.

impaired physical Mobility may be related to immobilization device, activity restrictions, pain, edema, decreased muscle strength, possibly evidenced by limited range of motion, limited ability to perform motor skills, gait changes.

Disruptive behavior disorder

PED/PSY

Refer to Oppositional defiant disorder

Disseminated intravascular coagulation MS

risk for Shock possibly evidenced by failure of regulatory mechanism (coagulation process) and active loss, hemorrhage.

ineffective Tissue Perfusion (specify) may be related to alteration of arterial or venous flow (microemboli throughout circulatory system, and hypovolemia), possibly evidenced by changes in respiratory rate and depth, changes in mentation, decreased urinary output, and development of acral cyanosis and focal gangrene.

Anxiety [specify level]/Fear may be related to learned response to threat [sudden change in health status/threat of death], possibly evidenced by sympathetic stimulation, restlessness, focus on self, and apprehension.

risk for impaired Gas Exchange possibly evidenced by [reduced oxygen-carrying capacity, development of acidosis, fibrin deposition in microcirculation, and ischemic damage of lung parenchyma].

acute Pain may be related to physical injury agent (bleeding into joints/muscles, with hematoma formation, and ischemic tissues with areas of acral cyanosis and focal gangrene), possibly evidenced by verbal reports, narrowed focus, alteration in muscle tone, guarding or distraction behaviors, restlessness, autonomic responses.

Dissociative disorders

PSY

[severe/panic] Anxiety/Fear may be related to a threat to current status, value conflict(s), unmet needs, (learned response to threat or phobic stimulus), possibly evidenced by maladaptive response to stress [e.g., dissociating self, fragmentation of the personality].

risk for self-directed Violence possibly evidenced by suicidal ideation/behavior, (mental health issues [e.g., dissociative state/conflicting personalities, depression, substance misuse]), panic states, and suicidal or homicidal behaviors.

disturbed Personal Identity may be related to low self-esteem, dysfunctional family processes, (dissociative identity disorder), possibly evidenced by fluctuating feelings about self, confusion about goals, inability to distinguish between internal and external stimuli, ineffective relationships, inconsistent behavior.

disabled family Coping may be related to ambivalent family relationships, differing coping styles between support persons, chronically unexpressed feelings, possibly evidenced by abandonment, rejection, aggression, hostility; disregard for client's needs, neglect of relationship with family member.

Diverticulitis

CH

acute Pain may be related to physical injury agent (inflammation of intestinal mucosa), possibly evidenced by verbal reports, guarding or distraction behavior, autonomic responses, and narrowed focus.

Diarrhea/Constipation may be related to altered structure and function, and presence of inflammation, possibly evidenced by signs and symptoms dependent on specific problem (e.g., increase or decrease in frequency of stools and change in consistency).

deficient Knowledge regarding disease process, potential complications, therapy, and self-care needs may be related to lack of information, misconceptions, possibly evidenced by statements of concern, request for information, and development of preventable complications.

risk for ineffective Health Management possibly evidenced by difficulty with prescribed regimen, ineffective choices in daily living for meeting health goal; insufficient knowledge of therapeutic regimen; perceived seriousness of condition [chronic nature of disease process and recurrent episodes despite cooperation with medical regimen].

Down syndrome

PED/CH

Also refer to Mental delay (formerly retardation)

risk for disproportionate Growth and/or delayed Development possibly evidenced by (genetic disorder).

risk for physical Trauma possibly evidenced by cognitive difficulties and poor muscle tone or coordination, weakness.

risk for imbalanced Nutrition: less than body requirements possibly evidenced by inability to ingest food, insufficient muscle tone and protruding tongue, [weak or ineffective sucking/swallowing].

interrupted Family Processes may be related to (situational or developmental crises, shift in health status of a family member), shift in family roles, possibly evidenced by decrease in mutual support, ineffective task completion, change in family satisfaction/relationship pattern.

risk for complicated Grieving [parent/caregiver] possibly evidenced by emotional disturbance [loss of "the perfect child," chronic condition requiring long-term care, and unresolved feelings].

risk for impaired Attachment possibly evidenced by ill infant/child who is unable to effectively initiate parental contact, disorganized infant behavioral, inability of parents to meet personal needs.

risk for Social Isolation possibly evidenced by withdrawal from usual social interactions and activities, assumption of total child care, and becoming over-indulgent or overprotective.

Dressler's syndrome

CH

acute Pain may be related to physical injury (tissue inflammation) possibly evidenced by verbal reports of chest pain, guarding or distraction behavior, self-focused, and changes in vital signs.

Anxiety [specify level] may be related to threat to current status, possibly evidenced by increase in tension, apprehensiveness, restlessness, distress, and uncertainty.

risk for ineffective Breathing Pattern possibly evidenced by pain on inspiration.

risk for impaired Gas Exchange possibly evidenced by (ventilation perfusion imbalance—pleural effusion, pulmonary infiltrates).

Drug overdose, acute (depressants) MS/PSY

Also refer to Substance dependence/abuse rehabilitation
ineffective Breathing Pattern/impaired Gas Exchange may be related to (ventilation-perfusion imbalance [neuromuscular impairment, central nervous system depression, decreased lung expansion]), possibly evidenced by changes in respirations, cyanosis, and abnormal arterial blood gases.

risk for physical Trauma/Suffocation/Poisoning possibly evidenced by central nervous system depression, agitation, hypersensitivity to the drug(s), psychological stress.

risk for self-/other-directed Violence possibly evidenced by suicidal behaviors, toxic reactions to drug(s).

risk for Infection possibly evidenced by [drug injection techniques, impurities in injected drugs, localized trauma]; malnutrition, immunosuppression.

Drug withdrawal

CH/MS

[disturbed Sensory Perception (specify)] may be related to biochemical imbalance, altered sensory integration possibly evidenced by sensory distortions, poor concentration, irritability, hallucinations.

risk for Injury possibly evidenced by central nervous system agitation (depressants).

risk for Suicide possibly evidenced by alcohol or substance abuse, legal or disciplinary problems, depressed mood (stimulants).

acute Pain/impaired Comfort may be related to biochemical changes [cessation of drug use], possibly evidenced by reports of muscle aches, malaise.

Self-Care deficit (specify) may be related to perceptual or cognitive impairment, therapeutic management (restraints), possibly evidenced by inability to meet own physical needs.

Insomnia may be related to cessation of substance use, fatigue, possibly evidenced by reports of insomnia or hypersomnia, decreased ability to function, increased irritability.

Fatigue may be related to altered body chemistry (drug withdrawal), sleep deprivation, malnutrition, poor physical condition, possibly evidenced by verbal reports of overwhelming lack of energy, inability to maintain usual level of physical activity, inability to restore energy after sleep, compromised concentration.

DTs

MS/PSY

Refer to Delirium tremens

Duchenne's muscular dystrophy

PED/CH

Refer to Muscular dystrophy (Duchenne's)

Duodenal ulcer

MS/CH

Refer to Ulcer, peptic

DVT

CH/MS

Refer to Thrombophlebitis

Dysmenorrhea

GYN

acute Pain may be related to physical/biological agent—exaggerated uterine contractions, muscular contractions, possibly evidenced by verbal reports, guarding or distraction behavior, narrowed focus, and changes in vital signs.

ineffective Coping may be related to ineffective tension release strategies, insufficient sense of control, (situational “crisis,” possibly evidenced by ineffective coping strategies, inability to deal with a situation, insufficient problem resolution).

Dyspareunia

GYN/PSY

Sexual dysfunction may be related to (alteration in body function), vulnerability, psychosocial abuse, possibly evidenced by alteration in sexual satisfaction, decrease in sexual desire, alteration in sexual activity.

Anxiety [specify] may be related to threat to current status, unmet needs, possibly evidenced by expressed concerns, distress, expressions of inadequacy.

Dysrhythmia, cardiac

CH/MS

risk for decreased Cardiac Output possibly evidenced by altered electrical conduction and reduced myocardial contractility.

deficient Knowledge regarding medical condition and therapy needs may be related to lack of information, misinterpretation, and unfamiliarity with information resources, possibly evidenced by questions, statement of misconception, failure to improve on previous regimen, and development of preventable complications.

risk for Activity Intolerance possibly evidenced by imbalance between oxygen supply and demand, and [cardiac depressant effects of certain drugs (beta blockers, antidysrhythmics)].

risk for Poisoning [digitalis toxicity] possibly evidenced by limited range of therapeutic effectiveness, lack of education or proper precautions, reduced vision, cognitive limitations.

Dysthymic disorder

PSY/CH

Refer to Depression, major

Dystocia

OB

Also refer to Labor, stage I [latent/active phases]

risk for maternal Injury possibly evidenced by alteration of muscle tone/contractile pattern, mechanical obstruction to fetal descent, maternal fatigue.

risk for fetal Injury possibly evidenced by prolonged labor, fetal malpresentations, tissue hypoxia and acidosis, abnormalities of the maternal pelvis, cephalopelvic disproportion.

risk for deficient Fluid Volume possibly evidenced by hypermetabolic state, vomiting, profuse diaphoresis, restricted oral intake, mild diuresis associated with oxytocin administration.

Eating disorders

CH/PSY

Refer to Anorexia nervosa; Bulimia nervosa

Ebola

MS

Also refer to Disseminated intravascular coagulation; Multiple organ dysfunction syndrome

acute Pain/impaired Comfort may be related to (illness-related symptoms), possibly evidenced by reports of distressing symptoms, anxiety, report of pain, facial expression of pain, self-focused.

Hyperthermia may be related to inflammatory process, possibly evidenced by increased body temperature, warm skin, headache.

risk for deficient Fluid Volume possibly evidenced by inadequate intake (nausea, painful swallowing, abdominal pain), increased losses (vomiting, diarrhea, hemorrhage/disseminated intravascular coagulation), hypermetabolic state (fever).

risk for Infection [spread of or secondary] possibly evidenced by (exposure to disease outbreak), insufficient knowledge [or resources] to avoid exposure to pathogens, malnutrition, (invasive procedure).

acute Confusion may be related to dehydration, malnutrition, (delirium or impaired metabolic functioning, infection), possibly evidenced by alterations in level of consciousness or cognition, restlessness/agitation, hallucinations.

Eclampsia

OB

Also refer to Hypertension, gestational

Anxiety [specify]/Fear may be related to (situational crisis), threat of change in current status or death (self/fetus), separation from support system, possibly evidenced by expressed concerns, apprehensiveness, increase in tension, decreased self-assurance, difficulty concentrating.

risk for maternal Injury possibly evidenced by tissue edema, hypoxia–tonic-clonic convulsions; abnormal blood profile–altered clotting factors.

impaired physical Mobility may be related to prescribed physical restrictions, discomfort, anxiety, possibly evidenced by difficulty turning, postural instability.

risk for Self-Care deficit (specify) possibly evidenced by weakness, discomfort, physical restrictions.

ECT

PSY

Refer to Electroconvulsive therapy

Ectopic pregnancy (tubal)

OB

Also refer to Abortion, spontaneous termination

acute Pain may be related to physical injury agent (distention/rupture of fallopian tube) possibly evidenced by verbal reports, guarding or distraction behavior, facial expression of pain, diaphoresis, and changes in vital signs.

risk for Bleeding/deficient Fluid Volume possibly evidenced by (pregnancy complication), hemorrhagic losses, and decreased or restricted intake.

Anxiety [specify level]/Fear may be related to threat of death and possible threat to current status (e.g., loss of ability to conceive), possibly evidenced by increase in tension, apprehensiveness, sympathetic stimulation, restlessness, and self-focused.

Eczema

CH

Refer to Dermatitis, contact/seborrheic

impaired Comfort may be related to [cutaneous inflammation and irritation] possibly evidenced by verbal reports, irritability, and scratching.

risk for Infection possibly evidenced by alteration in skin integrity.

Social Isolation may be related to alterations in physical appearance, possibly evidenced by expressed feelings of rejection and decreased interaction with peers.

Edema, pulmonary

MS

excess Fluid Volume may be related to decreased cardiac functioning, excessive fluid and sodium intake, possibly evidenced by dyspnea, presence of crackles (rales), pulmonary congestion on radiograph, restlessness, anxiety, and increased central venous pressure and pulmonary pressures.

impaired Gas Exchange may be related to (alveolar-capillary changes and ventilation-perfusion imbalance—fluid collection or shifts into interstitial space and alveoli), possibly evidenced by hypoxia, restlessness, and confusion.

Anxiety [specify level]/Fear may be related to stressors perceived threat of death [inability to breathe], possibly evidenced by responses ranging from apprehension to panic state, restlessness, and focus on self.

Elder abuse

CH/PSY

Refer to Abuse, physical/psychological

Electrical injury

MS

Also refer to Burns

risk for decreased Cardiac Output possibly evidenced by altered heart rate and rhythm (ventricular fibrillation, asystole).

impaired [internal] Tissue Integrity may be related to thermal injury (along path of current), altered circulation (massive edema), possibly evidenced by damaged or destroyed tissue, necrosis.

risk for ineffective peripheral Tissue Perfusion possibly evidenced by reduction of venous or arterial blood flow (vein coagulation, muscle edema), increased tissue pressure (compartment syndrome).

risk for physical Trauma/Suffocation possibly evidenced by muscle paralysis (central nervous system damage), loss of large- or small-muscle coordination (seizures).

Electroconvulsive therapy

PSY

Decisional Conflict may be related to lack of relevant or multiple and divergent sources of information, mistrust of regimen or healthcare personnel, sense of powerlessness, support system deficit.

acute Confusion may be related to [direct effects of electric shock on the central nervous system, medications, and anesthesia], possibly evidenced by fluctuation in cognition, agitation.

impaired Memory may be related to neurological disturbance (electrical shock), possibly evidenced by reported or observed experiences of forgetting, difficulty recalling recent events or factual information.

Emphysema

CH/MS

impaired Gas Exchange may be related to (alveolar capillary membrane changes [or destruction]), possibly evidenced by abnormal breathing pattern (dyspnea), restlessness, [changes in mentation], abnormal arterial blood gas values.

ineffective Airway Clearance may be related to increased production and retained tenacious secretions, decreased energy level, and muscle wasting, possibly evidenced by abnormal breath sounds (rhonchi), ineffective cough, changes in rate and depth of respirations, and dyspnea.

Activity Intolerance may be related to imbalance between oxygen supply and demand and physical deconditioning, possibly evidenced by reports of fatigue or generalized weakness, exertional dyspnea, and abnormal vital sign response to activity.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, inability to ingest food, possibly evidenced by insufficient interest in food, alteration in taste sensation, insufficient muscle tone, [fatigue, and weight loss].

risk for Infection possibly evidenced by stasis of body fluids, malnutrition (decrease in ciliary action, and chronic illness).

ineffective Health Management may be related to difficulty managing complex treatment regimen or navigating complex healthcare systems, excessive demands, powerlessness; perceived seriousness of condition, perceived benefit [of treatment], possibly evidenced by difficulty with prescribed regimen, failure to include treatment regimen in daily living, ineffective choices for meeting health goal.

Encephalitis

MS

risk for ineffective cerebral Tissue Perfusion possibly evidenced by cerebral edema altering or interrupting cerebral arterial or venous blood flow, hypovolemia, exchange problems at cellular level (acidosis).

Hyperthermia may be related to increased metabolic rate, illness, and dehydration, possibly evidenced

by increased body temperature; flushed, warm skin; and increased pulse and respiratory rates.

acute Pain may be related to physical injury agent (inflammation or irritation of the brain and cerebral edema) possibly evidenced by verbal reports of pain, photophobia, distraction behavior, restlessness, and changes in vital signs.

risk for physical Trauma/Suffocation possibly evidenced by restlessness, clonic-tonic activity, altered sensorium, cognitive impairment, generalized weakness, ataxia, vertigo.

Encopresis

PSY/PED

bowel Incontinence may be related to [situational or maturational crisis], stressors (predisposing vulnerability, threat to physical integrity—child/sexual abuse), possibly evidenced by involuntary passage of stool at least once monthly, strong odor of feces on client, hiding soiled clothing in inappropriate places.

disturbed Body Image/chronic low Self-Esteem may be related to negative view of self, maturational expectations, social factors, stigma attached to loss of body function in public, family's belief that condition is volitional, shame related to body odor, possibly evidenced by angry outbursts or oppositional behavior, verbalization of powerlessness, reluctance to engage in social activities.

compromised family Coping may be related to inadequate or incorrect information or understanding of condition, belief that behavior is volitional, disagreement regarding treatment or coping strategies, possibly evidenced by increasingly ineffective attempts to intervene with child, significant person describes preoccupation with personal reaction (excessive guilt, anger, blame regarding child's condition or behavior), overprotective behavior.

Endocarditis

MS

risk for decreased Cardiac Output possibly evidenced by inflammation of lining of heart and structural change in valve leaflets.

Anxiety [specify level] may be related to change in current status and threat of death, possibly evidenced by apprehensiveness, expressed concerns, and self-focused.

acute Pain may be related to physical injury agent (inflammatory process and effects of embolic phenomena), possibly evidenced by verbal reports, narrowed focus, distraction behavior, and autonomic responses (changes in vital signs).

risk for Activity Intolerance possibly evidenced by risk factors of imbalance between oxygen supply and demand, [debilitating condition].

risk for ineffective Tissue Perfusion (specify) possibly evidenced by embolic interruption of arterial flow (embolization of thrombi or valvular vegetations).

End-of-life care

CH

Refer to Hospice care

Endometriosis

GYN

acute/chronic Pain may be related to pressure of concealed bleeding, formation of adhesions, possibly evidenced by verbal reports (pain between and with menstruation), guarding or distraction behaviors, and narrowed focus.

Sexual dysfunction may be related to (alteration in body function, presence of adhesions, painful menses), possibly evidenced by undesired change in sexual function, decrease in sexual desire, change in interest toward others.

deficient Knowledge regarding pathophysiology of condition and therapy needs may be related to lack of information, misinterpretations, possibly evidenced by statements of concern and misconceptions.

Enteral feeding

MS/CH

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, possibly evidenced by body weight 10% or more under ideal, [decreased subcutaneous fat or muscle mass, changes in gastric motility and stool characteristics].

risk for Infection possibly evidenced by malnutrition, chronic illness, and associated conditions of invasive procedure, [surgical placement of feeding tube].

risk for Aspiration possibly evidenced by (presence of feeding tube, enteral feedings, increase in intragastric pressure, delayed gastric emptying, treatment regimen).

risk for imbalanced Fluid Volume possibly evidenced by active loss or failure of regulatory mechanisms (specific to underlying disease process or trauma), inability to obtain or ingest fluids.

Fatigue may be related to decreased metabolic energy production, increased energy requirements (hypermetabolic state, healing process), altered body chemistry (medications, chemotherapy), possibly evidenced by overwhelming lack of energy, inability to maintain usual routines or accomplish routine tasks, lethargy, impaired ability to concentrate.

Enteritis**MS/CH**

Refer to Colitis, ulcerative; Crohn's disease

Enuresis**PSY/PED**

impaired urinary Elimination may be related to multiple causality—situational or maturational crisis, psychogenic factors (predisposing vulnerability, threat to physical integrity—abuse), possibly evidenced by nocturnal or diurnal enuresis, strong odor of urine on client, hiding soiled clothing in inappropriate places.

disturbed Body Image/chronic low Self-Esteem may be related to negative view of self, maturational expectations, social factors, stigma attached to loss of body function in public, family's belief condition is volitional, shame related to body odor, possibly evidenced by angry outbursts or oppositional behavior, verbalization of powerlessness, reluctance to engage in social activities.

compromised family Coping may be related to inadequate or incorrect information or understanding of condition, belief that behavior is volitional, disagreement regarding treatment or coping strategies, possibly evidenced by increasingly ineffective attempts to intervene with child, SO describes preoccupation with personal reaction (excessive guilt, anger, blame regarding child's condition or behavior), over-protective behavior.

Epididymitis**MS**

acute Pain may be related to [inflammation, edema formation, and tension on the spermatic cord] possibly evidenced by verbal reports, guarding or distraction behaviors (restlessness), and changes in vital signs.

risk for Infection [spread] possibly evidenced by insufficient knowledge to avoid spread of infection.

deficient Knowledge regarding pathophysiology, outcome, and self-care needs may be related to lack of information, misinterpretations, possibly evidenced by statements of concern, misconceptions, and questions.

Epilepsy**CH**

Refer to Seizure disorder

Episiotomy**OB**

acute Pain may be related to physical injury agent (tissue trauma, edema, surgical incision) possibly evidenced by self-report of pain, guarding behavior, self-focused.

risk for Infection possibly evidenced by alteration in skin/traumatized tissue, [body excretions, inadequate hygiene].

risk for Sexual dysfunction possibly evidenced by associated condition of alteration in body structure (recent childbirth, presence of incision).

Epistaxis**CH**

[mild to moderate] Anxiety may be related to (situational crisis), threat to current status, interpersonal transmission, possibly evidenced by expressed concerns, apprehension, anxiety.

risk for Aspiration possibly evidenced by (uncontrolled nasal bleeding).

Epstein-Barr virus**CH**

Refer to Mononucleosis, infectious

Erectile dysfunction**CH/PSY**

Sexual dysfunction may be related to (altered body function), [side effects of medication], possibly evidenced by reports of disruption of sexual response pattern, inability to achieve desired satisfaction.

situational low Self-Esteem may be related to functional impairment, perceived failure to perform satisfactorily, rejection of other(s), possibly evidenced by self-negating verbalizations, expressions of helplessness, powerlessness.

Esophageal reflux disease**CH**

Refer to Gastroesophageal reflux disease

Esophageal varices**CH/MS**

Refer to Varices, esophageal

Esophagitis**CH**

Refer to Gastroesophageal reflux disease; Achalasia

ETOH withdrawal**MS/CH**

Refer to Alcohol intoxication, acute; Substance dependence/abuse rehabilitation

Evisceration**MS**

Refer to Dehiscence, abdominal wound

Facial reconstructive surgery**MS/CH**

Also refer to Surgery, general; Intermaxillary fixation
risk for ineffective Airway Clearance possibly evidenced by soft tissue edema, airway trauma, retained secretions.

impaired Skin Integrity may be related to [traumatic injury, surgical procedure (incisions/grafts), edema, altered circulation, possibly evidenced by disruption or destruction of skin layers].

Fear/Anxiety may be related to (situational crisis), memory of traumatic event, threat to self-concept

[disfigurement], possibly evidenced by expressed concerns, apprehension, uncertainty, decreased self-assurance, restlessness.

disturbed Body Image may be related to alteration in self-perception, cultural or spiritual incongruence, (trauma), possibly evidenced by negative feelings about body, fear of reaction by others, preoccupation with change, change in social involvement.

risk for Social Isolation possibly evidenced by feeling different from others, alteration in physical appearance.

Failure to thrive, adult

CH/MS

Frail Elderly Syndrome may be related to depression, apathy, aging process, fatigue, degenerative condition, possibly evidenced by expressed lack of appetite, difficulty performing self-care tasks, altered mood state, inadequate intake, weight loss, physical decline.

ineffective Protection may be related to inadequate nutrition, anemia, extremes of age, possibly evidenced by fatigue, weakness, deficient immunity, impaired healing, pressure sores.

Failure to thrive, infant/child

PED

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to ingest/digest food, or absorb nutrients); [physical deprivation; psychosocial factors], possibly evidenced by [lack of appropriate weight gain or weight loss], insufficient muscle tone, pale conjunctiva or mucous membranes, and [laboratory tests reflecting nutritional deficiency].

[risk for disproportionate Growth] and/or delayed Development possibly evidenced by maladaptive feeding behavior, economically disadvantaged, caregiver mental health issue, presence of abuse (physical, psychological, sexual).

risk for impaired Parenting possibly evidenced by lack of knowledge, inadequate bonding, unrealistic expectations for self/infant, and lack of appropriate response of child to relationship.

deficient Knowledge regarding pathophysiology of condition, nutritional needs, growth/development expectations, and parenting skills may be related to lack of information, misinformation, or misinterpretation, possibly evidenced by verbalization of concerns, questions, misconceptions; or development of preventable complications.

Fat embolism syndrome

MS

Refer to Pulmonary embolus; Respiratory distress syndrome, acute

Fatigue syndrome, chronic

CH

Fatigue may be related to disease state, inadequate sleep, possibly evidenced by verbalization of unremitting or overwhelming lack of energy, inability to maintain usual routines, listlessness, compromised concentration.

chronic Pain may be related to chronic physical disability, possibly evidenced by verbal reports of headache, sore throat, arthralgias, abdominal pain, muscle aches, altered ability to continue previous activities, changes in sleep pattern.

Self-Care deficit [specify] may be related to tiredness, pain, discomfort, possibly evidenced by reports of inability to perform desired activities of daily living.

risk for ineffective Role Performance possibly evidenced by health alterations, stress.

Febrile seizure

PED

Hyperthermia may be related to illness, dehydration, decreased ability to perspire, possibly evidenced by increase in body temperature; flushed, warm skin; seizures.

Fecal diversion

MS/CH

Refer to Colostomy

Fecal impaction

CH

Constipation may be related to irregular defecation habits, decreased activity, dehydration, abdominal muscle weakness, neurological impairment, possibly evidenced by inability to pass stool, abdominal distention, tenderness or pain, nausea, vomiting, anorexia.

Femoral popliteal bypass

MS

Also refer to Surgery, general

risk for ineffective peripheral Tissue Perfusion possibly evidenced by interruption of arterial blood flow, hypovolemia.

risk for peripheral Neurovascular Dysfunction possibly evidenced by vascular obstruction, immobilization, mechanical compression, dressings.

impaired Walking may be related to surgical incisions, dressings, possibly evidenced by inability to walk desired distance, climb stairs, negotiate inclines.

Fetal alcohol syndrome

PED

risk for Injury [central nervous system damage] possibly evidenced by external chemical factors (alcohol intake by mother), placental insufficiency, fetal drug withdrawal in utero or postpartum, and prematurity.

disorganized infant Behavior may be related to prematurity, environmental overstimulation, lack of containment or boundaries, possibly evidenced by change from baseline physiological measures, tremors, startles, twitches, hyperextension of arms and legs, deficient self-regulatory behaviors, deficient response to visual or auditory stimuli.

risk for impaired Parenting possibly evidenced by mental or physical illness, inability of mother to assume the overwhelming task of unselfish giving and nurturing, presence of stressors (financial or legal problems), lack of available or ineffective role model, interruption of bonding process, lack of appropriate response of child to relationship.

PSY

ineffective [maternal] Coping may be related to personal vulnerability, low self-esteem, inadequate coping skills, and multiple stressors (repeated over period of time), possibly evidenced by inability to meet basic needs, fulfill role expectations, or problem-solve; and excessive use of drug(s).

dysfunctional Family Processes may be related to lack of or insufficient support from others, mother's drug problem and treatment status, together with poor coping skills, lack of family stability, overinvolvement of parents with children and multigenerational addictive behaviors, possibly evidenced by abandonment, rejection, neglectful relationships with family members, and decisions and actions by family that are detrimental.

Fetal demise

OB

Refer to Perinatal loss/death of child

Fetal transfusion syndrome

OB

Refer to Twin-twin transfusion syndrome

Fibrocystic breast disease

CH

[mild to moderate] Anxiety may be related to situational crisis, threat to health status, family heredity, interpersonal transmission, possibly evidenced by expressed concerns, apprehension, uncertainty, fearfulness, focus on self, increased tension.

acute/chronic Pain may be related to physical agents (edema formation, nerve irritation), possibly evidenced by verbal reports, guarded or protective behavior, expressive behavior, self-focusing.

Fibroids, uterine

GYN

Refer to Uterine myomas

Fibromyalgia syndrome, primary

CH

acute/chronic Pain may be related to idiopathic diffuse condition, possibly evidenced by reports of aching pain in fibrous tissues (muscles, tendons, ligaments), muscle stiffness or spasm, disturbed sleep, guarding behaviors, fear of reinjury or exacerbation, restlessness, irritability, self-focusing, reduced interaction with others.

Fatigue may be related to disease state, stress, anxiety, depression, sleep deprivation, possibly evidenced by verbalization of overwhelming lack of energy, inability to maintain usual routines or level of physical activity, tired, feelings of guilt for not keeping up with responsibilities, increase in physical complaints, listlessness.

risk for Hopelessness possibly evidenced by chronic debilitating physical condition, prolonged activity restriction (possibly self-induced), creating isolation, lack of specific therapeutic cure, prolonged stress.

Flail chest

MS

Refer to Hemothorax; Pneumothorax

Food poisoning

CH/MS

Refer to Gastroenteritis

Fractures

MS/CH

Also refer to Casts; Traction

risk for physical Trauma [additional injury] possibly evidenced by insufficient knowledge of safety precautions, weakness, [loss of skeletal integrity, movement of skeletal fragments, use of traction apparatus].

acute Pain may be related to physical injury agent (muscle spasms, movement of bone fragments, tissue trauma, edema, traction or immobility device, stress, and anxiety), possibly evidenced by verbal reports, distraction behavior, self-focused or narrowed focus, facial expression of pain, guarding or protective behavior, alteration in muscle tone, and changes in vital signs.

risk for peripheral Neurovascular Dysfunction possibly evidenced by reduction or interruption of blood flow (direct vascular injury, tissue trauma, excessive edema, thrombus formation, hypovolemia).

impaired physical Mobility may be related to neuromuscular or skeletal impairment, pain, discomfort, restrictive therapies (bedrest, extremity immobilization), and psychological immobility, possibly evidenced by inability to purposefully move within the physical environment, imposed restrictions, reluctance

to attempt movement, limited range of motion, and decreased muscle strength or control.

risk for impaired Gas Exchange possibly evidenced by (alveolar-capillary membrane changes [interstitial or pulmonary edema, congestion]) or possibly (ventilation-perfusion imbalance [altered blood flow, blood or fat emboli]).

deficient Knowledge regarding healing process, therapy requirements, potential complications, and self-care needs may be related to lack of exposure or recall, misinterpretation of information, possibly evidenced by statements of concern, questions, and misconceptions.

Frostbite **MS/CH**

impaired Tissue Integrity may be related to altered circulation and thermal injury, possibly evidenced by damaged or destroyed tissue.

acute Pain may be related to physical injury agent (tissue ischemia or necrosis and edema formation) possibly evidenced by verbal reports, guarding or distraction behaviors, narrowed focus, and changes in vital signs.

risk for Infection possibly evidenced by alteration in skin/tissue integrity and associated conditions of impaired circulation, and [compromised immune response in affected area].

Fusion, cervical **MS**

Refer to Laminectomy, cervical

Fusion, lumbar **MS**

Refer to Laminectomy, lumbar

Gallstones **CH**

Refer to Cholelithiasis

Gangrene, dry **MS**

ineffective peripheral Tissue Perfusion may be related to interruption in arterial flow, possibly evidenced by cool skin temperature, change in color (black), atrophy of affected part, and presence of pain.

acute Pain may be related to physical injury agent (tissue hypoxia and necrotic process), possibly evidenced by verbal reports, guarding or distraction behaviors, narrowed focus, and changes in vital signs.

Gangrene, gas **MS**

impaired Tissue Integrity may be related to trauma, surgery, infection, altered circulation, possibly evidenced by edema, brown or serous exudate, bronze or blackish green skin color, gas bubbles or crepitation, pain.

[severe] Anxiety/Fear may be related to learned response to threat (situational crisis), threat of death, possibly evidenced by expressed concerns, distress, apprehension, fearfulness, restlessness, irritability, focus on self.

risk for Injury possibly evidenced by [therapeutic intervention (hyperbaric oxygen therapy)].

Gas, lung irritant **MS/CH**

ineffective Airway Clearance may be related to irritation or inflammation of airway, possibly evidenced by marked cough, abnormal breath sounds (wheezes), dyspnea, and tachypnea.

risk for impaired Gas Exchange possibly evidenced by (alveolar-capillary membrane changes [irritation or inflammation dependent on type of agent and length of exposure]).

Anxiety [specify level] may be related to threat to change in current status and threat of death, possibly evidenced by verbalizations, increased tension, apprehension, and sympathetic stimulation.

Gastrectomy, subtotal **MS**

Also refer to Surgery, general

risk for imbalanced Nutrition: less than body requirements possibly evidenced by (inability to ingest food or absorb nutrients), restricted oral intake, early satiety, change in digestive process.

risk for Fatigue possibly evidenced by malnutrition, anemia.

risk for Diarrhea possibly evidenced by malabsorption.

Gastric partitioning **MS**

Refer to Gastroplasty

Gastric resection **MS**

Refer to Gastrectomy, subtotal

Gastric ulcer **MS/CH**

Refer to Ulcer, peptic

Gastrinoma **MS/CH**

Refer to Zollinger-Ellison syndrome

Gastritis, acute **MS**

acute Pain may be related to physical injury agent (inflammation of gastric mucosa), possibly evidenced by verbal reports, guarding or distraction behaviors, and changes in vital signs.

risk for deficient Fluid Volume/Bleeding possibly evidenced by excessive losses through vomiting and

diarrhea, continued bleeding, reluctance to ingest or restrictions of oral intake.

Gastritis, chronic

CH

risk for imbalanced Nutrition: less than body requirements possibly evidenced by (inability to ingest food or absorb nutrients), prolonged nausea, vomiting, anorexia, epigastric pain.

deficient Knowledge regarding pathophysiology, psychological factors, therapy needs, and potential complications may be related to lack of information or recall, unfamiliarity with information resources, information misinterpretation, possibly evidenced by verbalization of concerns, questions, and continuation of problem or development of preventable complications.

Gastroenteritis

CH/MS

Diarrhea may be related to toxins, contaminants, travel, infectious process, parasites, possibly evidenced by at least three loose liquid stools per day, hyperactive bowel sounds, abdominal pain.

risk for deficient Fluid Volume possibly evidenced by excessive losses (diarrhea, vomiting), hypermetabolic state (infection), decreased intake (nausea, anorexia), extremes of age or weight.

risk for Infection [transmission] possibly evidenced by alteration in peristalsis, inadequate vaccination, insufficient knowledge to prevent contamination (inappropriate hand hygiene and food handling).

Gastroesophageal reflux disease (GERD)

CH

acute/chronic Pain may be related to acidic irritation of mucosa, muscle spasm, recurrent vomiting, possibly evidenced by reports of heartburn, distraction behaviors.

impaired Swallowing may be related to (esophageal reflux disease [GERD], achalasia) possibly evidenced by reports of heartburn or epigastric pain, “something stuck” when swallowing, food refusal or volume limiting, nighttime coughing or awakening.

risk for imbalanced Nutrition: less than body requirements possibly evidenced by insufficient dietary intake, food aversion, [recurrent vomiting].

risk for Insomnia possibly evidenced by physical discomfort [nighttime heartburn, regurgitation of stomach contents].

risk for Aspiration possibly evidenced by (incompetent lower esophageal sphincter, increase in gastric residual).

Gastrointestinal hemorrhage

MS

Refer to Gastritis, acute or chronic; Ulcer, peptic; Colitis, ulcerative; Crohn’s disease; Varices, esophageal

Gastroplasty

MS

Also refer to Surgery, general

ineffective Breathing Pattern may be related to decreased lung expansion, pain, anxiety, decreased energy, fatigue, tracheobronchial obstruction, possibly evidenced by dyspnea, tachypnea, changes in respiratory depth, reduced vital capacity, wheezes, rhonchi, abnormal arterial blood gases.

risk for ineffective peripheral Tissue Perfusion possibly evidenced by diminished blood flow, hypovolemia, immobility or bedrest, interruption of venous blood flow (thrombus).

risk for deficient Fluid Volume possibly evidenced by excessive gastric losses, nasogastric suction, diarrhea, reduced intake.

risk for imbalanced Nutrition: less than body requirements possibly evidenced by inability to ingest food or absorb nutrients [restricted oral intake, early satiety, change in digestive process].

Diarrhea may be related to treatment regimen [changes in dietary fiber and bulk], malabsorption, possibly evidenced by loose liquid stools >3 in 24 hours, bowel urgency, hyperactive bowel sounds.

Gender dysphoria

PSY

(For individuals experiencing persistent and marked distress regarding uncertainty about issues relating to personal identity, e.g., sexual orientation and behavior.) *Anxiety [specify level]* may be related to value conflict, threat to current status, unmet needs, possibly evidenced by increase in tension, helplessness, feeling of inadequacy, uncertainty, insomnia, self-focused.

ineffective Role Performance/disturbed Personal Identity may be related to (developmental crisis), conflict, inadequate role preparation, possibly evidenced by role confusion, uncertainty, insufficient knowledge of role requirements, insufficient external support for role enactment, ineffective adaptation to change.

ineffective Sexuality Pattern may be related to inadequate model, conflict about sexual orientation or variant preference, impaired relationship with a significant other, possibly evidenced by value conflict, change in sexual role, difficulty with sexual behavior.

risk for compromised/disabled family Coping possibly evidenced by insufficient information

available or misunderstanding of information by support person, family disorganization and role changes, and insufficient reciprocal support.

readiness for enhanced family Coping possibly evidenced by expresses desire to acknowledge growth impact of crisis/situation, to enhance connection with others who have experienced a similar situation.

Genetic disorder

CH/OB

Anxiety may be related to presence of specific risk factors (e.g., exposure to teratogens), situational crisis, threat to self-concept, conscious or unconscious conflict about essential values and life goals, possibly evidenced by increased tension, apprehension, uncertainty, feelings of inadequacy, expressed concerns.

deficient Knowledge regarding purpose and process of genetic counseling may be related to lack of awareness of ramifications of diagnosis, process necessary for analyzing available options, and information misinterpretation, possibly evidenced by verbalization of concerns, statement of misconceptions, request for information.

risk for interrupted Family Processes possibly evidenced by (situational crisis), individual/family vulnerability, difficulty reaching agreement regarding options.

Grieving may be related to anticipatory or actual loss [e.g., childbearing or reproductive issues], possibly evidenced by suffering, blame, despair, change in usual routines and activities of daily living.

Spiritual distress may be related to intense inner conflict about the outcome, normal grieving for the loss of the perfect child, anger that is often directed at God/greater power, religious beliefs or moral convictions, possibly evidenced by verbalization of inner conflict about beliefs, questioning of the moral and ethical implications of therapeutic choices, viewing situation as punishment, anger, hostility, and crying.

Genital herpes

CH

Refer to Herpes simplex; Sexually transmitted infection

Genital warts (human papillomavirus)

CH

Refer to Sexually transmitted infection

GERD

CH

Refer to Gastroesophageal reflux disease

GI bleeding

MS

Refer to Gastritis, acute or chronic; Ulcer, peptic

Gigantism

CH

Refer to Acromegaly

Gingivitis

CH

impaired oral Mucous Membrane Integrity may be related to ineffective oral hygiene, ill-fitting dentures, decreased salivation, hormonal changes, possibly evidenced by edema, gingival bleeding, hyperplasia, oral pain.

Glaucoma

CH

[disturbed visual Sensory Perception] may be related to altered sensory reception and altered status of sense organ (increased intraocular pressure, atrophy of optic nerve head), possibly evidenced by progressive loss of visual field.

Anxiety [specify level] may be related to change in current status, pain, unmet needs, possibly evidenced by apprehensiveness, uncertainty, and expressed concern regarding changes in life event.

Glomerulonephritis

PED

excess Fluid Volume may be related to failure of regulatory mechanism (inflammation of glomerular membrane inhibiting filtration), possibly evidenced by weight gain, edema, anasarca, intake greater than output, and blood pressure changes.

acute Pain may be related to physical injury agent (circulating toxins and edema), possibly evidenced by verbal reports, guarding or distraction behaviors, and changes in vital signs.

imbalanced Nutrition: less than body requirements may be related to (inability to ingest food or absorb nutrients [anorexia and dietary restrictions]) possibly evidenced by food aversion, alteration in taste sensation, and weight loss.

decreased Diversional Activity Engagement may be related to treatment modality and restrictions, fatigue, and malaise, possibly evidenced by statements of boredom, restlessness, and irritability.

Gluten sensitive enteropathy

CH

Refer to Celiac disease

Goiter

CH

disturbed Body Image may be related to alteration in self-perception possibly evidenced by verbalizations of feelings or perceptions, fear of reaction by others, preoccupation with change (e.g., visible swelling in neck, possibly actual change in structure).

Anxiety may be related to change in current status, progressive growth of mass, perceived threat of death.

risk for ineffective Airway Clearance possibly evidenced by tracheal compression or obstruction.

Gonorrhea

CH

Also refer to Sexually transmitted infection

risk for Infection [dissemination/bacteremia] possibly evidenced by [presence of infectious process in highly vascular area] and lack of knowledge to avoid exposure to pathogens.

acute Pain may be related to physical injury agent (inflammation of mucosa, effects of circulating toxins), possibly evidenced by verbal reports of genital or pharyngeal irritation, perineal or pelvic pain, guarding or distraction behaviors.

deficient Knowledge regarding disease cause, transmission, therapy, and self-care needs may be related to lack of information, misinterpretation, denial of exposure, possibly evidenced by statements of concern, questions, misconceptions, and inaccurate follow-through of instructions, development of preventable complications.

Gout

CH

acute Pain may be related to physical injury agent (inflammation of joint[s]) possibly evidenced by verbal reports, guarding or distraction behaviors, and changes in vital signs.

impaired physical Mobility may be related to joint pain, edema, possibly evidenced by reluctance to attempt movement, limited range of motion, and therapeutic restriction of movement.

deficient Knowledge regarding cause, treatment, and prevention of condition may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, misconceptions, and inaccurate follow-through of instructions.

Grand mal seizures

CH/PED

Refer to Seizure disorder

Grave's disease

CH

Refer to Hyperthyroidism

Guillain-Barré syndrome (acute polyneuritis)

MS

risk for ineffective Breathing Pattern/Airway Clearance possibly evidenced by weakness or paralysis of

respiratory muscles, impaired gag or swallow reflexes, decreased energy, fatigue.

[disturbed Sensory Perception (specify)] may be related to altered sensory reception, transmission, or integration (altered status of sense organs, sleep deprivation); therapeutically restricted environment; endogenous chemical alterations (electrolyte imbalance, hypoxia); and psychological stress, possibly evidenced by reported or observed change in usual response to stimuli, altered communication patterns, and measured change in sensory acuity and motor coordination.

impaired physical Mobility may be related to neuromuscular impairment, pain, discomfort, possibly evidenced by impaired coordination, partial or complete paralysis, decreased muscle strength or control.

Anxiety [specify level]/Fear may be related to change in current status, threat of death, possibly evidenced by increased tension, restlessness, helplessness, apprehension, uncertainty, fearfulness, focus on self, and sympathetic stimulation.

risk for Disuse Syndrome possibly evidenced by paralysis and pain.

Gulf War syndrome

CH/MS

[chronic] Fatigue may be related to unknown environmental exposure, stress, anxiety, disease state, possibly evidenced by overwhelming lack of energy, inability to maintain usual routines or level of physical activity, lethargic, compromised concentration.

Anxiety [specify] may be related to exposure to toxins, change in current status, threat of death, change in role function or economic status, unmet needs, possibly evidenced by expressed concerns, apprehension, uncertainty, fear of unspecific consequences, sleep disturbance, irritability, preoccupation.

impaired Memory may be related to neurological disturbances, possibly evidenced by reported or observed experiences of forgetting, inability to recall recent events.

chronic Pain may be related to chronic physical condition, possibly evidenced by verbal reports of muscle or joint pain, headaches, altered ability to continue previous activities, fatigue, reduced interaction with others.

Diarrhea may be related to environmental exposure to toxins, high stress levels/anxiety, possibly evidenced by liquid stools, abdominal pain.

[*disturbed visual Sensory Perception*] may be related to altered sensory reception, possibly evidenced by blurred vision, photosensitivity.

Hallucinogen abuse

CH/PSY

Also refer to Substance dependence/abuse rehabilitation *Anxiety/Fear* may be related to substance misuse, stressors, sensory deficit, response to phobic stimulus, threat to change in current status, threat of death, possibly evidenced by apprehensiveness, restlessness, feeling of alarm, terror, attack behavior, sympathetic stimulation.

Self-Neglect may be related to substance misuse, deficient executive function, possibly evidenced by inadequate personal/environmental hygiene, nonadherence to health activity.

Self-Care deficit (specify) may be related to (perceptual disorders, alteration in cognitive functioning), environmental barrier (restraints), possibly evidenced by inability to meet own physical needs.

Hand-foot-mouth disease

PED/CH

Also refer to Meningitis, acute meningococcal *impaired oral Mucous Membrane Integrity* may be related to infection, dehydration, possibly evidenced by oral lesions, ulcers, pain, difficulty eating.

risk for Infection [transmission] possibly evidenced by insufficient knowledge to avoid exposure to pathogens, [inadequate acquired immunity].

risk for deficient Fluid Volume possibly evidenced by deviations affecting intake (oral ulcers and pain), increased fluid needs (hypermetabolic state, fever).

Hansen's disease

CH

impaired Skin/Tissue integrity may be related to immunodeficiency, impaired circulation, alteration in sensation and pigmentation; and [invasion of tissues by bacterial infection], possibly evidenced by alteration in skin integrity, destroyed tissue.

risk for Infection [spread/transmission] possibly evidenced by insufficient knowledge to avoid exposure to/early treatment of infectious bacterial [*Mycobacterium leprae*] agent.

impaired physical Mobility may be related to neuromuscular and sensoriperceptual impairments, possibly evidenced by muscular weakness, or numbness or absence of sensation in hands, arms, legs, feet.

disturbed Body Image may be related to alteration in self-perception (e.g., due to biophysical illness, trauma, actual change in structure, missing body part) possibly evidenced by verbalizations fear of reaction or rejection by others, preoccupation with change.

Hantavirus

MS

Refer to Hantavirus pulmonary syndrome

Hantavirus pulmonary syndrome

MS

Also refer to Disseminated intravascular coagulation *acute Pain/impaired Comfort* may be related to physical injury agent (inflammatory process, circulating toxins), possibly evidenced by reports of headache, myalgia, gastrointestinal distress, fever.

impaired Gas Exchange may be related to associated condition of alveolar-capillary membrane changes (fluid collection or shifts into interstitial space or alveoli), possibly evidenced by abnormal breathing pattern (dyspnea, abnormal rate or depth of respirations), restlessness, irritability, somnolence, confusion.

[*moderate to severe*] *Anxiety* may be related to threat to current status, threat of death, interpersonal transmission, possibly evidenced by expressed concerns, distressed, apprehensiveness, extraneous movement.

risk for impaired spontaneous Ventilation possibly evidenced by respiratory muscle fatigue, problems with secretion management.

Hashimoto's thyroiditis

CH

Refer to Hypothyroidism; Goiter

Hay fever

CH

impaired Comfort may be related to noxious environmental stimuli irritation or inflammation of upper airway mucous membranes and conjunctiva, possibly evidenced by distressing symptoms, irritability, itching, and restlessness.

deficient Knowledge regarding underlying cause, appropriate therapy, and required lifestyle changes may be related to lack of information, possibly evidenced by statements of concern, questions, and misconceptions.

Headache

CH/MS

Also refer to Temporal arteritis

acute/chronic Pain may be related to biological/physical injuring agents [tension, nerve irritation or pressure, vasospasm, increased intracranial pressure], possibly evidenced by verbal or coded reports, pallor, facial expression of pain, guarding or distraction behavior, restlessness, self-focused, changes in sleep pattern or appetite, preoccupation with pain.

risk for ineffective Coping possibly evidenced by (situational crisis), personal vulnerability, inadequate resources, insufficient sense of control, ineffective tension release, overwhelming threat to self.

deficient Knowledge regarding condition, prognosis, and treatment needs may be related to lack of exposure or recall, unfamiliarity with information or resources, cognitive limitations, possibly evidenced by request for information, statement of misconceptions, inaccurate follow-through of instructions, development of preventable complications.

Head injury

MS/CH

Refer to Traumatic brain injury

Heart attack

MS

Refer to Myocardial infarction

Heart failure, chronic

MS

decreased Cardiac Output may be related to altered myocardial contractility, inotropic changes; alterations in rate, rhythm, and electrical conduction; and structural changes (valvular defects, ventricular aneurysm), possibly evidenced by tachycardia, dysrhythmias, changes in blood pressure, extra heart sounds, decreased urine output, diminished peripheral pulses, cool and ashen skin, orthopnea, crackles; dependent or generalized edema and chest pain.

excess Fluid Volume may be related to reduced glomerular filtration rate, increased antidiuretic hormone production, and sodium/water retention, possibly evidenced by orthopnea and abnormal breath sounds, S₃ heart sound, jugular vein distention, positive hepatojugular reflex, weight gain, hypertension, oliguria, generalized edema.

risk for impaired Gas Exchange possibly evidenced by (alveolar-capillary membrane changes [fluid collection or shifts into interstitial space and alveoli]).

CH

Activity Intolerance may be related to imbalance between oxygen supply and demand, physical deconditioning, sedentary lifestyle, possibly evidenced by weakness, fatigue; changes in vital signs in response to activity (dysrhythmias; exertional dyspnea, pallor, diaphoresis).

risk for impaired Skin Integrity possibly evidenced by alteration in fluid volume, inadequate nutrition, pressure over bony prominences, [prolonged chair or bedrest] and (impaired circulation).

deficient Knowledge regarding cardiac function, disease process, therapy, and self-care needs may be related to lack of information, misinterpretation, possibly evidenced by questions, statements of concern or

misconceptions; development of preventable complications or exacerbations of condition.

Heart transplantation

MS/CH

Refer to Cardiac surgery; Transplantation, recipient

Heat exhaustion

CH/MS

deficient Fluid Volume may be related to excessive losses (profuse sweating), hypermetabolic state (core temperature 101°F to 105°F [38.3°C to 40.6°C]), lack of intake, extremes of age, possibly evidenced by weakness, fatigue, slow pulse, decreased blood pressure, changes in mentation.

Heatstroke

MS

Hyperthermia may be related to prolonged exposure to hot environment, vigorous activity with failure of regulating mechanism of the body, possibly evidenced by high body temperature (greater than 105°F [40.6°C]), flushed/hot skin, tachycardia, and seizure activity.

decreased Cardiac Output may be related to functional stress of hypermetabolic state, altered circulating volume and venous return, and direct myocardial damage secondary to hyperthermia, possibly evidenced by decreased peripheral pulses, dysrhythmias, tachycardia, and changes in mentation.

Hematoma, epidural

MS

acute Confusion may be related to (alteration in cognitive functioning), possibly evidenced by alteration in level of consciousness, agitation, restlessness, misperception.

risk for decreased intracranial Adaptive Capacity possibly evidenced by brain injury, decreased cerebral perfusion pressure, systemic hypotension with intracranial hypertension).

risk for ineffective Breathing Pattern possibly evidenced by (neuromuscular impairment [injury to respiratory center of brain]), abnormal breathing pattern.

risk for deficient Fluid Volume possibly evidenced by restricted oral intake, hypermetabolic state, loss of fluid through normal or abnormal routes.

Hematoma, subdural-acute

MS

Refer to Traumatic brain injury

Hematoma, subdural-chronic

CH

acute/chronic Pain may be related to physical agent (space-occupying clot), possibly evidenced by reports of increasing daily headache.

acute/chronic Confusion may be related to head injury, alcohol abuse, possibly evidenced by fluctuations in cognition, increased agitation, restlessness, misperceptions, inappropriate responses.

impaired physical Mobility may be related to neuromuscular impairment (hemiparesis), decreased muscle strength, cognitive impairment, possibly evidenced by limited ability to perform gross or fine motor skills, gait changes, postural instability.

Hemiplegia, spastic

PED/CH

Refer to Palsy, cerebral

Hemodialysis

MS/CH

Also refer to Dialysis, general

risk for Injury [loss of vascular access] possibly evidenced by clotting or thrombosis, infection, disconnection, hemorrhage.

risk for deficient Fluid Volume possibly evidenced by excessive fluid losses or shifts via ultrafiltration, fluid restrictions, altered coagulation, disconnection of shunt.

risk for excess Fluid Volume possibly evidenced by rapid or excessive fluid intake—IV, blood, plasma expanders, or saline given to support blood pressure during procedure.

ineffective Protection may be related to chronic disease state, drug therapy, abnormal blood profile, inadequate nutrition, possibly evidenced by altered clotting, impaired healing, deficient immunity, fatigue, anorexia.

Hemophilia

PED

risk for Bleeding/deficient Fluid Volume possibly evidenced by (inherent coagulopathy, trauma/[hemorrhagic losses]).

risk for acute/chronic Pain possibly evidenced by nerve compression from hematomas, nerve damage, or hemorrhage into joint space.

risk for impaired physical Mobility possibly evidenced by joint hemorrhage, swelling, degenerative changes, and muscle atrophy.

ineffective Protection may be related to abnormal blood profile, possibly evidenced by altered clotting.

compromised family Coping may be related to prolonged nature of condition that exhausts the supportive capacity of significant person(s), possibly evidenced by protective behaviors disproportionate to client's abilities or need for autonomy.

Hemorrhage, postpartum

OB

risk for Shock possibly evidenced by (hypovolemia, hypotension).

[moderate] Anxiety may be related to (situational crisis), threat to current status or of death, interpersonal transmission or contagion, possibly evidenced by increased in tension, apprehensiveness, feeling of inadequacy, helplessness, sympathetic stimulation, self-focused.

risk for Infection possibly evidenced by alteration in skin integrity/traumatized tissue, stasis of body fluids (lochia), and (decreased hemoglobin, invasive procedure).

risk for impaired Attachment possibly evidenced by interruption in bonding process, physical condition, perceived threat to own survival.

Hemorrhage, prenatal

OB

risk for Shock possibly evidenced by (hypovolemia, hypotension—ectopic or molar pregnancy, abruptio placentae).

risk for disturbed Maternal-Fetal Dyad possibly evidenced by (pregnancy complication, compromised fetal oxygen transport—hypovolemia).

Anxiety may be related to threat of death [self/fetus], possibly evidenced by apprehensiveness, fear, increase in tension, sympathetic stimulation.

acute Pain may be related to physical agent (muscle contractions/cervical dilation, tissue trauma) possibly evidenced by self report, distraction behavior, and change in blood pressure/pulse.

risk for imbalanced Fluid Volume possibly evidenced by (treatment regimen—excessive or rapid replacement of fluid losses).

Hemorrhagic fever, viral

MS

Refer to Ebola; Hantavirus pulmonary syndrome

Hemorrhoidectomy

MS/CH

acute Pain may be related to physical injury agent (edema, surgical tissue trauma), possibly evidenced by verbal reports, guarding or distraction behaviors, self-focused, and changes in vital signs.

risk for urinary Retention possibly evidenced by perineal trauma, edema or swelling, and pain.

deficient Knowledge regarding therapeutic treatment and potential complications may be related to lack of information, misconceptions, possibly evidenced by statements of concern and questions.

Hemorrhoids

CH/OB

acute Pain may be related to [inflammation and edema of prolapsed varices], possibly evidenced by verbal reports and guarding or distraction behaviors.

Constipation may be related to pain on defecation and reluctance to defecate, possibly evidenced by frequency, less than usual pattern, and hard, formed stools.

Hemothorax

MS

Also refer to Pneumothorax

risk for physical Trauma/Suffocation possibly evidenced by concurrent disease or injury process, dependence on external device (chest drainage system), and lack of safety education or precautions.

Anxiety [specify level] may be related to threat to current status and threat of death, possibly evidenced by increase in tension, restlessness, expressed concern, sympathetic stimulation, and self-focused.

Hepatitis, acute viral

MS/CH

impaired Liver Function related to (viral infection) as evidenced by jaundice, hepatic enlargement, abdominal pain, marked elevations in serum liver function tests.

Fatigue may be related to decreased metabolic energy production, discomfort, altered body chemistry—changes in liver function, effect on target organs, possibly evidenced by reports of lack of energy, inability to maintain usual routines, decreased performance, and increased physical complaints.

imbalanced Nutrition: less than body requirements may be related to inability to (ingest food or absorb nutrients); [hypermetabolic state], possibly evidenced by food aversion or insufficient interest in food, alteration in taste sensation, [observed lack of intake, and weight loss].

acute Pain/impaired Comfort may be related to biological agent—inflammation and swelling of the liver, arthralgias, urticarial eruptions, and pruritus, possibly evidenced by verbal reports, guarding or distraction behaviors, focus on self, and changes in vital signs.

risk for Infection possibly evidenced by immunosuppression, malnutrition, insufficient knowledge to avoid exposure to pathogens or spread to others.

risk for impaired Tissue Integrity possibly evidenced by [bile salt accumulation in the tissues].

deficient Knowledge regarding disease process and transmission, treatment needs, and future expectations may be related to lack of information or recall, misinterpretation, unfamiliarity with resources, possibly evidenced by questions, statement of concerns, misconceptions, inaccurate follow-through of instructions, and development of preventable complications.

Hepatorenal syndrome

MS

Refer to Cirrhosis; Renal failure, acute

Hernia, hiatal

CH

chronic Pain may be related to injury agent [regurgitation of acidic gastric contents], possibly evidenced by self-reports, alteration in sleep pattern, facial expression of pain, and self-focused.

deficient Knowledge regarding pathophysiology, prevention of complications, and self-care needs may be related to lack of information, misconceptions, possibly evidenced by statements of concern, questions, and recurrence of condition.

Hernia, inguinal

MS

Refer to Herniorrhaphy

Herniated nucleus pulposus (ruptured intervertebral disc)

CH/MS

acute/chronic Pain may be related to injury agent [nerve compression/irritation and muscle spasms], possibly evidenced by self-reports, guarding or distraction behavior, preoccupation with pain, self-focused, narrowed focus, changes in vital signs [when pain is acute], altered muscle tone or function, changes in eating or sleeping patterns and libido, and physical or social withdrawal.

impaired physical Mobility may be related to pain (muscle spasms), therapeutic restrictions (e.g., rest, braces, or traction), muscular impairment, and depressive mood state, possibly evidenced by reports of pain on movement, reluctance to attempt or difficulty with purposeful movement, decreased muscle strength, impaired coordination, and limited range of motion.

decreased Diversional Activity Engagement may be related to length of recuperation period and therapy restrictions, physical limitations, pain and depression, possibly evidenced by statements of boredom, disinterest, “nothing to do,” and restlessness, irritability, withdrawal.

Herniorrhaphy

MS/PED

acute Pain may be related to physical injury agent (surgical disruption of skin, tissue, and muscle integrity), possibly evidenced by verbal or coded reports, alteration in muscle tone, distraction or guarding behaviors, narrowed focus, and autonomic responses.

risk for Injury possibly evidenced by surgical repair, insertion of graft, increased intra-abdominal pressure (straining at stool, heavy lifting, strenuous activity).

Heroin abuse

CH

risk for Infection possibly evidenced by malnutrition, altered immune state, insufficient knowledge or motivation to avoid pathogens, and environmental exposure [injection, reuse, or sharing of needles].

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (economically disadvantaged, psychological disorder), possibly evidenced by [substituting drug for food], insufficient interest in food, weight loss, insufficient muscle tone.

risk for physical Trauma possibly evidenced by personal vulnerability, cigarette smoking, lack of safety precautions, driving impaired or under the influence, high-crime neighborhood.

risk for ineffective Protection possibly evidenced by effects of substance use, malnutrition, chronic disease, lifestyle choices, unhealthy environment.

Heroin withdrawal

CH/MS

acute Pain/impaired Comfort may be related to [cessation of drug, drug cravings] possibly evidenced by self-reports, tremors, twitching; hot and cold flashes, diaphoresis, lacrimation, rhinorrhea.

[*severe*] *Anxiety* may be related to central nervous system hyperactivity, possibly evidenced by apprehensiveness, pervasive anxious feelings, jittery, restlessness, weakness, insomnia, anorexia.

risk for ineffective Health Management possibly evidenced by protracted withdrawal, economic difficulties, family or social support deficits, perceived barriers or benefits.

Herpes simplex

CH

acute Pain may be related to physical injury agent (localized inflammation and open lesions), possibly evidenced by verbal reports, distraction behaviors, and restlessness.

risk for [secondary] Infection possibly evidenced by broken or traumatized tissue, altered immune response, and untreated infection or treatment failure.

risk for Sexual dysfunction possibly evidenced by vulnerability (e.g., lack of knowledge, values conflict, or fear of transmitting the disease).

Herpes zoster (shingles)

CH

acute Pain may be related to inflammation, local lesions along sensory nerve(s), possibly evidenced by verbal reports, guarding or distraction behaviors, narrowed focus, and changes in vital signs.

deficient Knowledge regarding pathophysiology, therapeutic needs, and potential complications may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, and misconceptions.

High altitude pulmonary edema (HAPE) MS

Also refer to Mountain sickness, acute *impaired Gas Exchange* may be related to (ventilation-perfusion imbalance and alveolar-capillary membrane changes), possibly evidenced by abnormal breathing (dyspnea) and skin color (cyanosis), confusion, tachycardia, abnormal arterial blood gases.

excess Fluid Volume may be related to compromised regulatory mechanism, possibly evidenced by shortness of breath, anxiety, edema, abnormal breath sounds, pulmonary congestion.

High altitude sickness

MS

Refer to Mountain sickness, acute; High altitude pulmonary edema

High-risk pregnancy

OB

Refer to Pregnancy, high-risk

Hip replacement

MS

Refer to Total joint replacement

HIV infection

CH

Also refer to AIDS

risk-prone Health Behavior may be related to stressors, low self-efficacy, social anxiety, insufficient social support; negative perception of recommended healthcare strategy, possibly evidenced by nonacceptance of or minimizes health status change, failure to take action that prevents health problem.

deficient Knowledge regarding disease, prognosis, and treatment needs may be related to lack of exposure or recall, information misinterpretation, unfamiliarity with information resources, or cognitive limitation, possibly evidenced by statement of misconception, request for information, inappropriate or exaggerated behaviors (hostile, agitated, hysterical, apathetic), inaccurate follow-through of instructions, development of preventable complications.

risk for ineffective Health Management possibly evidenced by difficulty navigating complex healthcare systems, economically disadvantaged; difficulty managing complex treatment regimen, perceived seriousness of condition, perceived benefit/barrier, decisional conflict.

risk for complicated Grieving possibly evidenced by emotional disturbance and insufficient social support.

Hodgkin's disease

CH/MS

Also refer to Cancer; Chemotherapy

Anxiety [specify level]/Fear may be related to self-concept and threat of death, possibly evidenced by apprehensiveness, insomnia, self-focused, and increase in tension.

deficient Knowledge regarding diagnosis, pathophysiology, treatment, and prognosis may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, and misconceptions.

acute Pain/impaired Comfort may be related to physical injury agents (inflammatory response [fever, chills, night sweats] and pruritus), possibly evidenced by self-reports, distraction behavior, and self-focused.

risk for ineffective Breathing Pattern/Airway Clearance possibly evidenced by tracheobronchial obstruction (enlarged mediastinal nodes or airway edema).

Hospice/End-of-life care

CH

acute/chronic Pain may be related to biological, physical, psychological agent; chronic physical disability, possibly evidenced by verbal or coded report, preoccupation with pain, changes in appetite, sleep pattern, altered ability to continue desired activities, guarded or protective behavior, restlessness, irritability, narrowed focus—altered time perception, impaired thought processes.

Activity Intolerance/Fatigue may be related to, [bedrest or immobility, pain, progressive disease state or debilitating condition, depressive state], imbalance between oxygen supply and demand, possibly evidenced by generalized weakness/inability to maintain usual routine, verbalized [lack of desire or interest in activity, decreased performance, lethargy].

Grieving/Death Anxiety may be related to (terminal illness, anticipated loss) perceived imminence of death, anticipation of pain/suffering, possibly evidenced by anger, blaming, despair, alteration in sleep pattern, fear of pain/suffering related to dying; powerlessness, worried about the impact of one's death on significant other.

compromised/disabled family Coping/caregiver Role Strain may be related to prolonged disease or disability progression, family disorganization, ineffective family adaptation, increase in care needs,

possibly evidenced by difficulty performing/completing required tasks, protective behavior by support person incongruent with client's abilities/need for autonomy, family conflict.

risk for Spiritual distress possibly evidenced by stressors ineffective relationships, loneliness, perception of having unfinished business; separation from support system, social isolation, inability to forgive.

risk for Moral Distress possibly evidenced by conflicting information available for moral decision making; difficulty reaching end-of-life decisions; conflict among decision-makers, cultural incongruence.

Huntington's disease

CH

Hopelessness may be related to chronic progressive debilitating condition, possibly evidenced by despondent verbalizations, withdrawal from environs, angry outbursts.

impaired Walking may be related to movement disorder (altered gait, ataxia, dystonia), possibly evidenced by inability to walk required distances, navigate curbs or uneven surfaces, climb stairs.

chronic Confusion may be related to dementia, possibly evidenced by altered interpretation, progressive cognitive impairment, altered personality, impaired memory, impaired socialization.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to ingest food [difficulty swallowing, cognitive decline]), possibly evidenced by food aversion, food intake less than recommended daily allowance, [weight loss, decreased subcutaneous fat or muscle mass].

[total] Self-Care deficit may be related to neuromuscular impairment, cognitive decline, possibly evidenced by inability to perform desired activities of daily living.

risk for caregiver Role Strain possibly evidenced by (chronic illness), unpredictably of illness trajectory, extended duration of caregiving activities, complexity care activities, caregiver's competing role commitments, family isolation, lack of respite or recreation for caregiver, bizarre behavior of care receiver.

Hydrocephalus

PED/MS

ineffective cerebral Tissue Perfusion may be related to decreased arterial or venous blood flow (compression of brain tissue), possibly evidenced by changes in mentation, restlessness, irritability, reports of headache, pupillary changes, and changes in vital signs.

[*disturbed visual Sensory Perception*] may be related to pressure on sensory or motor nerves, possibly evidenced by reports of double vision, development of strabismus, nystagmus, pupillary changes, and optic atrophy.

risk for impaired physical Mobility possibly evidenced by neuromuscular impairment, decreased muscle strength, and impaired coordination.

risk for decreased intracranial Adaptive Capacity possibly evidenced by brain injury, changes in perfusion pressure and intracranial pressure.

CH

risk for Infection possibly evidenced by (invasive procedure—presence of shunt).

deficient Knowledge regarding condition, prognosis, long-term therapy needs, and medical follow-up may be related to lack of information, misperceptions, possibly evidenced by questions, statement of concern, request for information, and inaccurate follow-through of instructions, development of preventable complications.

Hydrophobia

Refer to Rabies

CH/MS

Hyperactivity disorder

PED/PSY

ineffective Impulse Control may be related to compunction, possibly evidenced by acting without thinking, temper outbursts.

defensive Coping may be related to mild neurological deficits, dysfunctional family system, abuse or neglect, possibly evidenced by denial of obvious problems, projection of blame or responsibility, grandiosity, difficulty in reality testing perceptions.

impaired Social Interaction may be related to disturbance in thought processes, sociocultural dissonance, possibly evidenced by discomfort in social situations, dysfunctional interaction with others.

compromised family Coping may be related to insufficient understanding of information by support person, exhaustion of support person's capacity, family disorganization, possibly evidenced by assistive behaviors by support person produce unsatisfactory results, support person reports inadequate understanding that interferes with effective behaviors, limitation between support person and client.

Hyperbilirubinemia

PED

neonatal Hyperbilirubinemia may be related to (premature infant, age ≤ 7 days, populations living at high

altitude, blood type incompatibility between mother and infant), deficient feeding pattern, delay in meconium passage, possibly evidenced by abnormal blood profile (elevated blood urea nitrogen), yellow-orange skin color, and yellow mucous membranes/sclera.

risk for Injury [effects of treatment] possibly evidenced by physical properties of phototherapy and effects on body regulatory mechanisms, invasive procedure (exchange transfusion), abnormal blood profile, chemical imbalances.

deficient Knowledge regarding condition prognosis, treatment, and safety needs may be related to lack of exposure or recall and information misinterpretation, possibly evidenced by questions, statement of concern, and inaccurate follow-through of instructions, development of preventable complications.

Hyperemesis gravidarum

OB

deficient Fluid Volume may be related to excessive gastric losses and reduced intake, possibly evidenced by dry mucous membranes, decreased and concentrated urine, decreased pulse volume and pressure, thirst, and hemoconcentration.

risk for Electrolyte Imbalance possibly evidenced by vomiting, dehydration.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to ingest or digest food, or absorb nutrients), possibly evidenced by food intake less than recommended daily allowance, insufficient interest in food or food aversion, and [weight loss].

risk for ineffective Coping possibly evidenced by (situational or maturational crisis [pregnancy, change in health status, projected role changes, concern about outcome]).

Hyperparathyroidism, primary

MS

risk for deficient Fluid Volume possibly evidenced by excessive losses through normal routes (vomiting, diarrhea, gastric bleed).

risk for Electrolyte Imbalance possibly evidenced by impaired regulatory mechanism, vomiting.

impaired urinary Elimination may be related to anatomic obstruction (renal calculi), possibly evidenced by decreased renal function.

risk for physical Trauma possibly evidenced by decreased calcium levels, bone fragility.

Hypertension

CH

deficient Knowledge regarding condition, therapeutic regimen, and potential complications may be related

to lack of information or recall, misinterpretation, cognitive limitations, or denial of diagnosis, possibly evidenced by statements of concern, questions, and misconceptions, inaccurate follow-through of instructions, and lack of blood pressure control.

risk-prone Health Behavior may be related to inadequate comprehension, low self-efficacy, negative perception of recommended healthcare strategy, (economically disadvantaged), possibly evidenced by minimizes/nonacceptance of health status change, failure to take action that prevents health problem.

risk for Activity Intolerance possibly evidenced by imbalance between oxygen supply and demand and physical deconditioning.

risk for Sexual dysfunction possibly evidenced by vulnerability (side effects of medications).

MS

risk for decreased Cardiac Output possibly evidenced by increased afterload (vasoconstriction), fluid shifts, hypovolemia, myocardial ischemia, ventricular hypertrophy and rigidity.

Hypertension, gestational

OB/CH

Also refer to Eclampsia

deficient Fluid Volume may be related to (compromised regulatory mechanisms [e.g., plasma protein loss, decreasing osmotic pressure]), possibly evidenced by increase in hematocrit, decrease in urine output, increase in urine concentration, sudden weight gain [edema, third spacing].

decreased Cardiac Output may be related to alteration in preload, afterload, possibly evidenced by preload—increase in hemodynamic readings, weight gain/edema, afterload—alteration in blood pressure, dyspnea.

risk for disturbed Maternal-Fetal Dyad possibly evidenced by pregnancy complication [e.g., compromised oxygen transport—vasospasm of spiral arteries, and maternal hypovolemia, hypertension].

deficient Knowledge regarding pathophysiology of condition, therapy, self-care, nutritional needs, and potential complications may be related to lack of information or recall, misinterpretation, possibly evidenced by statements of concern, questions, misconceptions, inaccurate follow-through of instructions, development of preventable complications.

Hypertension, intrapartum

OB

risk for imbalanced Fluid Volume possibly evidenced by compromised regulatory mechanism, fluid shifts,

excessive fluid intake, effects of drug therapy (oxytocin infusion).

risk for impaired fetal Gas Exchange possibly evidenced by altered blood flow, vasospasms, prolonged uterine contractions.

impaired urinary Elimination may be related to fluid shifts, hormonal changes, effects of medication, possibly evidenced by changes in amount and frequency of voiding, bladder distention, changes in urine specific gravity, presence of albumin.

risk for maternal Injury possibly evidenced by tonic-clonic convulsions, altered clotting factors (release of thromboplastin from placenta).

Hypertension, prenatal

OB

Refer to Hypertension, gestational

Hypertension, pulmonary

CH/MS

Refer to Pulmonary hypertension

Hyperthyroidism

CH

Also refer to Thyrotoxicosis

Fatigue may be related to hypermetabolic imbalance with increased energy requirements, irritability of central nervous system, and altered body chemistry, possibly evidenced by verbalization of overwhelming lack of energy to maintain usual routine, decreased performance, emotional lability and irritability, and impaired ability to concentrate.

Anxiety [specify level] may be related to stressors (e.g., hypermetabolic state, pseudocatecholamine effect of thyroid hormones), possibly evidenced by increased feelings of apprehension, overexcitement, or distress; irritability; emotional lability; shakiness; restless movements; tremors.

risk for imbalanced Nutrition: less than body requirements possibly evidenced by inability to ingest adequate food for [hypermetabolic rate, constant activity level, impaired absorption of nutrients (vomiting, diarrhea), hyperglycemia, relative insulin insufficiency].

risk for Dry Eye possibly evidenced by autoimmune diseases (thyroid disease), lack of spontaneous blink reflex, ocular surface damage.

Hypervolemia

CH/MS

excess Fluid Volume may be related to excess fluid and sodium intake, compromised regulatory mechanisms (renal failure, increased antidiuretic hormone), decreased plasma proteins, rapid or excessive administration of isotonic parenteral fluids, possibly evidenced by edema,

abnormal breath sounds, S₃ heart sound, shortness of breath, positive hepatjugular reflex—elevated central venous pressure, change in mental status.

Hypochondriasis

PSY

Refer to Somatoform disorders

Hypoglycemia

CH

acute Confusion may be related to (impaired metabolic functioning), possibly evidenced by restlessness, misperception, alteration in cognitive functioning/level of consciousness.

risk for unstable Blood Glucose Level possibly evidenced by insufficient diabetes management, inadequate blood glucose monitoring, ineffective medication management.

deficient Knowledge regarding pathophysiology of condition, therapy, and self-care needs may be related to lack of information or recall, misinterpretations, possibly evidenced by development of hypoglycemia and statements of questions, misconceptions.

Hypoparathyroidism (acute)

MS

risk for Electrolyte Imbalance possibly evidenced by impaired regulatory mechanism.

risk for Injury possibly evidenced by neuromuscular excitability—tetany and formation of renal stones.

acute Pain may be related to physical agent [recurrent muscle spasms], possibly evidenced by verbal reports, distraction behaviors, and narrowed focus.

risk for ineffective Airway Clearance possibly evidenced by spasm of the laryngeal muscles.

Anxiety [specify level] may be related to threat to current status, physiological responses.

Hypophysectomy

MS

Also refer to Surgery, general; Cancer

Fear/Anxiety may be related learned response to threat [situational crisis (nature of diagnosis and procedure), change in health status, perceived threat of death, separation from support system], possibly evidenced by expressed concerns, apprehension, being scared, increased tension, extraneous movement, difficulty concentrating.

risk for deficient Fluid Volume possibly evidenced by failure of regulatory mechanism (decreased antidiuretic hormone).

risk for Infection possibly evidenced by (invasive procedure, immunosuppression, chronic illness).

Sexual dysfunction may be related to altered body function (loss of anterior pituitary), possibly evidenced by [sterility, decreased libido, impotence (male), infertility, atrophy of vaginal mucosa (female)].

Hypothermia (systemic)

CH

Also refer to Frostbite

Hypothermia may be related to exposure to cold environment, inadequate clothing, age extremes (very young or elderly), damage to hypothalamus, consumption of alcohol or medications causing vasodilation, possibly evidenced by reduction in body temperature below normal range, shivering, cool skin, pallor.

deficient Knowledge regarding risk factors, treatment needs, and prognosis may be related to lack of information or recall, misinterpretation, possibly evidenced by statement of concerns, misconceptions, occurrence of problem, and development of complications.

Hypothyroidism

CH

Also refer to Myxedema

Fatigue may be related to decreased metabolic energy production, possibly evidenced by verbalization of unremitting or overwhelming lack of energy, inability to maintain usual routines, impaired ability to concentrate, decreased libido, irritability, listlessness, decreased performance, increase in physical complaints.

Constipation may be related to decreased peristalsis, lack of physical activity, possibly evidenced by frequency less than usual pattern, decreased bowel sounds, hard dry stools, and development of fecal impaction.

impaired physical Mobility may be related to weakness, fatigue, muscle aches, altered reflexes, and mucin deposits in joints and interstitial spaces, possibly evidenced by decreased muscle strength or control and impaired coordination.

[disturbed Sensory Perception (specify)] may be related to mucin deposits and nerve compression, possibly evidenced by paresthesias of hands and feet or decreased hearing.

Hypovolemia

CH/MS

deficient Fluid Volume may be related to active fluid loss (hemorrhage, vomiting, gastric intubation, diarrhea, burns, wounds, fistulas), regulatory failure (adrenal disease, recovery phase of acute renal failure, diabetic ketoacidosis, hyperosmolar nonketotic coma,

diabetes insipidus, sepsis), possibly evidenced by thirst, weight loss, poor skin turgor, dry mucous membranes, tachycardia, tachypnea, fatigue, decreased central venous pressure.

Hysterectomy

GYN/MS

Also refer to Surgery, general

acute Pain may be related to physical injury agent (tissue trauma, abdominal incision), possibly evidenced by verbal reports, guarding or distraction behaviors, and changes in vital signs.

risk for perioperative positioning Injury possibly evidenced by immobilization, lithotomy position.

impaired urinary Elimination/risk for [acute] urinary Retention possibly evidenced by mechanical trauma, surgical manipulation, presence of localized edema or hematoma, or nerve trauma with temporary bladder atony.

risk for Sexual dysfunction possibly evidenced by (altered body function and structure), vulnerability [perceived changes in femininity], decrease in sexual desire, and alteration in sexual excitation/satisfaction.

Ileal conduit

MS/CH

Refer to Urinary diversion

Ileocolitis

MS/CH

Refer to Crohn's disease

Ileostomy

MS/CH

Refer to Colostomy

Ileus

MS

acute Pain may be related to physical injury agent: (ischemia of intestinal tissue), possibly evidenced by verbal reports, guarding/distraction behaviors, narrowed focus, and changes in vital signs.

Diarrhea/Constipation may be related to presence of obstruction, changes in peristalsis, possibly evidenced by changes in frequency and consistency or absence of stool, alterations in bowel sounds, presence of pain, and cramping.

risk for deficient Fluid Volume possibly evidenced by risk factors of increased intestinal losses (vomiting, diarrhea) and decreased intake.

Immersion foot

MS

impaired Skin/Tissue Integrity may be related to hypothermia and moisture (cold and wet environment [above freezing], possibly evidenced by acute pain, [tissue maceration, soggy edema]).

[disturbed peripheral Sensory Perception] may be related to altered sensory reception, possibly evidenced by paresthesia, numbness.

risk for ineffective Health Maintenance possibly evidenced by lack of material resources, poor coping skills, inadequate knowledge of safety needs.

Impetigo

PED/CH

impaired Skin Integrity may be related to presence of [infectious process and pruritus], possibly evidenced by open, crusted lesions.

acute Pain may be related to physical agent (inflammation), possibly evidenced by verbal reports, distraction behavior, and self-focused.

risk for [secondary] Infection possibly evidenced by broken skin, traumatized tissue, altered immune response, and virulence or contagious nature of causative organism.

risk for Infection [transmission] possibly evidenced by insufficient knowledge to prevent infection of others.

Impotence

CH

Refer to Erectile dysfunction

Infant (at 4 weeks)

PED

readiness for enhanced Knowledge regarding infant care, developmental expectations, safety, and well-being possibly evidenced by expresses desire to enhance learning.

risk for imbalanced Nutrition (specify) possibly evidenced by inability to ingest, digest, or absorb adequate calories—insufficient intake, malabsorption, congenital problem, neglect or emotional abuse, or failure to thrive; obesity in one or both parents, rapid transition across growth percentiles.

risk for acute Pain possibly evidenced by [accumulation of gas in confined space with cramping of intestinal musculature].

risk for Infection possibly evidenced by [immature immunological response, increased environmental exposure].

risk for Sudden Infant Death possibly evidenced by sleeping position, secondhand smoke exposure, type of bedding used.

risk for disorganized infant Behavior possibly evidenced by immature development of sensory organs, inappropriate or inadequate environmental stimuli, effects of prenatal or intrapartum complications, drugs.

Infant of addicted mother

OB/PED

Neonatal Abstinence Syndrome may be related to (in-utero substance exposure secondary to maternal substance use), possibly evidenced by disorganized infant behavior, ineffective infant feeding pattern, impaired skin integrity, risk for impaired attachment.

ineffective Airway Clearance/impaired Gas Exchange may be related to [excess mucus production, depression of cough reflex and respiratory center, intrauterine asphyxia], possibly evidenced by abnormal breathing pattern (tachypnea, grunting respirations) and skin color (cyanosis), nasal flaring, hypoxia, acidosis.

impaired Parenting may be related to lack of available or ineffective role model, unmet emotional maturation needs of parent, lack of support between or from SO, interruption in bonding process, lack of appropriate response of infant, possibly evidenced by reports of role inadequacy or inability to care for infant, inattention to infant needs, inappropriate caretaking behaviors, lack of parental attachment behaviors.

disabled family Coping may be related to SO with chronically unexpressed feelings of guilt, anxiety, hostility, despair; dissonant discrepancy of coping styles; high-risk family situations, possibly evidenced by intolerance, rejection, abandonment, or desertion, neglectful relationships between family members, neglectful care of infant, distortion of reality of parent's health problem or substance use.

Infant of HIV-positive mother

OB/PED

Also refer to AIDS

risk for Infection possibly evidenced by [immature immune system, inadequate acquired immunity], (suppressed inflammatory response, invasive procedures), malnutrition.

risk for imbalanced Nutrition: risk for less than body requirements possibly evidenced by (inability to ingest, digest, or absorb nutrients [e.g., impaired suck or swallow, gastrointestinal infection, malabsorption, diarrhea]).

risk for delayed Development possibly evidenced by separation from SO, inadequate caretaking, inconsistent responsiveness, multiple caretakers, environmental and stimulation deficiencies, effects of chronic condition or disabilities.

deficient Knowledge regarding condition, prognosis, and treatment needs may be related to lack of exposure, misinterpretation, unfamiliarity with resources, lack of recall or interest in learning, possibly

evidenced by questions, statements of misconceptions, inaccurate follow-through of instructions, development of preventable complications.

Infection, ear

PED

Refer to Otitis media

Infection, prenatal

OB

Also refer to AIDS

risk for disturbed Maternal-Fetal Dyad possibly evidenced by inadequate prenatal care, (pregnancy complication-rupture of amniotic membranes, treatment-related side effects).

deficient Knowledge regarding treatment, prevention, and prognosis of condition may be related to lack of exposure to information or unfamiliarity with resources, misinterpretation, possibly evidenced by verbalization of problem, inaccurate follow-through of instructions, development of preventable complications, continuation of infectious process.

impaired Comfort may be related to body response to infective agent, properties of infection (e.g., skin or tissue irritation, development of lesions), possibly evidenced by verbal reports, illness-related symptoms, restlessness, withdrawal from social contacts.

Infection, puerperal

OB/CH

risk for Infection [spread/sepsis] possibly evidenced by alteration in skin integrity/traumatized tissues, (invasive procedures/increased environmental exposure, anemia, chronic disease).

acute Pain may be related to physical injury agent (infective agent and toxins), possibly evidenced by verbalizations, restlessness, guarding behavior, self-focusing, and changes in vital signs.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, possibly evidenced by food aversion, insufficient or lack of oral intake, [unanticipated weight loss].

risk for impaired Attachment possibly evidenced by interruption in bonding process, separation, physical barriers, maternal fatigue or apathy.

Infection, wound

MS/CH

risk for Surgical Site Infection/Infection [sepsis] possibly evidenced by presence of infection, broken skin, or traumatized tissues, stasis of body fluids, invasive procedures, increased environmental exposure, chronic disease (e.g., diabetes, anemia, malnutrition), altered immune response, and untoward effect of medications (e.g., opportunistic or secondary infection).

impaired Skin/Tissue Integrity may be related to alteration in fluid volume (circulation) inadequate nutrition; and [presence of systemic or local infection, wound drainage], possibly evidenced by [delayed healing, damaged tissues, invasion of body structures].

risk for delayed Surgical Recovery possibly evidenced by presence of infection, activity restrictions or limitations, nutritional deficiency.

Infertility

CH

situational low Self-Esteem may be related to functional impairment (inability to conceive), unrealistic self-expectations, sense of failure, possibly evidenced by self-negating verbalizations, expressions of helplessness, perceived inability to deal with situation.

chronic Sorrow may be related to perceived physical disability (inability to conceive), possibly evidenced by expressions of anger, disappointment, emptiness, self-blame, helplessness, sadness, feelings interfering with client's ability to achieve maximum well-being.

risk for Spiritual distress possibly evidenced by anxiety, ineffective relationships, pain, separation from support system, social isolation, anxiety, low self-esteem, [deteriorating relationship with SO, viewing situation as deserved or punishment for past behaviors].

Inflammatory bowel disease

CH

Refer to Colitis, ulcerative; Crohn's disease

Influenza

CH

acute Pain/impaired Comfort may be related to physical injury agent (inflammation, circulating toxins), possibly evidenced by verbal reports, distraction behaviors, and narrowed focus.

risk for deficient Fluid Volume possibly evidenced by excessive gastric losses, hypermetabolic state, and altered intake.

Hyperthermia may be related to effects of circulating toxins and dehydration, possibly evidenced by increased body temperature; warm, flushed skin; and tachycardia.

risk for ineffective Breathing Pattern possibly evidenced by response to infectious process, decreased energy, fatigue.

Inhalant intoxication/abuse

CH/PSY

Refer to Stimulant abuse

Insomnia, acute

CH

Insomnia may be related to daytime activity pattern, social or work schedule inconsistent with chronotype,

travel across time zones, fatigue, life change, physical conditions (dyspnea, gastroesophageal reflux, night sweats), possibly evidenced by verbal reports of difficulties, not feeling well-rested, less than age-normed total sleep time, changes in behavior and performance, physical signs (dark circles under eyes, frequent yawning).

Insomnia, chronic

CH

Sleep deprivation may be related to sustained environmental stimulation, sustained circadian asynchrony, prolonged use of pharmacological or dietary antisoporifics, prolonged pain, sleep apnea, dementia, narcolepsy, possibly evidenced by daytime drowsiness, decreased ability to perform, lethargy, slowed reaction, apathy.

Insulin resistance syndrome

CH

Refer to Metabolic syndrome

Insulin shock

MS/CH

Refer to Hypoglycemia

Intermaxillary fixation

MS/CH

Also refer to Surgery, general

risk for ineffective Airway Clearance possibly evidenced by soft tissue trauma, retained secretions.

risk for Aspiration possibly evidenced by (facial trauma or oral surgery, wired jaw), ineffective cough.

impaired Tissue Integrity may be related to tissue trauma or damage, intraoperative manipulation, mechanical fixation device, altered circulation, nutritional deficit, possibly evidenced by edema, hematoma, ecchymosis, erythema, inflammation, delayed healing.

impaired verbal Communication may be related to wiring of jaws, edema of mouth and surrounding structures, pain, possibly evidenced by inability or reluctance to talk.

risk for imbalanced Nutrition: less than body requirements possibly evidenced by inability to ingest food, weakness of muscles required for mastication/swallowing, insufficient interest in food.

Intervertebral disc excision

MS

Refer to Laminectomy, cervical or lumbar

Intestinal obstruction

MS

Refer to Ileus

Intestinal surgery (without diversion)

MS

Also refer to Surgery, general

risk for deficient Fluid Volume possibly evidenced by excessive losses through normal routes (vomiting,

diarrhea), excessive losses through abnormal routes (indwelling drains, nasogastric/intestinal suctioning, hemorrhage), insufficient replacement, fever.

risk for Infection possibly evidenced by (chronic disease), malnutrition, stasis of body fluids, altered peristalsis, and [opening of abdominal cavity and bowel].

Constipation/Diarrhea may be related to effects of anesthesia, surgical manipulation, decreased dietary intake or bulk, physical inactivity, irritation, malabsorption, pain, effects of medication, possibly evidenced by change in bowel habits, change in stool characteristics, hyper-/hypoactive bowel sounds, abdominal pain.

Intracranial infections

MS

Refer to Abscess, brain [acute]; Encephalitis; Meningitis, acute meningococcal

Irritable bowel syndrome

CH

acute Pain may be related to physical injury agent (increased sensitivity of intestine to distention, hypersensitivity to hormones gastrin and cholecystokinin, skin or tissue irritation, perirectal excoriation), possibly evidenced by verbal reports, guarding behavior, expressive behavior (restlessness, moaning, irritability).

Constipation may be related to motor abnormalities of longitudinal muscles, changes in frequency and amplitude of contractions, dietary restrictions, stress, possibly evidenced by change in bowel pattern—decreased frequency, sensation of incomplete evacuation, abdominal pain and distention.

Diarrhea may be related to motor abnormalities of longitudinal muscles, changes in frequency and amplitude of contractions, stress, possibly evidenced by precipitous passing of liquid stool on rising or immediately after eating, rectal urgency, incontinence, bloating.

Kanner's syndrome

PED/PSY

Refer to Autistic spectrum disorder

Kaposi's sarcoma, AIDS-related

CH/MS

Also refer to Chemotherapy

disturbed Body Image may be related to actual change in structure, (e.g., widely disseminated lesions of varied color in skin and mucous membranes), possibly evidenced by verbalizations, fear of rejection or reaction of others, negative feelings about body, hiding body parts, change in social involvement.

risk for deficient Fluid Volume possibly evidenced by extensive bleeding of visceral lesions.

Kawasaki disease

PED

Hyperthermia may be related to increased metabolic rate and dehydration, possibly evidenced by increased body temperature greater than normal range, flushed skin, increased respiratory rate, and tachycardia.

acute Pain may be related to physical injury agent (inflammation of blood vessels, and swelling of tissues) possibly evidenced by verbal reports, restlessness, guarding behaviors, and narrowed focus.

impaired Skin Integrity may be related to [inflammatory process], and alteration in fluid volume [edema formation], (impaired circulation), possibly evidenced by alteration in skin integrity (macular rash and desquamation).

impaired oral Mucous Membrane Integrity may be related to inflammatory process, dehydration, and mouth breathing, possibly evidenced by pain, hyperemia, and fissures of lips.

risk for decreased Cardiac Output possibly evidenced by structural changes and inflammation of coronary arteries, and alterations in rate and rhythm or conduction.

Ketoacidosis

CH

Refer to Diabetic ketoacidosis

Kidney disease, polycystic

CH

risk for [urinary tract] Infection possibly evidenced by inadequate primary defenses (traumatized tissue, stasis of body fluids), inadequate secondary defenses (suppressed inflammatory response), chronic disease.

acute/chronic Pain may be related to injuring agents—presence of cysts in kidneys or other organs, possibly evidenced by verbal report of back or lower side pain, headaches beyond tolerance, guarded or protective behavior, narrowed focus, sleep disturbance, distraction behaviors.

risk for excess Fluid Volume possibly evidenced by oliguria, edema, abnormal breath sounds, jugular vein distention, hypertension.

Kidney failure, acute

MS

Refer to Renal failure, acute

Kidney failure, chronic

CH/MS

Refer to Renal failure, chronic

Kidney stone(s)

CH

Refer to Calculi, urinary

Knee replacement

MS

Refer to Total joint replacement

Kwashiorkor**PED**

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake (economically disadvantaged), possibly evidenced by food intake less than recommended daily allowances, body weight 20% or more below ideal weight range, insufficient muscle tone, [decreased subcutaneous fat or muscle mass, abnormal laboratory studies].

risk for Infection possibly evidenced by malnutrition.

risk for disproportionate Growth possibly evidenced by malnutrition, caregiver maladaptive feeding behaviors, deprivation, poverty, impaired insulin response, infection.

Labor, breech presentation**OB**

Anxiety [specify level] may be related to situational crisis, threat to self/fetus, interpersonal transmission, possibly evidenced by increased tension, apprehension, fearfulness, restlessness, sympathetic stimulation.

risk for fetal Injury possibly evidenced by risk factors of entrapment of head, stretching of brachial plexus or spinal cord (nerve damage), hypoxia (brain damage).

Labor, dysfunctional**OB**

Refer to Dystocia

Labor, induced/augmented**OB**

deficient Knowledge regarding procedure, treatment needs, and possible outcomes may be related to lack of exposure or recall, information misinterpretation, and unfamiliarity with information resources, possibly evidenced by questions, statement of concern, misconception, and exaggerated behaviors.

risk for maternal Injury possibly evidenced by physical factor [e.g., adverse effects or response to therapeutic interventions].

risk for disturbed Maternal-Fetal Dyad possibly evidenced by (compromised fetal oxygen transport [e.g., altered placental perfusion, cord prolapse]).

labor Pain may be related to physical agent [e.g., characteristics of chemically stimulated contractions], cervical dilation, possibly evidenced by verbal reports, alteration in muscle tension, distraction or expressive behavior, and narrowed focus.

Labor, precipitous**OB**

Anxiety [specify level] may be related to (situational crisis), threat to current status [self/fetus], interpersonal transmission, possibly evidenced by increase in

tension; apprehensiveness, uncertainty, fear, restless, sympathetic stimulation.

risk for impaired Skin/Tissue Integrity possibly evidenced by [mechanical factors (e.g., pressure, shearing forces)].

labor Pain may be related to physical agent [e.g., rapid, strong uterine contractions], cervical dilation, fetal expulsion; psychological factors (anxiety), possibly evidenced by pain, sympathetic stimulation, expressive behavior (e.g., moaning, restlessness), self-focused.

Labor, preterm**OB/CH**

risk for disturbed Maternal-Fetal Dyad possibly evidenced by (compromised fetal oxygen transport, treatment regimen [side effects of tocolytics]).

risk for Poisoning possibly evidenced by dose-related toxic or side effects of tocolytics.

risk for fetal Injury possibly evidenced by (tissue hypoxia; chemical [e.g., pharmaceutical agents]).

Anxiety [specify level] may be related to (situational crisis), threat to change in current status [self/fetus], and interpersonal transmission, possibly evidenced by increase in tension, apprehensiveness, distress, uncertainty, restlessness, and changes in vital signs.

readiness for enhanced Knowledge regarding preterm labor treatment needs and prognosis possibly evidenced by expresses desire to enhance learning.

Labor, stage I (active phase)**OB**

labor Pain may be related to physical agent [e.g., tissue dilation, muscle hypoxia, and pressure on adjacent structures and nerve endings], possibly evidenced by uterine contraction, expressive behavior (restlessness), and narrowed focus, positioning to ease pain, alteration in vital signs.

impaired urinary Elimination may be related to multiple causality [e.g., altered intake, fluid shifts, hormonal changes, mechanical compression of bladder, and effects of regional anesthesia], possibly evidenced by frequent voiding, urinary urgency, urinary retention.

risk for ineffective [individual/couple] Coping possibly evidenced by (situational crises), uncertainty, inadequate confidence in ability to deal with situation, inability to conserve adaptive energies.

Labor, stage I (latent phase)**OB**

readiness for enhanced Childbearing Process possibly evidenced by expresses desire to enhance proactivity during labor and delivery.

risk for [mild] Anxiety possibly evidenced by (situational crisis), unmet needs, stressors, interpersonal transmission.

risk for ineffective Coping possibly evidenced by (situational crisis), insufficient sense of control, inadequate confidence in ability to deal with situation.

Labor, stage I (transition phase)

OB

labor Pain may be related to physical agent (e.g., mechanical pressure of presenting part, tissue dilation/stretching and tissue hypoxia, possibly evidenced by uterine contraction pain, expressive behavior, narrowed focus, changes in vital signs).

Fatigue may be related to (pregnancy), stressors, anxiety, increased physical exertion, possibly evidenced by lack of energy, compromised concentration, lethargy, increase in physical complaints.

risk for imbalanced Fluid Volume possibly evidenced by [reduced intake, excess fluid loss/hemorrhage, excess fluid retention], (treatment regimen—rapid fluid administration).

risk for decreased Cardiac Output possibly evidenced by (alteration in preload [e.g., decreased venous return, hypovolemia, changes in systemic vascular resistance]).

Labor, stage II (expulsion)

OB

labor Pain may be related to physical agents [e.g., pressure of presenting part, tissue stretching/dilation, and muscle hypoxia], possibly evidenced by uterine contraction, perineal pressure, facial expression of pain, expressive behavior (e.g., restlessness), narrowed focus, changes in vital signs, and autonomic responses (diaphoresis).

risk for decreased Cardiac Output possibly evidenced by (altered preload [e.g., fluctuations in venous return], altered afterload, altered heart rate).

risk for disturbed Maternal-Fetal Dyad possibly evidenced by (compromised fetal oxygen transport [e.g., mechanical compression of head or cord, prolonged labor, reduced placental perfusion, and maternal hyperventilation]).

risk for impaired Skin/Tissue Integrity possibly evidenced by mechanical factors—pressure, precipitous labor, large fetus, and application of forceps.

Fatigue may be related to stressors, sleep deprivation, increase in physical exertion, possibly evidenced by insufficient energy, tiredness.

Labor, stage III (placental expulsion)

OB

labor Pain may be related to physical agent [e.g., tissue trauma, physiological response following delivery],

possibly evidenced by pain, expressive behavior, uterine contraction.

risk for deficient Fluid Volume/Bleeding possibly evidenced by insufficient fluid intake, (excessive losses through normal routes [e.g., vomiting, diaphoresis, increased insensible water loss], pregnancy complication [e.g., uterine atony, lacerations of the birth canal, retained placental fragments]).

risk for maternal Injury possibly evidenced by physical factors [e.g., positioning during delivery and transfers], abnormal blood profile, exposure to pathogens.

readiness for enhanced Childbearing Process possibly evidenced by expresses desire to enhance: pro-activity during labor and delivery, attachment behavior.

Labor, stage IV (first 4 hr following delivery of placenta)

OB

Fatigue may be related to increased physical exertion, sleep deprivation, stressors, environmental stimuli, [hormonal changes], possibly evidenced by insufficient energy, alteration in concentration, lethargy/tiredness.

acute Pain may be related to chemical agent [e.g., effects of hormones and medications], physical factor [e.g., mechanical trauma, tissue edema, exhaustion, edema], psychological factor [anxiety], possibly evidenced by reports of self-report of pain, cramping (after-pains), expressive behavior, facial expression of pain.

risk for deficient Fluid Volume possibly evidenced by insufficient fluid intake, insufficient knowledge about fluid needs, (active fluid volume loss [e.g., myometrial fatigue, continued uteroplacental circulation, incomplete vasoconstriction], failure of regulatory mechanism [e.g., effects of pregnancy-induced hypertension]).

readiness for enhanced Childbearing Process possibly evidenced by expresses desire to enhance: attachment behavior, baby feeding techniques.

Laceration

CH

impaired Skin/Tissue Integrity may be related to [trauma], possibly evidenced by alteration in skin integrity, [invasion of body structures].

risk for Infection possibly evidenced by [trauma, tissue destruction, increased environmental exposure].

Laminectomy, cervical

MS

Also refer to Laminectomy, lumbar

risk for perioperative Positioning Injury possibly evidenced by immobilization, muscle weakness, obesity, advanced age.

risk for ineffective Airway Clearance possibly evidenced by retained secretions, pain, muscular weakness.

risk for impaired Swallowing possibly evidenced by (trauma [operative edema, pain], neuromuscular impairment).

Laminectomy, lumbar

MS

Also refer to Surgery, general

risk for ineffective Tissue Perfusion (specify) possibly evidenced by diminished or interrupted blood flow—pressure dressing, edema of operative site, hematoma formation; hypovolemia.

risk for [spinal] Trauma possibly evidenced by temporary weakness of spinal column, balancing difficulties, changes in muscle tone and coordination.

acute Pain may be related to physical injury agent (surgical manipulation, harvesting bone graft; localized inflammation, edema), possibly evidenced by altered muscle tone, verbal reports, distraction or guarding behaviors, autonomic changes—changes in vital signs, diaphoresis, pallor.

impaired physical Mobility may be related to imposed therapeutic restrictions, neuromuscular impairment, and pain, possibly evidenced by limited range of motion, decreased muscle strength and control, impaired coordination, and reluctance to attempt movement.

risk for [acute] urinary Retention possibly evidenced by reduced mobility, restrictions of position.

Laryngectomy

MS

Also refer to Cancer; Chemotherapy

ineffective Airway Clearance may be related to excessive mucus, retained secretions; (foreign body in airway—tracheotomy), possibly evidenced by dyspnea; alteration in respiratory rate and pattern; ineffective cough; diminished breath sounds; and cyanosis.

impaired Skin/Tissue Integrity may be related to [surgical removal of tissues and grafting, effects of radiation or chemotherapeutic agents], inadequate nutrition, and associated conditions of impaired circulation, [edema formation, and pooling or continuous drainage of secretions], possibly evidenced by disruption and destruction of skin and tissue layers.

impaired oral Mucous Membrane Integrity/risk for Dry Mouth may be related to dehydration, decrease in salivation, inadequate oral hygiene, surgical procedure, nil per os (NPO), and malnutritional, possibly evidenced by xerostomia (dry mouth), oral discomfort/

pain, mucosal denudation, impaired ability to swallow, and halitosis.

CH

impaired verbal Communication may be related to anatomic deficit (removal of vocal cords), physical barrier (tracheostomy tube), and required voice rest, possibly evidenced by inability to speak, change in vocal characteristics, and impaired articulation.

risk for Aspiration possibly evidenced by ineffective cough, (neck/oral surgery, impaired ability to swallow, enteral feedings), [tracheostomy].

Laryngitis

CH/PED

Refer to Croup

Latex allergy

CH

Latex Allergy Reaction may be related to hypersensitivity to latex rubber protein, possibly evidenced by contact dermatitis—erythema, blisters; type IV reaction—eczema, irritation; hypersensitivity—generalized edema, wheezing, bronchospasm, hypotension, cardiac arrest.

risk for risk-prone Health Behavior possibly evidenced by health status requiring change in occupation.

Laxative abuse

CH

perceived Constipation may be related to health beliefs, faulty appraisal, impaired cognition/thought processes, possibly evidenced by expectation of daily bowel movement, expected passage of stool at same time every day.

Lead poisoning, acute

PED/CH

Also refer to Lead poisoning, chronic

Contamination may be related to flaking or peeling paint (young children), improperly lead-glazed ceramic pottery, unprotected contact with lead (e.g., battery manufacture or recycling, bronzing, soldering or welding), imported herbal products or medicinals, possibly evidenced by abdominal cramping, headache, irritability, decreased attentiveness, constipation, tremors.

risk for physical Trauma possibly evidenced by loss of coordination, altered level of consciousness, clonic or tonic muscle activity, neurological damage.

risk for deficient Fluid Volume possibly evidenced by excessive vomiting, diarrhea, or decreased intake.

deficient Knowledge regarding sources of lead and prevention of poisoning may be related to

lack of information, misinterpretation, possibly evidenced by statements of concern, questions, and misconceptions.

Lead poisoning, chronic

CH

Also refer to Lead poisoning, acute

Contamination may be related to flaking or peeling paint (young children), improperly lead-glazed ceramic pottery, unprotected contact with lead (e.g., battery manufacture or recycling, bronzing, soldering or welding), imported herbal products or medicinals, possibly evidenced by chronic abdominal cramping, headache, personality changes, cognitive deficits, seizures, neuropathy.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to absorb nutrients—chemically induced changes in the gastrointestinal tract), possibly evidenced by food intake less than recommended daily allowance, abdominal discomfort, alteration in taste sensation, and [weight loss].

chronic Pain may be related to deposition of lead in soft tissues and bone, possibly evidenced by verbal reports, distraction behaviors, and focus on self.

risk for delayed Development/[disproportionate Growth] possibly evidenced by (lead poisoning, chronic illness).

Legionnaires' disease

CH/MS

Hyperthermia may be related to illness and inflammatory process, possibly evidenced by increased body temperature; flushed, warm skin; chills.

acute Pain/impaired Comfort may be related to [infectious agent and inflammatory response, effects of circulating toxins] possibly evidenced by reports of headache, myalgia, high fever, diaphoresis.

ineffective Airway Clearance may be related to excessive mucus, retained secretions, (infection— inflammation, edema formation), possibly evidenced by alteration in respiratory rate/pattern, abnormal breath sounds, dyspnea, cyanosis, ineffective cough.

impaired Gas Exchange may be related to (alveolar-capillary membrane changes— inflammatory process), and [hypoventilation], possibly evidenced by restlessness, [changes in mentation], dyspnea, tachycardia, abnormal skin color (pallor, cyanosis), and hypoxia.

Diarrhea may be related to infectious process, possibly evidenced by liquid stools, abdominal cramping.

risk for Infection [spread] possibly evidenced by stasis of body fluids/(decreased ciliary action, [secretions]), [presence of existing infection].

Leprosy

CH

Refer to Hansen's disease

Leukemia, acute

MS

Also refer to Chemotherapy

risk for Infection possibly evidenced by associated conditions of [alterations in mature white blood cells, increased number of immature lymphocytes, immunosuppression and bone marrow suppression, invasive procedures, and malnutrition].

Anxiety [specify level]/Fear may be related to change in current status, threat of death, and (situational crisis), possibly evidenced by sympathetic stimulation, apprehensiveness, helplessness, self-focused, and insomnia.

Activity Intolerance may be related to reduced energy stores, increased metabolic rate], imbalance between oxygen supply and demand (anemia, hypoxia); sedentary lifestyle due to therapeutic restrictions (isolation, bedrest), [effect of drug therapy], possibly evidenced by generalized weakness, reports of fatigue and exertional dyspnea, abnormal heart rate or blood pressure response.

acute Pain may be related to physical injury agents— infiltration of tissues, organs, central nervous system, or expanding bone marrow; chemical agents (antileukemic treatments)]; psychological manifestations— anxiety, fear, possibly evidenced by verbal reports of abdominal discomfort, arthralgia, bone pain, headache; distraction behaviors, narrowed focus, and autonomic responses— changes in vital signs.

risk for deficient Fluid Volume/Bleeding possibly evidenced by excessive losses (vomiting, hemorrhage, diarrhea, coagulopathy), decreased intake (nausea, anorexia), increased fluid need (hypermetabolic state/ fever), predisposition for kidney stone formation and tumor lysis syndrome.

Leukemia, chronic

CH

ineffective Protection may be related to abnormal blood profiles, drug therapy (cytotoxic agents, steroids), radiation treatments, possibly evidenced by deficient immunity, impaired healing, altered clotting, weakness.

Fatigue may be related to disease state, anemia, possibly evidenced by verbalizations, inability to maintain usual routines, listlessness.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, possibly evidenced by insufficient interest in food, [anorexia, weight loss, abdominal fullness, pain].

Lice, head

PED/CH

Refer to Pediculosis capitis

Lice, pubic

CH

Refer to Pediculosis capitis

Lightning injury

MS

Also refer to Electrical injury

acute Confusion may be related to [alteration in neuropsychological functioning—central nervous system involvement], possibly evidenced by alteration in consciousness and cognitive functioning, agitation, inability to initiate or sustain goal-directed behavior, misperceptions.

impaired Memory may be related to acute hypoxia, decreased cardiac output, electrolyte imbalance, neurological disturbance, possibly evidenced by inability to recall recent events, amnesia.

Liver failure

MS/CH

Refer to Cirrhosis; Hepatitis, acute viral

Liver transplantation

MS/CH

Refer to Transplantation, recipient

Lockjaw

MS

Refer to Tetanus

Long-term care

CH

(Also refer to condition requiring/contributing to need for facility placement.)

Anxiety [specify level]/Fear may be related to threat to current status, (situational crisis, major change—role functioning, socioeconomic status); unmet needs; possibly evidenced by apprehensiveness, restlessness, insomnia, repetitive questioning, pacing, purposeless activity, and self-focused.

Grieving may be related to [perceived, actual, or potential loss of physiopsychosocial well-being, personal possessions, and SO(s)], possibly evidenced by denial of feelings, depression, sorrow, guilt; alterations in activity level, sleep patterns, eating habits, and libido.

risk for Poisoning [drug toxicity] possibly evidenced by effects of aging (reduced metabolism, impaired circulation, precarious physiological balance, presence of multiple diseases and organ involvement)

and use of multiple prescribed and over-the-counter drugs.

impaired Memory may be related to neurological disturbances, hypoxia, fluid imbalance, possibly evidenced by inability to recall events/factual information, reports experience of forgetting.

Insomnia may be related to internal factors (illness, psychological stress, inactivity) and external factors (environmental changes, facility routines), possibly evidenced by reports of difficulty in falling asleep, not feeling rested, interrupted sleep, awakening earlier than desired, change in behavior or performance, increasing irritability, and listlessness.

risk for Relocation Stress Syndrome possibly evidenced by temporary or permanent move that may be voluntary or involuntary, lack of predeparture counseling, multiple losses, feeling of powerlessness, lack of or inappropriate use of support system, decreased psychosocial or physical health status.

risk for impaired Religiosity possibly evidenced by life transition, ineffective support or coping, lack of social interaction, depression.

LSD (lysergic acid diethylamide) intoxication

MS/PSY

Also refer to Hallucinogen abuse

risk for physical Trauma possibly evidenced by perceptual distortion, impaired judgment, dangerous decision making, changes in mood.

Anxiety [panic attack] may be related to substance use/stressors (e.g., drug side effects), possibly evidenced by severe apprehensiveness, fear of unspecific consequences, central nervous system excitation, central autonomic hyperactivity.

Lung cancer

MS/CH

Refer to Bronchogenic carcinoma

Lung transplantation

MS/CH

Also refer to Transplantation, recipient

risk for impaired Gas Exchange possibly evidenced by (ventilation-perfusion imbalance, [stenosis of bronchial or tracheal anastomosis]).

risk for Infection possibly evidenced by [immunosuppression, suppressed inflammatory response, antibiotic therapy, invasive procedures, chronic illness].

Lupus erythematosus, systemic (SLE)

CH

Fatigue may be related to inadequate energy production, increased energy requirements (chronic inflammation), overwhelming psychological or emotional

demands, states of discomfort, and altered body chemistry (including effects of drug therapy), possibly evidenced by reports of unremitting and overwhelming lack of energy, inability to maintain usual routines, decreased performance, lethargy, and decreased libido.

acute Pain may be related to physical injury agent (widespread inflammatory process affecting connective tissues, blood vessels, serosal surfaces and mucous membranes) possibly evidenced by verbal reports, guarding or distraction behaviors, self-focusing, and changes in vital signs.

impaired Skin/Tissue Integrity may be related to (immunodeficiency, and impaired circulation), possibly evidenced by presence of skin rash or lesions, ulcerations of mucous membranes, and photosensitivity.

disturbed Body Image may be related to (illness), possibly evidenced by alteration in body structure [e.g., presence of rash, lesions, ulcers, purpura, mottled erythema of hands, alopecia], hiding of body parts, negative feeling about body, fear of reaction by others, and change in social involvement.

Lyme disease

CH/MS

acute/chronic Pain may be related to systemic effects of toxins, presence of rash, urticaria, and joint swelling and inflammation, possibly evidenced by verbal reports, guarding behaviors, autonomic responses, and narrowed focus.

Fatigue may be related to increased energy requirements, altered body chemistry, and states of discomfort evidenced by reports of overwhelming lack of energy, inability to maintain usual routines, decreased performance, lethargy, and malaise.

risk for decreased Cardiac Output possibly evidenced by alteration in cardiac rate, rhythm, or conduction.

Lymphedema

CH

disturbed Body Image may be related to alteration in self-perception, and [physical changes—chronic swelling of extremity], possibly evidenced by fear of reaction by others, negative feeling about body, hiding body part, change in social involvement.

impaired Walking may be related to chronic or progressive swelling of lower extremity, possibly evidenced by difficulty walking required distances, climbing stairs, navigating uneven surfaces and declines.

risk for impaired Skin Integrity possibly evidenced by alteration in fluid volume (significant edema) and associated conditions of altered circulation, alteration in sensation.

Macular degeneration

CH

[disturbed visual Sensory Perception] may be related to altered sensory reception, possibly evidenced by reported or measured change in sensory acuity, change in usual response to stimuli.

Anxiety [specify level] may be related to (situational crisis), threat to current status, possibly evidenced by expressed concerns, apprehensiveness, feelings of inadequacy, diminished productivity, alteration in attention.

risk for impaired Social Interaction possibly evidenced by limited physical mobility, environmental barriers.

Malaria

MS/CH

Hyperthermia may be related to inflammatory process, possibly evidenced by increased body temperature (106°F [41.1°C]); flushed, warm skin; tachycardia; headache; altered consciousness.

acute Pain/impaired Comfort may be related to physical injury agent (infection, inflammatory response), possibly evidenced by reports of headache, backache, myalgia, malaise, high fever, shaking chills, abdominal discomfort.

risk for deficient Fluid Volume possibly evidenced by decreased intake (nausea, abdominal pain, prostration), excessive losses (vomiting, diarrhea), hypermetabolic state.

Fatigue may be related to disease state, anemia, lack of restful sleep, possibly evidenced by verbalization of unremitting or overwhelming lack of energy, inability to restore energy even after sleep, lethargy.

Mallory-Weiss syndrome

MS

Also refer to Achalasia (cardiospasm)

risk for deficient Fluid Volume possibly evidenced by excessive vascular losses, presence of vomiting, and reduced intake.

deficient Knowledge regarding causes, treatment, and prevention of condition may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, and recurrence of problem.

Malnutrition

CH

Also refer to Anorexia nervosa

Frail Elderly Syndrome may be related to depression, apathy, aging process, fatigue, degenerative condition, possibly evidenced by expressed lack of appetite, difficulty performing self-care tasks, altered mood state, inadequate intake, weight loss, physical decline.

ineffective Protection may be related to inadequate nutrition, anemia, extremes of age, possibly evidenced by fatigue, weakness, deficient immunity, impaired healing, pressure sores.

Marburg disease

MS

Refer to Ebola

Mastectomy

MS

impaired Skin/Tissue Integrity may be related to surgical procedure—removal of skin and tissue), impaired circulation, alteration in skin turgor and alteration in sensation possibly evidenced by alteration in skin and tissue integrity, tissue damage.

impaired physical Mobility may be related to neuromuscular impairment, pain, and edema formation, possibly evidenced by reluctance to attempt movement, limited range of motion, and decreased muscle mass and strength.

bathing/dressing Self-Care deficit may be related to temporary decreased range of motion of one or both arms, possibly evidenced by statements of inability to perform or complete self-care tasks.

disturbed Body Image/situational low Self-Esteem may be related to alteration in self-perception (e.g., loss of body part denoting femininity), behaviors inconsistent with self-value system possibly evidenced by not looking at or touching area, self-negating verbalizations, preoccupation with loss, and change in social involvement or relationship.

Mastitis

OB/GYN

acute Pain may be related to physical agent—inflammation and edema of breast tissues, possibly evidenced by self-report of pain, guarding or expressive behavior, self-focused, and changes in vital signs.

risk for Infection [spread/abscess formation] possibly evidenced by [traumatized tissues], stasis of body fluid, and insufficient knowledge to prevent complications.

deficient Knowledge regarding pathophysiology, treatment, and prevention may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, and misconceptions.

risk for ineffective Breastfeeding possibly evidenced by inability to feed on affected side, interruption in breastfeeding.

Mastoidectomy

PED/MS

Also refer to Surgery, general

risk for Infection [spread] possibly evidenced by [pre-existing infection, surgical trauma], and stasis of body fluids.

acute Pain may be related to physical injury agent (infection and edema formation), possibly evidenced by self-report of pain, distraction behavior, restlessness, self-focused, and changes in vital signs.

[disturbed auditory Sensory Perception] may be related to presence of surgical packing, edema, and surgical disturbance of middle ear structures, possibly evidenced by reported or tested hearing loss in affected ear.

Measles

CH/PED

acute Pain/impaired Comfort may be related to physical injury agent (viral infection) causing inflammation of mucous membranes, conjunctiva, and presence of extensive skin rash with pruritus, possibly evidenced by verbal/coded reports, distraction behaviors, self-focusing, and changes in vital signs.

Hyperthermia may be related to presence of viral toxins and inflammatory response, possibly evidenced by increased body temperature; flushed, warm skin; and tachycardia.

risk for [secondary] Infection possibly evidenced by altered immune response and traumatized dermal tissues.

deficient Knowledge regarding condition, transmission, and possible complications may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, misconceptions, and development of preventable complications.

Measles, German

PED/CH

Refer to Rubella

Melanoma, malignant

MS/CH

Refer to Cancer; Chemotherapy

Ménière's disease

CH

Also refer to Vertigo

[disturbed auditory Sensory Perception] may be related to altered state of sensory organ or sensory reception, possibly evidenced by change in sensory acuity, tinnitus, vertigo.

Nausea may be related to inner ear disturbance, possibly evidenced by verbal reports, vomiting.

risk for [total] Self-Care deficit possibly evidenced by perceptual impairment, recurrent nausea, general weakness.

Meningitis, acute meningococcal

MS

risk for Infection [spread] possibly evidenced by [hematogenous dissemination of pathogen], stasis of body fluids, (suppressed inflammatory response), and [exposure of others to pathogens].

risk for ineffective cerebral Tissue Perfusion possibly evidenced by cerebral edema altering or interrupting cerebral arterial or venous blood flow, hypovolemia, exchange problems at cellular level (acidosis).

Hyperthermia may be related to infectious process (increased metabolic rate) and dehydration, possibly evidenced by increased body temperature; warm, flushed skin; and tachycardia.

acute Pain may be related to physical injury agent bacterial or viral infection with inflammation and irritation of the meninges, with headache and spasm of extensor muscles (neck, shoulders, and back), possibly evidenced by verbal reports, guarding or distraction behaviors, narrowed focus, photophobia, and changes in vital signs.

risk for physical Trauma/Suffocation possibly evidenced by alterations in level of consciousness, possible development of clonic-tonic muscle activity (seizures), generalized weakness, prostration, ataxia, vertigo.

Meniscectomy

MS/CH

impaired Walking may be related to pain, joint instability, and imposed medical restrictions of movement, possibly evidenced by impaired ability to move about environment as needed or desired.

deficient Knowledge regarding postoperative expectations, prevention of complications, and self-care needs may be related to lack of information, possibly evidenced by statements of concern, questions, and misconceptions.

Menopause

GYN

ineffective Thermoregulation may be related to fluctuation of hormonal levels, possibly evidenced by skin flushed/warm to touch, diaphoresis, night sweats, cold hands and feet.

Fatigue may be related to change in body chemistry, lack of sleep, depression, possibly evidenced by reports of lack of energy, tiredness, inability to maintain usual routines, decreased performance.

risk for Sexual dysfunction possibly evidenced by lack of/misinformation about sexual function, perceived altered body function, changes in physical/sexual response, impaired/absent relationship with SO.

risk for stress urinary Incontinence possibly evidenced by changes in pelvic muscles and loss of structural support.

readiness for enhanced Health Management possibly evidenced by expresses desire to enhance management of symptoms.

Mental delay (formerly retardation)

CH

Also refer to Down syndrome

impaired verbal Communication may be related to developmental delay or impairment of cognitive and motor abilities, possibly evidenced by impaired articulation, difficulty with phonation, and inability to modulate speech or find appropriate words (dependent on degree of retardation).

risk for Self-Care deficit [specify] possibly evidenced by impaired cognitive ability and motor skills.

risk for Overweight or Obesity possibly evidenced by decreased metabolic rate coupled with impaired cognitive development, dysfunctional eating patterns, and sedentary activity level.

risk for sedentary Lifestyle possibly evidenced by lack of interest or motivation, resources; lack of training or knowledge of specific exercise needs, safety concerns, fear of injury.

impaired Social Interaction may be related to impaired thought processes, communication barriers, and knowledge or skill deficit about ways to enhance mutuality, possibly evidenced by dysfunctional interactions with peers, family, and/or SO(s), and verbalized or observed discomfort in social situation.

compromised family Coping may be related to chronic nature of condition and degree of disability that exhausts supportive capacity of SO(s), other situational or developmental crises or situations SO(s) may be facing, unrealistic expectations of SO(s), possibly evidenced by preoccupation of SO with personal reaction, SO(s) withdraw(s) or enter(s) into limited interaction with individual, protective behavior disproportionate (too much or too little) to client's abilities or need for autonomy.

impaired Home Maintenance may be related to impaired cognitive functioning, insufficient finances/family organization or planning, lack of knowledge, and inadequate support systems, possibly evidenced by requests for assistance, expression of difficulty in maintaining home, disorderly surroundings, and overtaxed family members.

risk for Sexual dysfunction possibly evidenced by risk factors of [biopsychosocial alteration of sexuality], inadequate or absent role models, misinformation/

lack of knowledge about sexual function, [absence of SO(s) and lack of appropriate behavior control].

Mesothelioma

CH/MS

Also refer to Asbestosis; Cancer

acute Pain may be related to physical injury agent (cancer of mesothelium of chest and abdominal cavity or around heart), possibly evidenced by reports of chest pain (initially nonpleuritic), irritability, self-focusing, autonomic responses.

Activity Intolerance may be related to imbalance between oxygen supply and demand, possibly evidenced by exertional dyspnea, fatigue.

Metabolic syndrome

CH

risk for unstable Blood Glucose Level possibly evidenced by ineffective medication management, excessive weight gain, average daily physical activity is less than recommended for gender/age.

sedentary Lifestyle may be related to deficient knowledge of health benefits of physical exercise, lack of interest, motivation, or resources, possibly evidenced by verbalized preference for activities low in physical activity, choosing a daily routine lacking physical exercise.

risk for ineffective Tissue Perfusion (specify) possibly evidenced by arterial plaque formation (elevated triglycerides, low levels of high-density lipoprotein), prothrombotic state, proinflammatory state.

Migraine

CH/MS

Refer to Headache

Miscarriage

OB

Refer to Abortion, spontaneous termination

Mitral insufficiency

MS/CH

Refer to Valvular heart disease

Mitral stenosis

MS/CH

Activity Intolerance may be related to imbalance between oxygen supply and demand, possibly evidenced by reports of fatigue, generalized weakness, exertional dyspnea, and abnormal heart rate response to activity.

impaired Gas Exchange may be related to [altered blood flow], possibly evidenced by abnormal breathing patterns (orthopnea, paroxysmal nocturnal dyspnea), restlessness, and hypoxia.

decreased Cardiac Output may be related to impeded blood flow as evidenced by jugular vein

distention, peripheral or dependent edema, orthopnea, paroxysmal nocturnal dyspnea.

deficient Knowledge regarding pathophysiology, therapeutic needs, and potential complications may be related to lack of information or recall, misinterpretation, possibly evidenced by statements of concern, questions, inaccurate follow-through of instructions, and development of preventable complications.

Mitral valve prolapse (MVP)

CH

Refer to Valvular heart disease

Mononucleosis, infectious

CH

Fatigue may be related to decreased energy production, states of discomfort, and increased energy requirements (inflammatory process), possibly evidenced by reports of overwhelming lack of energy, inability to maintain usual routines, lethargy, and malaise.

acute Pain/impaired Comfort may be related to physical injury agent (viral infection) causing inflammation of lymphoid and organ tissues, irritation of oropharyngeal mucous membranes, possibly evidenced by verbal reports, distraction behaviors, and self-focusing.

Hyperthermia may be related to inflammatory process, possibly evidenced by increased body temperature; warm, flushed skin; and tachycardia.

deficient Knowledge regarding disease transmission, self-care needs, medical therapy, and potential complications may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, misconceptions, and inaccurate follow-through of instructions.

Mood disorders

PSY

Refer to Depression, major; Bipolar disorder; Premenstrual dysphoric disorder

Mountain sickness, acute (AMS)

CH/MS

acute Pain may be related to physical injury agent (effect of lower levels of oxygen and reduced air pressure at high altitude), possibly evidenced by reports of headache, dizziness [and other discomforts, such as shortness of breath, nausea, swelling of extremities].

Fatigue may be related to stressors, increase in physical exertion, sleep deprivation, possibly evidenced by insufficient energy, nonrestorative sleep pattern, alteration in concentration, decreased performance.

risk for deficient Fluid Volume possibly evidenced by increased water loss (e.g., overbreathing dry air), exertion, inadequate fluid intake (nausea).

Multiple organ dysfunction syndrome MS

Also refer to specific organs involved; Sepsis; Ventilator assist/dependence

ineffective peripheral Tissue Perfusion may be related to hypovolemia, selective vasoconstriction, microvascular embolization, possibly evidenced by cool skin, diminished pulses.

impaired Gas Exchange may be related to (ventilation-perfusion imbalance), possibly evidenced by dyspnea, irritability, confusion, abnormal arterial blood gases.

Activity Intolerance may be related to imbalance between oxygen supply and demand, [bedrest], pain, possibly evidenced by abnormal heart rate and blood pressure response to activity, pallor, exertional discomfort, electrocardiogram changes (dysrhythmias, ischemia).

[*severe*] *Anxiety/Fear* may be related to (situational crisis), threat to current status, threat of death, unfamiliar setting, separation from support system, possibly evidenced by expressed concerns, apprehensiveness, increase in tension, fearfulness, restlessness, decreased perceptual field.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to digest food or absorb nutrients) and [increased metabolic demands], possibly evidenced by [weight loss, decreased subcutaneous fat and muscle mass, abnormal laboratory studies].

risk for Infection possibly evidenced by malnutrition and stasis of body fluids; (immunosuppression, invasive devices/[procedures, environmental exposure]).

Multiple personality PSY

Refer to Dissociative disorders

Multiple sclerosis CH

Fatigue may be related to decreased energy production, increased energy requirements to perform activities, psychological and emotional demands, pain or discomfort, medication side effects, possibly evidenced by verbalization of overwhelming lack of energy, inability to maintain usual routine, decreased performance, impaired ability to concentrate, increase in physical complaints.

[*disturbed visual/kinesthetic/tactile Sensory Perception*] may be related to delayed or interrupted neuronal transmission, possibly evidenced by impaired vision, diplopia, disturbance of vibratory or position sense, paresthesias, numbness, and blunting of sensation.

impaired physical Mobility may be related to neuromuscular impairment, discomfort or pain, sensoriperceptual impairments, decreased muscle strength, control, or mass, deconditioning, as evidenced by limited ability to perform motor skills, limited range of motion, gait changes, postural instability.

Powerlessness/Hopelessness may be related to chronic stress, prolonged activity restriction, social isolation, and associated condition of deterioration in physiological condition, possibly evidenced by dependency, depression, frustration about ability to perform previous activities, insufficient sense of control, inadequate participation in care.

impaired Home Maintenance may be related to effects of debilitating disease, impaired cognitive or emotional functioning, insufficient finances, and inadequate support systems, possibly evidenced by reported difficulty, observed disorderly surroundings, and poor hygienic conditions.

compromised/disabled family Coping may be related to situational crises, temporary family disorganization, and role changes, client providing little support in turn for SO(s), prolonged disease and disability progression that exhausts the supportive capacity of SO(s), feelings of guilt, anxiety, hostility, despair, and highly ambivalent family relationships, possibly evidenced by client who expresses or confirms concern about SOs' response to client's illness, SO(s) preoccupied with own personal reactions, intolerance, abandonment, neglectful care of the client, and distortion of reality regarding client's illness.

Mumps PED/CH

acute Pain may be related to physical injury agent (viral infection) with [inflammation, and enlargement of salivary glands], possibly evidenced by self-reports of pain, guarding or distraction behavior, self-focused, and autonomic responses (changes in vital signs).

Hyperthermia may be related to inflammatory process (increased metabolic rate) and dehydration, possibly evidenced by increased body temperature; warm, flushed skin; and tachycardia.

risk for deficient Fluid Volume possibly evidenced by factors influencing fluid needs—hypermetabolic state, and insufficient fluid intake.

Muscular dystrophy (Duchenne's) PED/CH

impaired physical Mobility may be related to musculoskeletal impairment and weakness, possibly evidenced by decreased muscle strength, control, and mass; limited range of motion; and impaired coordination.

risk for delayed Development possibly evidenced by genetic disorder/chronic illness, learning disability, altered ability to perform self-care or self-control activities appropriate to age.

risk for Overweight or Obesity possibly evidenced by sedentary lifestyle and dysfunctional eating patterns.

compromised family Coping may be related to [emotional conflicts—hereditary nature of condition], family disorganization, exhaustion of support person's capacity, possibly evidenced by support person reports preoccupation with own reaction to client's need, protective behavior by support person incongruent with client's abilities/need for autonomy.

Myasthenia gravis

MS

ineffective Breathing Pattern/Airway Clearance may be related to neuromuscular weakness and decreased energy, fatigue, possibly evidenced by dyspnea, changes in rate and depth of respiration, ineffective cough, and adventitious breath sounds.

impaired verbal Communication may be related to neuromuscular weakness, fatigue, and physical barrier (intubation), possibly evidenced by facial weakness, impaired articulation, hoarseness, and inability to speak.

impaired Swallowing may be related to (neuromuscular impairment—laryngeal and pharyngeal muscle abnormalities/fatigue), possibly evidenced by difficulty swallowing, coughing, choking, and recurrent pulmonary infection.

Anxiety [specify level]/Fear may be related to stressors, (major change), threat to current status, separation from support systems, and [inability to communicate], possibly evidenced by expressed concerns, increase in tension, restlessness, apprehensiveness, sympathetic stimulation, crying, self-focused, uncooperative behavior, withdrawal, anger.

CH

deficient Knowledge regarding drug therapy, potential for crisis (myasthenic or cholinergic), and self-care management may be related to inadequate information, misinterpretation, possibly evidenced by statements of concern, questions, and misconceptions; development of preventable complications.

impaired physical Mobility may be related to neuromuscular impairment, possibly evidenced by reports of progressive fatigue with repetitive or prolonged muscle use, impaired coordination, and decreased muscle strength and control.

[disturbed visual Sensory Perception] may be related to neuromuscular impairment, possibly evidenced by visual distortions (diplopia) and motor incoordination.

Myelitis, transverse

MS/CH

Refer to Paraplegia

Myeloma, multiple

MS/CH

Also refer to Cancer

acute/chronic Pain may be related to physical agent—destruction of tissues and bone, side effects of therapy, possibly evidenced by verbal or coded reports, guarding or protective behavior, changes in appetite, weight, sleep; reduced interaction with others.

impaired physical Mobility may be related to loss of integrity of bone structure, pain, deconditioning, depressed mood, possibly evidenced by verbalizations, limited range of motion, slowed movement, gait changes.

risk for ineffective Protection possibly evidenced by cancer, drug therapies, radiation treatments, inadequate nutrition.

Myocardial infarction

MS

Also refer to Myocarditis

acute Pain may be related to physical injury agent (ischemia of myocardial tissue), possibly evidenced by verbal reports, guarding or distraction behaviors (restlessness), facial mask of pain, self-focusing, and autonomic responses (diaphoresis, changes in vital signs).

Anxiety [specify level]/Fear may be related to threat of death, threat to current status; possibly evidenced by increase in tension, fearful attitude, apprehensiveness, expressed concerns or uncertainty, restlessness, sympathetic stimulation, and somatic complaints.

risk for decreased Cardiac Output possibly evidenced by changes in rate and electrical conduction, reduced preload, increased systemic vascular resistance, altered muscle contractility, depressant effects of some medications, infarcted or dyskinetic muscle, structural defects.

CH

risk for sedentary Lifestyle possibly evidenced by lack of resources; lack of training or knowledge of specific exercise needs, safety concerns, fear of injury

Myocarditis

MS

Also refer to Myocardial infarction

Activity Intolerance may be related to imbalance in oxygen supply and demand (myocardial inflammation)

or damage, cardiac depressant effects of certain drugs), and sedentary lifestyle (enforced bedrest), possibly evidenced by reports of fatigue, exertional dyspnea, abnormal heart rate and ECG response to activity (tachycardia, dysrhythmias, and palpitations) and generalized weakness.

risk for decreased Cardiac Output possibly evidenced by altered contractility, altered stroke volume.

deficient Knowledge regarding pathophysiology of condition, prognosis, treatment, self-care needs, and lifestyle changes may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, misconceptions, inaccurate follow-through of instructions, and development of preventable complications.

Myoclonus, nocturnal

CH

Sleep deprivation may be related to nonrestorative sleep pattern, (condition with periodic limb movement), possibly evidenced by irritability, drowsiness, decrease in functional ability, alteration in concentrate.

Myofascial pain syndrome

CH

Also refer to Fibromyalgia

acute/chronic Pain may be related to physical agent—nocturnal bruxism, possibly evidenced by self-reports of pain (temporomandibular region), headache, muscular tenderness to palpation, limitation in opening mouth.

risk for impaired Dentition possibly evidenced by (bruxism), inadequate oral hygiene (limitations in opening mouth).

Myringotomy

PED/MS

Refer to Mastoidectomy

Myxedema

CH

Also refer to Hypothyroidism

disturbed Body Image may be related to (alteration in body structure or function [loss of hair, thickening of skin, masklike facial expression, enlarged tongue, menstrual and reproductive disturbances]), possibly evidenced by negative feeling about body, fear of reaction by others, and change in social involvement.

Overweight may be related to decreased metabolic rate and activity level, possibly evidenced by weight gain greater than ideal for height and frame.

risk for decreased Cardiac Output possibly evidenced by alteration in heart rhythm, altered contractility.

Narcolepsy

CH

Sleep deprivation may be related to (narcolepsy, nightmares), nonrestorative sleep pattern, possibly evidenced by drowsiness[/hypersomnia], decrease in functional ability, hallucinations.

risk for physical Trauma possibly evidenced by sudden loss of muscle tone, momentary paralysis (cataplexy), sudden inappropriate sleep episodes.

Near drowning

MS

impaired Gas Exchange may be related to (ventilation perfusion imbalance, and alveolar-capillary membrane changes), possibly evidenced by severe hypoxia, abnormal skin color (pale or dusky skin), change in mentation (confusion to coma).

risk for Hypothermia possibly evidenced by submersion in very cold water.

NEC

PED

Refer to Necrotizing enterocolitis

Necrotizing cellulitis/fasciitis

MS

Also refer to Cellulitis; Sepsis

Hyperthermia may be related to inflammatory process, response to circulating toxins, possibly evidenced by body temperature above normal range; flushed, warm skin; tachycardia; altered mental status.

impaired Tissue Integrity may be related to inflammation and edema (infection), ischemia, possibly evidenced by damaged or destroyed tissue, dermal gangrene.

Necrotizing enterocolitis

PED

Also refer to Sepsis

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to digest food or absorb nutrients), possibly evidenced by abdominal pain, [gastric residuals after feedings, failure to gain weight].

risk for deficient Fluid Volume possibly evidenced by vomiting, third-space fluid losses (bowel inflammation, peritonitis), lack of oral intake.

Neglect/abuse

CH/PSY

Refer to Abuse, Battered child syndrome

Nephrectomy

MS

acute Pain may be related to physical injury agent (surgical tissue trauma), possibly evidenced by verbal reports, guarding or distraction behavior, self-focused, and changes in vital signs.

risk for deficient Fluid Volume possibly evidenced by excessive vascular losses and restricted intake.

ineffective Breathing Pattern may be related to incisional pain with decreased lung expansion, possibly evidenced by tachypnea, fremitus, changes in respiratory depth and chest expansion, and changes in arterial blood gases.

Constipation may be related to reduced dietary intake, decreased mobility, gastrointestinal obstruction (paralytic ileus), and incisional pain with defecation, possibly evidenced by decreased bowel sounds; reduced frequency/amount of stool; and hard, formed stool.

Nephrolithiasis

MS/CH

Refer to Calculi, urinary

Nephrotic syndrome

MS/CH

Also refer to Renal failure, acute/chronic
excess Fluid Volume may be related to compromised regulatory mechanism with changes in hydrostatic or oncotic vascular pressure and increased activation of the renin-angiotensin-aldosterone system, possibly evidenced by edema, anasarca, effusions, ascites, weight gain, intake greater than output, and blood pressure changes.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to ingest food or absorb adequate nutrients), possibly evidenced by [weight loss, muscle wasting (may be difficult to assess due to edema)], insufficient interest in food, alteration in taste sensation, and food intake less than recommended daily allowance.

risk for Infection possibly evidenced by (chronic illness and suppressed inflammatory responses).

risk for impaired Skin Integrity possibly evidenced by alteration in fluid volume, inadequate nutrition and associated conditions of immunodeficiency, and alteration in skin turgor.

Neuralgia, trigeminal

CH

acute Pain may be related to physical agent—sudden violent muscle spasm, possibly evidenced by verbal reports, guarding or distraction behavior, self-focused, and changes in vital signs.

deficient Knowledge regarding control of recurrent episodes, medical therapies, and self-care needs may be related to lack of information or recall and misinterpretation, possibly evidenced by statements of concern, questions, and exacerbation of condition.

Neural tube defect

Refer to Spina bifida

Neuritis

CH

acute/chronic Pain may be related to (damage to the nervous system), possibly evidenced by verbal reports, guarding or distraction behavior, self-focused, and changes in vital signs.

deficient Knowledge regarding underlying causative factors, treatment, and prevention may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, and misconceptions.

Newborn, growth deviations

PED

Also refer to Newborn, premature

[disproportionate Growth] may be related to maternal nutrition, substance use or abuse, multiple gestation, prematurity, maternal conditions (e.g., pregnancy-induced hypertension, diabetes), possibly evidenced by birth weight at or below 10th percentile or at or above 90th percentile (considering gestational age, ethnicity, etc.).

imbalanced Nutrition: less than body requirements may be related to [decreased nutritional stores, hyperplasia of pancreatic beta cells, and increased insulin production], possibly evidenced by [weight deviation from expected, decreased muscle mass/fat stores, electrolyte imbalance].

risk for ineffective Tissue Perfusion (specify) possibly evidenced by interruption of arterial or venous blood flow (hyperviscosity associated with polycythemia).

risk for physical Injury possibly evidenced by altered growth, delayed central nervous system or neurological development, abnormal blood profile.

risk for disorganized infant Behavior possibly evidenced by functional limitations related to growth deviations (restricting neonate's opportunity to seek out, recognize, and interpret stimuli), electrolyte imbalance, psychological stress, low energy reserves, poor organizational ability, limited ability to control environment.

Newborn, normal

PED

risk for impaired Gas Exchange possibly evidenced by [prenatal or intrapartal stressors, excess production of mucus, or cold stress].

risk for Hypothermia possibly evidenced by large body surface in relation to mass, limited amounts of insulating subcutaneous fat, nonrenewable sources

of brown fat and few white fat stores, thin epidermis with close proximity of blood vessels to the skin, inability to shiver, and movement from a warm uterine environment to a much cooler environment.

risk for impaired Attachment possibly evidenced by developmental transition or gain of a family member, anxiety associated with the parent role, lack of privacy (healthcare interventions, intrusive family/visitors).

readiness for enhanced Childbearing Process possibly evidenced by expresses desire to enhance baby feeding/care techniques and environmental safety for the baby.

Newborn at 1 week

PED

Also refer to Newborn, normal

risk for Injury possibly evidenced by physical (hyperbilirubinemia), environmental (inadequate safety precautions), chemical (drugs in breast milk), psychological (inappropriate parental stimulation or interaction).

risk for Constipation/Diarrhea possibly evidenced by type and amount of oral intake, medications or dietary intake of lactating mother, presence of allergies, infection.

risk for impaired Skin Integrity possibly evidenced by excretions (ammonia formation from urea), moisture, chemical injury agent (laundry detergent or diapering material), [mechanical factors (e.g., long fingernails)].

Newborn, postmature

PED

risk for impaired Gas Exchange possibly evidenced by (ventilation perfusion imbalances [meconium aspiration, pneumonitis]).

Hypothermia may be related to decreased subcutaneous fat stores, poor metabolic reserves, exposure to cool environment, decreased ability to shiver, possibly evidenced by reduction in body temperature, cool skin, pallor.

risk for imbalanced Nutrition: less than body requirements possibly evidenced by [placental insufficiency, decreased subcutaneous fat stores, decreased glycogen stores at birth (neonatal hypoglycemia)].

risk for impaired Skin Integrity possibly evidenced by alteration in skin turgor (dry, peeling skin); [long fingernails, absence of vernix caseous].

Newborn, premature

PED

impaired Gas Exchange may be related to (alveolar-capillary membrane changes [inadequate surfactant levels]), (ventilation-perfusion imbalance [immaturity

of pulmonary arteriole musculature]), possibly evidenced by [respiratory difficulties, inadequate oxygenation of tissues, and acidemia].

ineffective Breathing Pattern may be related to immaturity of the respiratory center, poor positioning, drug-related depression and metabolic imbalances, decreased energy, fatigue, possibly evidenced by dyspnea, tachypnea, periods of apnea, nasal flaring, use of accessory muscles, cyanosis, abnormal arterial blood gases, and tachycardia.

risk for ineffective Thermoregulation possibly evidenced by immature central nervous system development (temperature regulation center), decreased ratio of body mass to surface area, decreased subcutaneous fat, limited brown fat stores, inability to shiver or sweat, poor metabolic reserves, muted response to hypothermia, and frequent medical/nursing manipulations and interventions.

risk for deficient Fluid Volume possibly evidenced by extremes of age and weight, excessive fluid losses (thin skin, lack of insulating fat, increased environmental temperature, immature kidney/failure to concentrate urine).

risk for ineffective infant Feeding Pattern possibly evidenced by decreased energy, fatigue; poor positioning; drug-related depression; inability to coordinate sucking, swallowing, and breathing.

risk for disorganized infant Behavior possibly evidenced by prematurity (immaturity of central nervous system, hypoxia), lack of containment or boundaries, pain, overstimulation, separation from parents.

risk for Injury [central nervous system damage] possibly evidenced by tissue hypoxia, altered clotting factors, metabolic imbalances (hypoglycemia, electrolyte shifts, elevated bilirubin).

Newborn, small for gestational age

PED

Refer to Newborn, growth deviations

Newborn, special needs

PED

(Also refer to specific condition.)

[family] Grieving may be related to [perceived loss of the perfect child, alterations of future expectations], possibly evidenced by expression of distress at loss, sorrow, guilt, anger, choked feelings; interference with life activities, crying.

deficient parental Knowledge regarding condition and infant care may be related to lack of or unfamiliarity with information resources, misinterpretation, possibly evidenced by questions, concerns, misconceptions, hesitancy, or inadequate performance of activities.

risk for impaired Attachment possibly evidenced by delay or interruption in bonding process (separation, physical barriers), perceived threat to infant's survival, stressors (financial, family needs), lack of appropriate response of newborn, lack of support between or from SOs.

risk for ineffective family Coping possibly evidenced by situational crises, temporary preoccupation of SO trying to manage emotional conflicts and personal suffering, being unable to perceive or act effectively in regard to infant's needs, temporary family disorganization.

risk for (parental) Social Isolation possibly evidenced by perceived situational crisis, assuming sole or full-time responsibility for infant's care, lack of or inappropriate use of resources.

Nicotine abuse

CH

risk-prone Health Behavior may be related to lack of motivation to change behavior, low state of optimism, absence of social/SO support for change, failure to intend to change behavior, possibly evidenced by denial of health problem, failure to take action, failure to achieve optimal sense of control.

risk for Injury possibly evidenced by smoking habits (e.g., in bed, while driving, near combustible chemicals or oxygen), children playing with cigarettes or matches.

risk for impaired Gas Exchange possibly evidenced by [progressive airflow obstruction, decreased oxygen supply (carbon monoxide)].

risk for ineffective peripheral Tissue Perfusion possibly evidenced by reduction of arterial or venous blood flow.

Nicotine withdrawal

CH

readiness for enhanced Health Management (smoking cessation) possibly evidenced by expresses desire to enhance choices of daily living for meeting goals.

risk for Overweight possibly evidenced by eating in response to internal cues (substitution of food for activity of smoking).

risk for ineffective Health Management possibly evidenced by economic difficulties, lack of support from SO/friends, continued environmental exposure to secondhand smoke or smoking activity.

Nonketotic hyperosmolar syndrome

MS

deficient Fluid Volume may be related to excessive renal losses, inadequate oral intake, extremes of age,

presence of infection, possibly evidenced by sudden weight loss, dry skin and mucous membranes, poor skin turgor, hypotension, increased pulse, fever, change in mental status (confusion to coma).

decreased Cardiac Output may be related to decreased preload (hypovolemia), altered heart rhythm (hyper-/hypokalemia), possibly evidenced by decreased hemodynamic pressures (e.g., central venous pressure), electrocardiogram changes, dysrhythmias.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, [inadequate utilization of nutrients (insulin deficiency)], possibly evidenced by [recent weight loss, imbalance between glucose and insulin levels].

risk for physical Trauma possibly evidenced by weakness, cognitive limitations, altered consciousness, loss of large- or small-muscle coordination (risk for seizure activity).

Obesity

CH

Obesity may be related to excessive intake in relation to metabolic needs, possibly evidenced by weight 20% greater than ideal for height and frame, sedentary activity level, reported or observed dysfunctional eating patterns, and excess body fat by triceps skinfold or other measurements.

sedentary Lifestyle may be related to lack of interest or motivation, resources; lack of training or knowledge of specific exercise needs, safety concerns or fear of injury, possibly evidenced by demonstration of physical deconditioning, choice of a daily routine lacking physical exercise.

Activity Intolerance may be related to imbalance between oxygen supply and demand, and sedentary lifestyle, possibly evidenced by fatigue or weakness, exertional discomfort, and abnormal heart rate and blood pressure response to activity.

risk for Sleep deprivation possibly evidenced by nonrestorative sleep pattern, (sleep apnea).

PSY

disturbed Body Image may be related to alteration in self-perception [view of self in contrast to societal values], possibly evidenced by negative feeling about body, fear of reaction of others [lack of follow through with treatment plan].

impaired Social Interaction may be related to disturbance in self-concept, (absence of significant other), impaired mobility, possibly evidenced by dissatisfaction with social engagement, discomfort in social situations, dysfunctional interactions with others.

Obesity-hypoventilation syndrome**CH**

Refer to Pickwickian syndrome

Obsessive-compulsive disorder**PSY**

[severe] Anxiety may be related to earlier life conflicts, possibly evidenced by repetitive actions, recurring thoughts, decreased social and role functioning.

risk for impaired Skin/Tissue Integrity possibly evidenced by risk factors of psychogenic factors (repetitive behaviors related to cleansing [e.g., hand washing, brushing teeth, showering]).

risk for ineffective Role Performance possibly evidenced by stressors, anxiety, ineffective coping strategies.

Opioid abuse**CH/PSY**

Refer to Depressant abuse; Heroin abuse/withdrawal

Oppositional defiant disorder**PED/PSY**

ineffective Coping may be related to (situational or maturational crisis), ineffective tension release strategies, insufficient sense of control, insufficient social support, possibly evidenced by inability to meet role expectations, ineffective coping strategies, insufficient problem-solving skills, risk-taking behavior.

impaired Social Interaction may be related to disturbance in self-concept, sociocultural dissonance, insufficient skills to enhance mutuality, disturbance in thought processes, possibly evidenced by discomfort in social situations, impaired social functioning, dysfunctional interactions with others.

chronic low Self-Esteem may be related to inadequate respect from others, receiving insufficient approval from others, (repeated negative reinforcement, psychiatric disorder), possibly evidenced by exaggerates negative feedback about self [or brags about self, grandiosity], poor eye contact, repeatedly unsuccessful in life events [projection of blame/responsibility for problems].

disabled family Coping may be related to chronically unexpressed feelings by support person, ambivalent family relationships, differing coping styles between support persons, possibly evidenced by intolerance, rejection, hostility, aggression, depression, disregard for client's needs, family behaviors detrimental to well-being.

Organic brain syndrome**CH**

Refer to Alzheimer's disease

Osgood-Schlatter disease**PED**

acute Pain may be related to physical agent inflammation and swelling [region of patellar tendon],

possibly evidenced by verbal reports, protective behavior, change in muscle tone.

impaired Walking may be related to inflammatory process (knee), possibly evidenced by impaired ability to walk desired distances, climb or descend stairs.

risk for ineffective Health Management possibly evidenced by age (adolescence), perceived seriousness or benefit, failure to include treatment regimen in daily living.

Osteitis deformans**CH**

Refer to Paget's disease, bone

Osteoarthritis (degenerative joint disease)**CH**

Refer to Arthritis, rheumatoid

(Although this is a degenerative process versus the inflammatory process of rheumatoid arthritis, nursing concerns are the same.)

Osteomalacia**CH**

Refer to Rickets

Osteomyelitis**MS/CH**

acute Pain may be related to physical injury agent (typically bacterial infection), possibly evidenced by verbal reports, guarding or distraction behavior, self-focused, and autonomic responses (changes in vital signs).

Hyperthermia may be related to increased metabolic rate and infectious process, possibly evidenced by increased body temperature and warm, flushed skin.

ineffective bone Tissue Perfusion may be related to inflammatory reaction with thrombosis of vessels, destruction of tissue, edema, and abscess formation, possibly evidenced by bone necrosis, continuation of infectious process, and delayed healing.

risk for impaired Walking possibly evidenced by inflammation and tissue necrosis, pain, joint instability.

deficient Knowledge regarding pathophysiology of condition, long-term therapy needs, activity restriction, and prevention of complications may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, and misconceptions, and inaccurate follow-through of instructions.

Osteoporosis**CH**

risk for Trauma possibly evidenced by loss of bone density and integrity increasing risk of fracture with minimal or no stress.

acute/chronic Pain may be related to physical agent—vertebral compression on spinal nerve, muscles, or ligaments; spontaneous fractures, possibly evidenced by verbal reports, guarding or distraction behaviors, self-focus, and changes in sleep pattern.

impaired physical Mobility may be related to pain and musculoskeletal impairment, possibly evidenced by limited range of motion, reluctance to attempt movement, expressed fear of reinjury, and imposed restrictions or limitations.

Otitis media

PED

acute Pain may be related to physical injury agent (infection, allergy or blockage) possibly evidenced by verbal or coded report, guarding behavior, restlessness, crying.

[disturbed auditory Sensory Perception] may be related to decreased sensory reception, possibly evidenced by reported change in sensory acuity, auditory distortions, change in usual response to stimuli.

risk for delayed Development possibly evidenced by auditory impairment, frequent ear infections.

Ovarian cancer

MS

Also refer to Cancer

disturbed Body Image may be related to alteration in self-perception, possibly evidenced by alteration in body function, negative feeling about body, preoccupation with change/loss, and change in social involvement.

Sexual dysfunction may be related to (alteration in body function), vulnerability, insufficient knowledge/misinformation about sexual function, possibly evidenced by verbalizations of problem, alteration in sexual satisfaction, perceived sexual limitation, undesired change in sexual function.

Paget's disease, bone

CH

acute Pain may be related to physical agent—compression/entrapment of nerves, joint deformities, possibly evidenced by reports of headache, back or joint pain.

Fatigue may be related to disease state and hypermetabolic condition, possibly evidenced by overwhelming lack of energy, inability to maintain usual routines, tired.

disturbed Body Image may be related to alteration in self-perception, cultural incongruence, possibly evidenced by alteration in structure—enlarged skull, bowing of long bones, alteration in view of one's body, negative feeling about body, fear of reaction of others, change in social involvement.

[disturbed auditory Sensory Perception] may be related to altered sensory reception or transmission (nerve compression), possibly evidenced by decreased auditory acuity.

risk for impaired Walking possibly evidenced by bowing of long bones, hobbling gait, joint stiffness and pain, paresis or paralysis.

risk for Injury/Falls possibly evidenced by bone deformity or fragility, joint stiffness and pain, altered gait.

risk for decreased Cardiac Output possibly evidenced by excessive circulatory demands (metabolically active and highly vascular nature of lesions).

Palliative care

CH

Refer to Hospice care

Palsy, cerebral

PED/CH

impaired physical Mobility may be related to muscular weakness or hypertonicity, increased deep tendon reflexes, tendency to contractures, and underdevelopment of affected limbs, possibly evidenced by decreased muscle strength, control, mass; limited range of motion, and impaired coordination.

compromised family Coping may be related to permanent nature of condition, situational crisis, emotional conflicts, temporary family disorganization, and incomplete information or understanding of client's needs, possibly evidenced by verbalized anxiety or guilt regarding client's disability, inadequate understanding and knowledge base, and displaying protective behaviors disproportionate (too little or too much) to client's abilities or need for autonomy.

risk for delayed Development possibly evidenced by congenital disorder/brain injury, seizure disorder, visual/hearing impairment.

Pancreas transplantation

MS/CH

Refer to Transplantation, recipient

Pancreatic cancer

MS

Also refer to Cancer

acute Pain/impaired Comfort may be related to physical injury agent (tumor involving or invading nerves or organs that lie near the pancreas) possibly evidenced by verbal reports, guarding or distraction behavior, self-focused, and autonomic responses (changes in vital signs).

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to ingest or digest food, or absorb nutrients),

possibly evidenced by food intake less than recommended daily allowance, [anorexia, abdominal pain after eating, weight loss, cachexia].

risk for Infection possibly evidenced by stasis of body fluids (biliary obstruction), malnutrition.

risk for impaired Tissue Integrity possibly evidenced by poor skin turgor, skeletal prominence, presence of edema, ascites, bile salt accumulation in the tissues.

Pancreatitis

MS

acute Pain may be related to physical agent—obstruction of pancreatic and biliary ducts, chemical agent—contamination of peritoneal surfaces by pancreatic exudate, autodigestion of pancreas, extension of inflammation to the retroperitoneal nerve plexus, possibly evidenced by verbal reports, guarding or distraction behaviors, self-focused, grimacing, changes in vital signs, and alteration in muscle tone.

risk for deficient Fluid Volume/Bleeding possibly evidenced by excessive gastric losses (vomiting, nasogastric suctioning), increase in size of vascular bed (vasodilation, effects of kinins), third-space fluid transudation, ascites formation, alteration of clotting process, hemorrhage.

risk for unstable Blood Glucose Level possibly evidenced by (compromised physical health status), excessive stress, ineffective medication management.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to ingest or digest food, or absorb nutrients), possibly evidenced by food aversion, food intake less than recommended daily allowance, [anorexia, abdominal pain after eating, weight loss, cachexia].

risk for Infection possibly evidenced by stasis of body fluids, altered peristalsis, malnutrition, (alteration in pH of secretions, immunosuppression, and chronic illness).

Panic disorder

PSY

Fear may be related to response to phobic stimulus (unfounded morbid dread of a seemingly harmless object or situation, possibly evidenced by physiological symptoms, mental or cognitive behaviors indicative of panic, withdrawal from or total avoidance of situations that place client in contact with feared object).

[severe to panic] Anxiety may be related to stressors, contact with feared object or situation, limitations placed on ritualistic behavior, possibly evidenced by attacks of immobilizing apprehension,

physical, mental, or cognitive behaviors indicative of panic; expressed feelings of terror or inability to cope.

Paralysis, infantile

PED

Refer to Poliomyelitis

Paranoid personality disorder

PSY

risk for other-/self-directed Violence possibly evidenced by perceived threats of danger, paranoid delusions, and increased feelings of anxiety.

[severe] Anxiety may be related to unmet needs—has not mastered tasks of trust versus mistrust, possibly evidenced by [rigid delusional system (serves to provide relief from stress that justifies the delusion)], apprehensiveness, fear, uncertainty.

Powerlessness may be related to insufficient interpersonal interactions, anxiety, social marginalization, (complicates treatment regimen), possibly evidenced by alienation, insufficient sense of control.

[disturbed Sensory Perception (specify)] may be related to psychological stress, possibly evidenced by change in behavior pattern/usual response to stimuli.

compromised family Coping may be related to family disorganization/role changes, prolonged progression of condition that exhausts the supportive capacity of SO(s), possibly evidenced by family system not meeting physical, emotional, or spiritual needs of its members; inability to express or to accept wide range of feelings; inappropriate boundary maintenance; SO(s) describe(s) preoccupation with personal reactions.

Paranoid schizophrenia

PSY

Refer to Schizophrenia (schizophrenic disorders)

Paraphilias

PSY

ineffective Sexuality Pattern may be related to conflict with sexual orientation or variant preferences, possibly evidenced by alterations in achieving sexual satisfaction, difficulty achieving desired satisfaction in socially acceptable ways.

situational low Self-Esteem may be related to behavior inconsistent with values, (history of rejection, pattern of failure), possibly evidenced by situational challenge to self-worth, self-negating verbalizations, helplessness.

interrupted Family Processes may be related to (situational crisis [e.g., revelation of sexual deviance or dysfunction]), shift in family roles, (change in family social status), possibly evidenced by change

in communication pattern, change in family conflict resolution, change in family satisfaction, change in intimacy.

Paraplegia

MS/CH

Also refer to Quadriplegia

impaired Transfer Ability may be related to loss of muscle function and control, injury to upper extremity joints (overuse).

[disturbed kinesthetic/tactile Sensory Perception] may be related to neurological deficit with loss of sensory reception and transmission, psychological stress, possibly evidenced by reported or measured change in sensory acuity, change in usual response to stimuli, anxiety, disorientation, bizarre thinking, exaggerated emotional responses.

reflex urinary Incontinence/impaired urinary Elimination may be related to disruption of bladder innervation, bladder atony, fecal impaction, possibly evidenced by lack of awareness of bladder distention, retention, incontinence, or overflow, urinary tract infections—kidney stone formation, renal dysfunction.

situational low Self-Esteem may be related to alteration in body function, (functional impairment), possibly evidenced by self-negating verbalizations, situational challenge to self-worth, helplessness.

Sexual dysfunction may be related to (alteration in function), and vulnerability, possibly evidenced by seeking confirmation of desirability, perceived sexual limitation, and change in interest in self/others.

Parathyroidectomy

MS

acute Pain may be related to physical agent—surgical incision and effects of calcium imbalance [bone pain, tetany], possibly evidenced by verbal reports, guarding or distraction behavior, self-focused, and changes in vital signs.

risk for excess Fluid Volume possibly evidenced by preoperative renal involvement, stress-induced release of antidiuretic hormone, and changing calcium or other electrolyte levels.

risk for ineffective Airway Clearance possibly evidenced by edema formation and laryngeal nerve damage.

deficient Knowledge regarding postoperative care, complications, and long-term needs may be related to lack of information or recall, misinterpretation, possibly evidenced by statements of concern, questions, and misconceptions.

Parent-child relational problem

PED/PSY

impaired Parenting may be related to lack of or ineffective role model, lack of support between or from SO, interruption in bonding process, unrealistic expectations for self/child/partner, presence of stressors, lack of appropriate response of child to parent, possibly evidenced by frequent verbalization of disappointment in child, inability to care for or discipline child, lack of parental attachment behaviors, child abuse or abandonment.

ineffective Role Performance may be related to conflict, inadequate role model, domestic violence, insufficient role preparation, resources or rewards, low self-esteem [psychiatric or physical illness of the child], possibly evidenced by change in usual pattern of responsibility, role ambivalence/strain, uncertainty, inappropriate developmental expectations, ineffective adaptation to change.

interrupted Family Process may be related to situational crisis of child/adolescent, maturational crisis (e.g., adolescence, midlife), possibly evidenced by expressions of confusion and difficulty coping with situation; family system not meeting physical, emotional, or security needs of members; difficulty accepting help; parents not respecting each other's parenting practices.

compromised/disabled family Coping may be related to individual preoccupation with own emotional conflicts and personal suffering or anxiety about the crisis, temporary family disorganization, exhausted supportive capacity of members, highly ambivalent family relationships, possibly evidenced by detrimental decisions or actions, neglected relationships, intolerance, agitation, depression, hostility, aggression.

readiness for enhanced family Coping possibly evidenced by expresses desire to enhance contact with others who have experienced a similar situation.

Parenteral feeding

MS/CH

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to ingest/digest food, or absorb nutrients), possibly evidenced by [body weight 10% or more under ideal, decreased subcutaneous fat or muscle mass].

risk for Infection possibly evidenced by malnutrition, (invasive procedure), and (chronic illness).

risk for Injury [multifactor] possibly evidenced by catheter-related complications (air emboli, septic thrombophlebitis).

risk for imbalanced Fluid Volume possibly evidenced by active loss or failure of regulatory mechanisms (specific to underlying disease process or trauma), complications of therapy—high glucose solutions or hyperglycemia (hyperosmolar nonketotic syndrome and severe dehydration), inability to obtain or ingest fluids.

Fatigue may be related to decreased metabolic energy production, increased energy requirements (hypermetabolic state, healing process), altered body chemistry (medications, chemotherapy), possibly evidenced by overwhelming lack of energy, inability to maintain usual routines or accomplish routine tasks, lethargy, impaired ability to concentrate.

Parkinson's disease

CH

impaired Walking may be related to neuromuscular impairment (muscle weakness, tremors, bradykinesia) and musculoskeletal impairment (joint rigidity), possibly evidenced by inability to move about the environment as desired, increased occurrence of falls.

impaired Swallowing may be related to neuromuscular impairment, muscle weakness, possibly evidenced by reported or observed difficulty in swallowing, drooling, evidence of aspiration (choking, coughing).

impaired verbal Communication may be related to muscle weakness and incoordination, possibly evidenced by impaired articulation, difficulty with phonation, and changes in rhythm and intonation.

risk for Stress overload possibly evidenced by inadequate resources, chronic illness, physical demands.

caregiver Role Strain may be related to illness, severity of care receiver, psychological/cognitive problems in care receiver, caregiver is spouse, duration of caregiving required, lack of respite or recreation for caregiver, possibly evidenced by feeling stressed, depressed, worried; lack of resources or support, family conflict.

Passive-aggressive personality disorder

PSY

[moderate to severe] Anxiety may be related to conflict about life goals, unmet needs, threat to current status, stressors, possibly evidenced by worried about change in life event, blocking of thoughts, feeling of inadequacy, extraneous movements, irritability, tendency to blame others.

ineffective Coping may be related to insufficient sense of control, ineffective tension release strategies,

possibly evidenced by ineffective coping strategies; insufficient problem-solving skills.

chronic low Self-Esteem may be related to inadequate affection received; receiving insufficient approval from others, (psychiatric disorder), possibly evidenced by rejective of positive feedback, underestimates ability to deal with situation, passivity, non-assertive/indecisive behavior, dependent on others' opinions, (repeated negative reinforcement).

Powerlessness may be related to insufficient interpersonal interactions, possibly evidenced by alienation, insufficient sense of control, depression, inadequate participation in care, dependency.

PCP (phencyclidine) intoxication

MS/PSY

Also refer to Hallucinogen abuse

risk for self-/other-directed Violence possibly evidenced by negative body language, impulsiveness, (history of substance misuse, alteration in cognitive functioning, mental health issue).

risk for physical Trauma/Suffocation/Poisoning possibly evidenced by risk factors of impaired balance, alteration in cognitive functioning, alteration in sensation [decrease in pain perception], [increase in muscle strength, myoclonic jerks or convulsions].

risk for ineffective cerebral Tissue Perfusion possibly evidenced by substance abuse, (hypertensive crisis).

Pediculosis capitis

PED/CH

impaired Skin Integrity related to [presence of nits, intense itching, and scratching]; possibly evidenced by redness, [excoriation, disruption of skin surface].

risk for Infection [spread] possibly evidenced by insufficient knowledge to avoid exposure or transmission of parasite.

Pediculosis pubis

CH

Refer to Pediculosis capitis

Pelvic inflammatory disease

OB/GYN/CH

risk for Infection [spread] possibly evidenced by [presence of infectious process in highly vascular pelvic structures, delay in seeking treatment].

acute Pain may be related to inflammation, edema, and congestion of reproductive and pelvic tissues, possibly evidenced by verbal reports, guarding or distraction behaviors, self-focus, and changes in vital signs.

Hyperthermia may be related to inflammatory process and hypermetabolic state, possibly evidenced

by increased body temperature; warm, flushed skin; and tachycardia.

risk for situational low Self-Esteem possibly evidenced by perceived stigma of physical condition (infection of reproductive system).

deficient Knowledge regarding cause/complications of condition, therapy needs, and transmission of disease to others may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, misconceptions, and development of preventable complications.

Periarteritis nodosa

MS/CH

Refer to Polyarteritis nodosa

Pericarditis

MS

acute Pain may be related to physical agent—tissue inflammation and presence of effusion, possibly evidenced by verbal reports of pain, guarding or distraction behavior, self-focused, and changes in vital signs.

Activity Intolerance may be related to imbalance between oxygen supply and demand (restriction of cardiac filling and ventricular contraction, reduced cardiac output), possibly evidenced by reports of weakness, fatigue, exertional dyspnea, abnormal heart rate or blood pressure response (signs of heart failure).

risk for decreased Cardiac Output possibly evidenced by accumulation of fluid (effusion), restricted cardiac filling, and contractility.

Anxiety [specify level] may be related to threat to current status, threat of death, possibly evidenced by increased tension, apprehension, restlessness, and expressed concerns.

Perinatal loss/death of child

OB/CH

Grieving may be related to death of significant other—fetus/infant, possibly evidenced by distress, anger, blaming, alteration in sleep pattern.

situational low Self-Esteem may be related to unrealistic self-expectation, (developmental transition), possibly evidenced by self-negating verbalizations, helplessness, indecisive behavior, situational challenge to self-worth.

risk for ineffective Role Performance possibly evidenced by stressors, ineffective coping strategies, insufficient support system.

risk for interrupted Family Processes possibly evidenced by (situational crisis, developmental transition [loss of child]), shift in family roles.

risk for Spiritual distress possibly evidenced by stressors, depression, (loss of child, unexpected life event), separation from support system.

Peripheral arterial occlusive disease

CH

Refer to Arterial occlusive disease, peripheral

Peripheral vascular disease (atherosclerosis)

CH

ineffective peripheral Tissue Perfusion may be related to reduction or interruption of arterial or venous blood flow, possibly evidenced by changes in skin temperature and color, lack of hair growth, blood pressure and pulse changes in extremity, presence of bruits, and reports of claudication.

Activity Intolerance may be related to imbalance between oxygen supply and demand, possibly evidenced by reports of fatigue, weakness and exertional discomfort (claudication).

risk for impaired Skin/Tissue Integrity possibly evidenced by impaired circulation and alteration insensation.

Peritonitis

MS

risk for Infection [spread/sepsis/septic shock] possibly evidenced by alteration in skin integrity or traumatized tissue, altered peristalsis, and associated condition of immunosuppression and invasive procedures.

deficient Fluid Volume [mixed] may be related to fluid shifts from extracellular, intravascular, and interstitial compartments into intestines or peritoneal space, excessive gastric losses (vomiting, diarrhea, nasogastric suction), fever, hypermetabolic state, and restricted intake, possibly evidenced by dry mucous membranes, poor skin turgor, delayed capillary refill, weak peripheral pulses, diminished urinary output, dark, concentrated urine; hypotension, and tachycardia.

acute Pain may be related to chemical irritation of parietal peritoneum, trauma to tissues, abdominal distention—accumulation of fluid in abdominal or peritoneal cavity, possibly evidenced by verbal reports, muscle guarding or rebound tenderness, distraction behaviors, facial mask of pain, self-focus, and changes in vital signs.

risk for imbalanced Nutrition: less than body requirements possibly evidenced by (inability to ingest/digest food), abdominal pain, insufficient interest in food/food aversion.

Persian Gulf syndrome

CH/MS

Refer to Gulf War syndrome

Personality disorders; or**PSY**

Refer to Antisocial; Borderline; Obsessive-compulsive; Passive-aggressive; or Paranoid personality disorders

Pertussis**PED**

ineffective Airway Clearance may be related to retained secretions, excessive thick tenacious mucus, infection, possibly evidenced by dyspnea, adventitious breath sounds, hacking/paroxysmal cough.

deficient Fluid Volume may be related to decreased intake, anorexia, vomiting, increased insensible losses (fever, diaphoresis), possibly evidenced by decreased urine output and increased specific gravity, decreased blood pressure, increased pulse rate, decreased skin and tongue turgor, dry skin and mucous membranes.

risk for Infection [transmission/secondary] possibly evidenced by stasis of body fluids, malnutrition, insufficient knowledge to avoid exposure to pathogens.

risk for imbalanced Nutrition: less than body requirements possibly evidenced by inability to ingest food or absorb nutrients (anorexia, vomiting), and [increased metabolic demands].

risk for impaired Gas Exchange possibly evidenced by (ventilation/perfusion imbalance–atelectasis).

Pervasive developmental disorders **PED/PSY**

Refer to Autism spectrum disorder; Rett's syndrome; Asperger's disorder

Pheochromocytoma**MS**

Anxiety [specify level] may be related to excessive physiological (hormonal) stimulation of the sympathetic nervous system, situational crises, threat to or change in health status, possibly evidenced by apprehension, shakiness, restlessness, focus on self, fearfulness, diaphoresis, and sense of impending doom.

deficient Fluid Volume [mixed] may be related to excessive gastric losses (vomiting, diarrhea), hypermetabolic state, diaphoresis, and hyperosmolar diuresis, possibly evidenced by hemoconcentration, dry mucous membranes, poor skin turgor, thirst, and weight loss.

decreased Cardiac Output/ineffective Tissue Perfusion (specify) may be related to altered preload—decreased blood volume, altered systemic vascular resistance, and increased sympathetic activity (excessive secretion of catecholamines), possibly evidenced by cool, clammy skin, change in blood pressure (hypertension, postural hypotension), visual disturbances, severe headache, and angina.

deficient Knowledge regarding pathophysiology of condition, outcome, and preoperative and postoperative care needs may be related to lack of information or recall, possibly evidenced by statements of concern, questions, and misconceptions.

Phlebitis**CH**

Refer to Thrombophlebitis

Phobia**PSY**

Also refer to Anxiety disorder, generalized

Fear may be related to learned response to phobic stimulus, unfounded morbid dread of a seemingly harmless object or situation, possibly evidenced by sympathetic stimulation and reactions ranging from apprehension to panic, withdrawal from or total avoidance of situations that place individual in contact with feared object.

impaired Social Interaction may be related to intense fear of encountering feared object, activity or situation; and anticipated loss of control, possibly evidenced by reported change of style or pattern of interaction, discomfort in social situations, and avoidance of phobic stimulus.

Physical abuse**CH/PSY**

Refer to Abuse, physical; Battered child syndrome

Pickwickian syndrome**CH**

ineffective Breathing Pattern may be related to obesity, hypoventilation, possibly evidenced by decreased pulmonary function, hypercapnia, hypoxia, reduced effect of carbon dioxide in stimulating respirations.

PID**GYN/OB/CH**

Refer to Pelvic inflammatory disease

Pinkeye**CH**

Refer to Conjunctivitis, bacterial

Placenta previa**OB**

risk for Bleeding/Shock possibly evidenced by (pregnancy complication), hypotension, hypovolemia.

risk for disturbed Maternal-Fetal Dyad may be related to (pregnancy complication, alteration in fetal oxygen transport).

[severe] Anxiety may be related to threat of death, threat to current status, interpersonal contagion, stressors, possibly evidenced by distress, increase in tension, hypervigilance, sympathetic stimulation.

Plague, bubonic

MS

Hyperthermia may be related to illness, dehydration, possibly evidenced by increased body temperature, tachycardia, chills, confusion.

acute Pain may be related to inflammatory process, enlarged lymph nodes, possibly evidenced by verbal or coded reports, expressive behavior, autonomic responses.

risk for deficient Fluid Volume possibly evidenced by fever, decreased oral intake.

risk for impaired Skin Integrity possibly evidenced by (impaired circulation and immunodeficiency—*infectious process*).

Plague, pneumonic

MS

risk for Infection [spread] possibly evidenced by [contagious nature of disease, close contact with others].

Hyperthermia may be related to illness, dehydration, possibly evidenced by increased body temperature, tachycardia, chills, severe headache, confusion.

impaired Gas Exchange may be related to (alveolar-capillary membrane changes), possibly evidenced by abnormal breathing patterns (tachypnea, dyspnea, stridor), abnormal skin color (cyanosis), [hemoptysis].

deficient Fluid Volume may be related to fever, hypermetabolic state, decreased intake, bleeding diathesis (disseminated intravascular coagulation), possibly evidenced by weakness, decreased venous filling, decreased blood pressure, decreased skin turgor, dry mucous membranes, change in mental state.

Plantar fasciitis

CH

acute/chronic Pain may be related to inflammation, possibly evidenced by report of stabbing, burning pain, guarding or protective behavior, change in posture and gait, altered ability to continue previous activities.

impaired Walking may be related to musculoskeletal impairment, impaired balance, pain, possibly evidenced by impaired ability to walk required distances or climb stairs.

Pleural effusion

CH/MS

Also refer to Hemothorax

acute Pain may be related to inflammation/irritation of the parietal pleura, possibly evidenced by verbal reports, guarding or distraction behaviors, self-focus, and changes in vital signs.

ineffective Breathing Pattern may be related to pain on inspiration, possibly evidenced by decreased respiratory depth, tachypnea, and dyspnea.

risk for impaired Gas Exchange possibly evidenced by (ventilation perfusion imbalance).

Pleurisy

CH

acute Pain may be related to inflammation and irritation of the parietal pleura, possibly evidenced by verbal reports, guarding or distraction behaviors, self-focus, and changes in vital signs.

ineffective Breathing Pattern may be related to pain on inspiration, possibly evidenced by decreased respiratory depth, tachypnea, and dyspnea.

risk for Infection [pneumonia] possibly evidenced by stasis of pulmonary secretions, decreased lung expansion, and ineffective cough.

PMDD

GYN/PSY

Refer to Premenstrual dysphoric disorder

PMS

GYN/PSY

Refer to Premenstrual dysphoric disorder

Pneumoconiosis (black lung)

CH

Refer to Pulmonary fibrosis

Pneumonia

CH/MS

Refer to Bronchitis; Bronchopneumonia

Pneumonia, ventilator associated

CH

Refer to Bronchopneumonia

Pneumothorax

MS

Also refer to Hemothorax

ineffective Breathing Pattern may be related to decreased lung expansion (air accumulation), musculoskeletal impairment, pain, inflammatory process, possibly evidenced by dyspnea, tachypnea, altered chest excursion, respiratory depth changes, use of accessory muscles, nasal flaring, cough, cyanosis, and abnormal arterial blood gases.

risk for decreased Cardiac Output possibly evidenced by compression or displacement of cardiac structures.

acute Pain may be related to irritation of nerve endings within pleural space by foreign object (chest tube), possibly evidenced by verbal reports, guarding or distraction behaviors, self-focus, and changes in vital signs.

Poliomyelitis

CH

Also refer to Postpolio syndrome

ineffective Breathing Pattern may be related to neuromuscular dysfunction and intercostal muscle impairment, hypoventilation syndrome, possibly evidenced

by dyspnea, decreased depth of breathing, altered chest excursion, respiratory failure.

impaired physical Mobility related to neuromuscular dysfunction and musculoskeletal impairment, decreased muscle strength, control or mass; contracture, decreased endurance, pain, prescribed movement restriction or bracing, possibly evidenced by limited ability to move, uncoordinated or jerky movements, gait changes, exaggerated lateral postural sway, postural instability.

Self-Care deficit [specify] may be related to neuromuscular impairment, weakness, pain, fatigue, possibly evidenced by reported or observed inability to perform specified activities.

Polyarteritis nodosa **MS/CH**

ineffective Tissue Perfusion (specify) may be related to reduction or interruption of blood flow, possibly evidenced by organ tissue infarctions, changes in organ function, and development of organic psychosis.

Hyperthermia may be related to widespread inflammatory process, possibly evidenced by increased body temperature and warm, flushed skin.

acute Pain may be related to inflammation, tissue ischemia, and necrosis of affected area, possibly evidenced by verbal reports, guarding or distraction behaviors, self-focus, and changes in vital signs.

Polycythemia vera **CH**

Activity Intolerance may be related to imbalance between oxygen supply and demand, possibly evidenced by reports of fatigue, weakness.

ineffective Tissue Perfusion (specify) may be related to reduction or interruption of arterial or venous blood flow (insufficiency, thrombosis, or hemorrhage), possibly evidenced by pain in affected area, impaired mental ability, visual disturbances, and color changes of skin and mucous membranes.

Polyradiculitis, acute inflammatory **MS**

Refer to Guillain-Barré syndrome

Postconcussion syndrome **CH**

acute/chronic Pain may be related to neuronal damage, possibly evidenced by reports of headache.

Anxiety [specify level] may be related to stressors (e.g., situational crisis, change in health status, ongoing nature of disability, unmet needs), possibly evidenced by expressed concerns, apprehensiveness, uncertainty, feeling of inadequacy, self-focused, difficulty concentrating.

impaired Memory may be related to neurological disturbances possibly evidenced by inability to recall events/factual information, reports experience of forgetting.

Postmaturity syndrome **PED**

Refer to Newborn, postmature

Postmyocardial syndrome **CH**

Refer to Dressler's syndrome

Postoperative recovery period **MS**

ineffective Breathing Pattern may be related to neuromuscular and perceptual or cognitive impairment, decreased lung expansion and energy, and tracheobronchial obstruction, possibly evidenced by changes in respiratory rate and depth, reduced vital capacity, apnea, cyanosis, and noisy respirations.

risk for imbalanced Body Temperature possibly evidenced by exposure to cool environment, effect of medications and anesthetic agents, extremes of age or weight, and dehydration.

risk for acute Confusion possibly evidenced by (pharmaceutical agents—anesthesia), pain.

risk for deficit Fluid Volume possibly evidenced by restriction of oral intake, loss of fluid through abnormal routes (indwelling tubes, drains) and normal routes (vomiting, loss of vascular integrity, changes in clotting ability), extremes of age and weight.

acute Pain may be related to disruption of skin, tissue, and muscle integrity; musculoskeletal or bone trauma; and presence of tubes and drains, possibly evidenced by verbal reports, alteration in muscle tone, facial mask of pain, distraction or guarding behaviors, narrowed focus, and autonomic responses.

impaired Skin/Tissue Integrity may be related to [mechanical interruption of skin or tissues (surgical incision)], (impaired circulation, pharmaceutical agent, alteration in metabolism) possibly evidenced by alteration in skin and tissue integrity, acute pain.

risk for Surgical Site Infection possibly evidenced by increased environmental exposure to pathogens, surgical wound contamination, and associated conditions of type and duration of surgery, type of anesthesia and comorbidities, immunosuppression.

Postpartum blues **OB/PSY**

Refer to Depression, postpartum

Postpartum period, 4 to 48 hours **OB/CH**

acute Pain/impaired Comfort may be related to tissue trauma, edema, muscle contractions, bladder fullness,

and physical or psychological exhaustion, possibly evidenced by reports of cramping (afterpains), self-focusing, alteration in muscle tone, distraction behaviors, and changes in vital signs.

Breastfeeding (specify) may be related to level of knowledge, previous experiences, infant gestational age, level of support, physical structure or characteristics of the maternal breasts, possibly evidenced by maternal verbalization regarding level of satisfaction, observations of breastfeeding process, infant response and weight gain.

risk for impaired Attachment possibly evidenced by lack of support between or from SO(s), ineffective or no role model, anxiety associated with the parental role, unrealistic expectations, unmet social or emotional maturation needs of client/partner, presence of stressors (e.g., financial, housing, employment).

risk for deficient Fluid Volume/Bleeding possibly evidenced by excessive blood loss during delivery, reduced intake or inadequate replacement, nausea, vomiting, increased urine output, and insensible losses.

impaired urinary Elimination may be related to hormonal effects (fluid shifts, continued elevation in renal plasma flow), mechanical trauma, tissue edema, and effects of medication or anesthesia, possibly evidenced by frequency, dysuria, urgency, incontinence, or retention.

Constipation may be related to decreased muscle tone associated with diastasis recti, prenatal effects of progesterone, dehydration, excess analgesia or anesthesia, pain (hemorrhoids, episiotomy, or perineal tenderness), prelabor diarrhea and lack of intake, possibly evidenced by frequency less than usual pattern, hard-formed stool, straining at stool, decreased bowel sounds, and abdominal distention.

Insomnia may be related to pain, discomfort, intense exhilaration or excitement, anxiety, exhausting process of labor and delivery, and needs or demands of family members, possibly evidenced by verbal reports of difficulty in falling asleep or staying asleep, not feeling well-rested, interrupted sleep, lack of energy.

Postpartum period, 4 to 6 weeks OB/CH

readiness for enhanced family Coping possibly evidenced by family member(s) moving in direction of health-promoting and enriching lifestyle.

disturbed Body Image may be related to unrealistic expectations, permanency of some changes, possibly evidenced by negative feeling about body, feeling

of helplessness, preoccupation with change, focus on past appearance, fear of reaction of others.

risk for Sexual dysfunction possibly evidenced by [health-related transition (changes in body function including lactation)], lack of privacy, fear of pregnancy.

readiness for enhanced Parenting possibly evidenced by expressed desire to enhance parenting.

Postpartum period, postdischarge to 4 weeks OB/CH

risk for Fatigue possibly evidenced by physical and emotional demands of infant and other family members, psychological stressors, continued discomfort.

Breastfeeding (specify) may be related to level of knowledge and support, previous experiences, infant gestational age, physical structure or characteristics of maternal breast, demands of home life and employment, possibly evidenced by maternal verbalizations regarding level of satisfaction, observations of feeding process, infant response, and weight gain.

risk for imbalanced Nutrition: less than body requirements possibly evidenced by [intake insufficient to meet metabolic demands or correct existing deficiencies (e.g., lactation, anemia, excessive blood loss, infection, excessive tissue trauma, desire to regain prenatal weight)].

risk for Infection possibly evidenced by malnutrition, alteration in skin integrity/tissue trauma, and associated conditions of premature or prolonged rupture of amniotic membranes, decreased Hb, invasive procedures, increased environmental exposure.

risk for compromised family Coping possibly evidenced by (situational or developmental changes), family disorganization/role change, insufficient reciprocal support.

risk for impaired Parenting possibly evidenced by situational crisis—addition and demands of new family member, changes in responsibilities of family members; sleep disruption, lack of support from SO/family members, young parental age, life stressors—financial, employment, home environment, lack of resources.

Postpartum psychosis OB/PSY

Also refer to Depression, postpartum

ineffective Coping may be related to inadequate level of confidence in ability to cope with situation, inadequate sense of control, possibly evidenced by inability to meet basic needs, insufficient problem-solving skills, alteration in sleep pattern and/or concentration.

risk for other-directed Violence possibly evidenced by mood swings, increased anxiety, despondency, hopelessness, psychotic symptomatology.

Postpolio syndrome

CH

Fatigue may be related to disease state, stress, anxiety, sleep deprivation, depression, possibly evidenced by overwhelming lack of energy, inability to maintain usual routines or level of physical activity, difficulty concentrating.

chronic Pain may be related to chronic physical disability, joint degeneration, possibly evidenced by reports of deep aching pain, altered ability to continue previous activities, change in sleep patterns, reduced interaction with others.

impaired Walking/physical Mobility may be related to neuromuscular impairment, decreased muscle strength and atrophy, decreased endurance, pain, inability to stand erect (flat back syndrome), possibly evidenced by gait disturbances, joint or postural instability, decreased ability to perform gross motor skills.

Sleep deprivation may be related to sleep apnea (central and obstructive), chronic pain, possibly evidenced by daytime drowsiness, decreased ability to function, inability to concentrate.

impaired Swallowing may be related to neuromuscular impairment, pharyngeal muscle weakness, possibly evidenced by coughing, choking, recurrent pulmonary infections.

ineffective Airway Clearance may be related to neuromuscular dysfunction (muscle weakness and atrophy), retained secretions, possibly evidenced by diminished or adventitious breath sounds (chronic microatelectasis), poor cough (decreased pulmonary compliance, increased chest wall tightness).

Post-traumatic stress disorder

PSY

Post-Trauma Syndrome may be related to perceives event as traumatic, serious injury to loved one/self, survivor role, (history of abuse, witnessing violent death, exposure to war), possibly evidenced by anxiety, irritability, aggression, anger, avoidance behavior, denial, depression, repression, exaggerated startle response, flashbacks, intrusive dreams/thoughts, substance misuse.

risk for self-/other-directed Violence possibly evidenced by impulsiveness, access to weapon, conflict in interpersonal relation(s), insufficient personal resources, pattern of threatening violence, suicidal ideation.

ineffective Coping may be related to high-degree of threat, inaccurate threat appraisal, inadequate confidence in ability to cope with situation, insufficient sense of control, possibly evidenced by inability to meet basic needs, insufficient problem-solving skills, alteration in sleep pattern and/or concentration, substance misuse.

complicated Grieving may be related to insufficient social support, emotional disturbance, possibly evidenced by depression, anxiety, anger, mistrust, self-blame, traumatic distress, feeling of detachment from others, decrease in functioning in life roles, insufficient sense of well-being.

interrupted Family Processes may be related to shift in family roles, power shift among family members, (situational crisis, shift in health status of a family member), possibly evidenced by change in communication pattern, change in family satisfaction, changes in participation for decision making, decrease in emotional support, change in stress-reduction behavior.

Preeclampsia

OB

Refer to Hypertension, gestational; Abruptio placentae

Pregnancy, 1st trimester

OB/CH

risk for imbalanced Nutrition: less than body requirements possibly evidenced by insufficient intake (nausea, vomiting, inadequate financial resources and nutritional knowledge).

impaired Comfort may be related to hormonal influences, physical changes, possibly evidenced by verbal reports (nausea, breast changes, leg cramps, hemorrhoids, nasal stuffiness), alteration in muscle tone, inability to relax.

risk for disturbed Maternal-Fetal Dyad possibly evidenced by environmental or hereditary factors, problems of maternal well-being (e.g., malnutrition, substance use).

[maximally compensated] Cardiac Output may be related to increased fluid volume, maximal cardiac effort and hormonal effects of progesterone and relaxin (places the client at risk for hypertension and/or circulatory failure), and changes in peripheral resistance (afterload), possibly evidenced by variations in blood pressure and pulse, syncopal episodes, presence of pathological edema.

readiness for enhanced family Coping possibly evidenced by expresses desire to enhance health promotion, and choose experiences that optimize wellness.

risk for Constipation possibly evidenced by changes in dietary or fluid intake, smooth muscle relaxation, decreased peristalsis, and effects of medications (e.g., iron).

Fatigue/Insomnia may be related to increased carbohydrate metabolism, altered body chemistry, increased energy requirements to perform activities of daily living, discomfort, anxiety, inactivity, possibly evidenced by reports of overwhelming lack of energy, inability to maintain usual routines, difficulty falling asleep, dissatisfaction with sleep, decreased quality of life.

risk for ineffective Role Performance possibly evidenced by maturational crisis, developmental level, history of maladaptive coping, absence of support systems.

readiness for enhanced Childbearing process possibly evidenced by expresses desire to enhance: knowledge of childbearing process, management of unpleasant pregnancy symptoms.

Pregnancy, 2nd trimester

OB/CH

Also refer to Pregnancy, 1st trimester

ineffective Breathing Pattern may be related to impingement of the diaphragm by enlarging uterus, possibly evidenced by reports of shortness of breath, dyspnea, and changes in respiratory depth.

risk for [decompensated] Cardiac Output possibly evidenced by increased circulatory demand, changes in preload (decreased venous return) and afterload (increased peripheral vascular resistance), and ventricular hypertrophy.

risk for excess Fluid Volume possibly evidenced by changes in regulatory mechanisms, sodium and water retention.

Sexual dysfunction may be related to conflict regarding changes in sexual desire and expectations, fear of physical injury to woman/fetus, possibly evidenced by reported difficulties, limitations or changes in sexual behaviors or activities.

Pregnancy, 3rd trimester

OB/CH

Also refer to Pregnancy, 1st and 2nd trimesters

readiness for enhanced Childbearing Process possibly evidenced by expresses desire to enhance preparation for labor/delivery, newborn.

impaired urinary Elimination may be related to uterine enlargement, increased abdominal pressure, fluctuation of renal blood flow, and glomerular filtration rate, possibly evidenced by urinary frequency, urgency, dependent edema.

risk for ineffective Coping/compromised family Coping possibly evidenced by (situational or maturational crisis), vulnerability, insufficient sense of control, insufficient social support.

risk for disturbed Maternal-Fetal Dyad possibly evidenced by risk factors of (pregnancy complication—hypertension, infection, abnormal blood profile), substance misuse.

Pregnancy, adolescent

OB/CH

Also refer to Pregnancy, 1st, 2nd, and 3rd trimesters

interrupted Family Processes may be related to (situational or developmental transition, shift in health status of a family member); shift in family roles, possibly evidenced by change in expression of conflict within family, change in communication pattern, changes in participation for problem-solving or decision making, decrease in available emotional support.

Social Isolation may be related to (alterations in physical appearance), perceived incongruent social behavior with norms, insufficient personal resources, possibly evidenced by aloneness imposed by others, inability to meet expectations of others; withdrawn; desires to be alone; and absence of support system.

situational low Self-Esteem may be related to (developmental transition), alteration in body image, social role; behavior inconsistent with values, unrealistic self-expectations possibly evidenced by self-negating verbalizations, underestimates ability to deal with situation, situational challenge to self-worth, and [lack of follow-through or nonparticipation in prenatal care].

ineffective Childbearing Process may be related to insufficient knowledge of childbearing process, (unplanned/unwanted pregnancy), inadequate maternal nutrition, low maternal confidence, insufficient cognitive readiness for parenting, insufficient support system, possibly evidenced by inadequate prenatal care/lifestyle, unrealistic birth plan, inadequate preparation of home environment/newborn care items.

risk for impaired Parenting possibly evidenced by (young parental age, insufficient cognitive readiness for parenting; low educational level, unplanned pregnancy), insufficient knowledge about parenting skills, father of child uninvolved.

Pregnancy, high-risk

OB/CH

Also refer to Pregnancy, 1st, 2nd, and 3rd trimesters

Anxiety [specify level] may be related to (situational crisis), threat to current status, interpersonal transmission or contagion, possibly evidenced by increase

in tension, apprehensiveness, feeling of inadequacy, alteration in sleep pattern.

readiness for enhanced Knowledge regarding high-risk situation and preterm labor possibly evidenced by expresses desire to enhance learning.

risk for disturbed Maternal-Fetal Dyad possibly evidenced by (pregnancy complication—alteration in glucose metabolism, compromised fetal oxygen transport), substance misuse, physical abuse.

risk for maternal Injury possibly evidenced by physical—preexisting medical conditions, complications of pregnancy; insufficient knowledge of modifiable factors.

risk for Activity Intolerance possibly evidenced by imbalance between oxygen supply and demand; (circulatory or respiratory problems).

risk for compromised family Coping possibly evidenced by (situational crisis), family disorganization, insufficient support given by client to support person, family role change.

risk for ineffective Health Management possibly evidenced by difficulty managing complex treatment regimen, decisional conflicts, insufficient social support, economically disadvantaged, perceived seriousness of condition/susceptibility.

Pregnancy-induced hypertension **OB/CH**
Refer to Hypertension, gestational

Pregnancy, postmaturity **OB**

Anxiety [specify level] may be related to (situational crisis), threat to current status, interpersonal transmission or contagion, possibly evidenced by increase in tension, apprehensiveness, irritability, feeling of inadequacy, somatic complaints.

ineffective [uteroplacental] Tissue Perfusion may be related to placental involution, multiple infarcts, and villous degeneration, possibly evidenced by decrease in fetal motion, meconium staining of amniotic fluid, intrauterine growth restriction, late decelerations on fetal monitor.

risk for maternal Injury possibly evidenced by dysfunctional or prolonged labor.

risk for fetal Injury possibly evidenced by prolonged labor (tissue hypoxia, acidosis), meconium aspiration.

Premature ejaculation **CH**

Sexual dysfunction may be related to altered body function, partner-related issues, possibly evidenced by

reports of disruption of sexual response pattern, inability to achieve desired satisfaction.

situational low Self-Esteem may be related to functional impairment, perceived failure to perform satisfactorily, rejection of other(s), possibly evidenced by self-negating verbalizations, expressions of helplessness, powerlessness.

Premature infant **OB/PED**
Refer to Newborn, premature

Premenstrual dysphoric disorder **GYN/PSY**

chronic Pain may be related to cyclic changes in female hormones affecting other systems (e.g., vascular congestion, spasms), vitamin deficiency, fluid retention, possibly evidenced by increased tension, apprehension, jitteriness, verbal reports, distraction behaviors, somatic complaints, self-focusing, physical and social withdrawal.

[moderate to panic] Anxiety may be related to cyclic changes in female hormones affecting other systems, possibly evidenced by feelings of inability to cope or loss of control, depersonalization, increased tension, apprehension, jitteriness, somatic complaints, and impaired functioning.

ineffective Coping may be related to inaccurate threat appraisal, ineffective tension release strategies, [threat to self-concept, multiple stressors], possibly evidenced by reports of inability to cope, inadequate problem-solving skills, alteration in sleep pattern.

excess Fluid Volume may be related to abnormal alterations of hormonal levels, possibly evidenced by edema formation, weight gain, and periodic changes in emotional status/irritability.

deficient Knowledge regarding pathophysiology of condition and self-care and treatment needs may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, misconceptions, and continuation of condition, exacerbating symptoms.

Premenstrual tension syndrome **GYN/PSY**
Refer to Premenstrual dysphoric disorder

Prenatal substance abuse **OB**
Refer to Substance dependence/abuse, prenatal

Pressure ulcer or sore **CH**
Also refer to Ulcer, decubitus

ineffective peripheral Tissue Perfusion may be related to reduced or interrupted blood flow, possibly evidenced by presence of inflamed, necrotic lesion.

deficient Knowledge regarding cause, prevention of condition, and potential complications may be related to lack of information or misinterpretation, possibly evidenced by statements of concern, questions, misconceptions, and inaccurate follow-through of instructions.

Preterm labor

Refer to Labor, preterm

OB/CH

Prostate cancer

Also refer to Cancer; Prostatectomy

[acute/chronic] urinary Retention may be related to blockage of urethra, possibly evidenced by sensation of bladder fullness, dysuria, small and frequent voiding, residual urine, bladder distention.

acute Pain may be related to physical agent—destruction of tissues, pressure on surrounding structures, bladder distention, possibly evidenced by verbal reports of pain, restlessness, irritability, autonomic responses.

Prostatectomy

Also refer to Surgery, general

impaired urinary Elimination may be related to mechanical obstruction (blood clots, edema, trauma, surgical procedure, pressure or irritation of catheter and balloon) and loss of bladder tone, possibly evidenced by dysuria, frequency, dribbling, incontinence, retention, bladder fullness, suprapubic discomfort.

risk for Bleeding/deficient Fluid Volume possibly evidenced by trauma [to highly vascular area], restricted intake, postobstructive diuresis].

acute Pain may be related to irritation of bladder mucosa and tissue trauma/edema, possibly evidenced by verbal reports (bladder spasms), distraction behaviors, self-focus, and autonomic responses (changes in vital signs).

disturbed Body Image may be related to alteration in self-perception (e.g., perceived threat of altered body and sexual function) expression of negative feelings about body, and statements of concern regarding functioning.

CH

risk for Sexual dysfunction possibly evidenced by alteration in body function (e.g., incontinence, leakage of urine after catheter removal, involvement of genital area) and threat to self-concept, change in health status.

Prostatitis, acute

Also refer to Cystitis

acute Pain/impaired Comfort may be related to inflammatory response, possibly evidenced by reports of low back and pelvic pain, arthralgia, myalgia.

impaired urinary Elimination may be related to localized swelling, urinary tract infection, possibly evidenced by dysuria or burning on urination, frequency, urgency, nocturia, obstructed voiding.

Hyperthermia may be related to illness, possibly evidenced by high fever; chills; flushed, warm skin.

risk for ineffective Health Management possibly evidenced by length of therapy, perceived seriousness or benefits.

Prostatitis, chronic

Also refer to Cystitis

impaired Comfort/acute Pain may be related to inflammatory response, possibly evidenced by reports of back, pelvic, or scrotal discomfort; low-grade fever.

impaired urinary Elimination may be related to localized swelling, urinary tract infection, possibly evidenced by dysuria, frequency, urgency.

CH

CH

Pruritus

acute Pain may be related to cutaneous hyperesthesia and inflammation, possibly evidenced by verbal reports, distraction behaviors, and self-focus.

risk for impaired Skin Integrity possibly evidenced by [mechanical trauma (scratching) and development/rupture of vesicles or bullae].

CH

Psoriasis

impaired Skin Integrity may be related to [increased epidermal cell proliferation and absence of normal protective skin layers], possibly evidenced by alteration in skin integrity, redness [scaling papules and plaques].

disturbed Body Image may be related to cosmetically unsightly skin lesions, possibly evidenced by hiding affected body part, negative feelings about body, feelings of helplessness, and change in social involvement.

CH

Psychological abuse

Refer to Abuse, psychological

CH/PSY

PTSD

Refer to Post-traumatic stress disorder

PSY

Pulmonary edema

impaired Gas Exchange may be related to (alveolar-capillary membrane changes), possibly evidenced by

MS

abnormal breathing pattern (changes in rate and depth of respirations, dyspnea), restlessness, irritability, confusion.

[*moderate to severe*] *Anxiety* may be related to threat to current status, threat of death, interpersonal transmission, possibly evidenced by expressed concerns, distress, apprehensiveness, extraneous movement.

risk for impaired spontaneous Ventilation possibly evidenced by respiratory muscle fatigue, problems with secretion management.

Pulmonary edema, high altitude **MS**
Refer to High altitude pulmonary edema

Pulmonary embolus **MS**

ineffective Breathing Pattern may be related to tracheobronchial obstruction (inflammation, copious secretions or active bleeding), decreased lung expansion, inflammatory process, possibly evidenced by changes in depth or rate of respiration, dyspnea, use of accessory muscles, altered chest excursion, abnormal breath sounds (crackles, wheezes), and cough (with or without sputum production).

impaired Gas Exchange may be related to (ventilation-perfusion imbalance and alveolar-capillary membrane changes), possibly evidenced by abnormal breathing patterns (profound dyspnea), restlessness, somnolence, cyanosis, hypoxemia, and hypercapnia.

Fear/Anxiety [specify level] may be related to dyspnea, inability to breathe normally, threat of death, threat to current status, physiological response to hypoxemia, acidosis, and concern regarding unknown outcome of situation, possibly evidenced by restlessness, irritability, sympathetic stimulation (cardiovascular excitation, pupil dilation, sweating), crying impending sense of doom.

Pulmonary fibrosis **CH**

impaired Gas Exchange may be related to (alveolar-capillary membrane changes, ventilation-perfusion imbalance), possibly evidenced by abnormal breathing pattern (dyspnea), [nonproductive cough], abnormal skin color (cyanosis).

Anxiety [specify]/Fear may be related to threat to current status, threat of death, possibly evidenced by expressed concerns, apprehension, uncertainty, increased tension.

Activity Intolerance may be related to imbalance between oxygen supply and demand, possibly evidenced by, generalized weakness, exertional dyspnea,

abnormal heart rate and blood pressure response to activity, [cyanosis].

risk for Infection possibly evidenced by stasis of body fluids (secretions), (chronic illness), [drug therapies—corticosteroids, cytotoxins].

Pulmonary hypertension **CH/MS**

impaired Gas Exchange may be related to (alveolar-capillary changes), and [increased pulmonary vascular resistance], possibly evidenced by abnormal breathing pattern (dyspnea), irritability, somnolence, abnormal arterial blood gases.

decreased Cardiac Output may be related to increased pulmonary vascular resistance, decreased blood return to left side of heart, possibly evidenced by increased heart rate, dyspnea, fatigue.

Activity Intolerance may be related to imbalance between oxygen supply and demand, possibly evidenced by reports of weakness, fatigue, abnormal vital signs with activity.

[*mild to moderate*] *Anxiety* may be related to threat to current status, stress, threat to self-concept, possibly evidenced by expressed concerns, uncertainty, anxiety, awareness of physiological symptoms, diminished productivity and ability to problem-solve.

Pulmonic insufficiency **MS/CH**
Refer to Valvular heart disease

Pulmonic stenosis **MS/CH**
Refer to Valvular heart disease

Purpura, idiopathic thrombocytopenic **CH**

ineffective Protection may be related to abnormal blood profile, drug therapy (corticosteroids or immunosuppressive agents), possibly evidenced by altered clotting, fatigue, deficient immunity.

Activity Intolerance may be related to imbalance between oxygen supply and demand, possibly evidenced by weakness, fatigue, abnormal vital signs with activity.

deficient Knowledge regarding therapy choices, outcomes, and self-care needs may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, and misconceptions.

Pyelonephritis **MS**

acute Pain may be related to acute inflammation of renal tissues, possibly evidenced by verbal reports, guarding or distraction behaviors, self-focus, and changes in vital signs.

Hyperthermia may be related to inflammatory process and increased metabolic rate, possibly evidenced by increase in body temperature; warm, flushed skin; tachycardia; and chills.

impaired urinary Elimination may be related to inflammation and irritation of bladder mucosa, possibly evidenced by dysuria, urgency, and frequency.

deficient Knowledge regarding therapy needs and prevention may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, misconceptions, and recurrence of condition.

Pyloric stenosis

PED

deficient Fluid Volume may be related to excessive projectile vomiting, possibly evidenced by decreased, concentrated urine; poor skin turgor, dry skin and mucous membranes, lethargy.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to digest food or absorb nutrients), possibly evidenced by [weight loss], insufficient muscle tone, pale mucous membranes.

Quadriplegia

MS/CH

Also refer to Paraplegia

ineffective Breathing Pattern may be related to (spinal cord injury, neurological impairment), respiratory muscle fatigue[/weakness], possibly evidenced by abnormal breathing pattern, altered chest excursion, decreased in vital capacity, dyspnea, and [abnormal arterial blood gases].

risk for physical Trauma [additional spinal injury] possibly evidenced by weakness, [instability of spinal column].

Grieving may be related to [perceived loss of self, anticipated alterations in lifestyle and expectations, and limitation of future options and choices], possibly evidenced by expressions of distress, anger, sorrow; choked feelings; and changes in eating habits, sleep, communication patterns.

[total] Self-Care deficit related to (neuromuscular impairment) weakness, evidenced by inability to perform self-care tasks.

bowel Incontinence/Constipation may be related to disruption of nerve innervation, perceptual impairment, changes in dietary and fluid intake, change in activity level, possibly evidenced by inability to evacuate bowel voluntarily; increased abdominal pressure and distention; dry, hard formed stool; change in bowel sounds.

impaired bed/wheelchair Mobility may be related to loss of muscle function and control.

risk for Autonomic Dysreflexia possibly evidenced by risk factors of altered nerve function (spinal cord injury at T6 or above); bladder, bowel, or skin stimulation (tactile, pain, thermal).

impaired Home Maintenance may be related to permanent effects of injury, inadequate or absent support systems and finances, and lack of familiarity with resources, possibly evidenced by expressions of difficulties, requests for information and assistance, outstanding debts or financial crisis, and lack of necessary aids and equipment.

Rabies

CH/MS

Hyperthermia may be related to infection, possibly evidenced by fever, malaise.

risk for ineffective Airway Clearance possibly evidenced by excessive salivation, muscle spasms (laryngeal, pharyngeal).

deficient Fluid Volume related to inability to drink (severe painful pharyngeal muscle spasms), excessive salivation, possibly evidenced by extreme thirst, decreased skin turgor, decreased output/concentrated urine.

risk for physical Trauma possibly evidenced by progressive restlessness, uncontrollable excitement, inability to utilize physical restraints for safety.

Radiation syndrome/poisoning

MS

(Dependent on dose and duration of exposure)

[severe] Anxiety/Fear may be related to (situational crisis), threat of death, interpersonal transmission and contagion, unmet needs, possibly evidenced by expressed concerns, fearfulness, hopelessness, restlessness, agitation, anguish, increased tension, awareness of physiological symptoms.

deficient Fluid Volume may be related to intractable nausea, vomiting, diarrhea (gastrointestinal tissue necrosis and atrophy), interference with adequate intake (stomatitis, anorexia), hemorrhagic losses (thrombocytopenia), possibly evidenced by dry skin and mucous membranes, poor skin turgor, decreased venous filling, reduced pulse volume and pressure, hypotension, weakness, change in mentation.

acute Confusion may be related to (alteration in cognitive functioning, impaired metabolic functioning), possibly evidenced by alteration in level of consciousness, agitation, misperception.

ineffective Protection may be related to effects of radiation, abnormal blood profile (leukopenia,

thrombocytopenia, anemia), inadequate nutrition, possibly evidenced by neurosensory alterations, anorexia, deficient immunity, impaired healing, altered clotting, disorientation.

risk for Infection possibly evidenced by stasis of body fluids, altered peristalsis, and associated conditions decreased hemoglobin/anemia, leukopenia.

Sexual dysfunction may be related to altered body function, possibly evidenced by amenorrhea, decreased libido, infertility.

Radiation therapy

CH

Also refer to Brachytherapy; Cancer

Nausea may be related to therapeutic procedure, irritation to gastrointestinal system, possibly evidenced by verbal reports, vomiting, gastric stasis.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to ingest food or absorb nutrients), possibly evidenced by [weight loss], food aversion, reported altered taste sensation, sore buccal cavity, diarrhea.

impaired oral Mucous Membrane Integrity may be related to side effects of radiation, dehydration, and malnutrition, possibly evidenced by ulcerations, leukoplakia, decreased salivation, and reports of pain.

ineffective Protection may be related to inadequate nutrition, radiation, abnormal blood profile, disease state (cancer), possibly evidenced by impaired healing, deficient immunity, anorexia, fatigue.

Radical neck surgery

MS

Refer to Laryngectomy

Rape

CH

deficient Knowledge regarding required medical/legal procedures, prophylactic treatment for individual concerns (sexually transmitted infection, pregnancy), and community resources and supports may be related to lack of information, possibly evidenced by statements of concern, questions, misconceptions, and exacerbation of symptoms.

Rape-Trauma Syndrome related to actual or attempted sexual penetration without consent, possibly evidenced by wide range of emotional reactions, including anxiety, fear, anger, embarrassment, and multisystem physical complaints.

risk for impaired Tissue Integrity possibly evidenced by forceful sexual penetration and trauma to fragile tissues.

PSY

ineffective Coping may be related to high degree of threat, [personal vulnerability, unmet expectations, unrealistic perceptions, inadequate social support systems or coping methods, multiple stressors repeated over time], possibly evidenced by verbalizations of inability to cope or difficulty asking for help, inability to deal with a situation or meet role expectations, destructive behaviors toward self/others.

Sexual dysfunction may be related to biopsychosocial alteration of sexuality (stress of posttrauma response), vulnerability, loss of sexual desire, impaired relationship with SO, possibly evidenced by alteration in achieving sexual satisfaction, change in interest in self/others, preoccupation with self.

Raynaud's disease

CH

acute/chronic Pain may be related to vasospasm and altered perfusion of affected tissues, and ischemia or destruction of tissues, possibly evidenced by verbal reports, guarding of affected parts, self-focusing, and restlessness.

ineffective peripheral Tissue Perfusion may be related to periodic reduction of arterial blood flow to affected areas, possibly evidenced by pallor, cyanosis, coolness, numbness, paresthesia, slow healing of lesions.

deficient Knowledge regarding pathophysiology of condition, potential for complications, treatment, and self-care needs may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, and misconceptions; development of preventable complications.

Raynaud's phenomenon

CH

Refer to Raynaud's disease

Reactive attachment disorder

PED/PSY

Refer to Anxiety disorders—PED

Reflex sympathetic dystrophy

CH

Refer to Complex regional pain syndrome

acute/chronic Pain may be related to continued nerve stimulation, possibly evidenced by verbal reports, distraction or guarding behaviors, narrowed focus, changes in sleep patterns, and altered ability to continue previous activities.

ineffective peripheral Tissue Perfusion may be related to reduction of arterial blood flow (arteriole vasoconstriction), possibly evidenced by reports of pain, decreased skin temperature and pallor, diminished arterial pulsations, and tissue swelling.

[*disturbed tactile Sensory Perception*] may be related to altered sensory reception (neurological deficit, pain), possibly evidenced by change in usual response to stimuli, abnormal sensitivity of touch, physiological anxiety, and irritability.

risk for ineffective Role Performance possibly evidenced by situational crisis, chronic disability, debilitating pain.

risk for compromised family Coping possibly evidenced by temporary family disorganization and role changes and prolonged disability that exhausts the supportive capacity of SO(s).

Regional enteritis

CH

Refer to Crohn's disease

Renal disease, end-stage

CH/MS

Also refer to Renal failure, chronic

Death Anxiety may be related to progressive debilitating disease, unmet needs, inadequate support system, personal vulnerability, past negative experiences, possibly evidenced by fear of the process of dying or loss of abilities, concerns of unfinished business, powerlessness, loss of control, denial of impending death.

Renal failure, acute (Kidney injury, acute) MS

excess Fluid Volume may be related to compromised regulatory mechanisms (decreased kidney function), possibly evidenced by weight gain, edema, anasarca, intake greater than output, venous congestion, changes in blood pressure and central venous pressure, altered electrolyte levels, decreased hemoglobin and hematocrit, pulmonary congestion on x-ray.

risk for imbalanced Nutrition: less than body requirements possibly evidenced by (inability to ingest or digest foods or absorb nutrients), food aversion, sore buccal cavity, [therapeutic dietary restrictions].

risk for Infection possibly evidenced by malnutrition, immunosuppression, (invasive procedures or devices).

risk for acute Confusion possibly evidenced by (impaired metabolic functioning), malnutrition (electrolyte imbalance, increased blood urea nitrogen/creatinine, azotemia).

Renal failure, chronic

CH/MS

Also refer to Dialysis, general

risk for decreased Cardiac Output possibly evidenced by fluid imbalances affecting circulating volume, myocardial workload, and systemic vascular resistance;

alterations in rate, rhythm, and cardiac conduction (electrolyte imbalances, hypoxia); accumulation of toxins (urea); soft calcification.

risk for Bleeding possibly evidenced by inherent coagulopathy.

risk for chronic Confusion possibly evidenced by [long-term or progressive impairment in cognitive functioning associated with electrolyte imbalance, increased blood urea nitrogen/creatinine, azotemia, malnutrition, decreased hemoglobin].

risk for impaired Skin Integrity possibly evidenced by alteration in metabolism, immunodeficiency, impaired circulation and sensation, alteration in skin turgor, [reduced activity, immobility, accumulation of toxins in the skin].

risk for impaired oral Mucous Membrane Integrity possibly evidenced by decreased or lack of salivation, fluid restrictions, chemical irritation (conversion of urea in saliva to ammonia).

Renal transplantation

MS

Also refer to Transplantation, recipient

risk for excess Fluid Volume possibly evidenced by compromised regulatory mechanism (implantation of new kidney requiring adjustment period for optimal functioning).

disturbed Body Image may be related to alteration in self-perception (e.g., failure and subsequent replacement of body part and medication-induced changes in appearance), possibly evidenced by preoccupation with loss or change, negative feelings about body, and focus on past strength and function.

Fear may be related to [threat to health status—potential for transplant rejection or failure; and threat of death], possibly evidenced by increased tension, apprehension, concentration on source, and verbalizations of concern.

risk for Infection possibly evidenced by alteration in skin/tissue integrity, stasis of body fluids, malnutrition and associated conditions of immunosuppression, invasive procedures and chronic illness.

CH

risk for ineffective Coping/compromised family Coping possibly evidenced by (situational crises), family disorganization and role changes, prolonged disease exhausting supportive capacity of SO/family, therapeutic restrictions/long-term therapy needs.

Repetitive motion injury

CH

Refer to Carpal tunnel syndrome

Respiratory distress syndrome, acute MS

ineffective Airway Clearance may be related to loss of ciliary action, increased amount and viscosity of secretions, and increased airway resistance, possibly evidenced by presence of dyspnea, changes in depth and rate of respiration, use of accessory muscles for breathing, wheezes, crackles, cough with or without sputum production.

impaired Gas Exchange may be related to changes in (ventilation—perfusion imbalance), possibly evidenced by abnormal breathing patterns (tachypnea, use of accessory muscles), and abnormal skin color (cyanosis, hypoxia per arterial blood gases or oximetry), [anxiety and changes in mentation].

risk for deficient Fluid Volume possibly evidenced by active loss from diuretic use and restricted intake.

risk for decreased Cardiac Output possibly evidenced by alteration in preload (hypovolemia, vascular pooling, diuretic therapy, and increased intrathoracic pressure, use of ventilator, and positive end-expiratory pressure [PEEP]).

Anxiety [specify level]/Fear may be related to physiological factors (effects of hypoxemia), situational crisis, change in health status/threat of death, possibly evidenced by increased tension, apprehension, restlessness, focus on self, and sympathetic stimulation.

risk for [pulmonary] Injury possibly evidenced by increased airway pressure associated with mechanical ventilation (PEEP).

Respiratory distress syndrome (premature infant) PED

Also refer to Newborn, premature

impaired Gas Exchange may be related to (alveolar-capillary membrane changes, ventilation-perfusion imbalance), possibly evidenced by abnormal breathing patterns (tachypnea, use of accessory muscles and retractions, expiratory grunting), abnormal skin color (pallor or cyanosis), abnormal arterial blood gases, and tachycardia.

impaired Spontaneous Ventilation may be related to respiratory muscle fatigue and metabolic factors, possibly evidenced by dyspnea, increased metabolic rate, restlessness, use of accessory muscles, and abnormal arterial blood gases.

risk for Infection possibly evidenced by stasis of body fluids, malnutrition (absence of nutrient stores, increased metabolic demands), and invasive procedures.

risk for dysfunctional Gastrointestinal Mobility possibly evidenced by (decrease in gastrointestinal circulation).

risk for impaired Attachment possibly evidenced by premature/ill infant who is unable to effectively initiate parental contact (altered behavioral organization), separation, physical barriers, anxiety associated with the parental role and demands of infant.

Respiratory syncytial virus PED

impaired Gas Exchange may be related to (ventilation-perfusion imbalance), possibly evidenced by abnormal breathing patterns (dyspnea, apnea) abnormal arterial blood gases/hypoxia.

ineffective Airway Clearance may be related to infection, retained secretions, exudate in alveoli, inflammation of airways, possibly evidenced by dyspnea, adventitious breath sounds, cough.

risk for deficient Fluid Volume possibly evidenced by increased insensible losses (fever, diaphoresis), decreased oral intake.

Restless leg syndrome CH

Refer to Myoclonus, nocturnal

Retinal detachment CH

[disturbed visual Sensory Perception] related to decreased sensory reception, possibly evidenced by visual distortions, decreased visual field, and changes in visual acuity.

[mild to moderate] Anxiety may be related to (situational crisis), threat to current status and role function, possibly evidenced by expressed concerns, apprehensiveness, uncertainty, self-focused.

deficient Knowledge regarding therapy, prognosis, and self-care needs may be related to lack of information, misconceptions, possibly evidenced by statements of concern and questions.

risk for impaired Home Maintenance possibly evidenced by visual limitations, activity restrictions.

Rett's syndrome PED/PSY

Also refer to Autism spectrum disorder

delayed Development may be related to effects of physical and mental disability, possibly evidenced by delay or inability in performing skills and self-care or self-control activities appropriate for age.

impaired Walking/physical Mobility may be related to neuromuscular impairment, joint stiffness, contractures, disuse, possibly evidenced by limited

range of motion, inability to perform gross motor skills, walk, or reposition self.

risk for physical Trauma possibly evidenced by cognitive deficits, lack of muscle tone and coordination, seizure activity.

ineffective infant Feeding Pattern/imbalanced Nutrition: less than body requirements may be related to (neurological impairment), insufficient dietary intake, possibly evidenced by inability to coordinate sucking, swallowing, and breathing; weakness of muscles required for mastication/swallowing, food intake less than recommended daily allowance, [weight loss or failure to gain].

risk for complicated Grieving possibly evidenced by emotional disturbance [loss of “the perfect child,” chronic condition requiring long-term care].

Reye’s syndrome

PED

deficient Fluid Volume may be related to failure of regulatory mechanism (diabetes insipidus), excessive gastric losses (pernicious vomiting), and altered intake, possibly evidenced by increased and dilute urine output, sudden weight loss, decreased venous filling, dry mucous membranes, decreased skin turgor, hypotension, and tachycardia.

ineffective cerebral Tissue Perfusion may be related to diminished arterial or venous blood flow and hypovolemia, possibly evidenced by memory loss, altered consciousness, and restlessness, agitation.

risk for physical Trauma possibly evidenced by generalized weakness, reduced coordination, and cognitive deficits.

ineffective Breathing Pattern may be related to decreased energy and fatigue, cognitive impairment, tracheobronchial obstruction, and inflammatory process (aspiration pneumonia), possibly evidenced by tachypnea, abnormal arterial blood gases, cough, and use of accessory muscles.

Rheumatic fever

PED

acute Pain may be related to migratory inflammation of joints, possibly evidenced by verbal reports, guarding or distraction behaviors, self-focus, and changes in vital signs.

Hyperthermia may be related to inflammatory process, hypermetabolic state, possibly evidenced by increased body temperature; warm, flushed skin; and tachycardia.

Activity Intolerance may be related to physical deconditioning (generalized weakness, joint pain, and

medical restrictions or bedrest), possibly evidenced by reports of fatigue, exertional discomfort, and abnormal heart rate in response to activity.

risk for decreased Cardiac Output possibly evidenced by altered contractility.

Rheumatic heart disease

PED/MS

Also refer to Valvular heart disease

Activity Intolerance may be related to imbalance between oxygen supply and demand, physical deconditioning (generalized weakness), or sedentary lifestyle (prolonged bedrest), possibly evidenced by reported or observed weakness, fatigue, abnormal vital signs in response to activity (dysrhythmias, dyspnea, pallor).

risk-prone Health Behavior may be related to health status requiring change in lifestyle or restriction of desired activities, unrealistic expectations, negative attitudes, possibly evidenced by denial of situation, demonstration of nonacceptance of health status, failure to achieve optimal sense of control.

risk for ineffective Health Management possibly evidenced by complexity and duration of therapeutic regimen, imposed restrictions or limitations, economic difficulties, family patterns of healthcare, perceived seriousness or benefits.

risk for impaired Gas Exchange possibly evidenced by (alveolar-capillary membrane changes).

Rhinitis, allergic

CH

Refer to Hay fever

Rickets

PED

risk for [disproportionate Growth]/delayed Development possibly evidenced by inadequate nutrition, economically disadvantaged, chronic illness, prematurity.

deficient Knowledge regarding cause, pathophysiology, therapy needs and prevention may be related to lack of information, possibly evidenced by statements of concern, questions, misconceptions, and inaccurate follow-through of instructions.

Ringworm, tinea

CH

Also refer to Athlete’s foot

impaired Skin Integrity may be related to [fungal infection of the dermis], possibly evidenced by alteration in skin integrity (presence of lesions).

deficient Knowledge regarding infectious nature, therapy, and self-care needs may be related to lack of information, misinformation, possibly evidenced by statements of concern, questions, and recurrence and spread.

Rocky Mountain spotted fever**CH/MS**

Refer to Typhus

RSD**CH**

Refer to Reflex sympathetic dystrophy

RSV**PED**

Refer to Respiratory syncytial virus

Rubella**PED/CH**

acute Pain/impaired Comfort may be related to inflammatory effects of viral infection and presence of desquamating rash, possibly evidenced by verbal reports, distraction behaviors, restlessness.

deficient Knowledge regarding contagious nature, possible complications, and self-care needs may be related to lack of information, misinterpretations, possibly evidenced by statements of concern, questions, and inaccurate follow-through of instructions.

Rubeola**PED/CH**

Refer to Measles

Ruptured intervertebral disc**CH/MS**

Refer to Herniated nucleus pulposus

Sarcoidosis**CH**

Also refer to Pulmonary fibrosis

Fatigue may be related to disease state, anemia, possibly evidenced by lack of energy, lethargy, decreased performance, inability to maintain usual routines.

risk for Injury possibly evidenced by autoimmune dysfunction, abnormal blood profile—thrombocytopenia, leukopenia, anemia; sensory dysfunction.

SARS (sudden acute respiratory syndrome)**MS**

Hyperthermia may be related to inflammatory process, possibly evidenced by high fever, chills, rigors, headache.

acute Pain/impaired Comfort may be related to inflammation and circulating toxins, possibly evidenced by reports of myalgia, headache, malaise.

impaired Gas Exchange may be related to (ventilation-perfusion imbalance), possibly evidenced by dyspnea, confusion, restlessness, hypoxemia.

risk for impaired spontaneous Ventilation possibly evidenced by hypermetabolic state, infection, depletion of energy stores, respiratory muscle fatigue.

Death Anxiety may be related to uncertainty of prognosis, possibly evidenced by report of apprehension; increased pulse and respiratory rate, muscle tension, pupil dilation.

risk for ineffective Protection possibly evidenced by inadequate nutrition, abnormal blood profile (leukopenia, thrombocytopenia).

Scabies**CH**

impaired Skin Integrity may be related to [presence of invasive parasite and development of pruritus], possibly evidenced by alteration in skin integrity, redness.

deficient Knowledge regarding communicable nature, possible complications, therapy, and self-care needs may be related to lack of information, misinterpretation, possibly evidenced by questions and statements of concern about spread to others.

Scarlet fever**PED**

Hyperthermia may be related to effects of circulating toxins, possibly evidenced by increased body temperature; warm, flushed skin; and tachycardia.

acute Pain/impaired Comfort may be related to inflammation of mucous membranes and effects of circulating toxins (malaise, fever), possibly evidenced by verbal reports, distraction behaviors, guarding (decreased swallowing), and self-focus.

risk for deficient Fluid Volume possibly evidenced by hypermetabolic state (hyperthermia) and reduced intake.

Schizoaffective disorder**PSY**

risk for other-/self-directed Violence possibly evidenced by depressed mood, feelings of worthlessness, hopelessness, unsatisfactory parent-child relationship, feelings of abandonment by SOs, anger turned inward or directed at the environment, punitive superego, irrational feelings of guilt, numerous failures, misinterpretation of reality.

Social Isolation may be related to developmental regression, depressed mood, feelings of worthlessness, egocentric behaviors (offending others and discouraging relationships), delusional thinking, fear of failure, unresolved grief, possibly evidenced by sad, dull affect; absence of support systems; uncommunicative, withdrawn, or catatonic behavior; absence of eye contact; preoccupation with own thoughts; repetitive or meaningless actions.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (psychological disorder [e.g., lack of attention to or

recognition of hunger cues], possibly evidenced by insufficient interest in food, weight loss, pale mucous membranes, insufficient muscle tone [amenorrhea, abnormal laboratory studies].

Schizophrenia (schizophrenic disorders) PSY

ineffective Impulse Control may be related to mood disorder, (alteration in cognitive functioning, personality disorder), possibly evidenced by acting without thinking, irritability, temper outbursts, violent behavior, sexual promiscuity.

[disturbed Sensory Perception (specify)] may be related to biochemical/electrolyte imbalance, psychological stress, possibly evidenced by disorientation to space/time, hallucinations, change in behavior pattern.

impaired verbal Communication may be related to low self-esteem, vulnerability, (alteration in perception, psychotic disorder), possibly evidenced by inappropriate verbalizations, difficulty comprehending communication, difficulty in use of facial/body expressions.

Social Isolation may be related to (alterations in mental status), social behavior incongruent with norms, values incongruent with cultural norms, insufficient personal resources, and inability to engage in satisfying personal relationships, possibly evidenced by sad or flat affect, poor eye contact, withdrawn, desire to be alone, hostility, cultural incongruence, member of subculture, and history of rejection.

risk for self-/other-directed Violence possibly evidenced by insufficient personal resources, lack of social resources, social isolation, pattern of threatening violence, (psychological disorder, psychotic disorder, alteration in cognitive functioning).

ineffective Coping may be related to inaccurate threat appraisal, inadequate resources, insufficient social support, inadequate confidence in ability to deal with situation, possibly evidenced by difficulty organizing/inability to attend to information, insufficient problem-solving skills, inability to meet basic needs or role expectations, insufficient assess of social support, risk-taking behavior, destructive behavior toward others/self.

CH

disabled family Coping may be related to ambivalent family relationships, differing coping styles between support persons, or between support person and client, chronically unexpressed feelings, possibly evidenced by family behaviors detrimental to well-being, client dependence, prolonged hyperfocus on client, depression, rejection, abandonment.

ineffective Health Management may be related to difficulty managing complex treatment regimen, perceived barrier/benefit, family conflict, insufficient social support, possibly evidenced by failure to include treatment regimen in daily living, ineffective choices in daily living for meeting health goals, failure to take action to reduce risk factors.

Self-Neglect may be related to stressors, deficient executive function, inability to maintain control, (alteration in cognitive functioning), possibly evidenced by insufficient personal hygiene, nonadherence to health activity, insufficient environmental hygiene.

Sciatica

CH

acute/chronic Pain may be related to peripheral nerve root compression, possibly evidenced by verbal reports of pain, guarding or distraction behavior, and self-focused.

impaired physical Mobility may be related to neurological pain and muscular involvement, possibly evidenced by reluctance to attempt movement and decreased muscle strength and mass.

Scleroderma

CH

Also refer to Lupus erythematosus, systemic (SLE)

impaired physical Mobility may be related to musculoskeletal impairment and associated pain, possibly evidenced by decreased strength, decreased range of motion, and reluctance to attempt movement.

ineffective Tissue Perfusion (specify) may be related to reduced arterial blood flow (arteriolar vasoconstriction), possibly evidenced by changes in skin temperature and color, ulcer formation, and changes in organ function (cardiopulmonary, gastrointestinal, renal).

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (inability to ingest or digest food, or absorb nutrients), possibly evidenced by difficulty swallowing, food intake less than recommended daily allowance and [weight loss].

risk-prone Health Behavior may be related to stressors, inadequate comprehension, insufficient social support, possibly evidenced by nonacceptance of/minimizes health status change, failure to achieve optimal sense of control, failure to take action to prevent/[manage] health problem.

disturbed Body Image may be related to alteration in self-perception (e.g., skin changes, loss of hair; skin/muscle contractures), possibly evidenced by negative feeling about body; focus on past strength,

function, or appearance; expressions of fear of reaction by others; hiding body part; and change in social involvement.

Scoliosis

PED

disturbed Body Image may be related to alteration in self-perception (e.g., altered body structure), treatment regimen, possibly evidenced by negative feeling about body, change in social involvement, and preoccupation with situation or refusal to acknowledge problem.

deficient Knowledge regarding pathophysiology of condition, therapy needs, and possible outcomes may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, misconceptions, and inaccurate follow-through of instructions.

risk-prone Health Behavior may be related to inadequate comprehension, negative perception of recommended healthcare strategy, possibly evidenced by minimizing health status change, failure to take action that manages health problem.

Seasonal affective disorder

PSY

Refer to Affective disorder, seasonal

Sedative intoxication/abuse

CH/PSY

Refer to Depressant abuse

Seizure disorder

CH

deficient Knowledge regarding condition and medication control may be related to lack of information, misinterpretations, scarce financial resources, possibly evidenced by questions, statements of concern, misconceptions, incorrect use of anticonvulsant medication, recurrent episodes, or uncontrolled seizures.

disturbed Personal Identity may be related to perceived prejudice (stigma associated with condition, perception of being out of control or helpless), possibly evidenced by ineffective coping strategies, verbalization about feeling of strangeness (changed lifestyle, fear of rejection), [denial of problem resulting in lack of follow-through or nonparticipation in therapy].

impaired Social Interaction may be related to unpredictable nature of condition and self-concept disturbance, possibly evidenced by decreased self-assurance, verbalization of concern, discomfort in social situations, inability to receive or communicate a satisfying sense of belonging and caring, and withdrawal from social contacts and activities.

risk for Trauma/Suffocation possibly evidenced by weakness, balancing difficulties, cognitive limitations, altered consciousness, loss of large- or small-muscle coordination (during seizure).

Separation anxiety disorder

PED/PSY

Refer to Anxiety disorders—PED

Sepsis

MS

Also refer to Sepsis, puerperal

risk for deficient Fluid Volume possibly evidenced by marked increase in vascular compartment—massive vasodilation, vascular shifts to interstitial space, and reduced intake.

risk for decreased Cardiac Output possibly evidenced by decreased preload (venous return and circulating volume), altered afterload (increased systemic vascular resistance), negative inotropic effects of hypoxia, complement activation, and lysosomal hydrolase.

risk for Shock possibly evidenced by infection/sepsis, hypovolemia—fluid shifts or third spacing; hypotension, hypoxemia.

Sepsis, puerperal

OB

risk for Infection [spread] possibly evidenced by [presence of infection], alteration in skin integrity, (premature/prolonged rupture of amniotic membranes), stasis of body fluids, (invasive procedures, chronic illness [e.g., diabetes mellitus]).

Hyperthermia may be related to inflammatory process, hypermetabolic state, dehydration, effect of circulating endotoxins on the hypothalamus, possibly evidenced by increase in body temperature, warm, flushed skin; increased respiratory rate and tachycardia.

risk for impaired Attachment possibly evidenced by interruption in bonding process, physical illness, perceived threat to own survival.

risk for ineffective peripheral Tissue Perfusion possibly evidenced by interruption or reduction of blood flow—presence of infectious thrombi.

risk for Shock possibly evidenced by infection, hypovolemia, hypotension, hypoxemia.

Septicemia

MS

Refer to Sepsis

Serum sickness

CH

acute Pain may be related to physical agent—inflammation of the joints and skin eruptions, possibly evidenced by verbal reports of pain, guarding or distraction behavior, and self-focused.

deficient Knowledge regarding nature of condition, treatment needs, potential complications, and prevention of recurrence may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, misconceptions, and inaccurate follow-through of instructions.

Severe acute respiratory syndrome **MS**
Refer to SARS

Sexual desire disorder **PSY**
Sexual dysfunction may be related to insufficient knowledge/misinformation about sexual function, inadequate role model, (absence of significant other), vulnerability, presence of abuse, value conflict, possibly evidenced by alterations in sexual activity/sexual satisfaction, perceived sexual limitation.

Anxiety [moderate to severe] may be related to threat to current status, value conflict, unmet needs, (major change), possibly evidenced by increase in [sexual] tension, feeling of inadequacy, self-focused, extraneous movement, poor eye contact, glancing about, hypervigilance, cardiovascular excitation.

situational low Self-Esteem may be related to behavior inconsistent with values, (history of rejection, pattern of failure), possibly evidenced by situational challenge to self worth, helplessness, self-negating verbalizations.

Sexual dysfunctions **PSY**
Refer to Dyspareunia; Erectile dysfunction; Sexual desire disorder; Vaginismus

Sexually transmitted infection **GYN/CH**
risk for Infection [transmission] possibly evidenced by [contagious nature of infecting agent] and insufficient knowledge to avoid exposure to or transmission of pathogens.

impaired Skin/Tissue Integrity may be related to invasion of and irritation by pathogenic organism(s), possibly evidenced by [inflammation (e.g., in gonorrhea or chlamydial infection) or ulceration (e.g., in herpes simplex, syphilis)].

deficient Knowledge regarding condition, prognosis, potential complications, therapy needs, and transmission may be related to lack of information, misinterpretation, lack of interest in learning, possibly evidenced by statements of concern, questions, misconceptions, inaccurate follow-through of instructions, and development of preventable complications.

Shingles **CH**
Refer to Herpes zoster

Shock **MS**
Also refer to Shock, cardiogenic; Shock, hypovolemic/hemorrhagic; Sepsis
risk for Infection [progression] may be related to alteration in peristalsis or skin integrity; stasis of body fluids, malnutrition, possibly associated with immunosuppression.

ineffective Tissue Perfusion (specify) may be related to changes in circulating volume or vascular tone, possibly evidenced by changes in skin color and temperature and pulse pressure, reduced blood pressure, changes in mentation, and decreased urinary output.

risk for Shock may be related to alteration in peristalsis or skin integrity; stasis of body fluids, malnutrition, possibly associated with immunosuppression.

Shock, cardiogenic **MS**
Also refer to Shock

decreased Cardiac Output may be related to structural damage, decreased myocardial contractility, and presence of dysrhythmias, possibly evidenced by electrocardiogram changes, variations in hemodynamic readings, jugular vein distention, cold and clammy skin, diminished peripheral pulses, and decreased urinary output.

risk for impaired Gas Exchange possibly evidenced by (ventilation-perfusion imbalance, alveolar-capillary membrane changes).

Shock, hypovolemic/hemorrhagic **MS**
Also refer to Shock

deficient Fluid Volume may be related to excessive vascular loss, inadequate intake or replacement, possibly evidenced by hypotension, tachycardia, decreased pulse volume and pressure, change in mentation, and decreased, concentrated urine.

Shock, septic **MS**
Refer to Sepsis

Sicca syndrome **CH**
Refer to Sjögren syndrome

Sick building syndrome **CH**
Contamination may be related to presence of atmospheric or environmental contaminants (e.g., volatile organic compounds, carbon monoxide, asbestos, dust, fungi, molds, pollens, tobacco smoke), carpeted

flooring, inadequate ventilation, possibly evidenced by dermatological/gastrointestinal/pulmonary/neurological effects of contaminating agent(s).

Fatigue may be related to stressors [place of employment/residence], possibly evidenced by tiredness, lethargy, insufficient energy; impaired ability to maintain usual physical activity/routines.

Sick sinus syndrome

MS

Also refer to Dysrhythmia, cardiac
decreased Cardiac Output may be related to alterations in rate, rhythm, and electrical conduction, possibly evidenced by electrocardiogram indication of dysrhythmias, reports of palpitations, weakness, changes in mentation or consciousness, and syncope.

risk for Trauma possibly evidenced by changes in cerebral perfusion with altered consciousness, loss of balance.

SIDS

PED

Refer to Sudden infant death

Sinusitis, chronic

CH

acute/chronic Pain may be related to physical agent— inflammatory process, possibly evidenced by reports of [headache and facial] pain, irritability, alteration in sleep pattern, fatigue.

risk for Infection [spread] possibly evidenced by stasis of body fluids, [low-level chronic infection; improper handling of infectious material].

Sjögren syndrome

CH

impaired oral Mucous Membrane Integrity/Dry Mouth may be related to decreased salivation, possibly evidenced by xerostomia (dry mouth), oral pain or discomfort, self-report of bad or diminished taste, difficulty eating and swallowing.

risk for impaired Tissue Integrity/Dry Eye (cornea, mucous membranes) possibly evidenced by impaired production of tears, mucus.

risk for Infection possibly evidenced by [decreased secretions, tissue dryness and damage].

[risk for disturbed visual Sensory Perception] possibly evidenced by risk factors of altered sensory reception (light sensitivity, blurred vision, corneal ulcers).

Skin cancer

CH

impaired Skin Integrity may be related to [invasive growth, surgical excision], possibly evidenced by alteration of skin integrity [destruction of dermis].

risk for acute Pain possibly evidenced by ulceration of skin, surgical incision.

risk for disturbed Body Image possibly evidenced by skin lesion, surgical intervention.

deficient Knowledge regarding condition, prognosis, treatment, and prevention may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, misconceptions, inaccurate follow-through of instructions, development of preventable complications, or recurrence.

SLE

CH

Refer to Lupus erythematosus, systemic

Sleep apnea

CH

Sleep deprivation may be related to nonrestorative sleep pattern, (sleep apnea), possibly evidenced by drowsiness, fatigue, decrease in functional ability, alteration in concentration.

impaired Gas Exchange may be related to [altered oxygen supply—recurrent apneic episodes lasting 10 seconds to 2 minutes], possibly evidenced by abnormal breathing pattern, headache upon awakening, confusion, hypoxemia, hypercapnia, [dysrhythmias (e.g., extreme bradycardia, ventricular tachycardia)].

risk for ineffective Health Management possibly evidenced by difficulty managing treatment regimen, perceived seriousness or benefit.

Smallpox

MS

risk of Infection [spread] possibly evidenced by [contagious nature of organism], inadequate vaccination, (chronic illness, immunosuppression).

deficient Fluid Volume may be related to hypermetabolic state, decreased intake (pharyngeal lesions, nausea), increased losses (vomiting), fluid shifts from vascular bed, possibly evidenced by reports of thirst; decreased blood pressure, venous filling, and urinary output; dry mucous membranes; decreased skin turgor; change in mental state; elevated hematocrit.

impaired Tissue Integrity may be related to immunological deficit, possibly evidenced by disruption of skin surface, cornea, mucous membranes.

CH

interrupted Family Processes may be related to changes in interaction with community, shift in family roles, (situational crisis, shift in health status of family member), possibly evidenced by change in participation for problem-solving, change in family satisfaction, change in stress-reduction behavior, decrease in mutual support.

ineffective community Coping may be related to (exposure to disaster [bioterrorism]), inadequate resources for problem-solving, possibly evidenced by deficient community participation, elevated community illness rate, excessive community conflict, perceived community vulnerability or powerlessness.

Snake bite, venomous

MS

[severe] Anxiety/Fear may be related to (situational crisis), threat of death, possibly evidenced by uncertainty, apprehensiveness, irritability, jitteriness, increase in tension, tremors.

acute Pain/impaired Comfort may be related to effects of toxins [e.g., edema, erythema, nausea, fever, diaphoresis, muscle fasciculations], possibly evidenced by reports of pain and paresthesias, guarded behavior, restlessness, autonomic responses.

impaired Skin Integrity may be related to [snake bite] possibly evidenced by alteration in skin integrity, acute pain, redness.

risk for deficient Fluid Volume possibly evidenced by excessive losses (vomiting, edema formation, hemorrhage from mucous membranes).

Snow blindness

CH

[disturbed visual Sensory Perception] may be related to altered status of sense organ (irritation of the conjunctiva, hyperemia), possibly evidenced by intolerance to light (photophobia) and decreased or loss of visual acuity.

acute Pain may be related to irritation and vascular congestion [conjunctiva], possibly evidenced by verbal reports of pain, guarding or distraction behavior, and self-focused.

Somatoform disorders

PSY

ineffective Coping may be related to inadequate confidence to deal with situation, ineffective tension release strategies, possibly evidenced by inability to deal with situation, insufficient problem resolution/problem-solving skills, insufficient goal directed behavior, frequent illness, destructive behavior toward self, substance misuse.

chronic Pain may be related to alteration in sleep pattern, fatigue, emotional distress [severe level of repressed anxiety], social isolation, possibly evidenced by verbal reports of pain; facial expression of pain, self-focusing, alteration in ability to continue previous activities.

[disturbed Sensory Perception (specify)] may be related to psychological stress (narrowed perceptual

fields, expression of stress as physical problems or deficits), poor quality of sleep, presence of chronic pain, possibly evidenced by reported change in voluntary motor or sensory function (paralysis, anosmia, aphonia, deafness, blindness, loss of touch or pain sensation), *la belle indifférence* (lack of concern over functional loss).

impaired Social Interaction may be related to insufficient knowledge about ways, or skills, to enhance mutuality, communication barriers, socio-cultural dissonance, disturbance in thought processes, possibly evidenced by dysfunctional interactions with others, dissatisfaction with social engagement, impaired social functioning, family reports change in interaction.

Spina bifida

PED

Also refer to Paraplegia; Newborn, special needs *bowel Incontinence/Constipation* may be related to disruption of nerve innervation, perceptual impairment, reduced activity level, possibly evidenced by inability to evacuate bowel voluntarily, increased abdominal pressure or distention, dry and hard formed stool, change in bowel sounds.

risk for impaired Walking/physical Mobility possibly evidenced by neuromuscular impairment, developmental delay, musculoskeletal impairments—clubfoot, hip dislocation, joint deformities, kyphosis.

risk for decreased intracranial Adaptive Capacity possibly evidenced by structural changes (aqueductal stricture, malformation of brainstem).

risk for Infection possibly evidenced by (increased environmental exposure, invasive procedures, [cerebrospinal fluid leak]).

Spinal cord injury (SCI)

MS/CH

Refer to Paraplegia; Quadriplegia

Splenectomy

MS/CH

Refer to Surgery, general

risk for Infection possibly evidenced by insufficient knowledge to avoid exposure to pathogens and (invasive procedure/surgery, type of anesthesia, immunosuppression).

risk for ineffective Health Management possibly evidenced by length of therapy, economically disadvantaged, perceived benefits.

Spongiform encephalopathy

CH

Refer to Creutzfeldt-Jakob disease

Sprain of ankle or foot

CH

acute Pain may be related to physical injury agent—trauma, possibly evidenced by verbal reports of pain, guarding or distraction behavior, self-focused, and changes in vital signs.

impaired Walking may be related to (musculo-skeletal injury), pain, and [therapeutic restrictions], possibly evidenced by impaired ability to walk required distance, on uneven surface, or climb stairs.

Sprue, nontropical

CH

Refer to Celiac disease

Stapedectomy

MS

risk for Trauma possibly evidenced by increased middle-ear pressure with displacement of prosthesis and balancing difficulties, dizziness.

risk for Infection possibly evidenced by (invasive procedure), and environmental exposure to pathogens.

acute Pain may be related to surgical trauma, edema, and [presence of packing], possibly evidenced by verbal reports of pain, guarding or distraction behavior, and self-focused.

Stasis dermatitis

CH

Also refer to Venous insufficiency

impaired Skin Integrity may be related to alteration in fluid volume, and (impaired circulation), possibly evidenced by alteration in skin integrity, redness, alteration in pigmentation and sensation.

risk for Infection possibly evidenced by [circulatory stasis, edema formation (small-vessel vaso-constrictive reflexes) in lower extremities, persistent inflammation, tissue destruction].

STI

CH

Refer to Sexually transmitted infection

Stillbirth

OB

Refer to Perinatal loss/death of child

Stimulant abuse

CH

Also refer to Cocaine hydrochloride poisoning, acute; Substance dependence/abuse rehabilitation

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, possibly evidenced by [substituting drug for food], food intake less than recommended daily allowance, (economically disadvantaged), [weight loss], insufficient muscle tone, (psychological disorder).

risk for Infection possibly evidenced by altered immune state; malnutrition; (exposure to disease

[e.g., injection techniques, impurities of drugs; tissue trauma].

Insomnia may be related to substance consumption, anxiety/fear, stressors, physical discomfort, possibly evidenced by difficulty initiating sleep, dissatisfaction with sleep, insufficient energy, alteration in concentration, alteration in affect, [denial of need to sleep, racing thoughts].

PSY

Fear/Anxiety [specify] may be related to substance misuse; stressors; unmet needs; threat to change in current status, threat of death, (exposure to toxins, situational crisis), possibly evidenced by awareness of physiological symptoms; fear; cardiovascular excitation; increased respiration, restlessness, apprehensiveness, increase in wariness, alteration in sleep pattern.

ineffective Coping may be related to inaccurate threat appraisal/high degree of threat; ineffective tension release strategies; insufficient social support, possibly evidenced by substance misuse; ineffective coping skills; inability to meet basic needs; insufficient access of social support; risk-taking behavior/destructive behavior toward self.

[disturbed Sensory Perception (specify)] may be related to exogenous chemical, altered sensory reception, transmission, or integration (hallucination), altered status of sense organs, possibly evidenced by responding to internal stimuli from hallucinatory experiences, bizarre thinking, anxiety, panic changes in sensory acuity (sense of smell, taste).

Stomatitis

CH

impaired oral Mucous Membrane Integrity may be related to [infection], inadequate nutrition [vitamin deficiency], alcohol consumption, smoking, barrier to dental care, mouth breathing, possibly evidenced by oral pain; difficulty eating; oral lesions, ulcers; white patches or plaques in mouth, coated tongue.

risk for deficient Fluid Volume possibly evidenced by oral pain, difficulty swallowing.

Strep throat

CH

Hyperthermia may be related to illness and effects of toxins, inability to ingest sufficient fluids, possibly evidenced by body temperature above normal range, flushed dry skin, decreased urine output.

acute Pain may be related to injuring biological agent, possibly evidenced by self-report of pain, change in ability to eat, crying.

risk for Infection [transmission] possibly evidenced by insufficient knowledge to avoid exposure to or transmission of pathogen.

Stress disorder, acute

PSY

Refer to Post-traumatic stress disorder

Substance dependence/abuse, prenatal

OB

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, possibly evidenced by [substituting drug for food], anorexia, economically disadvantaged, [low weight gain or weight loss, protein/vitamin deficiencies].

risk for disturbed Maternal-Fetal Dyad possibly evidenced by substance misuse, (treatment regimen).

ineffective Denial/Coping may be related to insufficient sense of control, threat of unpleasant reality, excessive stress, ineffective tension release strategies, possibly evidenced by delay in seeking healthcare, does not admit impact of disease on life, ineffective coping strategies, substance misuse, risk-taking behavior, insufficient access of social support.

Powerlessness may be related to illness [substance addiction], ineffective coping strategies, low self-esteem, social marginalization/stigmatization, possibly evidenced by dependency, inadequate participation in care, insufficient sense of control.

chronic low Self-Esteem may be related to [social stigma attached to substance abuse, social expectation that one controls own behavior, continual negative evaluation of self, personal vulnerabilities], possibly evidenced by [not taking responsibility for self, lack of follow-through, self-destructive behavior, denial that substance use is a problem].

disabled Family Coping may be related to ambivalent family relationships, differing coping styles between support person(s)/client, family disorganization, possibly evidenced by client dependence, distortion of reality about client's health problem, family behaviors detrimental to well-being, neglect of treatment regimen.

Substance dependence/abuse rehabilitation

PSY/CH

(Following acute detoxification)

ineffective Denial may be related to threat of unpleasant reality, insufficient emotional support, excessive stress, possibly evidenced by does not admit impact of disease on life, delay in seeking healthcare.

Powerlessness may be related to ineffective coping strategies, low self-esteem, social marginalization,

stigmatization, possibly evidenced by dependency, insufficient sense of control, doubt about role performance, shame.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, possibly evidenced by food intake less than recommended daily allowance [substituting drug for food], economically disadvantaged, alteration in taste sensation, weight loss, insufficient muscle tone.

Sexual dysfunction may be related to altered body function (neurological damage and debilitating effects of drug use), vulnerability, value conflict, possibly evidenced by alteration in sexual activity/satisfaction, decrease in sexual desire, undesired change in sexual function.

dysfunctional Family Processes may be related to substance misuse, addictive personality, (family history of substance misuse), ineffective coping strategies, insufficient problem-solving skills, possibly evidenced by anger, frustration, self-blame, shame, embarrassment, repressed emotions, guilt, vulnerability, rationalization, controlling communication pattern, manipulation, blaming, enabling substance use pattern, inability to accept or receive help appropriately.

OB

risk for fetal Injury possibly evidenced by drug or alcohol use, exposure to teratogens.

deficient Knowledge regarding condition, effects on pregnancy, prognosis, and treatment needs may be related to lack or misinterpretation of information, lack of recall, cognitive limitations, interference with learning, possibly evidenced by statements of concern, questions, misconceptions, inaccurate follow-through of instructions, development of preventable complications, continued use in spite of complications.

Sudden infant death

PED

complicated Grieving may be related to emotional disturbance [unexpected loss of child], possibly evidenced by distress about the deceased person, feeling of emptiness, anger; self-blame, rumination.

risk for impaired Parenting possibly evidenced by recent crisis, change in family unit, maladaptive coping strategies, sleep disruption, depression.

risk for interrupted Family Processes possibly evidenced by situational crisis, loss of a family member.

risk for chronic Sorrow possibly evidenced by death of a loved one, anniversary dates (birth, death, etc.), trigger events (e.g., infants on TV, at play).

Suicide attempt

MS

Also refer to specific means, e.g., Drug overdose, acute; Wound, gunshot

PSY

Hopelessness may be related to long-term stress, abandonment, deteriorating physical or mental condition, challenged value or belief system, possibly evidenced by verbal cues, passivity, lack of involvement or withdrawal, angry outbursts.

risk for Suicide possibly evidenced by prior or current attempt, marked changes in behavior, attitude, or performance, impulsiveness, sudden euphoric recovery from major depression, living alone, loss of independence, economic instability, substance abuse, has a plan and available means.

chronic/situational low Self-Esteem may be related to losses, functional impairment, developmental changes, failures or rejection, possibly evidenced by evaluating self as unable to deal with events, expressions of helplessness, uselessness, shame, or guilt; self-negating verbalizations.

compromised family Coping may be related to family disorganization, role changes, prolonged disease or disability, (situational or developmental crises), possibly evidenced by client expressing concern about SO's response to problems, SO confirms ineffective supportive behaviors, SO withdraws from client.

Sunstroke

MS

Refer to Heatstroke

Surgery, general

MS

Also refer to Postoperative recovery period
deficient Knowledge regarding surgical procedure and expectation, postoperative routines, therapy, and self-care needs may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, and misconceptions.

Anxiety [specify level]/Fear may be related to (situational crisis), unfamiliarity with environment, threat to current status or threat of death and separation from support system, possibly evidenced by increase in tension, apprehensiveness, decreased self-assurance, fear, self-focused, sympathetic stimulation, and restlessness.

risk for perioperative Positioning Injury possibly evidenced by disorientation, immobilization, muscle weakness, obesity, edema.

risk for Injury possibly evidenced by physical factor—wrong client, procedure, site, implants,

equipment or materials; interactive conditions between individual and environment; external environment—physical design, structure of environment, exposure to equipment, instrumentation, positioning, use of pharmaceutical agents; internal environment—tissue hypoxia, abnormal blood profile or altered clotting factors, broken skin.

risk for imbalanced Fluid Volume possibly evidenced by preoperative fluid deprivation, blood loss, and excessive gastrointestinal losses—vomiting or gastric suction; inappropriate or rapid replacement.

Syndrome X

CH

Refer to Metabolic syndrome

Synovitis (knee)

CH

acute Pain may be related to physical agent—inflammation, effusion, possibly evidenced by verbal reports of pain, guarding or distraction behavior, self-focused, and changes in vital signs.

impaired Walking may be related to pain and insufficient [joint] strength, possibly evidenced by impaired ability to walk required distance.

Syphilis, congenital

PED

Also refer to Sexually transmitted infection

acute Pain may be related to physical agent—inflammation, edema, and development of skin lesions, possibly evidenced by self-report of pain, expressive/guarding behavior, facial expression of pain, and autonomic responses (changes in vital signs).

impaired Skin/Tissue Integrity may be related to [exposure to pathogens during vaginal delivery] possibly evidenced by alteration in skin integrity/tissue damage.

risk for [disproportionate Growth]/delayed Development possibly evidenced by congenital disorder, malnutrition, seizure disorder.

deficient Knowledge regarding pathophysiology of condition, transmissibility, therapy needs, expected outcomes, and potential complications may be related to caretaker/parental lack of information, misinterpretation, possibly evidenced by statements of concern, questions, and misconceptions.

Syringomyelia

MS

[disturbed Sensory Perception (specify)] may be related to altered sensory perception (neurological lesion), possibly evidenced by change in usual response to stimuli and motor incoordination.

impaired physical Mobility may be related to neuromuscular and sensory impairment, possibly evidenced by decreased muscle strength, control, and mass; and impaired coordination.

Self-Care deficit [specify] may be related to neuromuscular and sensory impairments, possibly evidenced by statement of inability to perform care tasks.

Tarsal tunnel syndrome

CH

acute/chronic Pain may be related to physical agent—pressure on nerve, possibly evidenced by verbal reports of pain, guarding behavior, alteration in ability to continue previous activities.

impaired Walking may be related to (neuromuscular impairment) and pain, possibly evidenced by impaired ability to walk desired distances, climb stairs, navigate curbs or uneven surfaces.

Tay-Sachs disease

PED

risk for delayed Development possibly evidenced by risk factors of genetic disorder, seizure disorder, visual/hearing impairment.

[disturbed visual Sensory Perception] may be related to neurological deterioration of optic nerve, possibly evidenced by loss of visual acuity.

CH

family Grieving may be related to anticipatory loss of significant other [infant/child], possibly evidenced by distress, anger, despair, blaming; alteration in sleep pattern, disorganization.

[family] Powerlessness may be related to (progressive illness, unpredictably of illness trajectory), [absence of therapeutic interventions], possibly evidenced by insufficient sense of control, and depression.

risk for Spiritual distress possibly evidenced by stressors [challenged belief and value system], illness, [anticipating] death.

compromised family Coping may be related to (situational crisis faced by support person), exhaustion of support person's capacity; family disorganization; possibly evidenced by support person reports preoccupations with reaction to client's need, and altered communication patterns.

TBI

MS/CH

Refer to Traumatic brain injury

Temporal arteritis

CH

acute Pain may be related to physical agent—arterial inflammation, possibly evidenced by reports of pain, facial expression of pain.

[risk for disturbed visual Sensory Perception]: possibly evidenced by altered reception (arterial inflammation, ischemic optic neuropathy).

risk for ineffective Health Management risk factors may include medication side effects, economic difficulties, perceived seriousness or benefits.

Temporomandibular joint syndrome

CH

chronic Pain may be related to (chronic musculoskeletal condition), possibly evidenced by reports of pain, self-focused.

risk for imbalanced Nutrition: less than body requirements possibly evidenced by risk factors of inability to ingest food, food intake less than recommended daily allowance, weakness of muscles required for mastication.

[risk for disturbed auditory Sensory Perception] possibly evidenced by altered sensory reception (tinnitus, occasional deafness).

Tendonitis

CH

acute/chronic Pain may be related to physical agent—inflammation, swelling of tendon, possibly evidenced by verbal reports of pain, guarding or protective behavior, alteration in ability to continue previous activities.

impaired physical Mobility may be related to pain, joint stiffness, musculoskeletal impairment, prescribed movement restrictions, possibly evidenced by limited range of motion, limited ability to perform fine or gross motor skills.

risk for ineffective Role Performance possibly evidenced by health alterations, fatigue, pain.

Testicular cancer

MS

Also refer to Cancer

disturbed Body Image may be related to (surgical procedure), alteration in self-perception, possibly evidenced by negative feeling about body, preoccupation with change, fear of reaction of others, and change in social environment.

Sexual dysfunction may be related to alteration in body structure/function, vulnerability, possibly evidenced by alteration in sexual satisfaction/activity.

Tetanus

MS

acute Pain may be related to biological injury agent—neurotoxic bacterium, possibly evidenced by self-report of pain, narrowed focus, facial expression of pain.

bowel/urinary Incontinence may be related to abnormally high abdominal/intestinal pressure possibly evidenced by urgency, inability to delay elimination.

risk for impaired Swallowing possibly evidenced by (neuromuscular impairment).

risk for impaired spontaneous Ventilation possibly evidenced by respiratory muscle fatigue/muscle spasms.

Tetraplegia

MS/CH

Refer to Quadriplegia

Thoracotomy

MS

Refer to Surgery, general; Hemothorax

Thrombophlebitis

CH/MS/OB

ineffective peripheral Tissue Perfusion may be related to interruption of venous blood flow, venous stasis, possibly evidenced by changes in skin color and temperature over affected area, development of edema, pain, diminished peripheral pulses, slow capillary refill.

acute Pain/impaired Comfort may be related to physical agent—vascular inflammation, edema formation, possibly evidenced by self-report, of pain, guarding or distraction behavior, restlessness, and self-focused.

risk for impaired physical Mobility possibly evidenced by pain and discomfort, restrictive therapies, and safety precautions.

deficient Knowledge regarding pathophysiology of condition, therapy, self-care needs, and risk of embolization may be related to lack of information or misinterpretation, possibly evidenced by statements of concern, questions, inaccurate follow-through of instructions, and development of preventable complications.

Thrombosis, venous

MS

Refer to Thrombophlebitis

Thrush

CH

impaired oral Mucous Membrane Integrity may be related to (infection) as evidenced by white patches or plaques, oral discomfort, mucosal irritation, bleeding.

risk for imbalanced Nutrition: less than body requirements possibly evidenced by inability to ingest food, food aversion.

Thyroidectomy

MS

Also refer to Hyperthyroidism; Hypoparathyroidism (acute), Hypothyroidism

risk for ineffective Airway Clearance possibly evidenced by tracheal obstruction—edema, hematoma formation, laryngeal spasms.

impaired verbal Communication may be related to (physiological condition—tissue edema, pain, vocal

cord injury or laryngeal nerve damage), possibly evidenced by difficulty/inability to speak.

risk for Injury [tetany] possibly evidenced by chemical imbalance—hypocalcemia, increased release of thyroid hormones; excessive central nervous system stimulation.

risk for head/neck physical Trauma possibly evidenced by loss of muscle control and support, and position of suture line.

acute Pain may be related to physical injury agent—manipulation of tissues and muscles, postoperative edema; (surgical procedure), possibly evidenced by verbal reports of pain, guarding or distraction behavior, narrowed focus, and autonomic responses—changes in vital signs.

Thyrotoxicosis

MS

Also refer to Hyperthyroidism

risk for decreased Cardiac Output possibly evidenced by uncontrolled hypermetabolic state increasing cardiac workload; changes in venous return and systemic vascular resistance; and alterations in rate, rhythm, and electrical conduction.

Anxiety [specific level] may be related to threat to current status, physiological factors and central nervous system stimulation (hypermetabolic state and pseudocatecholamine effect of thyroid hormones), possibly evidenced by apprehensiveness, uncertainty, alteration in concentration, extraneous movements, restlessness, and tremors.

deficient Knowledge regarding condition, treatment needs, and potential for complications or crisis situation may be related to lack of information or recall, misinterpretation, possibly evidenced by statements of concern, questions, misconceptions, and inaccurate follow-through of instructions.

TIA

CH

Refer to Transient ischemic attack

Tic douloureux

CH

Refer to Neuralgia, trigeminal

TMJ syndrome

CH

Refer to Temporomandibular joint syndrome

Tonsillectomy

PED/MS

Refer to Adenoidectomy

Tonsillitis

PED

acute Pain may be related to biological injury agent [bacteria or virus causing inflammation], possibly

evidenced by verbal reports of pain, guarding or distraction behavior, self-focused, and changes in vital signs.

Hyperthermia may be related to presence of inflammatory process, hypermetabolic state and dehydration, possibly evidenced by increased body temperature; warm, flushed skin; and tachycardia.

deficient Knowledge regarding cause/transmission, treatment needs, and potential complications may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, inaccurate follow-through of instructions, and recurrence of condition.

Total joint replacement **MS**

risk for Infection possibly evidenced by alteration in skin integrity, immunosuppression (long-term corticosteroid use), invasive procedures and surgical manipulation, implantation of foreign body, and [decreased mobility].

impaired physical Mobility may be related to pain and discomfort, musculoskeletal impairment, and surgery and restrictive therapies, possibly evidenced by reluctance to attempt movement, difficulty with purposefully moving within the physical environment, reports of pain or discomfort on movement, limited range of motion, and decreased muscle strength and control.

risk for ineffective peripheral Tissue Perfusion possibly evidenced by reduced arterial or venous blood flow, direct trauma to blood vessels, tissue edema, improper location or dislocation of prosthesis, and hypovolemia.

acute Pain may be related to physical injury agents [traumatized tissues, surgical intervention, degeneration of joints, muscle spasms], possibly evidenced by verbal reports of pain, guarding or distraction behavior, self-focused, and changes in vital signs.

risk for Constipation possibly evidenced by decrease in gastrointestinal motility—anesthesia, opiate analgesics; average daily physical activity is less than recommended for gender/age, insufficient fiber or fluid intake, dehydration.

Tourette's syndrome **CH**

chronic low Self-Esteem may be related to [inherited disorder], inadequate belonging, inadequate respect from others, possibly evidenced by shame, exaggerated negative feedback about self, hesitancy to try new experiences.

Social Isolation may be related to social behavior incongruent with norms, inability to engage in

satisfying personal relationships, possibly evidenced by disabling condition, feeling different from others, withdrawn, history of rejection.

risk for Injury possibly evidenced by adverse side effects of medications, negative response of uneducated individuals.

Toxemia of pregnancy **OB**

Refer to Hypertension, gestational

Toxic enterocolitis **PED/MS**

Also refer to Colostomy

deficient Fluid Volume may be related to fulminating losses into the bowel, diarrhea, lack of intake evidenced by decreased concentrated urine, dry mucous membranes, poor skin turgor, decreased venous filling, change in mentation.

risk for decreased Cardiac Output possibly evidenced by decreased venous return, altered heart rate and rhythm.

Toxic megacolon **MS**

Refer to Toxic enterocolitis

Toxic shock syndrome **MS**

Also refer to Sepsis

Hyperthermia may be related to inflammatory process, hypermetabolic state and dehydration, possibly evidenced by increased body temperature; warm, flushed skin; and tachycardia.

deficient Fluid Volume [isotonic] may be related to increased gastric losses (diarrhea, vomiting), fever, hypermetabolic state, and decreased intake, possibly evidenced by dry mucous membranes, increased pulse, hypotension, delayed venous filling, decreased concentrated urine, and hemoconcentration.

acute Pain may be related to biological injury agent—inflammatory process, effects of circulating toxins, possibly evidenced by verbal reports of pain, guarding or distraction behavior, self-focused, and changes in vital signs.

impaired Skin/Tissue Integrity may be related to [effects of circulating toxins and dehydration], possibly evidenced by alteration in skin integrity (desquamation rash), redness, and [inflammation of mucous membranes].

Traction **MS**

Also refer to Casts; Fractures

acute Pain may be related to physical injury agent—direct trauma to tissue and bone, muscle spasms, movement of bone fragments, edema, injury to soft

tissue], possibly evidenced by verbal reports of pain, guarding or distraction behavior, self-focused, alteration in muscle tone, and changes in vital signs.

impaired physical Mobility may be related to (neuromuscular and skeletal impairment), pain, and therapeutic restrictions of movement, possibly evidenced by limited range of motion, inability to move purposefully in environment, reluctance to attempt movement, and decreased muscle strength and control.

risk for Infection possibly evidenced by (invasive procedure [including insertion of foreign body through skin and bone]), presence of traumatized tissue, and reduced activity with stasis of body fluids.

decreased Diversional Activity Engagement may be related to length of hospitalization or therapeutic intervention and environmental lack of usual activity, possibly evidenced by statements of boredom, restlessness, and irritability.

Transfusion reaction, blood

MS

Also refer to Anaphylaxis

risk for imbalanced Body Temperature possibly evidenced by infusion of cold blood products, systemic response to toxins.

risk for impaired Skin Integrity possibly evidenced by (immunodeficiency).

Transient ischemic attack

CH

ineffective cerebral Tissue Perfusion may be related to interruption of blood flow (e.g., vasospasm), possibly evidenced by altered mental status, behavioral changes, language deficit, change in motor and sensory response.

Anxiety [specify level]/Fear may be related to threat to current status, stressors, (situational crisis), possibly evidenced by apprehensiveness, restlessness, irritability, self-focused.

risk for ineffective Denial possibly evidenced by change in health status requiring change in lifestyle, fear of consequences, lack of motivation.

Transplant, living donor

MS

Also refer to Surgery, general; Nephrectomy

Decisional Conflict may be related to conflicting information sources, conflict with moral obligation, possibly evidenced by vacillating among choices, recognizes undesired consequences of actions being considered, delay in decision making.

[moderate to severe] *Anxiety/Fear* may be related to (situational crisis), unconscious conflict

about essential beliefs or values, threat to current status or death, possibly evidenced by apprehensiveness, uncertainty, increase in tension, fear, sympathetic stimulation.

Transplantation, recipient

MS

Also refer to Surgery, general; Cardiac surgery

Anxiety [specify level]/Fear may be related to threat of current status, value conflict, (situational crisis), possibly evidenced by increase in tension, apprehensiveness, uncertainty, fear, sympathetic stimulation, insomnia.

risk for Infection possibly evidenced by (chronic illness, medically induced immunosuppression, suppressed inflammatory response, invasive procedures).

(Refer to specific conditions relative to compromise or failure of individual transplanted organ, e.g., Renal failure, acute; Heart failure, chronic; Pancreatitis.)

CH

compromised family Coping may be related to coexisting situations affecting the support person, exhaustion of support person's capacity, family disorganization or role changes, possibly evidenced by assistive behaviors by support person produce unsatisfactory results, protective behavior by support person incongruent with client's abilities/need for autonomy, support person reports preoccupation with own reaction to client's need.

ineffective Protection may be related to treatment regimen/pharmaceutical agents, compromised immune system possibly evidenced by weakness, maladaptive stress response.

readiness for enhanced Health Management possibly evidenced by expresses desire to enhance management of illness/prescribed regimens and management of risk factors.

risk for ineffective Health Management possibly evidenced by difficulty managing complex treatment regimen, navigating complex healthcare systems, (economically disadvantaged).

Transurethral resection of prostate

MS

Refer to Prostatectomy

Traumatic brain injury (TBI)

MS

ineffective cerebral Tissue Perfusion may be related to (brain injury), [interruption of blood flow], possibly evidenced by altered level of consciousness, memory loss, changes in motor or sensory responses, restlessness, changes in vital signs.

risk for decreased intracranial Adaptive Capacity possibly evidenced by brain injuries, systemic hypotension with intracranial hypertension.

risk for ineffective Breathing Pattern possibly evidenced by neuromuscular dysfunction—injury to respiratory center of brain; perception or cognitive impairment, tracheobronchial obstruction.

[disturbed Sensory Perception (specify)] may be related to altered sensory reception, transmission or integration (neurological trauma or deficit), possibly evidenced by disorientation to time, place, person; motor incoordination; altered communication patterns; restlessness or irritability; change in behavior pattern.

risk for Infection possibly evidenced by alteration in skin integrity/traumatized tissues, (invasive procedures, decreased ciliary action), stasis of body fluids, nutritional deficits, (suppressed inflammatory response).

risk for imbalanced Nutrition: less than body requirements possibly evidenced by food intake less than recommended daily allowance, altered ability to ingest food, weakness of muscles required for chewing or swallowing.

CH

impaired physical Mobility may be related to alteration in cognitive functioning, sensory-perceptual impairment, decrease in muscle strength or endurance, possibly evidenced by uncoordinated movement, decrease in range of motion, decrease in fine/gross motor skills.

risk for impaired Memory/chronic Confusion possibly evidenced by head injury, neurological disturbances.

interrupted Family Processes may be related to (situational transition and crisis, shift in health status of a family member), shift in family roles, possibly evidenced by change in family satisfaction, change in stress-reduction behavior, decrease in mutual support, change in communication pattern.

Self-Care deficit (specify) may be related to (neuromuscular or musculoskeletal impairment), weakness, pain, (perceptual disorder, alteration in cognitive functioning), possibly evidenced by inability to perform desired or appropriate activities of daily living.

Trench foot

MS

Refer to Immersion foot

Trichinosis

CH

acute Pain may be related to biological injury agent—parasitic invasion of intestines migrating to muscle

tissues, edema of upper eyelids, small localized hemorrhages, and development of urticaria], possibly evidenced by verbal reports of pain, guarding/distraction behavior, restlessness, and changes in vital signs.

deficient Fluid Volume may be related to hypermetabolic state (fever, diaphoresis); excessive gastric losses (vomiting, diarrhea); and decreased intake and difficulty swallowing, possibly evidenced by dry mucous membranes, decreased skin turgor, hypotension, decreased venous filling, decreased concentrated urine, and hemoconcentration.

ineffective Breathing Pattern may be related to myositis of the diaphragm and intercostal muscles, possibly evidenced by resulting changes in respiratory depth, tachypnea, dyspnea, and abnormal arterial blood gases.

deficient Knowledge regarding cause, prevention of condition, therapy needs, and possible complications may be related to lack of information, misinterpretation, possibly evidenced by statements of concern, questions, and misconceptions.

Tricuspid insufficiency

CH

Refer to Valvular heart disease

Tricuspid stenosis

CH

Refer to Valvular heart disease

Tubal pregnancy

OB

Refer to Ectopic pregnancy (tubal)

Tuberculosis (pulmonary)

CH

risk for Infection [spread/reactivation] possibly evidenced by status of body fluids (secretions), inadequate vaccination, (decrease in ciliary action, immunosuppression, chronic illness), insufficient knowledge to avoid exposure to pathogens [inadequate therapeutic intervention].

ineffective Airway Clearance may be related to (infection), excessive mucus, retained secretions, possibly evidenced by alteration in respiratory rate/pattern, excessive sputum, ineffective cough, adventitious breath sounds, and dyspnea.

risk for impaired Gas Exchange possibly evidenced by ventilation-perfusion imbalance—[decrease in effective lung surface; atelectasis; destruction of alveolar-capillary membrane].

Activity Intolerance may be related to imbalance between oxygen supply and demand, possibly evidenced by reports of fatigue, weakness, and exertional dyspnea.

imbalanced Nutrition: less than body requirements may be related to insufficient dietary intake, (economically disadvantaged), possibly evidenced by [weight loss], insufficient interest in food, or alteration in taste sensation, and insufficient muscle tone.

risk for ineffective Health Management possibly evidenced by complexity of therapeutic regimen, economic difficulties, family patterns of healthcare, perceived seriousness or benefits (especially during remission), side effects of therapy.

TURP

Refer to Prostatectomy

MS

Twin-twin transfusion syndrome

OB

decreased Cardiac Output may be related to altered preload (hypovolemia, anemia) to donor fetus, possibly evidenced by oliguria, oligohydramnios.

excess Fluid Volume may be related to excess fluid intake (shunting of circulation) to recipient fetus, possibly evidenced by polyuria, polyhydramnios.

[*risk for disproportionate Growth*] possibly evidenced multiple gestation with imbalanced circulation and nutrition to both fetuses.

Tympanoplasty

Refer to Stapedectomy

MS

Typhoid fever

MS

Also refer to Sepsis

risk for Infection [spread] possibly evidenced by inadequate knowledge to avoid exposure to pathogen (food or water, fecally contaminated objects).

risk for deficient Fluid Volume possibly evidenced by gastric irritation, ulcers.

imbalanced Nutrition: less than body requirements possibly evidenced by insufficient dietary intake, (inability to ingest or digest foods, or absorb nutrients); possibly evidenced by insufficient interest in food, food intake less than recommended daily allowance, abdominal pain, [weight loss].

Typhus

CH/MS

Hyperthermia may be related to generalized inflammatory process (vasculitis), possibly evidenced by increased body temperature, warm flushed skin, and tachycardia.

ineffective Tissue Perfusion (specify) may be related to reduction or interruption of blood flow—generalized vasculitis or thrombi formation, possibly evidenced by reports of headache, abdominal pain,

changes in mentation, and areas of peripheral ulceration or necrosis.

Ulcer, decubitus

CH/MS

impaired Skin/Tissue Integrity may be related to excretions, secretions, pressure over bony prominence, alteration in fluid volume, inadequate nutrition, [impaired physical mobility][and sensory impairments] evidenced by [tissue damage or destruction].

acute Pain may be related to physical agent—tissue trauma, inflammation, infection, dressing changes/débridement, possibly evidenced by verbal reports, distraction behaviors, and self-focus.

risk for Infection possibly evidenced by malnutrition, alteration in skin/tissue integrity, and associated conditions of chronic illness, immunosuppression [immobility, increased environmental exposure].

Ulcer, peptic (acute)

MS/CH

risk for Shock possibly evidenced by hypovolemia, hypotension.

acute Pain may be related to physical agent—caustic irritation and destruction of gastric or duodenal tissues, reflex muscle spasms in stomach wall possibly evidenced by verbal reports of pain, distraction behavior, self-focused, and changes in vital signs.

deficient Knowledge regarding condition, therapy, self-care needs, and potential complications may be related to lack of information or recall, misinterpretation, possibly evidenced by statements of concern, questions, misconceptions; inaccurate follow-through of instructions; and development of preventable complications or recurrence of condition.

Ulcer, pressure

CH/MS

Refer to Ulcer, decubitus

Ulcer, venous stasis

CH

Also refer to Venous insufficiency

impaired Skin/Tissue Integrity may be related to (impaired [venous] circulation, alteration in sensation), possibly evidenced by destruction of skin layers, invasion of body structures.

ineffective peripheral Tissue Perfusion may be related to interruption of venous flow—small-vessel vasoconstrictive reflex, possibly evidenced by skin discoloration, edema formation, altered sensation, delayed healing.

Ulnar neuropathy

CH

Refer to Cubital tunnel syndrome

Unconsciousness

MS

Refer to Coma

Upper GI bleeding

MS

Refer to Gastritis, acute or chronic; Ulcer, peptic

Urinary diversion

MS/CH

risk for impaired Skin Integrity possibly evidenced by excretions—character and flow of urine from stoma, chemical injury agent—reaction to adhesive product, and improperly fitting appliance.

disturbed Body Image may be related to alteration in self-perception; and psychosocial factors—disease process and associated treatment regimen, possibly evidenced by verbalization of change in body image, fear of reaction of others, negative feelings about body, not touching or looking at stoma, refusal to participate in care.

acute Pain may be related to physical injury agents (disruption of skin and tissues, presence of incisions and drains); biological factors—activity of disease process; and psychological factors—fear, anxiety, possibly evidenced by verbal reports of pain, self-focused, guarding or distraction behavior, restlessness, and autonomic responses—changes in vital signs.

impaired urinary Elimination may be related to surgical diversion, tissue trauma, and postoperative edema, possibly evidenced by loss of continence, changes in amount and character of urine, and urinary retention.

Urinary tract infection

CH

Refer to Cystitis

Urolithiasis

MS/CH

Refer to Calculi, urinary

Uterine bleeding, dysfunctional

GYN/MS

Anxiety [specify level] may be related to threat to change in status and unknown etiology, possibly evidenced by apprehensiveness, uncertainty, fear, expressed concerns, and self-focused.

Activity Intolerance may be related to imbalance between oxygen supply and demand (anemia), possibly evidenced by reports of fatigue, weakness.

Uterine myomas (also called fibroids)

GYN

Also refer to Anemia

acute Pain/impaired Comfort may be related to physical agent—growth, size, and location of tumors, possibly evidenced by reports of pressure, cramping, guarding behavior, irritability.

impaired urinary Elimination may be related to uterine pressure on bladder, possibly evidenced by frequent voiding, urinary urgency.

risk for deficient Fluid Volume possibly evidenced by excessive or chronic blood loss.

Uterus, rupture of, in pregnancy

OB

risk for Shock possibly evidenced by hypovolemia, hypotension.

acute Pain may be related to physical agent—tissue trauma and irritation of accumulating blood, possibly evidenced by verbal reports of pain, guarding or distraction behavior, self-focused, and autonomic responses—changes in vital signs.

Anxiety [specify level] may be related to threat of death of self/fetus, interpersonal contagion, physiological response—release of catecholamines, possibly evidenced by fearful or scared affect, sympathetic stimulation, fear, and expressed concerns.

UTI

CH

Refer to Cystitis

Vaginal hysterectomy

MS

Refer to Hysterectomy

Vaginismus

GYN/PSY

acute Pain may be related to biological or psychological injury agent [when something is entering the vagina (such as object or penis)], possibly evidenced by verbal reports of pain, expressive or distraction behavior, positioning to relieve pain, and self-focused.

Sexual dysfunction may be related to physical or psychological alteration in function (severe spasms of vaginal muscles), possibly evidenced by verbalization of problem, inability to achieve desired satisfaction, and alteration in relationship with SO.

Vaginitis

GYN/CH

impaired Tissue Integrity may be related to irritation or inflammation and mechanical trauma (scratching) of sensitive tissues, possibly evidenced by damaged or destroyed tissue, presence of lesions.

acute Pain may be related to biological agent inflammation/tissue trauma; chemical injury agent [e.g., bacterial, viral, fungal, chemicals in soaps, sprays, or clothing], possibly evidenced by verbal reports of pain, distraction behavior, and self-focused.

deficient Knowledge regarding hygienic needs, therapy, and sexual behaviors or transmission of organisms may be related to lack of information,

misinterpretation, possibly evidenced by statements of concern, questions, and misconceptions.

Vaginitis, bacterial

GYN

risk for impaired Tissue Integrity possibly evidenced by (alteration in sensation-vulvar or vaginal irritation, itching).

risk for [secondary] Infection possibly evidenced by prescribed antibiotic therapy, insufficient knowledge to avoid exposure to pathogens.

Valvular heart disease

MS

decreased Cardiac Output may be related to alteration in preload, increased arterial pressure and venous congestion, increased afterload, changes in electrical conduction, possibly evidenced by variations in hemodynamic parameters, dysrhythmias and electrocardiogram changes, dyspnea, adventitious breath sounds, cyanosis or pallor, jugular vein distention, fatigue.

Activity Intolerance may be related to imbalance between oxygen supply and demand (decreased or fixed cardiac output), possibly evidenced by reports of fatigue, generalized weakness, abnormal heart rate and blood pressure in response to activity, exertional discomfort or dyspnea.

Anxiety may be related to threat to change in current status (chronicity of disease), physiological effects, situational crisis (changes in lifestyle, hospitalization), possibly evidenced by expressed concerns, increased tension, apprehension, uncertainty, sympathetic stimulation, insomnia.

risk for excess Fluid Volume possibly evidenced by increased sodium and water retention, changes in glomerular filtration.

risk for ineffective Tissue Perfusion (specify) possibly evidenced by interruption of arterial-venous flow (systemic emboli), venous thrombosis (venous stasis, decreased activity).

VAP

MS/CH

Refer to Ventilator assist/dependence; Bronchopneumonia

Varices, esophageal

MS

Also refer to Ulcer, peptic (acute)

risk for Bleeding/deficient Fluid Volume possibly evidenced by (impaired liver function), [presence of varices, reduced intake, and gastric losses—vomiting; vascular loss].

Anxiety [specify level]/Fear may be related to change in current status and threat of death], possibly

evidenced by increase in tension, apprehensiveness, sympathetic stimulation, restlessness, self-focused and expressed concerns.

Varicose veins

CH

chronic Pain may be related to venous insufficiency and stasis, possibly evidenced by verbal reports.

disturbed Body Image may be related to change in structure (presence of enlarged, discolored tortuous superficial leg veins), possibly evidenced by hiding affected parts and negative feelings about body.

risk for impaired Skin/Tissue Integrity may be related to (impaired circulation, [venous stasis, and edema formation]).

Varicose veins ligation/stripping

MS

risk for ineffective peripheral Tissue Perfusion possibly evidenced by localized edema, vascular irritation, inadequate venous return, dressings.

impaired Skin Integrity may be related to [surgical procedure, pressure dressings, tissue edema, vascular engorgement], possibly evidenced by [incisions, development of complications (e.g., ulcerations)].

Varicose veins sclerotherapy

MS

risk for impaired Skin Integrity possibly evidenced by risk factors of [extravasation of sclerosing agent].

risk for ineffective Health Management possibly evidenced by perceived seriousness or benefit, required lifestyle and activity changes, postprocedure dressings.

Variola

MS

Refer to Smallpox

Vasculitis

CH

Refer to Polyarteritis nodosa; Temporal arteritis

Vasectomy

CH/MS

acute Pain/impaired Comfort may be related to physical injury agent [surgical manipulation of delicate tissues, edema/hematoma formation], possibly evidenced by verbal reports, guarding behavior, irritability.

deficient Knowledge regarding self-care and future expectations (issues of reproduction, safety/sexually transmitted diseases) may be related to information misinterpretation, lack of recall, possibly evidenced by verbalizations, misconceptions, inaccurate follow-through of instructions.

Venereal disease

CH

Refer to Sexually transmitted infection

Venous insufficiency**CH**

Also refer to Stasis dermatitis; Ulcer, venous stasis *chronic Pain/impaired Comfort* may be related to altered venous circulation, edema formation, possibly evidenced by reports of aching, fullness, tiredness of lower extremities with activity.

risk for risk-prone Health Behavior possibly evidenced by health status requiring change in lifestyle, lack of motivation to change behaviors.

risk for ineffective Health Management possibly evidenced by economic difficulties, perceived seriousness or benefit, social support deficit.

Ventilator assist/dependence**MS/CH**

ineffective Breathing Pattern/impaired spontaneous Ventilation may be related to neuromuscular dysfunction, respiratory muscle fatigue, spinal cord injury, hypoventilation syndrome, possibly evidenced by dyspnea, increased work of breathing/use of accessory muscles, reduced vital capacity and total lung volume, changes in respiratory rate, decreased PO_2/SaO_2 , increased PCO_2 .

ineffective Airway Clearance may be related to artificial airway in trachea, inability to or ineffective cough, possibly evidenced by changes in rate and depth of respirations, abnormal breath sounds, anxiety, restlessness, cyanosis.

impaired verbal Communication may be related to physical barrier (artificial airway), neuromuscular weakness or paralysis, possibly evidenced by inability to speak.

Fear/Anxiety [specify] may be related to threat of death or dependency on machine, change in health status or role functioning, possibly evidenced by hypervigilance, restlessness, fearfulness, apprehension, expressed concerns, insomnia, negative self-talk.

risk for impaired oral Mucous Membrane possibly evidenced by inability to swallow oral fluids, decreased salivation, ineffective oral hygiene, presence of endotracheal tube in mouth.

risk for imbalanced Nutrition: less than body requirements possibly evidenced by inability to ingest nutrients, increased metabolic demands.

risk for dysfunctional Ventilatory Weaning Response possibly evidenced by limited or insufficient energy stores, sleep disturbance, pain or discomfort, perceived inability to wean, decreased motivation, inadequate support or adverse environment, history of ventilator dependence greater than 1 week or unsuccessful weaning attempts.

Ventricular fibrillation**MS**

Also refer to Dysrhythmia, cardiac *decreased Cardiac Output* may be related to altered electrical conduction and reduced myocardial contractility, possibly evidenced by absence of measurable cardiac output, loss of consciousness, no palpable pulses.

Ventricular tachycardia**MS**

Also refer to Dysrhythmia, cardiac *risk for decreased Cardiac Output* possibly evidenced by alteration in heart rhythm, altered contractility.

Vertigo**CH**

[disturbed kinesthetic Sensory Perception] may be related to altered status of sensory organ (middle or inner ear), altered sensory integration, possibly evidenced by visual distortions, altered sense of balance, falls.

risk for Falls possibly evidenced by presence of postural hypotension, acute illness, medications, substance abuse.

West Nile Fever**CH/MS**

Hyperthermia may be related to infectious process, possibly evidenced by elevated body temperature, skin flushed and warm to touch, tachycardia, increased respiratory rate.

acute Pain may be related to biological injury agent [virus, circulating toxins] possibly evidenced by reports of headache, myalgia, eye pain, abdominal discomfort.

risk for deficient Fluid Volume possibly evidenced by hypermetabolic state, decreased intake, anorexia, nausea, losses from normal routes (vomiting, diarrhea).

risk for impaired Skin Integrity possibly evidenced by hyperthermia (circulating toxins) and associated conditions of alteration in fluid volume and skin turgor.

Whooping cough**PED**

Refer to Pertussis

Wilms' tumor**PED**

Also refer to Cancer; Chemotherapy

Anxiety [specify level]/Fear may be related to stressors (e.g., change in environment and interaction patterns with family members and threat of death), possibly evidenced by fearful/scared affect, distress, crying, insomnia, and sympathetic stimulation.

risk for Injury possibly evidenced by nature of tumor (vascular, mushy with very thin covering) with increased danger of metastasis when manipulated.

interrupted Family Processes may be related to situational crisis of life-threatening illness, possibly evidenced by a family system that has difficulty meeting physical, emotional, and spiritual needs of its members, and inability to deal with traumatic experience effectively.

decreased Diversional Activity Engagement may be related to environmental lack of age-appropriate activity (including activity restrictions) and length of hospitalization or treatment, possibly evidenced by restlessness, crying, lethargy, and acting-out behavior.

Withdrawal, drugs/alcohol

CH/MS

Refer to Alcohol intoxication, acute; Drug overdose, acute (depressants); Drug withdrawal

Wound, gunshot

MS

(Depends on site and speed/character of bullet.)

risk for Bleeding/deficient Fluid Volume possibly evidenced by (trauma), [vascular losses, restricted oral intake].

acute Pain may be related to physical injury agent [causing destruction of tissue (including organ and musculoskeletal), surgical repair, and therapeutic interventions] possibly evidenced by verbal reports, guarding or distraction behaviors, self-focus, and changes in vital signs.

impaired Tissue Integrity may be related to [mechanical factors—yaw of projectile and muzzle blast], possibly evidenced by damaged or destroyed tissue.

risk for Infection possibly evidenced by alteration in skin/tissue integrity and associated conditions of [increased environmental exposure] invasive procedures, and decreased hemoglobin.

CH

risk for Post-Trauma Syndrome possibly evidenced by risk factors of nature of incident (catastrophic accident, assault, suicide attempt) and possibly injury or death of other(s) involved.

Zollinger-Ellison syndrome

MS/CH

Also refer to Ulcer, peptic

Diarrhea may be related to intestinal irritation—hypersecretion of gastric acid, possibly evidenced by at least three loose liquid stools per day, abdominal pain, change in bowel sounds.

risk for impaired Skin/Tissue Integrity possibly evidenced by excretions, [esophageal regurgitation].

acute/chronic Pain may be related to physical agent (acidic irritation of esophageal mucosa [GERD]), muscle spasm, possibly evidenced by reports of heartburn, distraction behaviors.

risk for ineffective Health Management possibly evidenced by length of therapy, economic difficulties, perceived susceptibility.

APPENDIX A

NANDA-I's Taxonomy II

The 13 domains and their classes are as follows:

Domain 1 Health Promotion: The awareness of well-being or normality of function and the strategies used to maintain control of and enhance that well-being or normality of function

Class 1 Health Awareness: Recognition of normal function and well-being

Class 2 Health Management: Identifying, controlling, performing, and integrating activities to maintain health and well-being

Domain 2 Nutrition: The activities of taking in, assimilating, and using nutrients for the purposes of tissue maintenance, tissue repair, and the production of energy

Class 1 Ingestion: Taking food or nutrients into the body

Class 2 Digestion: The physical and chemical activities that convert foodstuffs into substances suitable for absorption and assimilation

Class 3 Absorption: The act of taking up nutrients through body tissues

Class 4 Metabolism: The chemical and physical processes occurring in living organisms and cells for the development and use of protoplasm, the production of waste and energy, with the release of energy for all vital processes

Class 5 Hydration: The taking in and absorption of fluids and electrolytes

Domain 3 Elimination and Exchange: Secretion and excretion of waste products from the body

Class 1 Urinary Function: The process of secretion, reabsorption, and excretion of urine

Class 2 Gastrointestinal Function: The process of absorption and excretion of the end products of digestion

Class 3 Integumentary Function: The process of secretion and excretion through the skin

Class 4 Respiratory Function: The process of exchange of gases and removal of the end products of metabolism

Domain 4 Activity/Rest: The production, conservation, expenditure, or balance of energy resources

Class 1 Sleep/Rest: Slumber, repose, ease, relaxation, or inactivity

Class 2 Activity/Exercise: Moving parts of the body (mobility), doing work, or performing actions often (but not always) against resistance

Class 3 Energy Balance: A dynamic state of harmony between intake and expenditure of resources

Class 4 Cardiovascular/Pulmonary Responses: Cardiopulmonary mechanisms that support activity/rest

Class 5 Self-Care: Ability to perform activities to care for one's body and bodily functions

Domain 5 Perception/Cognition: The human processing system including attention, orientation, sensation, perception, cognition, and communication

Class 1 Attention: Mental readiness to notice or observe

Class 2 Orientation: Awareness of time, place, and person

Class 3 Sensation/Perception: Receiving information through the senses of touch, taste, smell, vision, hearing, and kinesthesia and the comprehension of sensory data resulting in naming, associating, and/or pattern recognition

Class 4 Cognition: Use of memory, learning, thinking, problem-solving, abstraction, judgment, insight, intellectual capacity, calculation, and language

Class 5 Communication: Sending and receiving verbal and nonverbal information

Domain 6 Self-Perception: Awareness about the self

Class 1 Self-Concept: The perception(s) about the total self

Class 2 Self-Esteem: Assessment of one's own worth, capability, significance, and success

Class 3 Body Image: A mental image of one's own body

Domain 7 Role Relationships: The positive and negative connections or associations between people or groups of people and the means by which those connections are demonstrated

Class 1 Caregiving Roles: Socially expected behavior patterns by people providing care who are not healthcare professionals

Class 2 Family Relationships: Associations of people who are biologically related or related by choice

Class 3 Role Performance: Quality of functioning in socially expected behavior patterns

Domain 8 Sexuality: Sexual identity, sexual function, and reproduction

Class 1 Sexual Identity: The state of being a specific person in regard to sexuality and/or gender

Class 2 Sexual Function: The capacity or ability to participate in sexual activities

Class 3 Reproduction: Any process by which human beings are produced

Domain 9 Coping/Stress Tolerance: Contending with life events/life processes

Class 1 Post-trauma Responses: Reactions occurring after physical or psychological trauma

Class 2 Coping Responses: The process of managing environmental stress

Class 3 Neurobehavioral Stress: Behavioral responses reflecting nerve and brain function

Domain 10 Life Principles: Principles underlying conduct, thought, and behavior about acts, customs, or institutions viewed as being true or having intrinsic worth

Class 1 Values: The identification and ranking of preferred modes of conduct or end states

Class 2 Beliefs: Opinions, expectations, or judgments about acts, customs, or institutions viewed as being true or having intrinsic worth

Class 3 Value/Belief/Action Congruence: The correspondence or balance achieved among values, beliefs, and actions

Domain 11 Safety/Protection: Freedom from danger, physical injury, or immune system damage; preservation from loss; and protection of safety and security

Class 1 Infection: Host responses following pathogenic invasion

Class 2 Physical Injury: Bodily harm or hurt

Class 3 Violence: The exertion of excessive force or power so as to cause injury or abuse

Class 4 Environmental Hazards: Sources of danger in the surroundings

Class 5 Defensive Processes: The processes by which the self protects itself from the non-self

Class 6 Thermoregulation: The physiological process of regulating heat and energy within the body for purposes of protecting the organism

Domain 12 Comfort: Sense of mental, physical, or social well-being or ease

Class 1 Physical Comfort: Sense of well-being or ease and/or freedom from pain

Class 2 Environmental Comfort: Sense of well-being or ease in/with one's environment

Class 3 Social Comfort: Sense of well-being or ease with one's social situation

Domain 13 Growth/Development: Age-appropriate increases in physical dimensions, maturation of organ systems, and/or progression through the developmental milestones

Class 1 Growth: Increases in physical dimensions or maturity of organ systems

Class 2 Development: Progression or regression through a sequence of recognized milestones in life

APPENDIX B

Definitions of Taxonomy II Axes

AXIS 1 FOCUS OF THE DIAGNOSIS: The principal element or the fundamental and essential part, the root, of the diagnostic concept

AXIS 2 SUBJECT OF THE DIAGNOSIS: The subject of the diagnosis. Values are:

Individual: A single human being distinct from others, a person

Caregiver: A family member or helper who regularly looks after a child or sick, elderly, or disabled person

Family: Two or more people having continuous or sustained relationships, perceiving reciprocal obligations, sensing common meaning, and sharing certain obligations toward others; related by blood and/or choice

Group: A number of people with shared characteristics

Community: A group of people living in the same locale under the same governance; e.g., neighborhoods and cities

When the unit of care is not explicitly stated, it becomes the individual by default

AXIS 3 JUDGMENT: A descriptor or modifier that limits or specifies the meaning of the focus of the diagnosis. Values are:

Complicated: Consisting of many interconnecting parts or elements; intricate; involving many different and confusing aspects

Compromised: Made vulnerable or to function less effectively

Decreased: Smaller or fewer in size, amount, intensity, or degree

Defensive: Used or intended to defend or protect

Deficient/Deficit: Not having enough of a specified quality or ingredient; insufficient or inadequate

Delayed: Late, slow, or postponed

Deprivation: Lack or denial of something considered to be a necessity

Disabled: Limited in movements, senses, or activities

Disorganized: Not properly planned or controlled; scattered or inefficient

Disproportionate: Too large or too small in comparison with something else (norm)

Disturbed: Having had its normal pattern or function disrupted

Dysfunctional: Not operating normally or properly; unable to deal adequately with social norms

Emancipated: Free from legal, social, or political restrictions; liberated

Effective: Successful in producing a desired or intended result

Enhanced: Intensify, increase, or further improve the quality, value, or extent

Excess: An amount of something that is more than necessary, permitted, or desirable

Failure: The action or state of not functioning; lack of success

Frail: Weak and delicate; physically or mentally infirm through old age

Functional: Relating to the way in which something works or operates; of or having a specific activity, purpose, or task

Imbalanced: Lack of proportion or relation between corresponding things

Impaired: Weakened or damaged (something, especially a faculty or function)

Ineffective: Not producing any significant or desired effect

Insufficient: Not enough, inadequate, incapable, incompetent

Interrupted: A stop in continuous progress (of an activity or process); to break the continuity of something

Labile: Liable to change; easily altered; of or characterized by emotions which are easily aroused, freely expressed, and tend to alter quickly and spontaneously

Low: Below average in amount, extent, or intensity; small

Non-: expressing negation or absence

Organized: Arranged or structured in a systematic way; efficient

Overload: Too great a burden

Perceived: Become aware or conscious

(of something); come to realize or understand

Readiness for: Willingness to do something; state of being fully prepared for something

Risk for: Situation involving exposure to danger, possibility that something unpleasant or unwelcome will happen

Risk-prone: Likely or liable to suffer from, do, or experience something unpleasant or regrettable

Sedentary: (A way of life) characterized by much sitting and little physical exercise

Situational: Related to or dependant on a set of circumstances or state of affairs; relating to the location and surroundings of a place

Unstable: Prone to change, fail; not firmly established; likely to give way; not stable

AXIS 4 LOCATION: Describes the parts/regions of the body and/or their related functions—all tissues, organs, anatomical sites or structures. Values are:

Auditory

Bladder

Body

Bowel

Breast

Cardiac

Cardiopulmonary

Cardiovascular

Cerebral

Corneal

Dentition

Eye

Gastrointestinal

Genital

Gustatory

Intracranial

Kinesthetic

Liver

Mouth

Mucous membranes

Neurovascular

Olfactory

Oral

Peripheral

Peripheral vascular

Renal

Skin

Tactile

Tissue

Urinary

Urinary tract

Vascular

Venous

Visual

AXIS 5 AGE: The age of the person who is the subject of the diagnosis. Values are:

Fetus: Unborn human more than 8 weeks after conception, until birth

Neonate: Person <28 days of age

Infant: Person ≥28 days and <1 year of age

Child: Person aged 1 to 9 years, inclusive

Adolescent: Person aged 10 to 19 years, inclusive

Adult: Person older than 19 years of age unless national law defines a person as being an adult at an earlier age

Older adult: A person ≥65 years of age

AXIS 6 TIME: The duration of the focus of the diagnosis. Values are:

Acute: Lasting <3 months

Chronic: Lasting ≥3 months

Continuous: Uninterrupted, going on without stop

Intermittent: Stopping or starting again at intervals, periodic, cyclic

AXIS 7 STATUS OF THE DIAGNOSIS: The actuality or potentiality of the problem/health promotion opportunity/syndrome or to the categorization of the diagnosis as a health promotion diagnosis. Values are:

Problem-Focused: Undesirable human response to health conditions/life process that exists in the current moment (includes syndrome diagnoses)

Health Promotion: Motivation and desire to increase well-being and to actualize human health potential that exists in the current moment (Pender, Murdaugh, & Parsons, 2006)

Risk: Susceptibility for developing in the future an undesirable human response to health conditions/life processes (includes syndrome diagnoses)

Pender, N. J., Murdaugh, C. L., & Parsons, M. A. (2006). *Health Principles in Nursing Practice*. 5th ed. Upper Saddle River, NJ: Pearson Prentice-Hall.

Permission from NANDA International. (2018). *NANDA-I Nursing Diagnoses: Definitions & Classification 2018–2020*. New York: Thieme.

APPENDIX C

NANDA-I Nursing Diagnoses Organized According to Maslow's Hierarchy of Needs

SELF-ACTUALIZATION

Coping, readiness for enhanced
Coping, readiness for enhanced community
Coping, readiness for enhanced family
Decision-Making, readiness for enhanced
Development, risk for delayed
Emancipated Decision-Making, impaired
Emancipated Decision-Making, readiness for enhanced

Emancipated Decision-Making, risk for impaired
Health Literacy, readiness for enhanced
Hope, readiness for enhanced
Knowledge, readiness for enhanced
Power, readiness for enhanced
Religiosity, readiness for enhanced
Self-Concept, readiness for enhanced
Spiritual Well-Being, readiness for enhanced

SELF-ESTEEM

Body Image, disturbed
Coping, defensive
Coping, ineffective
Decisional Conflict
Denial, ineffective
Diversional Activity Engagement, decreased
Emotional Control, labile
Human Dignity, risk for compromised
Hopelessness
Impulse Control, ineffective
Moral Distress
Mood Regulation, impaired
Obesity
Overweight
Overweight, risk for
Personal Identity, disturbed

Post-Trauma Syndrome
Post-Trauma Syndrome, risk for
Powerlessness
Powerlessness, risk for
Rape-Trauma Syndrome
Resilience, impaired
Resilience, risk for impaired
Self-Esteem, chronic low
Self-Esteem, situational low
Self-Esteem, risk for chronic low
Self-Esteem, risk for situational low
Self-Mutilation
Self-Mutilation, risk for
Suicide, risk for
Violence, risk for other-directed
Violence, risk for self-directed

LOVE AND BELONGING

Attachment, risk for impaired
Communication, readiness for enhanced

Coping, compromised family
Coping, disabled family

- Development, risk for delayed
- Family Processes, dysfunctional
- Family Processes, interrupted
- Family Processes, readiness for enhanced
- Immigration Transition, risk for complicated
- Loneliness, risk for
- Parenting, impaired
- Parenting, readiness for enhanced
- Parenting, risk for impaired
- Religiosity, impaired
- Religiosity, risk for impaired

- Relocation Stress Syndrome
- Relocation Stress Syndrome, risk for
- Role Conflict, parental
- Role Performance, ineffective
- Sexual Dysfunction
- Social Interaction, impaired
- Social Isolation
- Sorrow, chronic
- Spiritual Distress
- Spiritual Distress, risk for

SAFETY AND SECURITY

- Acute Substance Withdrawal Syndrome
- Acute Substance Withdrawal Syndrome, risk for
- Adverse Reaction to Iodinated Contrast Media, risk for
- Allergy Reaction, risk for
- Anxiety
- Autonomic Dysreflexia
- Autonomic Dysreflexia, risk for
- Behavior, readiness for enhanced organized infant
- Communication, impaired verbal
- Confusion, acute
- Confusion, chronic
- Confusion, risk for acute
- Contamination
- Contamination, risk for
- Coping, ineffective community
- Death Anxiety
- Disuse Syndrome, risk for
- Dry Eye, risk for
- Dry Mouth, risk for
- Energy Field, imbalanced
- Falls, risk for
- Fear
- Female Genital Mutilation, risk for
- Grieving
- Grieving, complicated
- Grieving, risk for complicated
- Health Behavior, risk-prone
- Health Maintenance, ineffective
- Health Management, ineffective
- Health Management, ineffective family
- Health Management, readiness for enhanced
- Home Maintenance, impaired
- Hyperbilirubinemia, neonatal
- Hyperbilirubinemia, risk for neonatal

- Infection, risk for
- Injury, risk for
- Injury, risk for corneal
- Injury, risk for urinary tract
- Knowledge, deficient (specify)
- Latex Allergy Reaction
- Latex Allergy Reaction, risk for
- Lifestyle, sedentary
- Maternal-Fetal Dyad, risk for disturbed
- Memory, impaired
- Mobility, impaired bed
- Mobility, impaired wheelchair
- Neonatal Abstinence Syndrome
- Neurovascular Dysfunction, risk for peripheral
- Occupational Injury, risk for
- Perioperative Positioning Injury, risk for
- Poisoning, risk for
- Protection, ineffective
- Role Strain, caregiver
- Role Strain, risk for caregiver
- Self-Neglect
- Sitting, impaired
- Standing, impaired
- Stress Overload
- Sudden Infant Death, risk for
- Surgical Site Infection, risk for
- Thermal Injury, risk for
- Transfer Ability, impaired
- Trauma, risk for physical
- Trauma, risk for vascular
- Unilateral Neglect
- Thromboembolism, risk for venous
- Walking, impaired
- Wandering [specify sporadic or continuous]

PHYSIOLOGICAL NEEDS

Activity Intolerance [specify level]
Activity Intolerance, risk for
Adaptive Capacity, decreased intracranial
Airway Clearance, ineffective
Aspiration, risk for
Behavior, disorganized infant
Behavior, risk for disorganized infant
Bleeding, risk for
Blood Glucose Level, risk for unstable
Blood Pressure, risk for unstable
Breast Milk Production, insufficient
Breastfeeding, ineffective
Breastfeeding, interrupted
Breastfeeding, readiness for enhanced
Breathing Pattern, ineffective
Cardiac Output, decreased
Cardiac Output, risk for decreased
Childbearing Process, ineffective
Childbearing Process, risk for ineffective
Comfort, impaired
Comfort, readiness for enhanced
Constipation
Constipation, chronic functional
Constipation, perceived
Constipation, risk for
Constipation, risk for chronic functional
Dentition, impaired
Diarrhea
Eating Dynamics, ineffective adolescent
Eating Dynamics, ineffective child
Eating Dynamics, ineffective infant
Electrolyte Imbalance, risk for
Elimination, impaired urinary
Frail Elderly Syndrome
Frail Elderly Syndrome, risk for
Fatigue
Feeding Pattern, ineffective infant
Fluid Volume, deficient
Fluid Volume, excess
Fluid Volume, risk for deficient
Fluid Volume, risk for imbalanced
Gas Exchange, impaired
Gastrointestinal Motility, dysfunctional
Gastrointestinal Motility, risk for dysfunctional
Hyperthermia
Hypothermia
Hypothermia, risk for
Hypothermia, risk for perioperative
Incontinence, bowel
Incontinence, functional urinary
Incontinence, overflow urinary
Incontinence, reflex urinary
Incontinence, stress urinary
Incontinence, urge urinary
Incontinence, risk for urge urinary
Insomnia
Liver Function, risk for impaired
Metabolic Imbalance Syndrome, risk for
Mobility, impaired physical
Mucous Membrane, impaired oral
Mucous Membrane, risk for impaired oral
Nausea
Nutrition: less than body requirements, imbalanced
Nutrition, readiness for enhanced
Pain, acute
Pain, chronic
Pain, labor
Pain Syndrome, chronic
Pressure Ulcer, risk for
Retention, urinary [acute/chronic]
Self-Care, readiness for enhanced
Self-Care Deficit (specify): bathing, dressing, feeding, toileting
[Sensory Perception, disturbed (specify: visual, auditory, kinesthetic, gustatory, tactile, olfactory)]
Sexuality Pattern, ineffective
Skin Integrity, impaired
Skin Integrity, risk for impaired
Sleep, readiness for enhanced
Sleep Deprivation
Sleep Pattern, disturbed
Suffocation, risk for
Surgical Recovery, delayed
Surgical Recovery, risk for delayed
Swallowing, impaired
Thermoregulation, ineffective
Thermoregulation, risk for ineffective
Tissue Integrity, impaired
Tissue Integrity, risk for impaired
Tissue Perfusion, ineffective peripheral
Tissue Perfusion, risk for decreased cardiac
Tissue Perfusion, risk for ineffective cerebral
Tissue Perfusion, risk for ineffective peripheral
Ventilation, impaired spontaneous
Ventilatory Weaning Response, dysfunctional

DOENGES & MOORHOUSE'S DIAGNOSTIC DIVISION INDEX

ACTIVITY/REST—*Ability to engage in necessary/desired activities of life (work and leisure) and to obtain adequate sleep/rest*

Activity Intolerance [specify level], 28–32
 Activity Intolerance, risk for, 32–34
 Activity Planning, ineffective, 35–38
 Activity Planning, risk for ineffective, 38–40
 Disuse Syndrome, risk for, 260–266
 Diversional Activity Engagement, decreased, 266–269
 Fatigue, 324–329
 Insomnia, 504–508
 Lifestyle, sedentary, 522–526
 Mobility, impaired wheelchair, 553–556
 Sleep Deprivation, 810–815
 Sleep Pattern, disturbed, 815–818
 Sleep, readiness for enhanced, 818–820
 Transfer Ability, impaired, 918–921
 Walking, impaired, 952–955

CIRCULATION—*Ability to transport oxygen and nutrients necessary to meet cellular needs*

Adaptive Capacity, decreased intracranial, 49–53
 Autonomic Dysreflexia, 76–80
 Autonomic Dysreflexia, risk for, 81–83
 Bleeding, risk for, 93–96
 Blood Pressure, risk for unstable, 101–104
 Cardiac Output, decreased, 131–137
 Cardiac Output, risk for decreased, 138–140
 [Gastrointestinal Perfusion, risk for ineffective], 380–383
 Metabolic Imbalance Syndrome, risk for, 542–544
 Shock, risk for, 792–796
 Thromboembolism, risk for venous, 890–892
 Tissue Perfusion, ineffective peripheral, 902–907
 Tissue Perfusion, risk for decreased cardiac, 907–911
 Tissue Perfusion, risk for ineffective cerebral, 911–915
 Tissue Perfusion, risk for ineffective peripheral, 915–918

EGO INTEGRITY—*Ability to develop and use skills and behaviors to integrate and manage life experiences*

Anxiety, 63–68
 Body Image, disturbed, 104–108
 Coping, defensive, 213–216
 Coping, ineffective, 219–224
 Coping, readiness for enhanced, 227–229
 Death Anxiety, 234–237

Decisional Conflict, 238–241
 Decision-Making, readiness for enhanced, 241–244
 Denial, ineffective, 244–247
 Emancipated Decision-Making, impaired, 295–298
 Emancipated Decision-Making, readiness for enhanced, 298–300
 Emancipated Decision-Making, risk for impaired, 301
 Emotional Control, labile, 302–304
 Energy Field, imbalanced, 304–308
 Fear, 329–333
 Grieving, 384–388
 Grieving, complicated, 388–392
 Grieving, risk for complicated, 392–395
 Health Behavior, risk-prone, 400–403
 Hope, readiness for enhanced, 431–433
 Hopelessness, 427–431
 Human Dignity, risk for compromised, 434–436
 Impulse Control, ineffective, 461–463
 Mood Regulation, impaired, 557–559
 Moral Distress, 559–562
 Personal Identity, disturbed, 634–638
 Personal Identity, risk for disturbed, 638–641
 Post-Trauma Syndrome, 649–655
 Post-Trauma Syndrome, risk for, 655–659
 Power, readiness for enhanced, 667–669
 Powerlessness, 659–663
 Powerlessness, risk for, 664–667
 Rape-Trauma Syndrome, 675–680
 Relationship, ineffective, 680–683
 Relationship, readiness for enhanced, 683–686
 Relationship, risk for ineffective, 686–689
 Religiosity, impaired, 690–692
 Religiosity, readiness for enhanced, 693–695
 Religiosity, risk for impaired, 695–698
 Relocation Stress Syndrome, 698–702
 Relocation Stress Syndrome, risk for, 702–705
 Resilience, impaired, 705–709
 Resilience, readiness for enhanced, 709–712
 Resilience, risk for impaired, 712–715
 Self-Concept, readiness for enhanced, 748–750
 Self-Esteem, chronic low, 751–754
 Self-Esteem, risk for chronic low, 755–758
 Self-Esteem, risk for situational low, 759–761
 Self-Esteem, situational low, 762–765
 Sorrow, chronic, 829–831
 Spiritual Distress, 832–836
 Spiritual Distress, risk for, 836–839
 Spiritual Well-Being, readiness for enhanced, 840–842

ELIMINATION—*Ability to excrete waste products*

Constipation, 184–188
 Constipation, chronic functional, 188–192
 Constipation, perceived, 195–197
 Constipation, risk for, 197–200
 Constipation, risk for chronic functional, 192–195
 Diarrhea, 255–260
 Elimination, impaired urinary, 291–295
 Gastrointestinal Motility, dysfunctional, 370–375
 Gastrointestinal Motility, risk for dysfunctional, 376–379
 Incontinence, bowel, 464–467
 Incontinence, functional urinary, 467–470
 Incontinence, overflow urinary, 471–473
 Incontinence, reflex urinary, 474–476
 Incontinence, risk for urge urinary, 477–479
 Incontinence, stress urinary, 479–482
 Incontinence, urge urinary, 483–486
 Retention [acute/chronic], urinary, 715–720

FOOD/FLUID—*Ability to maintain intake of and utilize nutrients and liquids to meet physiological needs*

Blood Glucose Level, risk for unstable, 97–100
 Breast Milk Production, insufficient, 122–126
 Breastfeeding, ineffective, 109–114
 Breastfeeding, interrupted, 115–119
 Breastfeeding, readiness for enhanced, 119–122
 Dentition, impaired, 247–251
 Eating Dynamics, ineffective adolescent, 275–278
 Eating Dynamics, ineffective child, 279–282
 Eating Dynamics, ineffective infant, 282–285
 Electrolyte Imbalance, risk for, 285–290
 Feeding Pattern, ineffective infant, 333–336
 [Fluid Volume, deficient (hyper/hypotonic)], 339–343
 Fluid Volume, deficient [isotonic], 343–347
 Fluid Volume, excess, 348–351
 Fluid Volume, risk for deficient, 352–355
 Fluid Volume, risk for imbalanced, 355–358
 Liver Function, risk for impaired, 526–529
 Mucous Membrane Integrity, impaired oral, 562–568
 Mucous Membrane Integrity, risk for impaired oral, 568–570
 Nausea, 571–574
 Nutrition: less than body requirements, imbalanced, 582–588

Nutrition, readiness for enhanced, 589–591
Obesity, 591–595
Overweight, 599–605
Overweight, risk for, 605–609
Swallowing, impaired, 874–879

HYGIENE—*Ability to perform activities of daily living*

Self-Care, readiness for enhanced, 745–747
Self-Care Deficit: bathing, dressing, feeding, toileting, 738–744
Self-Neglect, 774–777

NEUROSENSORY—*Ability to perceive, integrate, and respond to internal and external cues*

Behavior, disorganized infant, 84–89
Behavior, readiness for enhanced organized infant, 89–91
Behavior, risk for disorganized infant, 92
Confusion, acute, 172–176
Confusion, chronic, 177–181
Confusion, risk for acute, 181–184
Memory, impaired, 538–541
Neurovascular Dysfunction, risk for peripheral, 578–582
[Sensory Perception, disturbed (specify: visual, auditory, kinesthetic, gustatory, tactile, olfactory)], 777–783
Stress Overload, 846–849
Unilateral Neglect, 931–935

PAIN/DISCOMFORT—*Ability to control internal/external environment to maintain comfort*

Chronic Pain Syndrome, 615–621
Comfort, impaired, 156–160
Comfort, readiness for enhanced, 160–163
Pain, acute, 609–614
Pain, chronic, 615–621
Pain, labor, 621–625

RESPIRATION—*Ability to provide and use oxygen to meet physiological needs*

Airway Clearance, ineffective, 55–60
Aspiration, risk for, 68–72
Breathing Pattern, ineffective, 126–131
Gas Exchange, impaired, 366–370
Ventilation, impaired spontaneous, 935–940
Ventilatory Weaning Response, dysfunctional, 940–945

SAFETY—*Ability to provide safe, growth-promoting environment*

Adverse Reaction to Iodinated Contrast Media, risk for, 53–55
Allergy Reaction, risk for, 60–62
Contamination, 200–206

Contamination, risk for, 206–209
Dry Eye, risk for, 270–272
Dry Mouth, risk for, 272–275
Falls, risk for, 308–312
Frail Elderly Syndrome, 359–363
Frail Elderly Syndrome, risk for, 363–365
Health Maintenance, ineffective, 410–413
Home Maintenance, impaired, 423–426
Hyperbilirubinemia, neonatal, 436–441
Hyperbilirubinemia, risk for neonatal, 441–444
Hyperthermia, 444–448
Hypothermia, 448–452
Hypothermia, risk for, 453–455
Hypothermia, risk for perioperative, 455–457
Infection, risk for, 487–492
Injury, risk for, 492–497
Injury, risk for corneal, 497–500
Injury, risk for urinary tract, 500–504
Latex Allergy Reaction, 515–519
Latex Allergy Reaction, risk for, 520–522
Maternal-Fetal Dyad, risk for disturbed, 533–538
Mobility, impaired bed, 545–548
Mobility, impaired physical, 548–553
Neonatal Abstinence Syndrome, 575–578
Occupational Injury, risk for, 595–599
Positioning Injury, risk for perioperative, 646–649
Poisoning, risk for, 641–646
Pressure Ulcer, risk for, 670–673
Protection, ineffective, 673–674
Self-Mutilation, 766–769
Self-Mutilation, risk for, 770–773
Sitting, impaired, 796–799
Skin Integrity, impaired, 800–806
Skin Integrity, risk for impaired, 806–810
Standing, impaired, 842–846
Sudden infant Death, risk for, 850–853
Suffocation, risk for, 853–857
Suicide, risk for, 857–862
Surgical Recovery, delayed, 862–867
Surgical Recovery, risk for delayed, 867–870
Surgical Site Infection, risk for, 870–874
Thermal Injury, risk for, 880–883
Thermoregulation, ineffective, 884–886
Thermoregulation, risk for ineffective, 887–889
Tissue Integrity, impaired, 892–898
Tissue Integrity, risk for impaired, 898–902
Trauma, risk for physical, 921–927
Trauma, risk for vascular, 927–930
Violence, risk for other-directed, 945
Violence, risk for self-directed, 946–951
Wandering [specify: sporadic or continual], 955–959

SEXUALITY—*[Component of Ego Integrity and Social Interaction] Ability to meet requirements/characteristics of male/female role*

Childbearing Process, ineffective, 141–148
Childbearing Process, readiness for enhanced, 148–154
Childbearing Process, risk for ineffective, 155
Female Genital Mutilation, risk for, 336–339
Sexual Dysfunction, 784–788
Sexuality Pattern, ineffective, 789–792

SOCIAL INTERACTION—*Ability to establish and maintain relationships*

Attachment, risk for impaired, 72–76
Communication, impaired verbal, 164–169
Communication, readiness for enhanced, 169–172
Coping, compromised family, 210–212
Coping, disabled family, 216–219
Coping, ineffective community, 224–226
Coping, readiness for enhanced community, 229–231
Coping, readiness for enhanced family, 232–234
Family Processes, dysfunctional, 313–317
Family Processes, interrupted, 317–320
Family Processes, readiness for enhanced, 321–323
Immigration Transition, risk for complicated, 458–461
Loneliness, risk for, 530–533
Parenting, impaired, 625–630
Parenting, readiness for enhanced, 630–633
Parenting, risk for impaired, 633–634
Role Conflict, parental, 720–723
Role Performance, ineffective, 723–727
Role Strain, caregiver, 727–733
Role Strain, risk for caregiver, 733–737
Social Interaction, impaired, 820–825
Social Isolation, 825–828

TEACHING/LEARNING—*Ability to incorporate and use information to achieve health lifestyle/optimal wellness*

Development, risk for delayed, 251–255
Growth, risk for disproportionate, 395–399
Health, deficient community, 403–406
Health Literacy, readiness for enhanced, 407–409
Health Management, ineffective, 417–420
Health Management, ineffective family, 414–416
Health Management, readiness for enhanced, 421–423
Knowledge, deficient, 509–513
Knowledge, readiness for enhanced, 513–515

NURSING DIAGNOSES INDEX

- Activity Intolerance [Specify Level], 28–32
- Activity Intolerance [Specify Level], risk for, 32–34
- Activity Planning, ineffective, 35–38
- Activity Planning, ineffective, risk for, 38–40
- Acute Substance Withdrawal Syndrome, 41–45
- Acute Substance Withdrawal Syndrome, risk for, 45–49
- Adaptive Capacity, decreased intracranial, 49–53
- Adverse Reaction to Iodinated Contrast Media, risk for, 53–55
- Airway Clearance, ineffective, 55–60
- Allergy Reaction, risk for, 60–62
- Anxiety [Specify Level], 63–68
- Aspiration, risk for, 68–72
- Attachment, risk for impaired, 72–76
- Autonomic Dysreflexia, 76–80
- Autonomic Dysreflexia, risk for, 81–83

- Behavior, disorganized infant, 84–89
- Behavior, readiness for enhanced organized infant, 89–91
- Behavior, risk for disorganized infant, 92
- Bleeding, risk for, 93–96
- Blood Glucose Level, risk for unstable, 97–100
- Blood Pressure, risk for unstable, 101–104
- Body Image, disturbed, 104–108
- Breastfeeding, ineffective, 109–114
- Breastfeeding, interrupted, 115–119
- Breastfeeding, readiness for enhanced, 119–122
- Breast Milk Production, insufficient, 122–126
- Breathing Pattern, ineffective, 126–131

- Cardiac Output, decreased, 131–137
- Cardiac Output, risk for decreased, 138–140
- Childbearing Process, ineffective, 141–148
- Childbearing Process, readiness for enhanced, 148–154
- Childbearing Process, risk for ineffective, 155
- Comfort, impaired, 156–160
- Comfort, readiness for enhanced, 160–163
- Communication, impaired verbal, 164–169
- Communication, readiness for enhanced, 169–172
- Confusion, acute, 172–176
- Confusion, chronic, 177–181
- Confusion, risk for acute, 181–184
- Constipation, 184–188
- Constipation, chronic functional, 188–192
- Constipation, perceived, 195–197

- Constipation, risk for, 197–200
- Constipation, risk for chronic functional, 192–195
- Contamination, 200–206
- Contamination, risk for, 206–209
- Coping, compromised family, 210–212
- Coping, defensive, 213–216
- Coping, disabled family, 216–219
- Coping, ineffective, 219–224
- Coping, ineffective community, 224–226
- Coping, readiness for enhanced, 227–229
- Coping, readiness for enhanced community, 229–231
- Coping, readiness for enhanced family, 232–234

- Death Anxiety, 234–237
- Decisional Conflict [specify level], 238–241
- Decision-Making, readiness for enhanced, 241–244
- Denial, ineffective, 244–247
- Dentition, impaired, 247–251
- Development, risk for delayed, 251–255
- Diarrhea, 255–260
- Disuse Syndrome, risk for, 260–266
- Diversional Activity Engagement, decreased, 266–269
- Dry Eye, risk for, 270–272
- Dry Mouth, risk for, 272–275

- Eating Dynamics, ineffective adolescent, 275–278
- Eating Dynamics, ineffective child, 279–282
- Eating Dynamics, ineffective infant, 282–285
- Electrolyte Imbalance, risk for, 285–290
- Elimination, impaired urinary, 291–295
- Emancipated Decision-Making, impaired, 295–298
- Emancipated Decision-Making, readiness for enhanced, 298–300
- Emancipated Decision-Making, risk for impaired, 301
- Emotional Control, labile, 302–304
- Energy Field, imbalanced, 304–308

- Falls, risk for, 308–312
- Family Processes, dysfunctional, 313–317
- Family Processes, interrupted, 317–320
- Family Processes, readiness for enhanced, 321–323
- Fatigue, 324–329
- Fear [specify focus], 329–333
- Feeding Pattern, ineffective infant, 333–336
- Female Genital Mutilation, risk for, 336–339

- [Fluid Volume, deficient hyper/hypotonic], 339–343
- Fluid Volume, deficient [isotonic], 343–347
- Fluid Volume, excess, 348–351
- Fluid Volume, risk for deficient, 352–355
- Fluid Volume, risk for imbalanced, 355–358
- Frail Elderly Syndrome, 359–363
- Frail Elderly Syndrome, risk for, 363–365

- Gas Exchange, impaired, 366–370
- Gastrointestinal Motility, dysfunctional, 370–375
- Gastrointestinal Motility, risk for dysfunctional, 376–379
- [Gastrointestinal Perfusion, risk for ineffective], 380–383
- Grieving, 384–388
- Grieving, complicated, 388–392
- Grieving, risk for complicated, 392–395
- Growth, risk for disproportionate, 395–399

- Health Behavior, risk-prone, 400–403
- Health, deficient community, 403–406
- Health Literacy, readiness for enhanced, 407–409
- Health Maintenance, ineffective, 410–413
- Health Management, ineffective, 417–420
- Health Management, ineffective family, 414–416
- Health Management, readiness for enhanced, 421–423
- Home Maintenance, impaired, 423–426
- Hopelessness, 427–431
- Hope, readiness for enhanced, 431–433
- Human Dignity, risk for compromised, 434–436
- Hyperbilirubinemia, neonatal, 436–441
- Hyperbilirubinemia, risk for neonatal, 441–444
- Hyperthermia, 444–448
- Hypothermia, 448–452
- Hypothermia, risk for, 453–455
- Hypothermia, risk for perioperative, 455–457

- Immigration Transition, risk for complicated, 458–461
- Impulse Control, ineffective, 461–463
- Incontinence, bowel, 464–467
- Incontinence, functional urinary, 467–470
- Incontinence, overflow urinary, 471–473
- Incontinence, reflex urinary, 474–476
- Incontinence, risk for urge urinary, 477–479
- Incontinence, stress urinary, 479–482
- Incontinence, urge urinary, 483–486
- Infection, risk for, 487–492
- Injury, risk for, 492–497

Injury, risk for corneal, 497–500
 Injury, risk for urinary tract, 500–504
 Insomnia, 504–508

Knowledge, deficient, 509–513
 Knowledge, readiness for enhanced [specify level], 513–515

Latex Allergy Reaction, 515–519
 Latex Allergy Reaction, risk for, 520–522
 Lifestyle, sedentary, 522–526
 Liver Function, risk for impaired, 526–529
 Loneliness, risk for, 530–533

Maternal-Fetal Dyad, risk for disturbed, 533–538
 Memory, impaired, 538–541
 Metabolic Imbalance Syndrome, risk for, 542–544
 Mobility, impaired bed, 545–548
 Mobility, impaired physical, 548–553
 Mobility, impaired wheelchair, 553–556
 Mood Regulation, impaired, 557–559
 Moral Distress, 559–562
 Mucous Membrane Integrity, impaired oral, 562–568
 Mucous Membrane Integrity, risk for impaired oral, 568–570

Nausea, 571–574
 Neonatal Abstinence Syndrome, 575–578
 Neurovascular Dysfunction, risk for peripheral, 578–582
 Nutrition, imbalanced: less than body requirements, 582–588
 Nutrition, readiness for enhanced, 589–591

Obesity, 591–595
 Occupational Injury, risk for, 595–599
 Overweight, 599–605
 Overweight, risk for, 605–609

Pain, acute, 609–614
 Pain, chronic, 615–621
 Pain, labor, 621–625
 Pain Syndrome, chronic, 615–621
 Parenting, impaired, 625–630
 Parenting, readiness for enhanced, 630–633
 Parenting, risk for impaired, 633–634
 Personal Identity, disturbed, 634–638
 Personal Identity, risk for disturbed, 638–641
 Poisoning, risk for, 641–646

Positioning Injury, risk for perioperative, 646–649
 Post-Trauma Syndrome, 649–655
 Post-Trauma Syndrome, risk for, 655–659
 Powerlessness, 659–663
 Powerlessness, risk for, 664–667
 Power, readiness for enhanced, 667–669
 Pressure Ulcer, risk for, 670–673
 Protection, ineffective, 673–674

Rape-Trauma Syndrome, 675–680
 Relationship, ineffective, 680–683
 Relationship, readiness for enhanced, 683–686
 Relationship, risk for ineffective, 686–689
 Religiosity, impaired, 690–692
 Religiosity, readiness for enhanced, 693–695
 Religiosity, risk for impaired, 695–698
 Relocation Stress Syndrome, 698–702
 Relocation Stress Syndrome, risk for, 702–705
 Resilience, impaired, 705–709
 Resilience, readiness for enhanced, 709–712
 Resilience, risk for impaired, 712–715
 Retention, urinary [acute/chronic], 715–720
 Role Conflict, parental, 720–723
 Role Performance, ineffective, 723–727
 Role Strain, caregiver, 727–733
 Role Strain, risk for caregiver, 733–737

Self-Care Deficit: bathing, dressing, feeding, toileting, 738–744
 Self-Care, readiness for enhanced, 745–747
 Self-Concept, readiness for enhanced, 748–750
 Self-Esteem, chronic low, 751–754
 Self-Esteem, risk for chronic low, 755–758
 Self-Esteem, risk for situational low, 759–761
 Self-Esteem, situational low, 762–765
 Self-Mutilation, 766–769
 Self-Mutilation, risk for, 770–773
 Self-Neglect, 774–777
 [Sensory Perception, disturbed (specify: visual, auditory, kinesthetic, gustatory, tactile, olfactory)], 777–783
 Sexual Dysfunction, 784–788
 Sexuality Pattern, ineffective, 789–792
 Shock, risk for, 792–796
 Sitting, impaired, 796–799
 Skin Integrity, impaired, 800–806
 Skin Integrity, risk for impaired, 806–810

Sleep Deprivation, 810–815
 Sleep Pattern, disturbed, 815–818
 Sleep, readiness for enhanced, 818–820
 Social Interaction, impaired, 820–825
 Social Isolation, 825–828
 Sorrow, chronic, 829–831
 Spiritual Distress, 832–836
 Spiritual Distress, risk for, 836–839
 Spiritual Well-Being, readiness for enhanced, 840–842
 Standing, impaired, 842–846
 Stress Overload, 846–849
 Sudden Infant Death, risk for, 850–853
 Suffocation, risk for, 853–857
 Suicide, risk for, 857–862
 Surgical Recovery, delayed, 862–867
 Surgical Recovery, risk for delayed, 867–870
 Surgical Site Infection, risk for, 870–874
 Swallowing, impaired, 874–879

Thermal Injury, risk for, 880–883
 Thermoregulation, ineffective, 884–886
 Thermoregulation, risk for ineffective, 887–889
 Thromboembolism, risk for venous, 890–892
 Tissue Integrity, impaired, 892–898
 Tissue Integrity, risk for impaired, 898–902
 Tissue Perfusion, ineffective peripheral, 902–907
 Tissue Perfusion, risk for decreased cardiac, 907–911
 Tissue Perfusion, risk for ineffective cerebral, 911–915
 Tissue Perfusion, risk for ineffective peripheral, 915–918
 Transfer Ability, impaired, 918–921
 Trauma, risk for physical, 921–927
 Trauma, risk for vascular, 927–930

Unilateral Neglect, 931–935

Ventilation, impaired spontaneous, 935–940
 Ventilatory Weaning Response, dysfunctional, 940–945
 Violence, risk for other-directed, 945
 Violence, risk for self-directed, 946–951

Walking, impaired, 952–955
 Wandering [specify: sporadic or continual], 955–959
