NURSING DIAGNOSIS HANDBOOK

An Evidence-Based Guide to Planning Care

NANDA-I Diagnoses

Decreased **activity** tolerance, 126
Risk for decreased **activity** tolerance, 131
Ineffective **activity** planning, 131
Risk for ineffective **activity** planning, 134
Ineffective **airway** clearance, 135
Risk for **allergy** reaction, 140
Anxiety, 144
Death **anxiety**, 147
Risk for **aspiration**, 151
Risk for impaired **attachment**, 157
Autonomic dysreflexia, 162
Risk for **autonomic dysreflexia**, 166
Risk for **bleeding**, 167
Risk for unstable **blood pressure**, 171
Disturbed **body image**, 175
Insufficient **breast milk** production, 178
Ineffective **breastfeeding**, 181
Interrupted **breastfeeding**, 184
Readiness for enhanced **breastfeeding**, 187
Ineffective **breathing** pattern, 189
Decreased **cardiac** output, 194
Risk for decreased **cardiac** output, 202
Risk for decreased **cardiac** tissue perfusion, 203
Risk for impaired **cardiovascular** function, 208
Caregiver role strain, 209
Risk for **caregiver role strain**, 214
Risk for ineffective **cerebral** tissue perfusion, 215
Ineffective **childbearing** process, 218
Readiness for enhanced **childbearing** process, 222
Risk for ineffective **childbearing** process, 226
Impaired **comfort**, 226
Readiness for enhanced **comfort**, 230
Readiness for enhanced **communication**, 234
Impaired verbal **communication**, 237
Acute **confusion**, 242
Chronic **confusion**, 248
Risk for acute **confusion**, 253
Constipation, 254
Risk for **constipation**, 260
Perceived **constipation**, 261
Chronic functional **constipation**, 264
Risk for chronic functional **constipation**, 269
Contamination, 270
Risk for **contamination**, 274
Impaired bowel **continence**, 275
Risk for adverse reaction to iodinated **contrast media**, 281
Readiness for enhanced community **coping**, 284
Defensive **coping**, 287
Ineffective **coping**, 290
Readiness for enhanced **coping**, 296
Ineffective community **coping**, 300
Compromised family **coping**, 303
Disabled family **coping**, 309
Readiness for enhanced family **coping**, 312
Readiness for enhanced **decision-making**, 314
Decisional conflict, 317
Risk for **elopement** attempt, 320
Impaired emancipated **decision-making**, 323
Readiness for enhanced emancipated **decision-making**, 327
Risk for impaired emancipated **decision-making**, 330
Readiness for enhanced **exercise** engagement, 333
Ineffective **denial**, 337
Impaired **dentition**, 341
Delayed child **development**, 349
Risk for delayed child **development**, 352
Delayed infant motor **development**, 353
Risk for delayed infant motor **development**, 356
Diarrhea, 357
Risk for **disuse** syndrome, 363
Decreased **diversional activity** engagement, 368
Ineffective adolescent **eating** dynamics, 372
Ineffective child **eating** dynamics, 375
Risk for **electrolyte** imbalance, 378
Labile **emotional control**, 381
Imbalanced **energy field**, 385
Ineffective dry **eye** self-management, 387
Risk for dry **eye**, 390
Risk for adult **falls**, 391
Risk for child **falls**, 398
Dysfunctional **family** processes, 401
Interrupted **family** processes, 405
Readiness for enhanced **family** processes, 408
Fatigue, 411
Fear, 417
Ineffective infant **feeding** dynamics, 421
Risk for **female genital mutilation**, 424
Risk for imbalanced **fluid** volume, 427
Deficient **fluid** volume, 431
Excess **fluid** volume, 437
Risk for deficient **fluid** volume, 442
Frail elderly syndrome, 442
Risk for **frail elderly** syndrome, 445
Impaired **gas** exchange, 446
Risk for dysfunctional **gastrointestinal** motility, 451
Dysfunctional **gastrointestinal** motility, 451
Risk for unstable blood **glucose** level, 456
Maladaptive **grieving**, 462
Risk for maladaptive **grieving**, 466
Readiness for enhanced **grieving**, 467
Deficient community **health**, 473
Risk-prone **health** behavior, 475
Ineffective **health** self-management, 480
Readiness for enhanced **health** self-management, 484
Ineffective family **health** self-management, 488
Ineffective **health** maintenance behaviors, 491
Ineffective **home** maintenance behaviors, 495
Readiness for enhanced **home** maintenance behaviors, 499
Risk for ineffective **home** maintenance behaviors, 501
Readiness for enhanced **hope**, 502
Hopelessness, 504
Risk for compromised **human dignity**, 508
Neonatal **hyperbilirubinemia**, 511
Risk for neonatal **hyperbilirubinemia**, 515
Hyperthermia, 517

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Hypothermia, 523
Risk for **hypothermia**, 530
Neonatal **hypothermia**, 530
Risk for neonatal **hypothermia**, 532
Risk for **perioperative hypothermia**, 533
Disturbed family **identity** syndrome, 538
Risk for disturbed family **identity** syndrome, 541
Disturbed personal **identity**, 542
Risk for disturbed personal **identity**, 549
Risk for complicated **immigration transition**, 549
Ineffective **impulse** control, 552
Disability-associated urinary **incontinence**, 555
Mixed urinary **incontinence**, 559
Stress urinary **incontinence**, 563
Urge urinary **incontinence**, 567
Risk for urge urinary **incontinence**, 572
Disorganized **infant** behavior, 573
Readiness for enhanced organized **infant** behavior, 578
Risk for disorganized **infant** behavior, 578
Risk for **infection**, 579
Risk for surgical site **infection**, 585
Risk for **injury**, 592
Risk for corneal **injury**, 596
Risk for occupational **injury**, 599
Nipple-areolar complex **injury**, 604
Risk for nipple-areolar complex **injury**, 606
Risk for urinary tract **injury**, 607
Insomnia, 610
Deficient **knowledge**, 614
Readiness for enhanced **knowledge**, 618
Risk for **latex allergy** reaction, 620
Readiness for enhanced health **literacy**, 623
Risk for impaired **liver** function, 626
Risk for **loneliness**, 630
Ineffective **lymphedema** self-management, 633
Risk for ineffective **lymphedema** self-management, 638
Risk for disturbed **maternal–fetal** dyad, 639
Impaired **memory**, 642
Risk for **metabolic** syndrome, 646
Impaired bed **mobility**, 650
Impaired physical **mobility**, 655
Impaired wheelchair **mobility**, 659
Impaired **mood** regulation, 663
Moral distress, 665
Risk for dry **mouth**, 668
Nausea, 674
Neonatal abstinence syndrome, 680
Readiness for enhanced **nutrition**, 683
Imbalanced **nutrition:** less than body requirements, 686
Impaired **oral mucous membrane** integrity, 692
Risk for impaired **oral mucous membrane** integrity, 698
Obesity, 698
Overweight, 703
Risk for **overweight**, 707
Acute **pain**, 712
Chronic **pain**, 719
Chronic **pain** syndrome, 728
Labor **pain**, 728
Impaired **parenting**, 732
Readiness for enhanced **parenting**, 736
Risk for impaired **parenting**, 739
Risk for **perioperative positioning** injury, 739
Risk for **peripheral neurovascular** dysfunction, 745
Risk for **poisoning**, 747
Post-trauma syndrome, 752
Risk for **post-trauma** syndrome, 756
Readiness for enhanced **power**, 759
Powerlessness, 761
Risk for **powerlessness**, 765
Adult **pressure injury**, 765
Risk for adult **pressure injury**, 770
Child **pressure injury**, 771
Risk for child **pressure injury**, 776
Neonatal **pressure injury**, 777
Risk for neonatal **pressure injury**, 780
Ineffective **protection**, 781
Rape-trauma syndrome, 787
Ineffective **relationship**, 791
Readiness for enhanced **relationship**, 794
Risk for ineffective **relationship**, 797
Impaired **religiosity**, 798
Readiness for enhanced **religiosity**, 801
Risk for impaired **religiosity**, 805
Relocation stress syndrome, 805
Risk for **relocation** stress syndrome, 811
Impaired **resilience**, 811
Readiness for enhanced **resilience**, 814
Risk for impaired **resilience**, 816
Parental **role** conflict, 819
Ineffective **role** performance, 822
Sedentary lifestyle, 825
Readiness for enhanced **self-care**, 830
Bathing **self-care** deficit, 836
Dressing **self-care** deficit, 840
Feeding **self-care** deficit, 843
Toileting **self-care** deficit, 847
Readiness for enhanced **self-concept**, 851
Chronic low **self-esteem**, 854
Situational low **self-esteem**, 858
Risk for chronic low **self-esteem**, 861
Risk for situational low **self-esteem**, 861
Risk for **self-mutilation**, 864
Self-mutilation, 864
Self-neglect, 868
Sexual dysfunction, 871
Ineffective **sexuality** pattern, 877
Risk for **shock**, 882
Impaired **sitting**, 887
Impaired **skin** integrity, 890
Risk for impaired **skin** integrity, 895
Sleep deprivation, 898
Readiness for enhanced **sleep**, 902
Disturbed **sleep** pattern, 906
Impaired **social** interaction, 910
Social isolation, 913
Chronic **sorrow**, 916

Spiritual distress, 920
Risk for **spiritual** distress, 924
Readiness for enhanced **spiritual** well-being, 924
Impaired **standing**, 929
Stress overload, 931
Acute **substance withdrawal** syndrome, 935
Risk for acute **substance withdrawal** syndrome, 940
Ineffective infant **suck-swallow response**, 945
Risk for **sudden infant death**, 949
Risk for **suffocation**, 951
Risk for **suicidal behavior**, 955
Delayed **surgical** recovery, 962
Risk for delayed **surgical** recovery, 966
Impaired **swallowing**, 967
Risk for **thermal** injury, 972
Ineffective **thermoregulation**, 974
Risk for ineffective **thermoregulation**, 979
Risk for **thrombosis**, 979
Disturbed **thought process**, 983
Impaired **tissue** integrity, 986
Risk for impaired **tissue** integrity, 991
Ineffective peripheral **tissue perfusion**, 992
Risk for ineffective peripheral **tissue perfusion**, 997
Impaired **transfer** ability, 997
Risk for physical **trauma**, 1002
Unilateral neglect, 1008
Impaired **urinary** elimination, 1010
Urinary retention, 1015
Risk for **urinary retention**, 1020
Risk for **vascular trauma**, 1020
Impaired spontaneous **ventilation**, 1024
Dysfunctional adult **ventilatory** weaning response, 1030
Dysfunctional **ventilatory** weaning response, 1036
Risk for other-directed **violence**, 1037
Risk for self-directed **violence**, 1042
Impaired **walking**, 1045
Wandering, 1048

To nursing colleagues throughout the world who continue to demonstrate unwavering commitment to providing exceptional care, physical, emotional, and spiritual care. Special thanks to my family. To my husband and children, whose unconditional love and support are ever present in my life. To my parents and sisters for always encouraging me to follow my passion. Finally, to Betty Ackley and Gail Ladwig for their steadfast commitment to the profession of nursing as expert teachers and prolific authors. Your leadership and spirit continue to inform nursing practice excellence.
Mary Beth Flynn Makic

To all the nurses who are working on the front lines. To my best friend and the love of my life, Kent Martinez-Kratz. To my children, Maxwell, Jesse, and Sierra, whose love, inspiration, and wit make my life complete. To my first fans, my parents Angel and Eva, and siblings, Debra and Jason. To Gail Ladwig for being the absolute best nursing professor, mentor, colleague, and comadre. And finally, to Betty Ackley's memory, for inspiring excellence in nursing education and practice.
Marina Reyna Martinez-Kratz

About the Authors

Mary Beth Flynn Makic is a Professor at the University of Colorado College of Nursing in Aurora, Colorado, where she teaches in the undergraduate, graduate, and doctoral programs. She is the director of the Adult-Gerontology Clinical Nurse Specialist Program at the College of Nursing. She has worked predominately in critical care for 33 years. Mary Beth is best known for her publications and presentations, regionally and nationally, as an expert on evidence-based practice in nursing. Her practice expertise and research focus are trauma, general surgical, and burn-injured client populations; acute wound healing; pressure ulcer prevention; and hospital-acquired conditions (HACs). She is passionate about nurses' understanding and translating current best evidence into practice to optimize client and family outcomes. She is coeditor of *Trauma Nursing: from Resuscitation through Rehabilitation,* fifth edition, and *Introduction to Critical Care Nursing,* eighth edition. She is actively involved in several professional nursing and interprofessional organizations.

Marina Reyna Martinez-Kratz is a Professor of Nursing at Jackson College in Jackson, Michigan. She is a registered nurse with 33 years of experience and is a Certified Nurse Educator. She received her nursing degrees from Jackson Community College and the University of Michigan. Her expertise in nursing practice has focused on psychiatric nursing, professional issues, and nutrition. In 1998 Marina joined the faculty at Jackson Community College and currently teaches nursing courses in Behavioral Health, Capstone Nursing, and Nutrition. In addition, Marina serves on the Nursing Outcomes and Professional Development Committees and is a Mandated Reporter Trainer. She has served as a behavioral health consultant for several health care facilities, contributes to and reviews many academic publications, and has presented at the state and national level. Marina belongs to many professional organizations and serves as the National League for Nursing Ambassador for Jackson College. Marina's passion is helping students learn to think like nurses! Marina is the proud mother of three children and has been married to her partner and best friend Kent for 32 years.

Preface

Ackley and Ladwig's Nursing Diagnosis Handbook: An Evidence-Based Guide to Planning Care is a convenient reference to help the practicing nurse or nursing student make a nursing diagnosis and write a care plan with ease and confidence. This handbook helps nurses correlate nursing diagnoses with known information about clients on the basis of assessment findings; established medical, surgical, or psychiatric diagnoses; and the current treatment plan.

Making a nursing diagnosis and planning care are complex processes that involve diagnostic reasoning and critical thinking skills. Nursing students and practicing nurses cannot possibly memorize the extensive list of defining characteristics, related factors, and risk factors for the 267 diagnoses approved by NANDA-International (NANDA-I). There are also two additional diagnoses that the authors think are significant: Hearing Loss and Vision Loss. These diagnoses are contained in Appendix E (on the Evolve website). This book correlates suggested nursing diagnoses with what nurses know about clients and offers a care plan for each nursing diagnosis.

Section I, Nursing Process, Clinical Reasoning, Nursing Diagnosis, and Evidence-Based Nursing, is divided into two parts. Part A includes an overview of the nursing process. This section provides information on how to make a nursing diagnosis and directions on how to plan nursing care. It also includes information on using clinical reasoning and judgment skills, eliciting the "client's story," recognizing patterns in client responses, and synthesizing information to form decisions that will guide care based on analyzing and understanding the client's concerns. Part B includes advanced nursing concepts: concept mapping, QSEN (Quality and Safety Education for Nurses), evidence-based nursing care, quality nursing care, person-centered care, safety, informatics in nursing, and team/collaborative work with a multiprofessional team.

In **Section II, Guide to Nursing Diagnosis,** the nurse can look up symptoms and problems and their suggested nursing diagnoses for more than 1450 client symptoms; medical, surgical, and psychiatric diagnoses; diagnostic procedures; surgical interventions; and clinical states.

In **Section III, Guide to Planning Care,** the nurse can find care plans for all nursing diagnoses suggested in Section II. We have included the suggested nursing outcomes from the Nursing Outcomes Classification (NOC) and interventions from the Nursing Interventions Classification (NIC) by the Iowa Intervention Project. We believe this work is a significant addition to the nursing process to further define nursing practice with standardized language.

Scientific rationales based on research are included for most of the interventions. This is done to make the evidence basis for the specific nursing practice apparent to the nursing student and practicing nurse.

Special features of the 13th edition of *Ackley and Ladwig's Nursing Diagnosis Handbook: An Evidence-Based Guide to Planning Care* include the following:

- Labeling of classic older research studies that are still relevant as Classic Evidence-Based (CEB)
- Sixty-seven revised nursing diagnoses approved by NANDA-I
- Use of the terms *At-Risk Populations* and *Associated Conditions* with the diagnostic indicators as approved by NANDA-I.
- Twenty-nine new nursing diagnoses recently approved by NANDA-I, along with the retirement of four nursing diagnoses: Reflex Urinary Incontinence, Grieving, Decreased Intracranial Adaptive Capacity, and Latex Allergy Reaction.
- Seventeen revisions of nursing diagnoses made by NANDA-I in existing nursing diagnoses:
  - **Old diagnosis:** Ineffective Health Maintenance
    Revised diagnosis: Ineffective Health Maintenance Behaviors
  - **Old diagnosis:** Ineffective Health Management
    Revised diagnosis: Ineffective Health Self-Management
  - **Old diagnosis:** Readiness for Enhanced Health Management
    Revised diagnosis: Readiness for Enhanced Health Self-Management
  - **Old diagnosis:** Ineffective Family Health Management
    Revised diagnosis: Ineffective Family Health Self-Management
  - **Old diagnosis:** Impaired Home Maintenance
    Revised diagnosis: Ineffective Home Maintenance Behaviors
    - **Old domain:** 4 Activity/Rest
    - **New domain:** 1 Health Promotion
  - **Old diagnosis:** Ineffective Infant Feeding Pattern
    Revised diagnosis: Ineffective Infant Suck-Swallow Response
  - **Old diagnosis:** Risk for Metabolic Imbalance Syndrome
    Revised diagnosis: Risk for Metabolic Syndrome
  - **Old diagnosis:** Functional Urinary Incontinence
    Revised diagnosis: Disability-Associated Urinary Incontinence
  - **Old diagnosis:** Bowel Incontinence
    Revised diagnosis: Impaired Bowel Continence

- **Old diagnosis:** Activity Intolerance
  Revised diagnosis: Decreased Activity Tolerance
- **Old diagnosis:** Risk for Activity Intolerance
  Revised diagnosis: Risk for Decreased Activity Tolerance
- **Old diagnosis:** Complicated Grieving
  Revised diagnosis: Maladaptive Grieving
- **Old diagnosis:** Risk for Complicated Grieving
  Revised diagnosis: Risk for Maladaptive Grieving
- **Old diagnosis:** Risk for Falls
  Revised diagnosis: Risk for Adult Falls
- **Old diagnosis:** Risk for Pressure Ulcer
  Revised diagnosis: Risk for Adult Pressure Injury
- **Old diagnosis:** Risk for Suicide
  Revised diagnosis: Risk for Suicidal Behavior
- **Old diagnosis:** Risk for Delayed Development
  Revised diagnosis: Risk for Delayed Child Development

- Further addition of pediatric and critical care interventions to appropriate care plans
- An associated Evolve Online Course Management System that includes a Care Plan Template, critical thinking case studies, NIC and NOC labels, PowerPoint slides, review questions for the NCLEX-RN® exam, and appendixes for Nursing Diagnoses Arranged by Maslow's Hierarchy of Needs, Nursing Diagnoses Arranged by Gordon's Functional Health Patterns, Motivational Interviewing for Nurses, Wellness-Oriented Diagnostic Categories, and Nursing Care Plans for Hearing Loss and Vision Loss

The following features of *Ackley and Ladwig's Nursing Diagnosis Handbook: A Guide to Planning Care* are also available:

- Suggested nursing diagnoses for more than 1450 clinical entities, including signs and symptoms, medical diagnoses, surgeries, maternal-child disorders, mental health disorders, and geriatric disorders
- Labeling of nursing research as EBN (Evidence-Based Nursing) and clinical research as EB (Evidence-Based) to identify the source of evidence-based rationales
- An Evolve Online Courseware System with a Care Plan Template that helps the student or nurse write a nursing care plan
- Rationales for nursing interventions that are based on nursing research and best practices
- Nursing references identified for each care plan
- A complete list of NOC Outcomes on the Evolve website
- A complete list of NIC Interventions on the Evolve website
- Nursing care plans that contain many holistic interventions
- Care plans written by leading national nursing experts from throughout the United States, along with international contributors, who together represent all of the major nursing specialties and have extensive experience with nursing diagnoses, the nursing process, and evidence-based practice. Several contributors are the original submitters/authors of the nursing diagnoses established by NANDA-I
- A format that facilitates analyzing signs and symptoms by the process already known by nurses, which involves using defining characteristics of nursing diagnoses to make a diagnosis
- Use of NANDA-I terminology and approved diagnoses
- An alphabetical format for Sections II and III, which allows rapid access to information
- Nursing care plans also listed by domains and class, consistent with NANDA-I
- Nursing care plans for all nursing diagnoses listed in Section II
- Specific geriatric interventions in appropriate plans of care
- Specific client/family teaching interventions in each plan of care
- Information on culturally competent nursing care included where appropriate
- Inclusion of commonly used abbreviations (e.g., AIDS, MI, HF) and cross-references to complete terms in Section II

We acknowledge the work of NANDA-I, which is used extensively throughout this text. The original NANDA-I work can be found in *NANDA-I Nursing Diagnoses: Definitions & Classification 2021–2023*, 12th edition.

We and the consultants and contributors trust that nurses will find this 13th edition of *Ackley and Ladwig's Nursing Diagnosis Handbook: An Evidence-Based Guide to Planning Care* a valuable tool that simplifies the process of identifying appropriate nursing diagnoses for clients and planning for their care, thus allowing nurses more time to provide evidence-based care that promote each client's recovery.

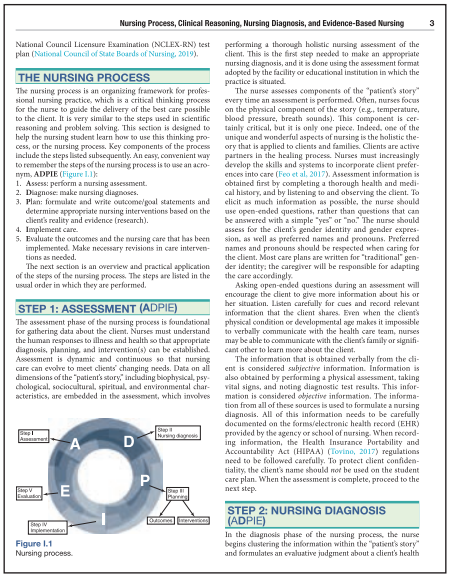
Acknowledgments

We would like to thank the following people at Elsevier: Sandy Clark, Senior Content Strategist, who supported us with the 13th edition of the text with intelligence and kindness; Jennifer Wade and Rae Robertson, Senior Content Development Specialists, who were a continual source of support; and a special thank you to Clay Broeker for the project management of this edition.

With gratitude, we acknowledge nurses and student nurses, who are always an inspiration for us to provide fresh and accurate material. We are honored that they continue to value this text and to use it in their studies and practice.

We would like to thank all of the dedicated contributors who are experts in their fields of nursing. We appreciate all of their hard work.

Care has been taken to confirm the accuracy of the information presented in this book. However, the authors, editors, and publisher cannot accept any responsibility for consequences resulting from errors or omissions of the information in this book and make no warranty, expressed or implied, with respect to its contents. The reader should use practices suggested in this book in accordance with agency policies and professional standards. Every effort has been made to ensure the accuracy of the information presented in this text.



We hope you find this text a useful resource for your nursing practice.

Mary Beth Flynn Makic
Marina Reyna Martinez-Kratz

How to Use *Nursing Diagnosis Handbook: An Evidence-Based Guide to Planning Care*

STEP 1: ASSESS

Following the guidelines in Section I (Nursing Process, Clinical Reasoning, Nursing Diagnosis, and Evidence-Based Nursing), begin to formulate your nursing diagnosis by gathering and documenting the objective and subjective information about the client.

Nursing Process, Clinical Reasoning, Nursing Diagnosis, and Evidence-Based Nursing 3

National Council Licensure Examination (NCLEX-RN) test plan (National Council of State Boards of Nursing, 2019).

THE NURSING PROCESS

The nursing process is an organizing framework for professional nursing practice, which is a critical thinking process for the nurse to guide the delivery of the best care possible to the client. It is very similar to the steps used in scientific reasoning and problem solving. This section is designed to help the nursing student learn how to use this thinking process, or the nursing process. Key components of the process include the steps listed subsequently. An easy, convenient way to remember the steps of the nursing process is to use an acronym, **ADPIE** (Figure I.1):

1. Assess: perform a nursing assessment.
2. Diagnose: make nursing diagnoses.
3. Plan: formulate and write outcome/goal statements and determine appropriate nursing interventions based on the client's reality and evidence (research).
4. Implement care.
5. Evaluate the outcomes and the nursing care that has been implemented. Make necessary revisions in care interventions as needed.

The next section is an overview and practical application of the steps of the nursing process. The steps are listed in the usual order in which they are performed.

STEP 1: ASSESSMENT (ADPIE)

The assessment phase of the nursing process is foundational for gathering data about the client. Nurses must understand the human responses to illness and health so that appropriate diagnosis, planning, and intervention(s) can be established. Assessment is dynamic and continuous so that nursing care can evolve to meet clients' changing needs. Data on all dimensions of the "patient's story," including biophysical, psychological, sociocultural, spiritual, and environmental characteristics, are embedded in the assessment, which involves performing a thorough holistic nursing assessment of the client. This is the first step needed to make an appropriate nursing diagnosis, and it is done using the assessment format adopted by the facility or educational institution in which the practice is situated.

The nurse assesses components of the "patient's story" every time an assessment is performed. Often, nurses focus on the physical component of the story (e.g., temperature, blood pressure, breath sounds). This component is certainly critical, but it is only one piece. Indeed, one of the unique and wonderful aspects of nursing is the holistic theory that is applied to clients and families. Clients are active partners in the healing process. Nurses must increasingly develop the skills and systems to incorporate client preferences into care (Feo et al, 2017). Assessment information is obtained first by completing a thorough health and medical history, and by listening to and observing the client. To elicit as much information as possible, the nurse should use open-ended questions, rather than questions that can be answered with a simple "yes" or "no." The nurse should assess for the client's gender identity and gender expression, as well as preferred names and pronouns. Preferred names and pronouns should be respected when caring for the client. Most care plans are written for "traditional" gender identity; the caregiver will be responsible for adapting the care accordingly.

Asking open-ended questions during an assessment will encourage the client to give more information about his or her situation. Listen carefully for cues and record relevant information that the client shares. Even when the client's physical condition or developmental age makes it impossible to verbally communicate with the health care team, nurses may be able to communicate with the client's family or significant other to learn more about the client.

The information that is obtained verbally from the client is considered *subjective* information. Information is also obtained by performing a physical assessment, taking vital signs, and noting diagnostic test results. This information is considered *objective* information. The information from all of these sources is used to formulate a nursing diagnosis. All of this information needs to be carefully documented on the forms/electronic health record (EHR) provided by the agency or school of nursing. When recording information, the Health Insurance Portability and Accountability Act (HIPAA) (Tovino, 2017) regulations need to be followed carefully. To protect client confidentiality, the client's name should *not* be used on the student care plan. When the assessment is complete, proceed to the next step.

Figure I.1
Nursing process.

STEP 2: NURSING DIAGNOSIS (ADPIE)

In the diagnosis phase of the nursing process, the nurse begins clustering the information within the "patient's story" and formulates an evaluative judgment about a client's health

STEP 2: DIAGNOSE

Turn to Section II, Guide to Nursing Diagnosis, and locate the client's symptoms, clinical state, medical or psychiatric diagnoses, and anticipated or prescribed diagnostic studies or surgical interventions (listed in alphabetical order). Note suggestions for appropriate nursing diagnoses.

Then use Section III, Guide to Planning Care, to evaluate each suggested nursing diagnosis and "related to" (r/t) etiology statement. Section III is a listing of care plans according to NANDA-I, arranged alphabetically by diagnostic concept, for each nursing diagnosis referred to in Section II. Determine the appropriateness of each nursing diagnosis by comparing the Defining Characteristics and/or Risk Factors to the client data collected.

40 Chronic Obstructive Pulmonary Disease (COPD)

C

Chronic Obstructive Pulmonary Disease (COPD)
See COPD (Chronic Obstructive Pulmonary Disease)

Chronic Pain
See Pain Management, Chronic

Chronic Renal Failure (Chronic Renal Disease)
See Renal Failure

Chvostek's Sign
See Hypocalcemia

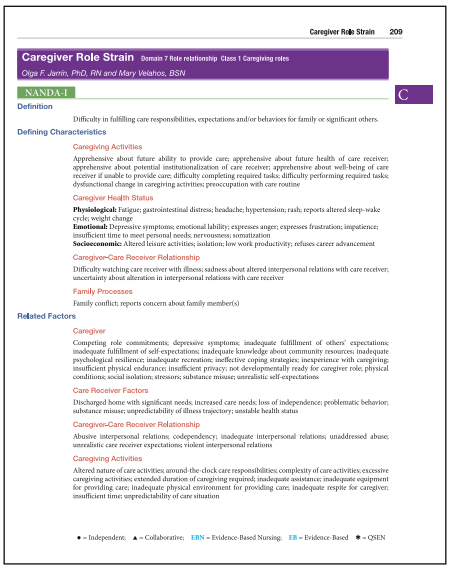
Circumcision
Acute Pain r/t surgical intervention
Risk for Bleeding: Risk factor: surgical trauma
Risk for Infection: Risk factor: surgical wound
Readiness for Enhanced Knowledge: Parent: expresses an interest in learning

Cirrhosis
Chronic Confusion r/t chronic organic disorder with increased ammonia levels, substance abuse
Defensive Coping r/t inability to accept responsibility to stop substance abuse
Fatigue r/t malnutrition
Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding correlation between lifestyle habits and disease process
Nausea r/t irritation to gastrointestinal system
Imbalanced Nutrition: Less than Body Requirements r/t loss of appetite, nausea, vomiting
Chronic Pain r/t liver enlargement
Chronic Low Self-Esteem r/t chronic illness
Chronic Sorrow r/t presence of chronic illness
Risk for Bleeding: Risk factors: impaired blood coagulation, bleeding from portal hypertension
Risk for Injury: Risk factors: substance intoxication, potential delirium tremens
Risk for Impaired Oral Mucous Membrane Integrity: Risk factors: altered nutrition, inadequate oral care
Risk for Impaired Skin Integrity: Risk factors: altered nutritional state, altered metabolic state

Cleft Lip/Cleft Palate
Ineffective Airway Clearance r/t common feeding and breathing passage, postoperative laryngeal, incisional edema
Ineffective Breastfeeding r/t infant anomaly
Impaired Verbal Communication r/t inadequate palate function, possible hearing loss from infected eustachian tubes
Fear: Parental r/t special care needs, surgery
Maladaptive Grieving r/t loss of perfect child
Ineffective Infant Feeding Dynamics r/t fear resulting in inadequate feeding
Ineffective Infant Suck-Swallow Response r/t cleft lip, cleft palate
Impaired Physical Mobility r/t imposed restricted activity, use of elbow restraints
Impaired Oral Mucous Membrane Integrity r/t surgical correction
Acute Pain r/t surgical correction, elbow restraints
Impaired Skin Integrity r/t incomplete joining of lip, palate ridges
Chronic Sorrow r/t birth of child with congenital defect
Risk for Aspiration: Risk factor: common feeding and breathing passage
Risk for Disturbed Body Image: Risk factors: disfigurement, speech impediment
Risk for deficient Fluid Volume: Risk factor: inability to take liquids in usual manner
Risk for Infection: Risk factors: invasive procedure, disruption of eustachian tube development, aspiration
Readiness for Enhanced Knowledge: Parent: expresses an interest in learning

Clotting Disorder
Fear r/t threat to well-being
Risk for Bleeding: Risk factor: impaired clotting
Readiness for Enhanced Knowledge: expresses an interest in learning
See Anticoagulant Therapy; DIC (Disseminated Intravascular Coagulation); Hemophilia

Cocaine Baby
See Neonatal Abstinence Syndrome



Codependency
Caregiver Role Strain r/t codependency
Impaired Verbal Communication r/t psychological barriers
Ineffective Coping r/t inadequate support systems
Decisional Conflict r/t support system deficit
Ineffective Denial r/t unmet self-needs
Powerlessness r/t lifestyle of helplessness

Cold, Viral
See Infectious Processes

Colectomy
Constipation r/t decreased activity, decreased fluid intake
Imbalanced Nutrition: Less than Body Requirements r/t high metabolic needs, decreased ability to ingest or digest food
Acute Pain r/t recent surgery
Risk for Surgical Site Infection: Risk factor: invasive procedure
Readiness for Enhanced Knowledge: expresses an interest in learning
See Abdominal Surgery

STEP 3: DETERMINE OUTCOMES

Use Section III, Guide to Planning Care, to find appropriate outcomes for the client. Use either the NOC Outcomes with the associated rating scales or Client Outcomes as desired.

Caregiver Role Strain 209

Caregiver Role Strain Domain 7 Role relationship Class 1 Caregiving roles
Olga F. Jarrín, PhD, RN and Mary Velahos, BSN

NANDA-I C

Definition
Difficulty in fulfilling care responsibilities, expectations and/or behaviors for family or significant others.

Defining Characteristics

Caregiving Activities
Apprehensive about future ability to provide care; apprehensive about future health of care receiver; apprehensive about potential institutionalization of care receiver; apprehensive about well-being of care receiver if unable to provide care; difficulty completing required tasks; difficulty performing required tasks; dysfunctional change in caregiving activities; preoccupation with care routine

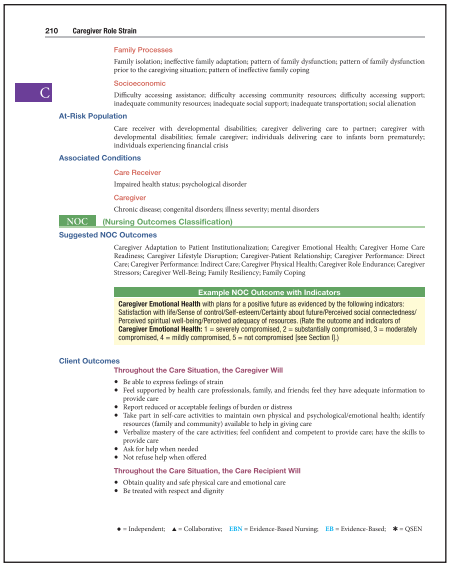
Caregiver Health Status
Physiological: Fatigue; gastrointestinal distress; headache; hypertension; rash; reports altered sleep-wake cycle; weight change
Emotional: Depressive symptoms; emotional lability; expresses anger; expresses frustration; impatience; insufficient time to meet personal needs; nervousness; somatization
Socioeconomic: Altered leisure activities; isolation; low work productivity; refuses career advancement

Caregiver–Care Receiver Relationship
Difficulty watching care receiver with illness; sadness about altered interpersonal relations with care receiver; uncertainty about alteration in interpersonal relations with care receiver

Family Processes
Family conflict; reports concern about family member(s)

Related Factors

Caregiver
Competing role commitments; depressive symptoms; inadequate fulfillment of others' expectations; inadequate fulfillment of self-expectations; inadequate knowledge about community resources; inadequate psychological resilience; inadequate recreation; ineffective coping strategies; inexperience with caregiving; insufficient physical endurance; insufficient privacy; not developmentally ready for caregiver role; physical conditions; social isolation; stressors; substance misuse; unrealistic self-expectations



Care Receiver Factors
Discharged home with significant needs; increased care needs; loss of independence; problematic behavior; substance misuse; unpredictability of illness trajectory; unstable health status

Caregiver–Care Receiver Relationship
Abusive interpersonal relations; codependency; inadequate interpersonal relations; unaddressed abuse; unrealistic care receiver expectations; violent interpersonal relations

Caregiving Activities
Altered nature of care activities; around-the-clock care responsibilities; complexity of care activities; excessive caregiving activities; extended duration of caregiving required; inadequate assistance; inadequate equipment for providing care; inadequate physical environment for providing care; inadequate respite for caregiver; insufficient time; unpredictability of care situation

● = Independent; ▲ = Collaborative; EBN = Evidence-Based Nursing. EB = Evidence-Based ✱ = QSEN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

210 Caregiver Role Strain

Family Processes

Family isolation; ineffective family adaptation; pattern of family dysfunction; pattern of family dysfunction prior to the caregiving situation; pattern of ineffective family coping

C

Socioeconomic

Difficulty accessing assistance; difficulty accessing community resources; difficulty accessing support; inadequate community resources; inadequate social support; inadequate transportation; social alienation

At-Risk Population

Care receiver with developmental disabilities; caregiver delivering care to partner; caregiver with developmental disabilities; female caregiver; individuals delivering care to infants born prematurely; individuals experiencing financial crisis

Associated Conditions

Care Receiver

Impaired health status; psychological disorder

Caregiver

Chronic disease; congenital disorders; illness severity; mental disorders

NOC (Nursing Outcomes Classification)

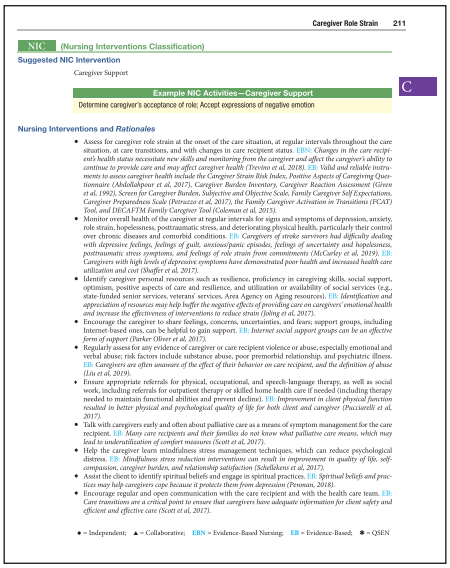
Suggested NOC Outcomes

Caregiver Adaptation to Patient Institutionalization; Caregiver Emotional Health; Caregiver Home Care Readiness; Caregiver Lifestyle Disruption; Caregiver–Patient Relationship; Caregiver Performance: Direct Care; Caregiver Performance: Indirect Care; Caregiver Physical Health; Caregiver Role Endurance; Caregiver Stressors; Caregiver Well-Being; Family Resiliency; Family Coping

Example NOC Outcome with Indicators

Caregiver Emotional Health with plans for a positive future as evidenced by the following indicators: Satisfaction with life/Sense of control/Self-esteem/Certainty about future/Perceived social connectedness/Perceived spiritual well-being/Perceived adequacy of resources. (Rate the outcome and indicators of **Caregiver Emotional Health:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes



Throughout the Care Situation, the Caregiver Will

- Be able to express feelings of strain
- Feel supported by health care professionals, family, and friends; feel they have adequate information to provide care
- Report reduced or acceptable feelings of burden or distress
- Take part in self-care activities to maintain own physical and psychological/emotional health; identify resources (family and community) available to help in giving care
- Verbalize mastery of the care activities; feel confident and competent to provide care; have the skills to provide care
- Ask for help when needed
- Not refuse help when offered

Throughout the Care Situation, the Care Recipient Will

- Obtain quality and safe physical care and emotional care
- Be treated with respect and dignity

♦ = Independent; ▲ = Collaborative; EBN = Evidence-Based Nursing; EB = Evidence-Based; ★ = QSEN

Caregiver Role Strain 211

NIC (Nursing Interventions Classification)

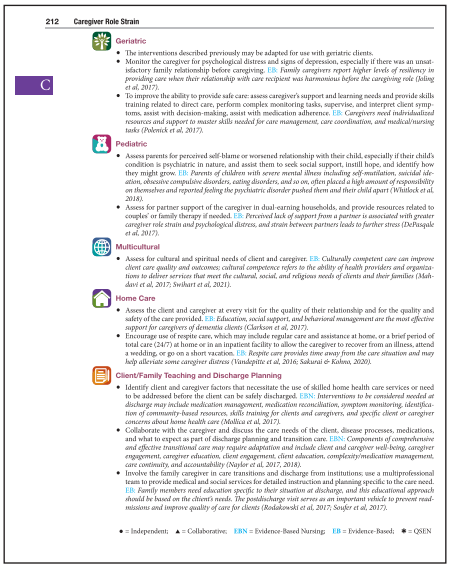
Suggested NIC Intervention

Caregiver Support

C

Example NIC Activities—Caregiver Support

Determine caregiver's acceptance of role; Accept expressions of negative emotion



Nursing Interventions and *Rationales*

- Assess for caregiver role strain at the onset of the care situation, at regular intervals throughout the care situation, at care transitions, and with changes in care recipient status. EBN: *Changes in the care recipient's health status necessitate new skills and monitoring from the caregiver and affect the caregiver's ability to continue to provide care and may affect caregiver health (Trevino et al, 2018).* EB: *Valid and reliable instruments to assess caregiver health include the Caregiver Strain Risk Index, Positive Aspects of Caregiving Questionnaire (Abdollahpour et al, 2017), Caregiver Burden Inventory, Caregiver Reaction Assessment (Given et al, 1992), Screen for Caregiver Burden, Subjective and Objective Scale, Family Caregiver Self Expectations, Caregiver Preparedness Scale (Petruzzo et al, 2017), the Family Caregiver Activation in Transitions (FCAT) Tool, and DECAFTM Family Caregiver Tool (Coleman et al, 2015).*
- Monitor overall health of the caregiver at regular intervals for signs and symptoms of depression, anxiety, role strain, hopelessness, posttraumatic stress, and deteriorating physical health, particularly their control over chronic diseases and comorbid conditions. EB: *Caregivers of stroke survivors had difficulty dealing with depressive feelings, feelings of guilt, anxious/panic episodes, feelings of uncertainty and hopelessness, posttraumatic stress symptoms, and feelings of role strain from commitments (McCurley et al, 2019).* EB: *Caregivers with high levels of depressive symptoms have demonstrated poor health and increased health care utilization and cost (Shaffer et al, 2017).*
- Identify caregiver personal resources such as resilience, proficiency in caregiving skills, social support, optimism, positive aspects of care and resilience, and utilization or availability of social services (e.g., state-funded senior services, veterans' services, Area Agency on Aging resources). EB: *Identification and appreciation of resources may help buffer the negative effects of providing care on caregivers' emotional health and increase the effectiveness of interventions to reduce strain (Jolley et al, 2017).*
- Encourage the caregiver to share feelings, concerns, uncertainties, and fears; support groups, including Internet-based ones, can be helpful to gain support. EB: *Internet social support groups can be an effective form of support (Parker Oliver et al, 2017).*
- Regularly assess for any evidence of caregiver or care recipient violence or abuse, especially emotional and verbal abuse; risk factors include substance abuse, poor premorbid relationship, and psychiatric illness. EB: *Caregivers are often unaware of the effect of their behavior on care recipient, and the definition of abuse (Liu et al, 2019).*
- Ensure appropriate referrals for physical, occupational, and speech-language therapy, as well as social work, including referrals for outpatient therapy or skilled home health care if needed (including therapy needed to maintain functional abilities and prevent decline). EB: *Improvement in client physical function resulted in better physical and psychological quality of life for both client and caregiver (Pucciarelli et al, 2017).*
- Talk with caregivers early and often about palliative care as a means of symptom management for the care recipient. EB: *Many care recipients and their families do not know what palliative care means, which may lead to underutilization of comfort measures (Scott et al, 2017).*
- Help the caregiver learn mindfulness stress management techniques, which can reduce psychological distress. EB: *Mindfulness stress reduction interventions can result in improvement in quality of life, self-compassion, caregiver burden, and relationship satisfaction (Schellekens et al, 2017).*
- Assist the client to identify spiritual beliefs and engage in spiritual practices. EB: *Spiritual beliefs and practices may help caregivers cope because it protects them from depression (Penman, 2018).*
- Encourage regular and open communication with the care recipient and with the health care team. EB: *Care transitions are a critical point to ensure that caregivers have adequate information for client safety and efficient and effective care (Scott et al, 2017).*

♦ = Independent; ▲ = Collaborative; EBN = Evidence-Based Nursing; EB = Evidence-Based; ★ = QSEN

PLAN INTERVENTIONS

Use Section III, Guide to Planning Care, to find appropriate interventions for the client. Use the Nursing Interventions as found in that section.

212 Caregiver Role Strain

C

Geriatric

- The interventions described previously may be adapted for use with geriatric clients.
- Monitor the caregiver for psychological distress and signs of depression, especially if there was an unsatisfactory family relationship before caregiving. EB: *Family caregivers report higher levels of resiliency in providing care when their relationship with care recipient was harmonious before the caregiving role (Jolley et al, 2017).*
- To improve the ability to provide safe care: assess caregiver's support and learning needs and provide skills training related to direct care, perform complex monitoring tasks, supervise, and interpret client symptoms, assist with decision-making, assist with medication adherence. EB: *Caregivers need individualized resources and support to master skills needed for care management, care coordination, and medical/nursing tasks (Polenick et al, 2017).*

Pediatric

- Assess parents for perceived self-blame or worsened relationship with their child, especially if their child's condition is psychiatric in nature, and assist them to seek social support, instill hope, and identify how they might grow. EB: *Parents of children with severe mental illness including self-mutilation, suicidal ideation, obsessive compulsive disorders, eating disorders, and so on, often placed a high amount of responsibility on themselves and reported feeling the psychiatric disorder pushed them and their child apart (Whitlock et al, 2018).*
- Assess for partner support of the caregiver in dual-earning households, and provide resources related to couples' or family therapy if needed. EB: *Perceived lack of support from a partner is associated with greater caregiver role strain and psychological distress, and strain between partners leads to further stress (DePasquale et al, 2017).*

Multicultural

- Assess for cultural and spiritual needs of client and caregiver. EB: *Culturally competent care can improve client care quality and outcomes; cultural competence refers to the ability of health providers and organizations to deliver services that meet the cultural, social, and religious needs of clients and their families (Mahdavi et al, 2017; Swihart et al, 2021).*

Home Care

- Assess the client and caregiver at every visit for the quality of their relationship and for the quality and safety of the care provided. EB: *Education, social support, and behavioral management are the most effective support for caregivers of dementia clients (Clarkson et al, 2017).*
- Encourage use of respite care, which may include regular care and assistance at home, or a brief period of total care (24/7) at home or in an inpatient facility to allow the caregiver to recover from an illness, attend a wedding, or go on a short vacation. EB: *Respite care provides time away from the care situation and may help alleviate some caregiver distress (Vandepitte et al, 2016; Sakurai & Kohno, 2020).*

Client/Family Teaching and Discharge Planning

- Identify client and caregiver factors that necessitate the use of skilled home health care services or need to be addressed before the client can be safely discharged. EBN: *Interventions to be considered needed at discharge may include medication management, medication reconciliation, symptom monitoring, identification of community-based resources, skills training for clients and caregivers, and specific client or caregiver concerns about home health care (Mollica et al, 2017).*
- Collaborate with the caregiver and discuss the care needs of the client, disease processes, medications, and what to expect as part of discharge planning and transition care. EBN: *Components of comprehensive and effective transitional care may require adaptation and include client and caregiver well-being, caregiver engagement, caregiver education, client engagement, client education, complexity/medication management, care continuity, and accountability (Naylor et al, 2017, 2018).*
- Involve the family caregiver in care transitions and discharge from institutions; use a multiprofessional team to provide medical and social services for detailed instruction and planning specific to the care need. EB: *Family members need education specific to their situation at discharge, and this educational approach should be based on the client's needs. The postdischarge visit serves as an important vehicle to present readmissions and improve quality of care for clients (Rodakowski et al, 2017; Snyder et al, 2017).*

♦ = Independent; ▲ = Collaborative; EBN = Evidence-Based Nursing; EB = Evidence-Based; ★ = QSEN

GIVE NURSING CARE

Administer nursing care following the plan of care based on the interventions.

EVALUATE NURSING CARE

Evaluate nursing care administered using either the NOC Outcomes or Client Outcomes. If the outcomes were not met and the nursing interventions were not effective, reassess the client and determine if the appropriate nursing diagnoses were made.

DOCUMENT

Document all of the previous steps using the format provided in the clinical setting. A Care Plan Template is available in the Evolve online resources to assist with documentation.

Contents

SECTION I **Nursing Process, Clinical Reasoning, Nursing Diagnosis, and Evidence-Based Nursing, 1**

An explanation of how to make a nursing diagnosis using diagnostic reasoning, which is critical thinking, followed by information on how to plan care using the nursing process, standardized nursing language, and evidence-based nursing.

SECTION II **Guide to Nursing Diagnosis, 17**

An alphabetized list of medical, surgical, and psychiatric diagnoses, diagnostic procedures, clinical states, symptoms, and problems, with suggested nursing diagnoses. This section enables the nursing student as well as the practicing nurse to make a nursing diagnosis quickly to save time.

SECTION III **Guide to Planning Care, 125**

Section III contains the actual nursing diagnosis care plans for each accepted nursing diagnosis of the North American Nursing Diagnosis Association—International (NANDA-I): the definition, defining characteristics, risk factors, related factors, suggested NOC outcomes, client outcomes, suggested NIC interventions, interventions with rationales, geriatric interventions, pediatric interventions, critical care interventions (when appropriate), home care interventions, culturally competent nursing interventions (when appropriate), and client/family teaching and discharge planning for each alphabetized nursing diagnosis.

SECTION

I Nursing Process, Clinical Reasoning, Nursing Diagnosis, and Evidence-Based Nursing

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS, and Marina Martinez-Kratz, MS, RN, CNE

Section I is divided into two parts. Part A includes an overview of the nursing process. This section provides information on how to make a nursing diagnosis and directions on how to plan nursing care. It also includes information on using clinical reasoning skills and eliciting the "patient's story." Part B includes advanced nursing concepts.

Part A: The Nursing Process: Using Clinical Reasoning Skills to Determine Nursing Diagnoses and Plan Care

1. **A**ssessing: performing a nursing assessment by gathering subjective and objective data.
2. **D**iagnosing: identifying and making nursing diagnoses.
3. **P**lanning: formulating and writing outcome statements and determining appropriate nursing interventions based on appropriate best evidence (e.g., research, practice guidelines, practice standards).
4. **I**mplementing: applying nursing care interventions to achieve client outcomes.
5. **E**valuating: appraising the outcomes and the nursing care that has been implemented. Make necessary revisions in care interventions as needed to achieve client-centered goals.

Part B: Advanced Nursing Process Concepts

- Concept mapping
- Evidence-based nursing care
- Person-centered care
- Quality and Safety Education for Nurses (QSEN)

PART A The Nursing Process: Using Clinical Reasoning Skills to Determine Nursing Diagnoses and Plan Care

The primary goals of nursing care are to (1) determine client/family responses to human problems, level of wellness, and need for assistance; (2) provide physical care, emotional care, teaching, guidance, and counseling; and (3) implement interventions aimed at prevention and assisting the client in meeting his or her own needs and health-related goals. The nurse must always focus on assisting clients and families to their highest level of functioning and self-care. The nursing care that is provided should be structured in a way that allows clients the ability to influence their health care and accomplish their self-efficacy goals.

The nursing process, which is a problem-solving approach to the identification and treatment of client problems, provides a framework for assisting clients and families to their optimal level of functioning. The nursing process involves five dynamic and fluid phases: **assessment, diagnosis, planning, implementation,** and **evaluation.** Clinical reasoning is inherent within the nursing process and is an iterative process by which the nurse makes clinical judgments to analyze and understand clients' concerns and form decisions to guide care (Tanner, 2006; Koharchik et al, 2015). It is a process by which the nurse gathers data, recognizes patterns in client responses, and synthesizes information to guide nursing care decisions. Although clinical reasoning skills evolve with experience, it is a logical process by which nurses gather cues (assessment and outcome data), process the information to understand the client's needs and goals (diagnosis), initiate a plan of care (planning and implementation), observe and evaluate outcomes (evaluation), and finally reflect on what was learned from this client–nurse interaction (Levett-Jones et al, 2010; Cappelletti et al, 2014). Clinical judgment is the prioritization of decisions based on the assessment data to guide nursing care (Thompson et al, 2013; Cappelletti et al, 2014). The nurse employs complex cognitive processes that require gathering and analyzing client data and understanding the significance of the information to determine interventions, weigh alternative actions, and adjust the plan of care as deemed necessary based on the nurse's clinical judgment (Cappelletti et al, 2014; Wright & Scardaville, 2021). Identifying priority nursing diagnoses can facilitate clinical judgment based on the understanding of client priorities for care and desired health outcomes.

Within each phase of the nursing process, the client and family story is embedded and is used as a foundation for knowledge, judgment, and actions brought to the client care experience. A description of the "patient's story" and each aspect of the nursing process follows.

THE "PATIENT'S STORY"

The "patient's story" is a term used to describe objective and subjective information about the client that describes who the client is as a person in addition to their medical history. Specific aspects of the story include physiological, psychological, family, and social characteristics; available resources; environmental context; knowledge; and motivation. Care is influenced, and often driven, by what the client states—verbally, nonverbally, and through their physiological state. The "patient's story" is fluid and must be explored and understood throughout the client's health care experience.

There are multiple sources for obtaining the "patient's story." The primary source for eliciting this story is through communicating directly with the client and the client's family. It is important to understand how the illness (or wellness) state has affected the client physiologically, psychologically, and spiritually. The client's perception of his or her health state is important to understand and may have an impact on subsequent interventions and the established goals for care. At times, clients will be unable to tell their story verbally, but there is still much they can communicate through their physical state. The client's family (as the client defines them) is a valuable source of information and can provide a rich perspective on the client. Other valuable sources of the "patient's story" include the client's health record. Every time a piece of information is added to the health record, it becomes a part of the "patient's story."

Understanding the "patient's story" is critically important, in that psychological, socioeconomic, and spiritual characteristics play a significant role in the client's ability and desire to access health care. Also, knowing and understanding the "patient's story" is an integral first step in giving person-centered care. In today's health care world, the focus is on the client, which leads to increased satisfaction with care. Improving the client's health care experience is tied to reimbursement through value-based purchasing of care to reward providers for the quality of care they provide (Centers for Medicare and Medicaid Services, 2019).

All nursing care is driven by the client's story. The nurse must have a clear understanding of the story to effectively complete the nursing process. Understanding the full story also provides an avenue for identifying mutual goals with the client and family aimed at improving client outcomes and goals. The "patient's story" is terminology that is used to describe a holistic assessment of information about the client, including the client's and the family's input as much as possible. In this text, we use the term "patient's story" in quotes whenever we refer to the specific process. In all other places, we use the term *client* in place of the word *patient*. The term *patient* aligns with the understanding of an individual awaiting medical care (Merriam-Webster, 2021). Use of the word *client,* on the other hand, represents engagement in service, which we believe is more respectful and empowering for the person. *Client* is also the term that is used in the National

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Council Licensure Examination (NCLEX-RN) test plan (National Council of State Boards of Nursing, 2019).

THE NURSING PROCESS

The nursing process is an organizing framework for professional nursing practice, which is a critical thinking process for the nurse to guide the delivery of the best care possible to the client. It is very similar to the steps used in scientific reasoning and problem solving. This section is designed to help the nursing student learn how to use this thinking process, or the nursing process. Key components of the process include the steps listed subsequently. An easy, convenient way to remember the steps of the nursing process is to use an acronym, **ADPIE** (Figure I.1):

1. **A**ssess: perform a nursing assessment.
2. **D**iagnose: make nursing diagnoses.
3. **P**lan: formulate and write outcome/goal statements and determine appropriate nursing interventions based on the client's reality and evidence (research).
4. **I**mplement care.
5. **E**valuate the outcomes and the nursing care that has been implemented. Make necessary revisions in care interventions as needed.

The next section is an overview and practical application of the steps of the nursing process. The steps are listed in the usual order in which they are performed.

STEP 1: ASSESSMENT (ADPIE)

The assessment phase of the nursing process is foundational for gathering data about the client. Nurses must understand the human responses to illness and health so that appropriate diagnosis, planning, and intervention(s) can be established. Assessment is dynamic and continuous so that nursing care can evolve to meet clients' changing needs. Data on all dimensions of the "patient's story," including biophysical, psychological, sociocultural, spiritual, and environmental characteristics, are embedded in the assessment, which involves performing a thorough holistic nursing assessment of the client. This is the first step needed to make an appropriate nursing diagnosis, and it is done using the assessment format adopted by the facility or educational institution in which the practice is situated.

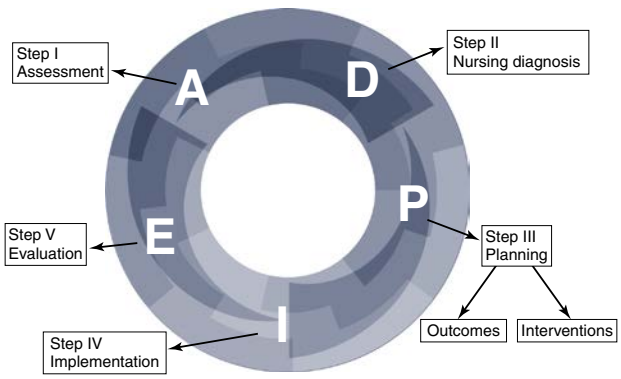

Figure I.1
Nursing process.

The nurse assesses components of the "patient's story" every time an assessment is performed. Often, nurses focus on the physical component of the story (e.g., temperature, blood pressure, breath sounds). This component is certainly critical, but it is only one piece. Indeed, one of the unique and wonderful aspects of nursing is the holistic theory that is applied to clients and families. Clients are active partners in the healing process. Nurses must increasingly develop the skills and systems to incorporate client preferences into care (Feo et al, 2017). Assessment information is obtained first by completing a thorough health and medical history and by listening to and observing the client. To elicit as much information as possible, the nurse should use open-ended questions rather than questions that can be answered with a simple "yes" or "no." The nurse should assess for the client's gender identity and gender expression, as well as preferred names and pronouns. Preferred names and pronouns should be respected when caring for the client. Most care plans are written for "traditional" gender identity; the caregiver will be responsible for adapting the care accordingly.

Asking open-ended questions during an assessment will encourage the client to give more information about his or her situation. Listen carefully for cues and record relevant information that the client shares. Even when the client's physical condition or developmental age makes it impossible to verbally communicate with the health care team, nurses may be able to communicate with the client's family or significant other to learn more about the client.

The information that is obtained verbally from the client is considered *subjective* information. Information is also obtained by performing a physical assessment, taking vital signs, and noting diagnostic test results. This information is considered *objective* information. The information from all of these sources is used to formulate a nursing diagnosis. All of this information needs to be carefully documented on the forms/electronic health record (EHR) provided by the agency or school of nursing. When recording information, Health Insurance Portability and Accountability Act (HIPAA) (Tovino, 2017) regulations need to be followed carefully. To protect client confidentiality, the client's name should *not* be used on the student care plan. When the assessment is complete, proceed to the next step.

STEP 2: NURSING DIAGNOSIS (ADPIE)

In the diagnosis phase of the nursing process, the nurse begins clustering the information within the "patient's story" and formulates an evaluative judgment about a client's health

status. Only after a thorough analysis—which includes recognizing cues, sorting through and organizing or clustering the information, and determining client strengths and unmet needs—can an appropriate diagnosis be made. This process of thinking is called *clinical reasoning*. Clinical reasoning is a cognitive process that uses formal and informal thinking strategies to gather and analyze client information, evaluate the significance of this information, and determine the value of alternative actions (Benner, 2010). Benner (2010) described this cognitive process as "thinking like a nurse." Watson and Rebair (2014) referred to "noticing" as a precursor to clinical reasoning. By noticing, the nurse can preempt possible risks or support subtle changes toward recovery. Noticing can be the activity that stimulates nursing action before words are exchanged, preempting need. The nurse synthesizes the evidence while also knowing the client as part of clinical reasoning that informs client-specific diagnoses (Cappelletti et al, 2014; Koharchik et al, 2015).

The nursing diagnoses that are used throughout this book are taken from NANDA International, Inc. (NANDA-I) (Herdman et al, 2020). The complete nursing diagnosis list is on the inside front cover of this text, and it can also be found on the Evolve website that accompanies this text. The diagnoses used throughout this text are listed in alphabetical order by the **diagnostic concept.** For example, *impaired wheelchair mobility* is found under *mobility,* not under *wheelchair* or *impaired* (Herdman et al, 2020). There are 13 domains for nursing diagnosis and these are listed below the nursing diagnosis along with the class.

The holistic assessment of the client helps determine the type of diagnosis that should be used to guide nursing interventions. For example, if during the assessment a client is noted to have unsteady gait and balance disturbance and states, "I'm concerned I will fall while walking down my stairs," but has not fallen previously, the client would be identified as having a "risk" nursing diagnosis. However, if a client states, "I am having increasing problems with leaking urine when I sneeze or cough," this is an actual problem for the client.

Once the diagnosis is determined, the next step is to determine defining characteristics and related factors. A client may have many nursing and medical diagnoses, and determining the priority with which each should be addressed requires clinical reasoning and application of knowledge.

Formulating a Nursing Diagnosis With Defining Characteristics and Related Factors

A working nursing diagnosis may have two or three parts. The two-part system consists of the nursing diagnosis and the "related to" (r/t) statement: "Related factors are etiologies, circumstances, facts, or influences that have some type of relationship with the nursing diagnosis (e.g., cause, contributed factor)" (Herdman et al, 2020). The two-part system is often used when the defining characteristics, or signs and symptoms identified in the assessment, may be obvious to those caring for the client.

The three-part system consists of the nursing diagnosis, the r/t statement, and the defining characteristics, which are "observable cues/inferences that cluster as manifestations of an actual or wellness nursing diagnosis" (Herdman et al, 2020).

Some nurses refer to the three-part diagnostic statement as the **PES system:**

P (problem)—The nursing diagnosis label: a concise term or phrase that represents a pattern of related cues. The nursing diagnosis is taken from the official NANDA-I list.
E (etiology)—"Related to" (r/t) phrase or etiology: related cause or contributor to the problem.
S (symptoms)—Defining characteristics phrase: symptoms that the nurse identified in the assessment.

Here we use the example of a beginning nursing student who is attempting to understand the nursing process and how to make a nursing diagnosis:

Problem: Use the nursing diagnosis label deficient **Knowledge** from the NANDA-I list. Remember to check the definition: "Absence or deficiency of cognitive information related to a specific topic" (Herdman et al, 2020).
Etiology: r/t unfamiliarity with information about the nursing process and nursing diagnosis. At this point, the beginning nurse would not be familiar with available resources regarding the nursing process.
Symptoms: Defining characteristics, as evidenced by (aeb) verbalization of lack of understanding: "I don't understand this, and I really don't know how to make a nursing diagnosis."

When using the **PES** system, look at the **S** first and then formulate the three-part statement. (You would have gotten the **S,** symptoms, which are defining characteristics, from your assessment.)

Therefore, the three-part nursing diagnosis is: Deficient **Knowledge** r/t unfamiliarity with information about the nursing process and nursing diagnosis aeb verbalization of lack of understanding.

Types of Nursing Diagnoses

There are three different types of nursing diagnoses.

Problem-Focused Diagnosis. "A clinical judgment concerning an undesirable human response to a health condition/life process that exists in an individual, family, group or community" (Herdman et al, 2020, p 98). Defining characteristics are observable cues/inferences that cluster as manifestations of a diagnosis (e.g., signs or symptoms) (Herdman et al, 2020, p 103). "Related factors are an integral component of all problem-focused diagnoses. Related factors, also called etiological factors are antecedent factors shown to have a patterned relationship with the human response (e.g., cause, contributing factor)" (Herdman et al, 2020, p 103).

Example of a Problem-Focused Nursing Diagnosis. **Overweight** related to excessive intake in relation to metabolic

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

needs, concentrating food intake at the end of the day aeb weight 25% over ideal for height and frame. Note: This is a three-part nursing diagnosis.

Risk Diagnosis. Risk nursing diagnosis is a "clinical judgment concerning the susceptibility of an individual, caregiver, family, group, or community for developing an undesirable human response to health conditions/life processes" (Herdman et al, 2020, p 98). "Risk factors are antecedent factors that increase the susceptibility of an individual, caregiver, family, group, or community to an undesirable human response (e.g. environmental, psychological)" (Herdman et al, 2020, p 103).

Example of a Risk Nursing Diagnosis. Risk for **Overweight:** Risk factor: abnormal eating behavior pattern, concentrating food at the end of the day. Note: This is a two-part nursing diagnosis.

Health Promotion Nursing Diagnosis. A clinical judgment concerning motivation and desire to increase well-being and to actualize health potential. These responses are expressed by a readiness to enhance specific health behaviors and can be used in any health state. Health promotion responses may exist in an individual, caregiver, family, group, or community (Herdman et al, 2020). Health promotion is different from prevention in that health promotion focuses on being as healthy as possible, as opposed to preventing a disease or problem. The difference between health promotion and disease prevention is that the reason for the health behavior should always be a positive one. *With a health promotion diagnosis, the outcomes and interventions should be focused on enhancing health.*

Example of a Health Promotion Nursing Diagnosis. Readiness for Enhanced **Nutrition** aeb willingness to change eating pattern and eat healthier foods. Note: This is a two-part nursing diagnosis.

Application and Examples of Making a Nursing Diagnosis

When the assessment is complete, identify common patterns/symptoms of response *to actual or potential health problems from the assessment* and select an appropriate nursing diagnosis label using clinical reasoning skills. Use the steps with Case Study 1. (The same steps can be followed using an actual client assessment in the clinical setting or in a student assessment.)

A. Highlight or underline the relevant symptoms (defining characteristics). As you review your assessment information, ask the following questions: Is this normal? Is this an ideal situation? Is this a problem for the client? You may go back and validate information with the client.
B. Make a list of the symptoms (underlined or highlighted information).
C. Cluster similar symptoms.
D. Analyze/interpret the symptoms. (What do these symptoms mean or represent when they are together?)
E. Select a nursing diagnosis label from the NANDA-I list that fits the appropriate defining characteristics and nursing diagnosis definition.

Case Study 1—Older Client with Breathing Problems

A. Underline the Symptoms (Defining Characteristics)

A 73-year-old man has been admitted to the unit with a diagnosis of chronic obstructive pulmonary disease (COPD). He states that he has "difficulty breathing when walking short distances." He also states that his "heart feels like it is racing" (heart rate is 110 beats per minute) at the same time. He states that he is "tired all the time," and while talking to you about his story, he is continually wringing his hands and looking out the window.

B. List the Symptoms (Subjective and Objective)

"Difficulty breathing when walking short distances"; "heart feels like it is racing"; heart rate is 110 beats per minute; "tired all the time"; continually wringing his hands and looking out the window.

C. Cluster Similar Symptoms

"Difficulty breathing when walking short distances"
"Heart feels like it is racing"; heart rate = 110 beats per minute
"Tired all the time"
Continually wringing his hands
Looking out the window

D. Analyze

Interpret the Subjective Symptoms (What the Client Has Stated)

"Difficulty breathing when walking short distances" = exertional discomfort: a defining characteristic of Decreased **Activity** Tolerance
"Heart feels like it is racing" = abnormal heart rate response to activity: a defining characteristic of Decreased **Activity** Tolerance
"Tired all the time" = verbal report of weakness: a defining characteristic of Decreased **Activity** Tolerance

Interpret the Objective Symptoms (Observable Information)

Continually wringing his hands = extraneous movement, hand/arm movements: a defining characteristic of **Anxiety**
Looking out the window = poor eye contact, glancing about: a defining characteristic of **Anxiety**
Heart rate = 110 beats per minute

E. Select the Nursing Diagnosis Label

In Section II look up *dyspnea (difficulty breathing)* or *dysrhythmia (abnormal heart rate or rhythm),* which are chosen because they are high priority, and you will find the nursing diagnosis Decreased **Activity** Tolerance listed with these symptoms. Is this diagnosis appropriate for this client?

To validate that the diagnosis Decreased **Activity** Tolerance is appropriate for the client, turn to Section III and read the NANDA-I definition of the nursing diagnosis Decreased **Activity** Tolerance: "Insufficient endurance to complete

required or desired daily activities" (Herdman et al, 2020, p 307). When reading the definition, ask, "Does this definition describe the symptoms demonstrated by the client?" "Is any more assessment information needed?" "Should I take his blood pressure or take an apical pulse rate?" If the appropriate nursing diagnosis has been selected, the definition should describe the condition that has been observed.

The client may also have defining characteristics for this particular diagnosis. Are the client's symptoms that you identified in the list of defining characteristics (e.g., verbal report of fatigue, abnormal heart rate response to activity, exertional dyspnea)?

Another way to use this text and to help validate the diagnosis is to look up the client's medical diagnosis in Section II. This client has a medical diagnosis of COPD. Is Decreased **Activity** Tolerance listed with this medical diagnosis? Consider whether the nursing diagnosis makes sense given the client's medical diagnosis (in this case, COPD). There may be times when a nursing diagnosis is not directly linked to a medical diagnosis (e.g., Ineffective **Coping**) but is nevertheless appropriate given nursing's holistic approach to the client/family.

The process of identifying significant symptoms, clustering or grouping them into logical patterns, and then choosing an appropriate nursing diagnosis involves diagnostic reasoning (critical thinking) skills that must be learned in the process of becoming a nurse. This text serves as a tool to help the learner in this process.

"Related to" Phrase or Etiology

The second part of the nursing diagnosis is the "related to" (r/t) phrase. Related factors (etiological factors) are those that appear to show some type of patterned relationship with the human response that supports the nursing diagnosis. Such factors may be described as antecedent to, associated with, related to, contributing to, or abetting. Pathophysiological and psychosocial changes, such as developmental age and cultural and environmental situations, may be causative or contributing factors.

Often, a nursing diagnosis is complementary to a medical diagnosis and vice versa. Ideally, the etiology (r/t statement), or cause, of the nursing diagnosis is something that can be treated independently by a nurse. When this is the case, the diagnosis is identified as an independent nursing diagnosis.

If medical intervention is also necessary, it might be identified as a collaborative nursing diagnosis. A carefully written, individualized r/t statement enables the nurse to plan nursing interventions and refer for diagnostic procedures, medical treatments, pharmaceutical interventions, and other interventions that will assist the client/family in accomplishing goals and return to a state of optimum health. Diagnoses and treatments provided by the multiprofessional team all contribute to the client/family outcome. The coordinated effort of the team can only improve outcomes for the client/family and decrease duplication of effort and frustration among the health care team and the client/family.

The etiology is *not* the medical diagnosis. It may be the underlying issue contributing to the nursing diagnosis, but a medical diagnosis is *not* something the nurse can treat independently, without provider orders. In the case of the client with COPD, think about what happens when someone has COPD. How does this condition affect the client? What is happening to him because of this diagnosis?

For each suggested nursing diagnosis, the nurse should refer to the statements listed under the heading Related Factors (r/t) in Section III. These r/t factors may or may not be appropriate for the individual client. If they are not appropriate, the nurse should develop and write an r/t statement that is appropriate for the client. For the client from Case Study 1, a two-part statement could be made here:

Problem = Decreased **Activity** Tolerance
Etiology = r/t imbalance between oxygen supply and demand

It was already determined that the client had Decreased **Activity** Tolerance. With the respiratory symptoms identified from the assessment, the imbalance between oxygen supply and demand is appropriate.

Defining Characteristics Phrase

The defining characteristics phrase is the third part of the three-part diagnostic system, and it consists of the signs and symptoms that have been gathered during the assessment phase. The phrase "as evidenced by" (aeb) may be used to connect the etiology (r/t) with the defining characteristics. The use of identifying defining characteristics is similar to the process that the health care provider uses when making a medical diagnosis. For example, the health care provider who observes the following signs and symptoms—diminished inspiratory and expiratory capacity of the lungs, complaints of dyspnea on exertion, difficulty in inhaling and exhaling deeply, and sometimes chronic cough—may make the medical diagnosis of COPD. This same process is used to identify the nursing diagnosis of Decreased **Activity** Tolerance.

Put It All Together: Writing the Three-Part Nursing Diagnosis Statement

Problem—Choose the label (nursing diagnosis) using the guidelines explained previously. A list of nursing diagnosis labels can be found in Section II.

Etiology—Write an r/t phrase (etiology). These can be found in Section II.

Symptoms—Write the defining characteristics (signs and symptoms) or the "as evidenced by" (aeb) list. A list of the signs and symptoms associated with each nursing diagnosis can be found in Section III.

Case Study 1—73-Year-Old Male Client With Chronic Obstructive Pulmonary Disease (Continued)

Using the information from the earlier case study/example, the nursing diagnostic statement would be as follows:

Problem—Decreased **Activity** Tolerance.
Etiology—r/t imbalance between oxygen supply and demand.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Symptoms—Verbal reports of fatigue, exertional dyspnea ("difficulty breathing when walking"), and abnormal heart rate response to activity ("racing heart"); heart rate 110 beats per minute.

Therefore, the nursing diagnostic statement for the client with COPD is Decreased **Activity** Tolerance r/t imbalance between oxygen supply and demand aeb verbal reports of fatigue, exertional dyspnea, and abnormal heart rate in response to activity.

Consider a second case study:

Case Study 2—Woman with Insomnia

As before, the nurse always begins with an assessment. To make the nursing diagnosis, the nurse follows the steps below.

A. Underline the Symptoms

A 45-year-old woman comes to the clinic and asks for medication to help her sleep. She states that she is worrying too much and adds, "It takes me about an hour to get to sleep, and it is very hard to fall asleep. I feel like I can't do anything because I am so tired. My job has become very stressful because of a new boss and too much work."

B. List the Symptoms (Subjective and Objective)

Asks for medication to help her sleep; states she is worrying about too much; "It takes me about an hour to get to sleep"; "it is very hard to fall asleep"; "I feel like I can't do anything because I am so tired"; "My job has become very stressful because of a new boss and too much work."

C. Cluster Similar Symptoms

Asks for medication to help her sleep.
"It takes me about an hour to get to sleep."
"It is very hard to fall asleep."
"I feel like I can't do anything because I am so tired."
"I am worrying too much."
"My job is stressful."
"Too much work."

D. Analyze/Interpret the Symptoms

Subjective Symptoms

Asks for medication to help her sleep; "It takes me about an hour to get to sleep"; "it is very hard to fall asleep"; "I feel like I can't do anything because I am so tired." (All defining characteristics = verbal complaints of difficulty with sleeping.)
States she is worrying too much (anxiety): "My job is stressful."

Objective Symptoms

None

E. Select a Nursing Diagnosis with Related Factors and Defining Characteristics

Look up "sleep" in Section II. Listed under the heading "Disturbed **Sleep** Pattern" in Section II is the following information:

Insomnia (nursing diagnosis) r/t anxiety and stressors

This client states she is worrying too much, which may indicate anxiety; she also recently has increased job stress.

Look up **Insomnia** in Section III. Check the definition: "Inability to initiate or maintain sleep, which impairs functioning" (Herdman et al, 2020, p 301). Does this describe the client in the case study? What are the related factors? What are the symptoms? Write the diagnostic statement:

Problem—**Insomnia**
Etiology—r/t anxiety, stressors
Symptoms—Difficulty falling asleep; "I am so tired, I can't do anything."

The nursing diagnostic statement is written in this format: **Insomnia** r/t anxiety and stressors aeb difficulty falling asleep.

Note: There are additional case studies available for both student and faculty use on the Evolve website that accompanies this text.

After the diagnostic statement is written, proceed to the next step: planning.

STEP 3: PLANNING (ADPIE)

The planning phase of the nursing process includes the identification of priorities and the determination of appropriate client-specific outcomes and interventions. The nurse, in collaboration with the client and family (as applicable) and the rest of the health care team, must determine the urgency of the identified problems and prioritize client needs. *Mutual goal setting,* along with *symptom pattern recognition* and *triggers,* helps prioritize interventions and determine which interventions are going to provide the greatest impact. *Symptom pattern recognition* and/or *triggers* is a process of identifying symptoms that clients have related to their illness, understanding which symptom patterns require intervention, and identifying the associated time frame to intervene effectively. For example, a client with heart failure is noted to gain 5 pounds overnight. Coupling this symptom with other symptoms of edema and shortness of breath while walking can be referred to as "symptom pattern recognition"; in this case, that the client is retaining fluid. The nurse, and often the client/family, recognize these symptoms as an immediate *cause* and that more action/intervention is needed to avoid a potential adverse outcome.

Nursing diagnoses should be prioritized based on urgent needs, diagnoses with a high level of congruence with defining characteristics, related factors, or risk factors (Herdman et al, 2020, p 105). The use of ABC (airway, breathing, and circulation) and safety is a method to rank threats to the client's immediate survival or safety. The highest priority can also be determined by using Maslow's hierarchy of needs. In this hierarchy, priority is given to immediate problems that may be life-threatening (thus ABC). For example, Ineffective **Airway** Clearance, aeb the symptoms of increased secretions and increased use of inhaler related to asthma, creates an immediate cause compared with the nursing diagnosis of **Anxiety,** a love and belonging or security need, which makes

it a lesser priority than Ineffective **Airway** Clearance. Refer to Appendix A on Evolve for assistance in prioritizing nursing diagnoses.

The planning phase should be done, whenever possible, with the client/family and the multidisciplinary team to maximize efforts and understanding and increase compliance with the proposed plan and outcomes. For a successful plan of care, measurable goals and outcomes, including nursing interventions, must be identified.

SMART Outcomes

When writing outcome statements, it can be helpful to use the acronym SMART, which means the outcome must be:

Specific
Measurable
Attainable
Realistic
Timed

The SMART acronym is used in business, education, and health care settings. This method assists the nurse in identifying client outcomes more effectively.

Once priorities are established, outcomes for the client can be easily identified. Client-specific outcomes are determined based on the mutually set goals. Outcomes refer to the measurable degree of the client's response. The client's response/outcome may be intentional and favorable, such as leaving the hospital 2 days after surgery without any complications. The client's outcome can be negative and unintentional, such as demonstrating a surgical site infection. Generally, outcomes are described in relation to the client's response to interventions; for example, the client's cough becomes more productive after the client begins using the controlled coughing technique.

Based on the "patient's story"; the nursing assessment; the mutual goals and outcomes identified by the caregiving team and the client, caregiver, and family; and the clinical reasoning that the nurse uses to prioritize his or her work, the nurse then decides what interventions to use. Based on the nurse's clinical judgment and knowledge, nursing interventions are defined as *all treatments that a nurse performs to enhance client outcomes*.

The selection of appropriate, effective interventions can be individualized to meet the mutual goals established by the client/family. It is then the nurses' education, experiences, and skills that allow them to select and carry out interventions to meet that mutual goal.

Outcomes

After the appropriate priority setting of the nursing diagnoses and interventions are determined, outcomes are developed and decided on. This text includes standardized Nursing Outcomes Classification (NOC) measurement of health outcomes written by a large team of University of Iowa College of Nursing faculty and students in conjunction with clinicians from a variety of settings (Moorhead et al, 2018). NOC was developed to be used with nursing diagnosis and provides a standard language by which nurse-sensitive outcomes can be measured along a continuum in response to a nursing intervention or interventions. The outcomes are stated as concepts that reflect a client, caregiver, family, or community state, as a perception of behavior rather than as expected goals (Moorhead et al, 2018).

It is very important for the nurse to *involve* the client and/or family in determining appropriate outcomes. The use of outcomes information creates a continuous feedback loop that is essential to improve nursing quality, ensure client safety, and secure the best possible client outcomes (Sim et al, 2018). The minimum requirements for rating an outcome are when the outcome is selected (i.e., the baseline measure) and when care is completed (i.e., the discharge summary). Depending on how rapidly the client's condition is expected to change, some settings (e.g., acute care hospitals, rehabilitation centers, community care settings) may evaluate once a week, once a day, or once a shift. A five-point Likert-type scale is used with all outcomes and indications used to evaluate progress toward achieving the outcome; however, because measurement times are not standardized, they can be individualized for the client and the setting (Moorhead et al, 2018).

Development of appropriate outcomes can be completed one of two ways: using the NOC list or developing an appropriate outcome statement, both of which are included in Section III with each nursing diagnosis. The suggested outcome statements for each nursing diagnosis in this text can be used as written or modified as necessary to meet the needs of the client. The Evolve website includes a list of additional NOC outcomes. For more information about NOC, refer to the NOC text (Moorhead et al, 2018).

Because the NOC outcomes are specific, they enhance nursing professional practice by helping the nurse measure and record the nurse sensitive outcomes before and after interventions have been performed. The nurse can also choose to have clients rate their own progress using the Likert-type rating scale. This involvement can help increase client motivation to progress *toward* outcomes.

After client outcomes are selected or written and *discussed* with a client, the nurse plans nursing care with the client and establishes a means that will help the client achieve the selected outcomes. The usual means are through nursing interventions.

Interventions

Interventions are like road maps directing the best ways to provide nursing care. The more clearly a nurse writes an intervention, the easier it will be to complete the journey and arrive at the destination of desired client outcomes. Nursing interventions are treatments based on clinical judgment and knowledge, supported by evidence, that a nurse performs to enhance client outcomes (Butcher et al, 2018). Section

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

III includes suggested interventions and rationales for each nursing diagnosis. The interventions are identified as independent (autonomous actions that are initiated by the nurse in response to a nursing diagnosis) or collaborative (actions that the nurse performs in collaboration with other health care professionals and that may require a health care provider's order and may be in response to both medical and nursing diagnoses). The nurse may choose the interventions appropriate for the client and individualize them accordingly or determine additional interventions.

This text also contains several suggested interventions from the Nursing Interventions Classification (NIC), which is a comprehensive standardized classification of interventions that nurses perform (Butcher et al, 2018). NIC is used along with NOC and nursing diagnoses as client-specific care plans are developed. NIC includes both physiological and psychosocial interventions and covers all nursing specialties. A list of NIC interventions is included on the Evolve website. For more information about NIC interventions, refer to the NIC text (Butcher et al, 2018).

Putting It All Together—Recording the Care Plan

The nurse must document the actual care plan, including prioritized nursing diagnostic statements, outcomes, and interventions. This may be done electronically or in writing. To ensure continuity of care, the plan must be documented and shared with all health care personnel caring for the client. This text provides rationales, most of which are research based, to validate that the interventions are appropriate and workable.

The Evolve website includes an electronic care plan constructor that can be easily accessed, updated, and individualized. Many agencies are using electronic records, and this is an ideal resource. See the inside front cover of this text for information regarding access to the Evolve website, or go to http://evolve.elsevier.com/Ackley/NDH.

STEP 4: IMPLEMENTATION (ADPIE)

The implementation phase includes the "carrying out" of the specific, individualized, jointly agreed-on interventions in the plan of care. Often, the interventions implemented are focused on *symptom management,* which is alleviating symptoms. Typically, nursing care does not involve "curing" the medical condition causing the symptom; rather, nursing care focuses on caring for the client, caregiver, and family so that they can function at their highest level.

The implementation phase of the nursing process is the point at which you actually give nursing care. You perform the interventions that have been individualized to the client. All the hard work you put into the previous steps (ADP) can now be actualized to assist the client. As the interventions are performed, make sure that they are appropriate for the client. Consider that the client who was having difficulty breathing was also older. He may need extra time to carry out any activity. Check the rationale and research that are provided to determine why the intervention is being used. The evidence should support the individualized actions that you are implementing.

Client outcomes are achieved by the performance of the nursing interventions in collaboration with other disciplines and the client, caregiver, or family. During this phase, the nurse continues to assess the client to determine whether the interventions are effective and the desired outcomes are met.

STEP 5: EVALUATION (ADPIE)

The final phase of the nursing process is evaluation. This step occurs not only at the end of the nursing process but also throughout the process. Evaluation of an intervention is, in essence, another nursing assessment; hence, the dynamic feature of the nursing process. The nurse reassesses the client, taking into consideration where the client was before the intervention (i.e., baseline) and where the client is after the intervention. Nurses are also in a great place (at the bedside) to evaluate how clients respond to other, multiprofessional interventions, and their assessment of the client's response is valuable to determine whether the client's plan of care needs to be altered or not. For example, the client may receive 2 mg of morphine intravenously for pain (a pharmaceutical intervention to treat pain), and the nurse is the member of the health care team who can best assess how the client responded to that medication. Did the client receive relief from pain? Did the client develop any side effects? The nurse's documented evaluation of the client's response will be very helpful to the entire health care team.

The client/family can often tell the nurse how the intervention helped or did not help. This reassessment requires the nurse to revisit the mutual outcomes and goals set earlier and ask, "Are we moving toward that goal, or does the goal seem unreachable after the intervention?" If the outcomes were not met, the nurse begins again with assessment and determines the reason they were not met. Consider the SMART acronym and Case Study 1. Were the outcomes **S**pecific? Were the outcomes **M**easurable? Did the client's heart rate decrease? Did the client indicate that it was easier to breathe when walking from his bed to the bathroom? Were the outcomes **A**ttainable and **R**ealistic? Did he still report "being tired"? Did you allow adequate **T**ime for a positive outcome? Also ask yourself whether you identified the correct nursing diagnosis. Should the interventions be changed? At this point, the nurse can look up any new symptoms or conditions that have been identified and adjust the care plan as needed. Decisions about implementing additional interventions may be necessary; if so, they should be made in collaboration with the client, caregiver, and family, if possible. In some instances, the client/caregiver-family/nurse triad will establish new, achievable goals and continue to cycle through the nursing process until the mutual goals are achieved.

Another important part of the evaluation phase is documentation. The nurse should use the facility's tool for

documentation and record the nursing activity that was performed, as well as the results of the nursing interventions. Many facilities use problem-oriented charting, in which the nurse evaluates the care and client outcomes as part of charting. Documentation is also necessary for legal reasons, because in a legal dispute, *if it wasn't charted or recorded, it wasn't done*.

Many health care providers use critical pathways or care maps to plan nursing care. The use of nursing diagnoses should be an integral part of any critical pathway/care map to ensure that nursing care needs are being assessed and appropriate nursing interventions are planned and implemented.

PART B Advanced Nursing Process Concepts

Conceptual Mapping and the Nursing Process

Conceptual mapping is an active learning strategy that promotes critical thinking and clinical judgment by providing a schematic representation of concepts and meaning within a framework that helps increase clinical understanding and competency (George et al, 2014; Daley et al, 2016; Kaddoura et al, 2016). Nurses identify complex client problems that require critical thinking to identify priority interventions based on current best evidence to affect client outcomes (Kaddoura et al, 2016). Concept mapping facilitates critical thinking and encourages a deeper understanding of the complexity of concepts that influence nursing practice interventions (George et al, 2014; Daley et al, 2016). The process involves developing a diagram or pictorial representation of newly generated ideas. A concept map begins with a central theme or concept, and then related information is diagrammed radiating from the central theme. A concept map can be used to diagram the critical thinking strategy involved in applying the nursing process in practice.

Start with a blank sheet of paper; the client should be at the center of the paper. The next step involves linking to the person, via lines, the symptoms (defining characteristics, related factors, and risk factors) from the assessment to help determine the appropriate nursing diagnosis.

Figure I.2 is an example of how a concept map can be used to begin the nursing diagnostic process.

After the symptoms are visualized, similar ones can be put together to formulate a nursing diagnosis using another concept map (Figure I.3).

The central theme in this concept map is the nursing diagnosis: Decreased **Activity** Tolerance, with the defining characteristics/client symptoms as concepts that lead to and support the nursing diagnosis. The conceptual map can then be used as a method for determining outcomes and interventions as desired. The nursing process is a thinking process. Using conceptual mapping is a method to help the nurse or nursing student think more effectively about the client.

Quality and Safety Education for Nurses

The Quality and Safety Education for Nurses (QSEN; https://qsen.org/) project represents the nursing profession's response to the five health care competencies articulated by the Institute of Medicine (now called the National Academy of Medicine) (Institute of Medicine, 2003). These competencies were adopted by nursing leaders to guide nursing education to better meet the evolving needs of clients and the health care system (Cronenwett et al, 2007). The QSEN project defined the six competencies for nursing: person-centered care, teamwork and collaboration, evidence-based practice (EBP), quality improvement, safety, and informatics (Cronenwett et al, 2007). The objective of the QSEN project is to provide nurses with the knowledge, skills, and attitudes critical for improving the quality and safety of health care systems. Initially, QSEN was developed to enhance nursing education, but it has since been incorporated into practice settings (Lyle-Edrosolo & Waxman, 2016). Additionally, the core elements of the QSEN map to key practice initiatives identified by The Joint Commission (TJC) and the American Nurses Credentialing Center Magnet (Magnet) recognition program (The Joint Commission, 2021). A crosswalk of the similarities of the QSEN competencies to TJC and Magnet demonstrates the alignment of the QSEN competencies to guide nursing practice excellence to improve the quality and safety of health care (Lyle-Edrosolo & Waxman, 2016; QSEN, 2020). The following are the competencies that were identified.

Person-Centered Care

Person-centered care is the ability to "recognize the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect

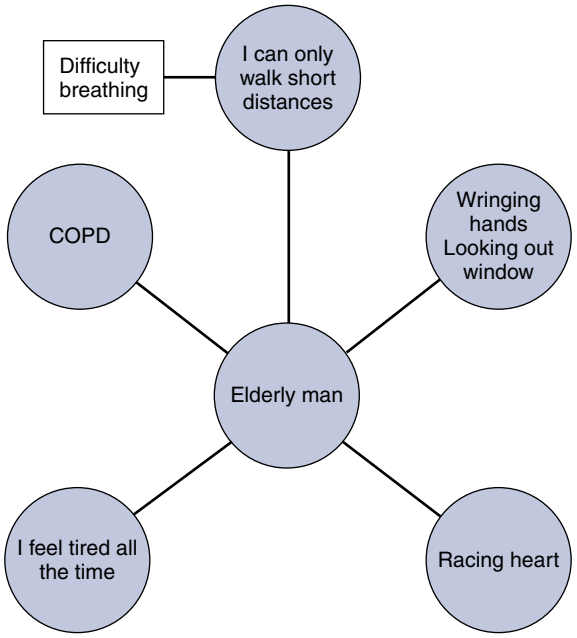

Figure I.2
Example of a concept map.

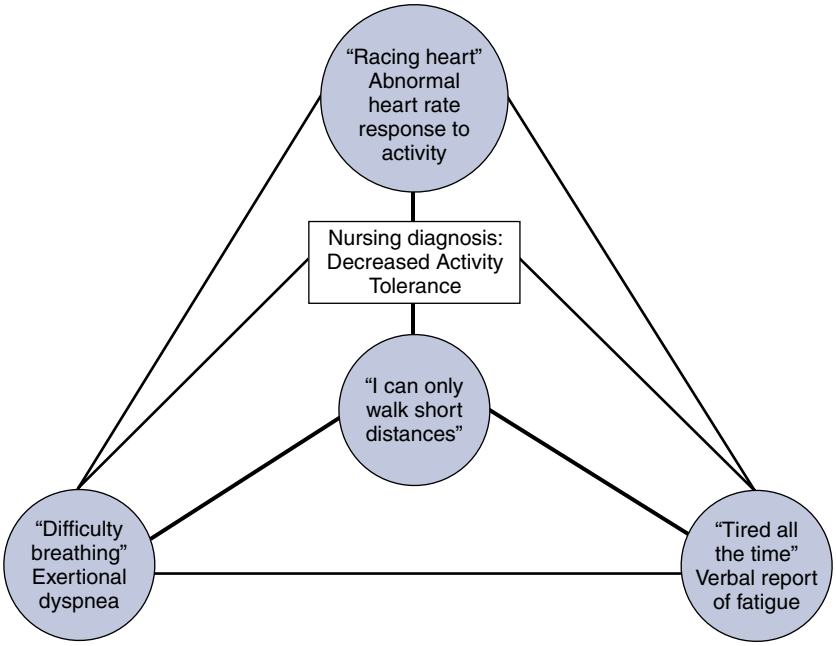

Figure I.3
Formulating a nursing diagnosis using a concept map.

for patient's preferences, values, and needs" (QSEN, 2020). Person-centered care begins with the nurse learning as much as possible about the client, including their "patient's story," as explained in Part A of this text. The nursing process, using nursing diagnosis, is intrinsically all about person-centered care when the nurse engages the client/family as a full partner in the entire process: assessment, nursing diagnosis selection, outcomes, interventions, and evaluation. This competency is about providing care in partnership with the client and family. The client, family, nurse, health care provider, and other health care workers form a team to collaborate with the client and family in every way possible to achieve health.

Client education needs to be centered on the needs of the client, addressing behavior-changing techniques to accomplish the defined goals. At present, too often new health information is given to clients in the form of a lecture, handout, admonishment, or direction where the client is powerless. Conversations need to occur between the client and nurse to understand behavioral changes that can be implemented to achieve goals. Motivational interviewing is a technique based on reinforcement of the client's present thoughts and motivations on behavior change and based on respect for the client as an individual (Moradi et al, 2016). This technique has been used for almost 30 years and has an extensive research base showing effectiveness by engaging in conversations to empower clients to identify strategies and tools to achieve health care goals. To learn more about motivational interviewing, refer to Appendix C on Evolve.

Addressing the unique cultural needs of clients is another example of person-centered care. Culturally competent care planning is based on cultural awareness and assessments, which enables integration of client values, beliefs, and preferences linked to culture(s). Cultural awareness encompasses the nurse's assessment of personal knowledge, sensitivity, humility, and organizational support to deliver culturally focused care (Sharifi et al, 2019). This text provides the addition of multicultural interventions that reflect the client's cultural preferences, values, and needs.

Person-centered care can help nurses change attitudes toward clients, especially when caring for older clients (Flagg, 2015). Caring for the retired school teacher who raised four children can be different from just caring for the client woman in Room 234 who has her call light on frequently and is incontinent of urine at too-frequent intervals. Including the client and family in the bedside report and care decisions is key to client satisfaction and enhances the overall quality of care (Flagg, 2015).

Teamwork and Collaboration

Teamwork and collaboration are defined as the ability to "function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision-making to achieve quality client care" (QSEN, 2020). Multiprofessional collaboration and practice has the ability to embrace care interventions that improve quality and safety initiatives across clients' lifespans and all health care settings (Stalter et al, 2017). The need for collaboration by health care professionals is a reality of contemporary health care practice and is identified within each nursing diagnosis in this text. Many nursing interventions are referrals to other health care

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

personnel to best meet the client's needs; thus collaborative interventions are designated with a triangular symbol ▲.

Evidence-Based Practice

QSEN defines evidence-based practice (EBP) as the integration of best current evidence with clinical expertise and client, caregiver, and family preferences and values for delivery of optimal health care (QSEN, 2020). It is well established that EBP results in higher quality care for clients than care that is based on traditional nursing knowledge (Buccheri & Sharifi, 2017; Makic & Granger, 2019). It is imperative that each nurse and nursing student develop clinical inquiry skills, which means the nurse continually questions whether care is being given in the best way possible based on a review of the quality and strength of the evidence (Buccheri & Sharifi, 2017). Basing nursing practice on evidence, inclusive of research and other forms of evidence, is a concept that is incorporated throughout this text. EBP is a systematic process that uses current evidence in making decisions about the care of clients, including evaluation of quality and applicability of existing research, client preferences, clinical expertise, and available health care resources (Melnyk & Fineout-Overholt, 2019). To determine the best way of giving care, the use of EBP is needed. To make this happen, nurses need to access the evidence, critically appraise the evidence, and then apply the evidence in practice (Makic & Granger, 2019).

This text includes evidence-based rationales whenever possible. An effort is made to provide research-based rationales. The evidence ranges along a continuum from a case study about a single client to a systematic review performed by experts to quality improvement reports that provide information to guide nursing care. Every attempt has been made to supply the most current evidence for the nursing interventions. In Section III, the abbreviation **EBN** is used when interventions have a scientific rationale supported by nursing research. The abbreviation **EB** is used when interventions have a scientific rationale supported by research that has been obtained from disciplines other than nursing. **CEB** is used as a heading for classic research that has not been replicated or is older. It may be either nursing research or research from other disciplines. Many times the **CEB**-labeled research will be the seminal studies that were conducted addressing client concern or nursing care intervention.

When using **EBP,** it is vitally important that the client's concerns and individual situations be taken into consideration. The nurse must always use critical thinking when applying evidence-based guidelines to any particular nursing situation. Each client is unique in his or her needs and capabilities. To improve outcomes, clinicians and clients should collaborate to formulate a treatment plan that incorporates both evidence-based data and client preferences within the context of each client's specific clinical situation (Mackey & Bassendowski, 2017). This text integrates current best evidence and the nursing process, and it assists the nurse in increasing the use of evidence-based interventions in the clinical setting.

Quality Improvement

Quality improvement has been used for many years, with processes in place to ensure that the client receives appropriate care. The QSEN quality improvement competency is defined as the ability of the nurse to use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems (QSEN, 2020). QSEN resources supporting quality improvement initiatives are available at the QSEN website (http://qsen.org/competencies/quality-improvement-resources-2/). As with EBP, quality improvement initiatives need to critically examine research and other forms of strong evidence in supporting process changes. Research is the basis on which best practices should be supported (Makic, 2020). Research and other forms of evidence, such as quality improvement studies, provide a growing body of evidence to guide practice.

It is essential for nurses to participate in the work of quality and performance improvement to attain and sustain excellence in nursing care. As nurses are educated about performance and quality measures, they are more likely to value these activities and make quality improvement part of their nursing practice (Trent et al, 2017). Although there is a potential overlap of work in quality departments and EBP/research departments, the hope is that quality departments collaborate closely with EBP/research departments to improve the practice of nursing. Best evidence should be used to guide nursing practice interventions, and quality improvement critically evaluates and enhances the process of care to ensure effective delivery of high-quality, evidence-based care to clients.

Safety

Safety is defined as minimizing risk of harm to clients and providers through both system effectiveness and individual performance (QSEN, 2020). Client safety is a priority when health care is delivered. Nurses are required to adhere to established standards of care as a guideline for providing safe client care. Internal organizational policies and procedures established by health care institutions should be based on the most relevant and current evidence to guide safe practice standards. External standards of care are established by regulatory agencies (e.g., TJC), professional organizations (e.g., the American Nurses Association), and health care organizations. QSEN competencies align well with external agencies guiding safe practice expectations (Lyle-Edrosolo & Waxman, 2016).

Client safety was identified as a priority of care by TJC through the launch of the National Patient Safety Goals in 2002. TJC continually reviews and establishes standards for improving client safety that include the need for increased handwashing, better client identification before receiving medications or treatments, and protection of suicidal clients from self-harm. Many of the safety standards have been incorporated into the care plans in this text.

Informatics

QSEN defines informatics as the nurse's ability to use information and technology to communicate, manage knowledge,

mitigate error, and support decision-making (QSEN, 2020). The use of information technology is a critical part of the nurse's professional role, and every nurse must be computer literate (Technology Informatics Guiding Education Reform [TIGER], 2018). Key technology and computer proficiencies for nursing practice should include basic computer system and desktop skills; the ability to search for client information; communication using email; ability to search electronic health care databases; and use of technology for client education, client documentation, and client monitoring (Hubner et al, 2017; TIGER, 2018).

In addition to computer literacy, nurses must also acquire informatic knowledge that addresses client privacy and the security of health care information as it applies to the use of technology (Hubner et al, 2017; TIGER, 2018). Because nurses document on the EHR and use smartphones for access to information on medications, diagnoses, and treatments, there are constant threats to client confidentiality, which needs to be maintained through secure-access systems. Nurses also use clinical decision support systems in many facilities that contain order sets tailored for conditions or types of clients. These systems include information vital to nurses and also may provide alerts about potentially dangerous situations when giving client care.

Nurses need access to technology to effectively bring evidence to the client's bedside because evidence is constantly evolving. The use of informatics is integral in the use of EBP. As evidence changes, practice should also change. Moving best evidence consistently into practice requires behavior changes by the clinician and system to effectively implement best evidence into practice. Similarly, habits in practice that result in unnecessary care need to be deimplemented (van Bodegrom-Vos et al, 2017). The Choosing Wisely campaign primarily focused on deimplementing unnecessary medical tests or treatments that were found to not provide benefit to clients (Levinson et al, 2015). Similarly, there are interventions that nurses should question because these interventions may not be beneficial for clients. The American Academy of Nursing maintains a list of nursing interventions that should be questioned as to client benefit. Continually reviewing the evidence to implement best practices while deimplementing interventions that are no longer supported by evidence or may no longer be truly necessary requires the nurses to remain actively engaged in EBP as a practice norm (Makic & Granger, 2019; American Academy of Nursing, 2021).

EBP, safety initiatives, informatics, person-centered care, teamwork, and quality work together in a synergistic manner, leading to excellence in nursing care. Quality care needs to be more than safe; the care should result in the best outcome possible for the client. For this to happen, the client should receive care that is based on evidence of the effectiveness of the nursing care interventions.

The nursing process is continually evolving. This text is all about *thinking* for the nurse to help the client in any way possible. Our goal is to present state-of-the-art information to help the nurse and nursing student provide the best care possible.

SECTION

II

Guide to Nursing Diagnosis

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS and Marina Martinez-Kratz, MS, RN, CNE

Section II is an alphabetical listing of client symptoms, client problems, medical diagnoses, psychosocial diagnoses, and clinical states. Each of these will have a list of possible nursing diagnoses. You may use this section to find suggestions for nursing diagnoses for your client.

- Assess the client using the format provided by the clinical setting.
- Locate the client's symptoms, problems, clinical state, diagnoses, surgeries, and diagnostic testing in the alphabetical listing contained in this section.
- Note suggestions given for appropriate nursing diagnoses.
- Evaluate the suggested nursing diagnoses to determine whether they are appropriate for the client and are supported by the information that was found in the assessment.
- Use Section III (which contains an alphabetized list of all NANDA-I approved nursing diagnoses) to validate this information and check the definition, defining characteristics (if appropriate), risk factors, related factors, at-risk populations, and associated conditions. Determine whether the nursing diagnosis you have selected is appropriate for the client.

A

Abdominal Distention

Chronic Functional Constipation r/t habitually suppresses urge to defecate, impaired physical mobility, inadequate dietary intake, insufficient fiber intake, insufficient fluid intake

Constipation r/t decreased activity, decreased fluid intake, decreased fiber intake, pathological process

Dysfunctional Gastrointestinal Motility r/t decreased perfusion of intestines, medication effect

Nausea r/t irritation of gastrointestinal tract

Imbalanced Nutrition: Less Than Body Requirements r/t nausea, vomiting

Acute Pain r/t retention of air, gastrointestinal secretions

Delayed Surgical Recovery r/t retention of gas, secretions

Abdominal Hysterectomy

See Hysterectomy

Abdominal Pain

Dysfunctional Gastrointestinal Motility r/t decreased perfusion, medication effect

Acute Pain r/t injury, pathological process

Abdominal Surgery

Constipation r/t decreased activity, decreased fluid intake, anesthesia, opioids

Dysfunctional Gastrointestinal Motility r/t medication or anesthesia effect, trauma from surgery

Imbalanced Nutrition: Less Than Body Requirements r/t high metabolic needs, decreased ability to ingest or digest food

Acute Pain r/t surgical procedure

Ineffective Peripheral Tissue Perfusion r/t immobility, abdominal surgery

Risk for Delayed Surgical Recovery: Risk factor: extensive surgical procedure

Risk for Surgical Site Infection: Risk factor: invasive procedure

Risk for Thrombosis: Risk factor: impaired physical mobility, smoking

Readiness for Enhanced Knowledge: expresses an interest in learning

See Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Abdominal Trauma

Disturbed Body Image r/t scarring, change in body function, need for temporary colostomy

Ineffective Breathing Pattern r/t abdominal distention, pain

Deficient Fluid Volume r/t hemorrhage, active fluid volume loss

Dysfunctional Gastrointestinal Motility r/t decreased perfusion

Acute Pain r/t abdominal trauma

Risk for Bleeding: Risk factor: trauma and possible contusion/rupture of abdominal organs

Risk for Infection: Risk factor: possible perforation of abdominal structures

Ablation, Radiofrequency Catheter

Fear r/t invasive procedure

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: catheterization of heart

Abortion, Induced

Compromised Family Coping r/t unresolved feelings about decision

Acute Pain r/t surgical intervention

Chronic Low Self-Esteem r/t feelings of guilt

Chronic Sorrow r/t loss of potential child

Risk for Bleeding: Risk factor: trauma from abortion

Risk for Infection: Risk factors: open uterine blood vessels, dilated cervix

Risk for Post-Trauma Syndrome: Risk factor: psychological trauma of abortion

Risk for Spiritual Distress: Risk factor: perceived moral implications of decision

Readiness for Enhanced Health Literacy: expresses desire to enhance personal health care decisions

Readiness for Enhanced Knowledge: expresses an interest in learning

Abortion, Spontaneous

Disturbed Body Image r/t perceived inability to carry pregnancy, produce child

Disabled Family Coping r/t unresolved feelings about loss

Ineffective Coping r/t personal vulnerability

Interrupted Family Processes r/t unmet expectations for pregnancy and childbirth

Fear r/t implications for future pregnancies

Risk for Maladaptive Grieving r/t loss of fetus

Acute Pain r/t uterine contractions, surgical intervention

Situational Low Self-Esteem r/t feelings about loss of fetus

Chronic Sorrow r/t loss of potential child

Risk for Bleeding: Risk factor: trauma from abortion

Risk for Infection: Risk factors: septic or incomplete abortion of products of conception, open uterine blood vessels, dilated cervix

Risk for Post-Trauma Syndrome: Risk factor: psychological trauma of abortion

Risk for Spiritual Distress: Risk factor: loss of fetus

Readiness for Enhanced Knowledge: expresses an interest in learning

Abruptio Placentae <36 Weeks

Anxiety r/t unknown outcome, change in birth plans

Death Anxiety r/t unknown outcome, hemorrhage, or pain

Interrupted Family Processes r/t unmet expectations for pregnancy and childbirth

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Fear r/t threat to well-being of self and fetus

Impaired Gas Exchange: Placental r/t decreased uteroplacental area

Acute Pain r/t irritable uterus, hypertonic uterus

Impaired Tissue Integrity: Maternal r/t possible uterine rupture

Risk for Bleeding: Risk factor: separation of placenta from uterus causing bleeding

Risk for Infection: Risk factor: partial separation of placenta

Risk for Disturbed Maternal–Fetal Dyad: Risk factors: trauma of process, lack of energy of mother

Risk for Shock: Risk factor: separation of placenta from uterus

Readiness for Enhanced Knowledge: expresses an interest in learning

Abscess Formation

Acute Pain r/t inflammation

Ineffective Protection r/t inadequate nutrition, abnormal blood profile, drug therapy, depressed immune function

Impaired Tissue Integrity r/t altered circulation, nutritional deficit or excess

Readiness for Enhanced Knowledge: expresses an interest in learning

Abuse, Child

See Child Abuse

Abuse, Spouse, Parent, or Significant Other

Anxiety r/t threat to self-concept, situational crisis of abuse

Caregiver Role Strain r/t chronic illness, self-care deficits, lack of respite care, extent of caregiving required

Impaired Verbal Communication r/t psychological barriers of fear

Compromised Family Coping r/t abusive patterns

Defensive Coping r/t low self-esteem

Disturbed Family Identity Syndrome r/t unaddressed domestic violence

Dysfunctional Family Processes r/t inadequate coping skills

Insomnia r/t psychological stress

Post-Trauma Syndrome r/t history of abuse

Powerlessness r/t lifestyle of helplessness

Chronic Low Self-Esteem r/t negative family interactions

Risk for Impaired Emancipated Decision-Making: Risk factor: inability to verbalize needs and wants

Risk for Female Genital Mutilation: Risk factor: lack of family knowledge about impact of practice on physical health

Risk for Self-Directed Violence: Risk factor: history of abuse

Accessory Muscle Use (to Breathe)

Ineffective Breathing Pattern (See **Breathing Pattern, Ineffective,** Section III)

See Asthma; Bronchitis; COPD (Chronic Obstructive Pulmonary Disease); Respiratory Infections, Acute Childhood (Croup, Epiglottis, Pertussis, Pneumonia, Respiratory Syncytial Virus)

Accident Prone

Frail Elderly Syndrome r/t history of falls

Acute Confusion r/t altered level of consciousness

Ineffective Coping r/t personal vulnerability, situational crises

Ineffective Impulse Control (See **Impulse Control, Ineffective,** Section III)

Risk for Injury: Risk factor: history of accidents

Wandering r/t overstimulating environment

Achalasia

Ineffective Coping r/t chronic disease

Acute Pain r/t stasis of food in esophagus

Impaired Swallowing r/t neuromuscular impairment

Risk for Aspiration: Risk factor: nocturnal regurgitation

Acid-Base Imbalances

Risk for Electrolyte Imbalance: Risk factors: renal dysfunction, diarrhea, treatment-related side effects (e.g., medications, drains)

Acidosis, Metabolic

Acute Confusion r/t acid-base imbalance, associated electrolyte imbalance

Impaired Memory r/t effect of metabolic acidosis on brain function

Imbalanced Nutrition: Less Than Body Requirements r/t inability to ingest, absorb nutrients

Risk for Electrolyte Imbalance: Risk factor: effect of metabolic acidosis on renal function

Risk for Injury: Risk factors: disorientation, weakness, stupor

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: dysrhythmias from hyperkalemia

Risk for Shock: Risk factors: abnormal metabolic state, presence of acid state impairing function, decreased tissue perfusion

Acidosis, Respiratory

Decreased Activity Tolerance r/t imbalance between oxygen supply and demand

Impaired Gas Exchange r/t ventilation-perfusion imbalance

Impaired Memory r/t hypoxia

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: dysrhythmias associated with respiratory acidosis

Acne

Disturbed Body Image r/t biophysical changes associated with skin disorder

Ineffective Health Self-Management r/t insufficient knowledge of therapeutic regimen

Impaired Skin Integrity r/t hormonal changes (adolescence, menstrual cycle)

Acromegaly

Decreased Activity Tolerance

Ineffective Airway Clearance r/t airway obstruction by enlarged tongue

Disturbed Body Image r/t changes in body function and appearance

A

Impaired Physical Mobility r/t joint pain

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: increased atherosclerosis from abnormal health status

Risk for Unstable Blood Glucose Level: Risk factor: abnormal physical health status

Sexual Dysfunction r/t changes in hormonal secretions

Risk for Overweight: Risk factor: energy expenditure less than energy intake

Activity Intolerance, Potential to Develop

Decreased Activity Tolerance r/t sedentary behavior, deconditioning

Acute Abdominal Pain

Deficient Fluid Volume r/t air and fluids trapped in bowel, inability to drink

Acute Pain r/t pathological process

Risk for Dysfunctional Gastrointestinal Motility: Risk factor: ineffective gastrointestinal tissue perfusion

See Abdominal Pain

Acute Alcohol Intoxication

Ineffective Breathing Pattern r/t depression of the respiratory center from excessive alcohol intake

Acute Confusion r/t central nervous system depression

Dysfunctional Family Processes r/t abuse of alcohol

Risk for Aspiration: Risk factor: depressed reflexes with acute vomiting

Risk for Infection: Risk factor: impaired immune system from malnutrition associated with chronic excessive alcohol intake

Risk for Injury: Risk factor: chemical (alcohol)

Acute Back Pain

Anxiety r/t situational crisis, back injury

Constipation r/t decreased activity, effect of pain medication

Ineffective Coping r/t situational crisis, back injury

Impaired Physical Mobility r/t pain

Acute Pain r/t back injury

Readiness for Enhanced Knowledge: expresses an interest in learning

Acute Confusion

See Confusion, Acute

Acute Coronary Syndrome

Decreased Cardiac Output r/t cardiac disorder

Risk for Decreased Cardiac Tissue Perfusion (See **Cardiac Tissue Perfusion, Risk for Decreased,** Section III)

See Angina; Myocardial Infarction (MI)

Acute Lymphocytic Leukemia (ALL)

See Cancer; Chemotherapy; Child with Chronic Condition; Leukemia

Acute Renal Failure

See Renal Failure

Acute Respiratory Distress Syndrome

See ARDS (Acute Respiratory Distress Syndrome)

Acute Substance Withdrawal

Acute Substance Withdrawal Syndrome: Risk factor: developed dependence to alcohol or other addictive substances

Anxiety r/t unknown outcome of withdrawal sequence, physiological effects

Imbalanced Energy Field r/t hyperactivity of energy flow

Impaired Comfort r/t restlessness and agitation

Acute Confusion r/t effects of substance withdrawal

Ineffective Coping r/t situational crisis, withdrawal

Labile Emotional Control r/t lack of control over the progression of withdrawal process

Fear r/t threat to well-being of self

Insomnia r/t physical and psychological effects of substance withdrawal

Imbalanced Nutrition: Less than Body Requirements r/t nausea, anxiety

Powerlessness r/t loss of ability to control withdrawal process

Risk for Acute Confusion: Risk factor: possible alteration in level of consciousness

Risk for Injury: Risk factor: alteration in sensory perceptual functioning

Risk for Suicidal Behavior: Risk factor: psychic pain

Risk for Other-Directed Violence: Risk factors: poor impulse control, hallucinations

Risk for Self-Directed Violence: Risk factors: poor impulse control, hallucinations

Adams–Stokes Syndrome

See Dysrhythmia

Addiction

See Alcoholism; Substance Abuse

Addison's Disease

Decreased Activity Tolerance r/t weakness, fatigue

Disturbed Body Image r/t increased skin pigmentation

Deficient Fluid Volume r/t failure of regulatory mechanisms

Imbalanced Nutrition: Less than Body Requirements r/t chronic illness

Risk for Injury: Risk factor: weakness

Readiness for Enhanced Knowledge: expresses an interest in learning

Adenoidectomy

Acute Pain r/t surgical incision

Ineffective Airway Clearance r/t hesitation or reluctance to cough as a result of pain, fear

Nausea r/t anesthesia effects, drainage from surgery

Risk for Aspiration: Risk factors: postoperative drainage, impaired swallowing

Risk for Bleeding: Risk factor: surgical incision

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Risk for Deficient Fluid Volume: Risk factors: decreased intake as a result of painful swallowing, effects of anesthesia

Risk for Dry Mouth: Risk factor: mouth breathing due to nasal congestion

Risk for Imbalanced Nutrition: Less than Body Requirements: Risk factor: reluctance to swallow

Readiness for Enhanced Knowledge: expresses an interest in learning

Adhesions, Lysis of

See Abdominal Surgery

Adjustment Disorder

Anxiety r/t inability to cope with psychosocial stressor

Ineffective Coping r/t stressors

Impaired Mood Regulation r/t emotional instability

Labile Emotional Control r/t emotional disturbance

Risk-Prone Health Behavior r/t assault to self-esteem

Disturbed Personal Identity r/t psychosocial stressor (specific to individual)

Situational Low Self-Esteem r/t change in role function

Impaired Social Interaction r/t absence of significant others or peers

Adjustment Impairment

Risk-Prone Health Behavior (See **Health Behavior, Risk-Prone,** Section III)

Adolescent, Pregnant

Anxiety r/t situational and maturational crisis, pregnancy

Disturbed Body Image r/t pregnancy superimposed on developing body

Decisional Conflict: Keeping Child Versus Giving up Child Versus Abortion r/t lack of experience with decision-making, interference with decision-making, multiple or divergent sources of information, lack of support system

Disabled Family Coping r/t highly ambivalent family relationships, chronically unresolved feelings of guilt, anger, despair

Ineffective Coping r/t situational and maturational crisis, personal vulnerability

Ineffective Denial r/t fear of consequences of pregnancy becoming known

Ineffective Adolescent Eating Dynamics r/t lack of knowledge of nutritional needs during pregnancy

Interrupted Family Processes r/t unmet expectations for adolescent, situational crisis

Fear r/t labor and delivery

Deficient Knowledge r/t pregnancy, infant growth and development, parenting

Imbalanced Nutrition: Less than Body Requirements r/t lack of knowledge of nutritional needs during pregnancy and as growing adolescent

Ineffective Role Performance r/t pregnancy

Situational Low Self-Esteem r/t feelings of shame and guilt about becoming or being pregnant

Impaired Social Interaction r/t self-concept disturbance

Social Isolation r/t absence of supportive significant others

Risk for Impaired Attachment: Risk factor: anxiety associated with the parent role

Risk for Disturbed Family Identity Syndrome: Risk Factor: excessive stress

Risk for Urge Urinary Incontinence: Risk factor: pressure on bladder by growing uterus

Risk for Disturbed Maternal–Fetal Dyad: Risk factors: immaturity, substance use

Risk for Impaired Parenting: Risk factors: adolescent parent, unplanned or unwanted pregnancy, single parent

Readiness for Enhanced Childbearing Process: reports appropriate prenatal lifestyle

Readiness for Enhanced Health Literacy: expresses desire to enhance social support for health

Readiness for Enhanced Knowledge: expresses an interest in learning

Adoption, Giving Child up for

Decisional Conflict r/t unclear personal values or beliefs, perceived threat to value system, support system deficit

Ineffective Coping r/t stress of loss of child

Interrupted Family Processes r/t conflict within family regarding relinquishment of child

Maladaptive Grieving r/t loss of child, loss of role of parent

Insomnia r/t depression or trauma of relinquishment of child

Social Isolation r/t making choice that goes against values of significant others

Chronic Sorrow r/t loss of relationship with child

Risk for Spiritual Distress: Risk factor: perceived moral implications of decision

Readiness for Enhanced Spiritual Well-Being: harmony with self-regarding final decision

Adrenocortical Insufficiency

Deficient Fluid Volume r/t insufficient ability to reabsorb water

Ineffective Protection r/t inability to tolerate stress

Delayed Surgical Recovery r/t inability to respond to stress

Risk for Shock: Risk factors: deficient fluid volume, decreased cortisol to initiate stress response to insult to body

See Addison's Disease; Shock, Hypovolemic

Advance Directives

Death Anxiety r/t planning for end-of-life health decisions

Decisional Conflict r/t unclear personal values or beliefs, perceived threat to value system, support system deficit

Maladaptive Grieving r/t possible loss of self, significant other

Readiness for Enhanced Spiritual Well-Being: harmonious interconnectedness with self, others, higher power, God

Affective Disorders

See Depression (Major Depressive Disorder); Dysthymic Disorder; Manic Disorder, Bipolar I; SAD (Seasonal Affective Disorder)

A

Age-Related Macular Degeneration

See Macular Degeneration

Aggressive Behavior

Fear r/t real or imagined threat to own well-being

Risk for Other-Directed Violence (See **Violence, Other-Directed, Risk for,** Section III)

Aging

Death Anxiety r/t fear of unknown, loss of self, impact on significant others

Impaired Dentition r/t ineffective oral hygiene

Risk for Frail Elderly Syndrome: Risk factors: >70 years, activity intolerance, impaired vision

Maladaptive Grieving r/t multiple losses, impending death

Ineffective Health Maintenance Behaviors r/t powerlessness

Hearing Loss r/t exposure to loud noises, aging

Impaired Urinary Elimination r/t impaired vision, impaired cognition, neuromuscular limitations, altered environmental factors

Impaired Resilience r/t aging, multiple losses

Sleep Deprivation r/t aging-related sleep-stage shifts

Risk for Caregiver Role Strain: Risk factor: inability to handle increasing needs of significant other

Risk for Impaired Emancipated Decision-Making: Risk factor: inability to process information regarding health care decisions

Risk for Injury: Risk factors: vision loss, hearing loss, decreased balance, decreased sensation in feet

Risk for Loneliness: Risk factors: inadequate support system, role transition, health alterations, depression, fatigue

Risk for Ineffective Thermoregulation: Risk factor: aging

Readiness for Enhanced Community Coping: providing social support and other resources identified as needed for elderly client

Readiness for Enhanced Family Coping: ability to gratify needs, address adaptive tasks

Readiness for Enhanced Health Self-Management: knowledge about medication, nutrition, exercise, coping strategies

Readiness for Enhanced Knowledge: specify need to improve health

Readiness for Enhanced Nutrition: need to improve health

Readiness for Enhanced Relationship: demonstrates understanding of partner's insufficient function

Readiness for Enhanced Sleep: need to improve sleep

Readiness for Enhanced Spiritual Well-Being: one's experience of life's meaning, harmony with self, others, higher power, God, environment

Agitation

Acute Confusion r/t side effects of medication, hypoxia, decreased cerebral perfusion, alcohol abuse or withdrawal, substance abuse or withdrawal, sensory deprivation or overload

Sleep Deprivation r/t sustained inadequate sleep hygiene, sundown syndrome

Agoraphobia

Anxiety r/t real or perceived threat to physical integrity

Ineffective Coping r/t inadequate support systems

Fear r/t leaving home, going out in public places

Impaired Social Interaction r/t disturbance in self-concept

Social Isolation r/t altered thought process

Agranulocytosis

Delayed Surgical Recovery r/t abnormal blood profile

Risk for Infection: Risk factor: abnormal blood profile

Readiness for Enhanced Knowledge: expresses an interest in learning

AIDS (Acquired Immunodeficiency Syndrome)

Death Anxiety r/t fear of premature death

Disturbed Body Image r/t chronic contagious illness, cachexia

Caregiver Role Strain r/t unpredictable illness course, presence of situation stressors

Diarrhea r/t inflammatory bowel changes

Interrupted Family Processes r/t distress about diagnosis of human immunodeficiency virus (HIV) infection

Fatigue r/t disease process, stress, decreased nutritional intake

Fear r/t powerlessness, threat to well-being

Maladaptive Grieving: Family/Parental r/t potential or impending death of loved one

Maladaptive Grieving: Individual r/t loss of physical and psychosocial well-being

Hopelessness r/t deteriorating physical condition

Imbalanced Nutrition: Less than Body Requirements r/t decreased ability to eat and absorb nutrients as a result of anorexia, nausea, diarrhea; oral candidiasis

Chronic Pain r/t tissue inflammation and destruction

Impaired Resilience r/t chronic illness

Situational Low Self-Esteem r/t crisis of chronic contagious illness

Ineffective Sexuality Pattern r/t possible transmission of disease

Social Isolation r/t self-concept disturbance, therapeutic isolation

Chronic Sorrow r/t chronic illness

Spiritual Distress r/t challenged beliefs or moral system

Risk for Deficient Fluid Volume: Risk factors: diarrhea, vomiting, fever, bleeding

Risk for Infection: Risk factor: inadequate immune system

Risk for Loneliness: Risk factor: social isolation

Risk for Impaired Oral Mucous Membrane Integrity: Risk factor: immunological deficit

Risk for Impaired Skin Integrity: Risk factors: immunological deficit, diarrhea

Risk for Spiritual Distress: Risk factor: physical illness

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Readiness for Enhanced Health Literacy: expresses desire to enhance understanding of health information to make health care choices

Readiness for Enhanced Knowledge: expresses an interest in learning

See AIDS, Child; Cancer; Pneumonia

AIDS, Child

Impaired Parenting r/t congenital acquisition of infection secondary to intravenous (IV) drug use, multiple sexual partners, history of contaminated blood transfusion

Risk for Disturbed Family Identity Syndrome: Risk factor: excessive stress

See AIDS (Acquired Immunodeficiency Syndrome); Child with Chronic Condition; Hospitalized Child; Terminally Ill Child, Adolescent; Terminally Ill Child, Infant/Toddler; Terminally Ill Child, Preschool Child; Terminally Ill Child, School-Age Child/Preadolescent; Terminally Ill Child/Death of Child, Parent

AIDS Dementia

Chronic Confusion r/t viral invasion of nervous system

See Dementia

Airway Obstruction/Secretions

Ineffective Airway Clearance (See **Airway Clearance, Ineffective,** Section III)

Alcohol Withdrawal

Anxiety r/t situational crisis, withdrawal

Acute Confusion r/t effects of alcohol withdrawal

Ineffective Coping r/t personal vulnerability

Dysfunctional Family Processes r/t abuse of alcohol

Insomnia r/t effect of alcohol withdrawal, anxiety

Imbalanced Nutrition: Less than Body Requirements r/t poor dietary habits

Chronic Low Self-Esteem r/t repeated unmet expectations

Acute Substance Withdrawal Syndrome: Risk factor: developed dependence to alcohol

Risk for Deficient Fluid Volume: Risk factors: excessive diaphoresis, agitation, decreased fluid intake

Risk for Other-Directed Violence: Risk factor: substance withdrawal

Risk for Self-Directed Violence: Risk factor: substance withdrawal

Readiness for Enhanced Knowledge: expresses an interest in learning

Alcoholism

Anxiety r/t loss of control

Risk-Prone Health Behavior r/t lack of motivation to change behaviors, addiction

Acute Confusion r/t alcohol abuse

Chronic Confusion r/t neurological effects of chronic alcohol intake

Defensive Coping r/t denial of reality of addiction

Disabled Family Coping r/t codependency issues due to alcoholism

Ineffective Coping r/t use of alcohol to cope with life events

Labile Emotional Control r/t substance abuse

Ineffective Denial r/t refusal to acknowledge addiction

Dysfunctional Family Processes r/t alcohol abuse

Ineffective Home Maintenance Behaviors r/t memory deficits, fatigue

Insomnia r/t irritability, nightmares, tremors

Impaired Memory r/t alcohol abuse

Self-Neglect r/t effects of alcohol abuse

Imbalanced Nutrition: Less than Body Requirements r/t anorexia, inappropriate diet with increased carbohydrates

Powerlessness r/t alcohol addiction

Ineffective Protection r/t malnutrition, sleep deprivation

Chronic Low Self-Esteem r/t failure at life events

Social Isolation r/t unacceptable social behavior, values

Acute Substance Withdrawal Syndrome: Risk factor: developed dependence to alcohol

Risk for Injury: Risk factor: alteration in sensory or perceptual function

Risk for Loneliness: Risk factor: unacceptable social behavior

Risk for Acute Substance Withdrawal Syndrome: Risk factor: developed dependence to alcohol

Risk for Other-Directed Violence: Risk factors: reactions to substances used, impulsive behavior, disorientation, impaired judgment

Risk for Self-Directed Violence: Risk factors: reactions to substances used, impulsive behavior, disorientation, impaired judgment

Alcoholism, Dysfunctional Family Processes

Dysfunctional Family Processes (See **Family Processes, Dysfunctional,** Section III)

Disturbed Family Identity Syndrome: Risk factor: excessive stress

Alkalosis

See Metabolic Alkalosis

ALL (Acute Lymphocytic Leukemia)

See Cancer; Chemotherapy; Child with Chronic Condition; Leukemia

Allergies

Risk for Allergy Reaction: Risk factors: chemical factors, dander, environmental substances, foods, insect stings, medications

Risk for Latex Allergic Reaction: Risk factor: repeated exposure to products containing latex

Readiness for Enhanced Knowledge: expresses an interest in learning

Alopecia

Disturbed Body Image r/t loss of hair, change in appearance

A

Readiness for Enhanced Knowledge: expresses an interest in learning

ALS (Amyotrophic Lateral Sclerosis)

See Amyotrophic Lateral Sclerosis (ALS)

Altered Mental Status

See Confusion, Acute; Confusion, Chronic; Memory Deficit

Alzheimer's Disease

Caregiver Role Strain r/t duration and extent of caregiving required

Chronic Confusion r/t loss of cognitive function

Compromised Family Coping r/t interrupted family processes

Frail Elderly Syndrome r/t alteration in cognitive functioning

Ineffective Home Maintenance Behaviors r/t impaired cognitive function, inadequate support systems

Hopelessness r/t deteriorating condition

Insomnia r/t neurological impairment, daytime naps

Impaired Memory r/t neurological disturbance

Impaired Physical Mobility r/t severe neurological dysfunction

Self-Neglect r/t loss of cognitive function

Powerlessness r/t deteriorating condition

Self-Care Deficit: Specify r/t loss of cognitive function, psychological impairment

Social Isolation r/t fear of disclosure of memory loss

Wandering r/t cognitive impairment, frustration, physiological state

Risk for Chronic Functional Constipation: Risk factor: impaired cognitive functioning

Risk for Injury: Risk factor: confusion

Risk for Loneliness: Risk factor: potential social isolation

Risk for Relocation Stress Syndrome: Risk factors: impaired psychosocial health, decreased health status

Risk for Other-Directed Violence: Risk factors: frustration, fear, anger, loss of cognitive function

Readiness for Enhanced Knowledge: Caregiver: expresses an interest in learning

See Dementia

AMD (Age-Related Macular Degeneration)

See Macular Degeneration

Amenorrhea

Imbalanced Nutrition: Less than Body Requirements r/t inadequate food intake

See Sexuality, Adolescent

AMI (Acute Myocardial Infarction)

See MI (Myocardial Infarction)

Amnesia

Acute Confusion r/t alcohol abuse, delirium, dementia, drug abuse

Dysfunctional Family Processes r/t alcohol abuse, inadequate coping skills

Impaired Memory r/t excessive environmental disturbance, neurological disturbance

Post-Trauma Syndrome r/t history of abuse, catastrophic illness, disaster, accident

Amniocentesis

Anxiety r/t threat to self and fetus, unknown future

Decisional Conflict r/t choice of treatment pending results of test

Risk for Infection: Risk factor: invasive procedure

Amnionitis

See Chorioamnionitis

Amniotic Membrane Rupture

See Premature Rupture of Membranes

Amputation

Disturbed Body Image r/t negative effects of amputation, response from others

Maladaptive Grieving r/t loss of body part, future lifestyle changes

Impaired Physical Mobility r/t musculoskeletal impairment, limited movement

Acute Pain r/t surgery, phantom limb sensation

Chronic Pain r/t surgery, phantom limb sensation

Ineffective Peripheral Tissue Perfusion r/t impaired arterial circulation

Impaired Skin Integrity r/t poor healing, prosthesis rubbing

Risk for Bleeding: Risk factor: vulnerable surgical site

Risk for Impaired Tissue Integrity: Risk factor: mechanical factors impacting site

Readiness for Enhanced Knowledge: expresses an interest in learning

Amyotrophic Lateral Sclerosis (ALS)

Death Anxiety r/t impending progressive loss of function leading to death

Ineffective Breathing Pattern r/t compromised muscles of respiration

Impaired Verbal Communication r/t weakness of muscles of speech, deficient knowledge of ways to compensate and alternative communication devices

Decisional Conflict: Ventilator Therapy r/t unclear personal values or beliefs, lack of relevant information

Impaired Resilience r/t perceived vulnerability

Chronic Sorrow r/t chronic illness

Impaired Swallowing r/t weakness of muscles involved in swallowing

Impaired Spontaneous Ventilation r/t weakness of muscles of respiration

Risk for Aspiration: Risk factor: impaired swallowing

Risk for Spiritual Distress: Risk factor: chronic debilitating condition

See Neurological Disorders

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Anal Fistula

See Hemorrhoidectomy

Anaphylactic Shock

Deficient Fluid Volume r/t compromised regulatory mechanism

Ineffective Airway Clearance r/t laryngeal edema, bronchospasm

Risk for Latex Allergic Reaction r/t abnormal immune mechanism response

Impaired Spontaneous Ventilation r/t acute airway obstruction from anaphylaxis process

Anaphylaxis Prevention

Risk for Allergy Reaction (See **Allergy Reaction, Risk for,** Section III)

Anasarca

Excess Fluid Volume r/t excessive fluid intake, cardiac/renal dysfunction, loss of plasma proteins

Risk for Decreased Cardiac Output: Risk factor: imbalanced fluid volume

Risk for Impaired Skin Integrity: Risk factor: impaired circulation to skin from edema

Anemia

Anxiety r/t cause of disease

Impaired Comfort r/t feelings of always being cold from decreased hemoglobin and decreased metabolism

Fatigue r/t decreased oxygen supply to the body, increased cardiac workload

Impaired Memory r/t change in cognition from decreased oxygen supply to the body

Delayed Surgical Recovery r/t decreased oxygen supply to body, increased cardiac workload

Risk for Bleeding (See **Bleeding, Risk for,** Section III)

Risk for Injury: Risk factor: alteration in peripheral sensory perception

Readiness for Enhanced Knowledge: expresses an interest in learning

Anemia, in Pregnancy

Anxiety r/t concerns about health of self and fetus

Fatigue r/t decreased oxygen supply to the body, increased cardiac workload

Risk for Infection: Risk factor: reduction in oxygen-carrying capacity of blood

Risk for Disturbed Maternal–Fetal Dyad: Risk factor: compromised oxygen transport

Readiness for Enhanced Knowledge: expresses an interest in learning

Anemia, Sickle Cell

See Anemia; Sickle Cell Anemia/Crisis

Anencephaly

See Neural Tube Defects (Meningocele, Myelomeningocele, Spina Bifida, Anencephaly)

Aneurysm, Abdominal Aortic Repair Surgery

Risk for Deficient Fluid Volume: Risk factor: hemorrhage r/t potential abnormal blood loss

Risk for Surgical Site Infection: Risk factor: invasive procedure

See Abdominal Surgery

Aneurysm, Cerebral

See Craniectomy/Craniotomy; Subarachnoid Hemorrhage

Anger

Anxiety r/t situational crisis

Defensive Coping r/t inability to acknowledge responsibility for actions and results of actions

Labile Emotional Control r/t stressors

Fear r/t environmental stressor, hospitalization

Maladaptive Grieving r/t significant loss

Risk-Prone Health Behavior r/t assault to self-esteem, disability requiring change in lifestyle, inadequate support system

Powerlessness r/t health care environment

Risk for Compromised Human Dignity: Risk factors: inadequate participation in decision-making, perceived dehumanizing treatment, perceived humiliation, exposure of the body, cultural incongruity

Risk for Post-Trauma Syndrome: Risk factor: inadequate social support

Risk for Other-Directed Violence: Risk factors: history of violence, rage reaction

Risk for Self-Directed Violence: Risk factors: history of violence, history of abuse, rage reaction

Angina

Decreased Activity Tolerance r/t acute pain, dysrhythmias

Anxiety r/t situational crisis

Decreased Cardiac Output r/t myocardial ischemia, medication effect, dysrhythmia

Ineffective Coping r/t personal vulnerability to situational crisis of new diagnosis, deteriorating health

Ineffective Denial r/t deficient knowledge of need to seek help with symptoms

Maladaptive Grieving r/t pain, loss of health

Acute Pain r/t myocardial ischemia

Ineffective Sexuality Pattern r/t disease process, medications, loss of libido

Readiness for Enhanced Knowledge: expresses an interest in learning

See MI (Myocardial Infarction)

Angiocardiography (Cardiac Catheterization)

See Cardiac Catheterization

Angioplasty, Coronary

Fear r/t possible outcome of interventional procedure

Ineffective Peripheral Tissue Perfusion r/t vasospasm, hematoma formation

A

Risk for Bleeding: Risk factors: possible damage to coronary artery, hematoma formation

Risk for Decreased Cardiac Tissue Perfusion: Risk factors: ventricular ischemia, dysrhythmias

Readiness for Enhanced Knowledge: expresses an interest in learning

Anomaly, Fetal/Newborn (Parent Dealing with)

Anxiety r/t threat to role functioning, situational crisis

Decisional Conflict: Interventions for Fetus or Newborn r/t lack of relevant information, spiritual distress, threat to value system

Disabled Family Coping r/t chronically unresolved feelings about loss of perfect baby

Ineffective Coping r/t personal vulnerability in situational crisis

Interrupted Family Processes r/t unmet expectations for perfect baby, lack of adequate support systems

Fear r/t real or imagined threat to baby, implications for future pregnancies, powerlessness

Maladaptive Grieving r/t loss of ideal child

Hopelessness r/t long-term stress, deteriorating physical condition of child, lost spiritual belief

Deficient Knowledge r/t limited exposure to situation

Impaired Parenting r/t interruption of bonding process

Powerlessness r/t complication threatening fetus or newborn

Parental Role Conflict r/t separation from newborn, intimidation with invasive or restrictive modalities, specialized care center policies

Situational Low Self-Esteem r/t perceived inability to produce a perfect child

Social Isolation r/t alterations in child's physical appearance, altered state of wellness

Chronic Sorrow r/t loss of ideal child, inadequate bereavement support

Spiritual Distress r/t test of spiritual beliefs

Risk for Impaired Attachment: Risk factor: ill infant unable to effectively initiate parental contact as result of altered behavioral organization

Risk for Disorganized Infant Behavior: Risk factor: congenital disorder

Risk for Impaired Parenting: Risk factors: interruption of bonding process; unrealistic expectations for self, infant, or partner; perceived threat to own emotional survival; severe stress; lack of knowledge

Risk for Spiritual Distress: Risk factor: lack of normal child to raise and carry on family name

Anorectal Abscess

Disturbed Body Image r/t odor and drainage from rectal area

Acute Pain r/t inflammation of perirectal area

Risk for Constipation: Risk factor: fear of painful elimination

Readiness for Enhanced Knowledge: expresses an interest in learning

Anorexia

Deficient Fluid Volume r/t inability to drink

Imbalanced Nutrition: Less than Body Requirements r/t loss of appetite, nausea, vomiting, laxative abuse

Delayed Surgical Recovery r/t inadequate nutritional intake

Risk for Delayed Surgical Recovery: Risk factor: inadequate nutritional intake

Anorexia Nervosa

Decreased Activity Tolerance r/t fatigue, weakness

Disturbed Body Image r/t misconception of actual body appearance

Constipation r/t lack of adequate food, fiber, and fluid intake

Defensive Coping r/t psychological impairment, eating disorder

Disabled Family Coping r/t highly ambivalent family relationships

Ineffective Denial r/t fear of consequences of therapy, possible weight gain

Diarrhea r/t laxative abuse

Interrupted Family Processes r/t situational crisis

Ineffective Adolescent Eating Dynamics r/t food refusal

Ineffective Family Health Self-Management r/t family conflict, excessive demands on family associated with complexity of condition and treatment

Imbalanced Nutrition: Less than Body Requirements r/t inadequate food intake, excessive exercise

Chronic Low Self-Esteem r/t repeated unmet expectations

Ineffective Sexuality Pattern r/t loss of libido from malnutrition

Risk for Infection: Risk factor: malnutrition resulting in depressed immune system

Risk for Spiritual Distress: Risk factor: low self-esteem

See Maturational Issues, Adolescent

Anosmia (Smell, Loss of Ability to)

Imbalanced Nutrition: Less than Body Requirements r/t loss of appetite associated with loss of smell

Antepartum Period

See Pregnancy, Normal; Prenatal Care, Normal

Anterior Repair, Anterior Colporrhaphy

Urinary Retention r/t edema of urinary structures

Risk for Urge Urinary Incontinence: Risk factor: trauma to bladder

Readiness for Enhanced Knowledge: expresses an interest in learning

See Vaginal Hysterectomy

Anticoagulant Therapy

Risk for Bleeding: Risk factor: altered clotting function from anticoagulant

Risk for Deficient Fluid Volume: Hemorrhage: Risk factor: altered clotting mechanism

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Readiness for Enhanced Knowledge: expresses an interest in learning

Antisocial Personality Disorder

Defensive Coping r/t excessive use of projection

Ineffective Coping r/t frequently violating the norms and rules of society

Labile Emotional Control r/t psychiatric disorder

Hopelessness r/t abandonment

Impaired Social Interaction r/t sociocultural conflict, chemical dependence, inability to form relationships

Spiritual Distress r/t separation from religious or cultural ties

Ineffective Health Self-Management r/t excessive demands on family

Risk for Loneliness: Risk factor: inability to interact appropriately with others

Risk for Impaired Parenting: Risk factors: inability to function as parent or guardian, emotional instability

Risk for Self-Mutilation: Risk factors: self-hatred, depersonalization

Risk for Other-Directed Violence: Risk factor: history of violence, altered thought patterns

Anuria

See Renal Failure

Anxiety

See **Anxiety,** Section III

Anxiety Disorder

Ineffective Activity Planning r/t unrealistic perception of events

Anxiety r/t unmet security and safety needs

Death Anxiety r/t fears of unknown, powerlessness

Decisional Conflict r/t low self-esteem, fear of making a mistake

Defensive Coping r/t overwhelming feelings of dread

Disabled Family Coping r/t ritualistic behavior, actions

Imbalanced Energy Field r/t feelings of restlessness and apprehension

Impaired Mood Regulation r/t functional impairment, impaired social functioning, alteration in sleep pattern

Ineffective Coping r/t inability to express feelings appropriately

Ineffective Denial r/t overwhelming feelings of hopelessness, fear, threat to self

Insomnia r/t psychological impairment, emotional instability

Labile Emotional Control r/t emotional instability

Powerlessness r/t lifestyle of helplessness

Self-Care Deficit r/t ritualistic behavior, activities

Sleep Deprivation r/t prolonged psychological discomfort

Risk for Spiritual Distress: Risk factor: psychological distress

Readiness for Enhanced Knowledge: expresses an interest in learning

Aortic Valvular Stenosis

See Congenital Heart Disease/Cardiac Anomalies

Aphasia

Anxiety r/t situational crisis of aphasia

Impaired Verbal Communication r/t decrease in circulation to brain

Ineffective Coping r/t loss of speech

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding information on aphasia and alternative communication techniques

Aplastic Anemia

Decreased Activity Tolerance r/t imbalance between oxygen supply and demand

Fear r/t ability to live with serious disease

Risk for Bleeding: Risk factor: inadequate clotting factors

Risk for Infection: Risk factor: inadequate immune function

Readiness for Enhanced Knowledge: expresses an interest in learning

Apnea in Infancy

See Premature Infant (Child); Premature Infant (Parent); SIDS (Sudden Infant Death Syndrome)

Apneustic Respirations

Ineffective Breathing Pattern r/t perception or cognitive impairment, neurological impairment

Appendectomy

Deficient Fluid Volume r/t fluid restriction, hypermetabolic state, nausea, vomiting

Acute Pain r/t surgical incision

Delayed Surgical Recovery r/t rupture of appendix

Risk for Infection: Risk factors: perforation or rupture of appendix, peritonitis

Risk for Surgical Site Infection: Risk factor: surgical incision

Readiness for Enhanced Knowledge: expresses an interest in learning

See Hospitalized Child; Surgery, Postoperative Care

Appendicitis

Deficient Fluid Volume r/t anorexia, nausea, vomiting

Acute Pain r/t inflammation

Risk for Infection: Risk factor: possible perforation of appendix

Readiness for Enhanced Knowledge: expresses an interest in learning

Apprehension

Anxiety r/t threat to self-concept, threat to health status, situational crisis

Death Anxiety r/t apprehension over loss of self, consequences to significant others

A

ARDS (Acute Respiratory Distress Syndrome)

Ineffective Airway Clearance r/t excessive tracheobronchial secretions

Death Anxiety r/t seriousness of physical disease

Impaired Gas Exchange r/t damage to alveolar-capillary membrane, change in lung compliance

Impaired Spontaneous Ventilation r/t damage to alveolar-capillary membrane

See Ventilated Client, Mechanically

Arrhythmia

See Dysrhythmia

Arterial Insufficiency

Ineffective Peripheral Tissue Perfusion r/t interruption of arterial flow

Delayed Surgical Recovery r/t ineffective tissue perfusion

Arthritis

Decreased Activity Tolerance r/t chronic pain, fatigue, weakness

Disturbed Body Image r/t ineffective coping with joint abnormalities

Impaired Physical Mobility r/t joint impairment

Chronic Pain r/t progression of joint deterioration

Self-Care Deficit: Specify r/t pain with movement, damage to joints

Readiness for Enhanced Knowledge: expresses an interest in learning

See JRA (Juvenile Rheumatoid Arthritis)

Arthrocentesis

Acute Pain r/t invasive procedure

Arthroplasty (Total Hip Replacement)

See Total Joint Replacement (Total Hip/Total Knee/Shoulder); Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Arthroscopy

Impaired Physical Mobility r/t surgical trauma of knee

Readiness for Enhanced Knowledge: expresses an interest in learning

Ascites

Ineffective Breathing Pattern r/t increased abdominal girth

Imbalanced Nutrition: Less than Body Requirements r/t loss of appetite

Chronic Pain r/t altered body function

Readiness for Enhanced Knowledge: expresses an interest in learning

See Ascites; Cancer; Cirrhosis

Asperger's Syndrome

Ineffective Relationship r/t poor communication skills, lack of empathy

See Autism

Asphyxia, Birth

Ineffective Breathing Pattern r/t depression of breathing reflex secondary to anoxia

Ineffective Coping r/t uncertainty of child outcome

Fear (Parental) r/t concern over safety of infant

Impaired Gas Exchange r/t poor placental perfusion, lack of initiation of breathing by newborn

Maladaptive Grieving r/t loss of perfect child, concern of loss of future abilities

Impaired Spontaneous Ventilation r/t brain injury

Risk for Impaired Attachment: Risk factors: ill infant who is unable to initiate parental contact, hospitalization in critical care environment

Risk for Delayed Child Development: Risk factors: lack of oxygen to brain

Risk for Disorganized Infant Behavior: Risk factor: lack of oxygen to brain

Risk for Injury: Risk factor: lack of oxygen to brain

Risk for Ineffective Cerebral Tissue Perfusion: Risk factor: poor placental perfusion or cord compression resulting in lack of oxygen to brain

Aspiration, Danger of

Risk for Aspiration (See **Aspiration, Risk for,** Section III)

Assault Victim

Post-Trauma Syndrome r/t assault

Rape-Trauma Syndrome r/t rape

Impaired Resilience r/t frightening experience, post-trauma stress response

Risk for Post-Trauma Syndrome: Risk factors: perception of event, inadequate social support, unsupportive environment, diminished ego strength, duration of event

Risk for Spiritual Distress: Risk factors: physical, psychological stress

Assaultive Client

Risk for Injury: Risk factors: confused thought process, impaired judgment

Risk for Other-Directed Violence: Risk factors: paranoid ideation, anger

Asthma

Decreased Activity Tolerance r/t fatigue, energy shift to meet muscle needs for breathing to overcome airway obstruction

Ineffective Airway Clearance r/t tracheobronchial narrowing, excessive secretions

Anxiety r/t inability to breathe effectively, fear of suffocation

Disturbed Body Image r/t decreased participation in physical activities

Ineffective Breathing Pattern r/t anxiety

Ineffective Coping r/t personal vulnerability to situational crisis

Ineffective Health Self-Management (See **Health Management, Ineffective,** Section III)

Ineffective Home Maintenance Behaviors r/t deficient knowledge regarding control of environmental triggers

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Sleep Deprivation r/t ineffective breathing pattern, cough

Readiness for Enhanced Health Self-Management (See **Health Self-Management, Readiness for Enhanced,** Section III)

Readiness for Enhanced Knowledge: expresses an interest in learning

See Child with Chronic Condition; Hospitalized Child

Ataxia

Anxiety r/t change in health status

Disturbed Body Image r/t staggering gait

Impaired Physical Mobility r/t neuromuscular impairment

Risk for Falls: Risk factors: gait alteration, instability

Atelectasis

Ineffective Breathing Pattern r/t loss of functional lung tissue, depression of respiratory function or hypoventilation because of pain

Impaired Gas Exchange r/t decreased alveolar-capillary surface

Anxiety r/t alteration in respiratory pattern

See Atelectasis

Atherosclerosis

See MI (Myocardial Infarction); CVA (Cerebrovascular Accident); Peripheral Vascular Disease (PVD)

Athlete's Foot

Impaired Skin Integrity r/t effects of fungal agent

Readiness for Enhanced Knowledge: expresses an interest in learning

See Pruritus

ATN (Acute Tubular Necrosis)

See Renal Failure

Atrial Fibrillation

See Dysrhythmia

Atrial Septal Defect

See Congenital Heart Disease/Cardiac Anomalies

Attention Deficit Disorder

Risk-Prone Health Behavior r/t intense emotional state

Disabled Family Coping r/t significant person with chronically unexpressed feelings of guilt, anxiety, hostility, and despair

Ineffective Impulse Control (See **Impulse Control, Ineffective,** Section III)

Chronic Low Self-Esteem r/t difficulty in participating in expected activities, poor school performance

Social Isolation r/t unacceptable social behavior

Risk for Delayed Child Development: Risk factor: behavior disorders

Risk for Falls: Risk factor: rapid non-thinking behavior

Risk for Loneliness: Risk factor: social isolation

Risk for Impaired Parenting: Risk factor: lack of knowledge of factors contributing to child's behavior

Risk for Spiritual Distress: Risk factor: poor relationships

Autism

Impaired Verbal Communication r/t speech and language delays

Compromised Family Coping r/t parental guilt over etiology of disease, inability to accept or adapt to child's condition, inability to help child and other family members seek treatment

Disturbed Personal Identity r/t inability to distinguish between self and environment, inability to identify own body as separate from those of other people, inability to integrate concept of self

Self-Neglect r/t impaired socialization

Impaired Social Interaction r/t communication barriers, inability to relate to others, failure to develop peer relationships

Risk for Delayed Child Development: Risk factor: autism

Risk for Disturbed Family Identity Syndrome: Risk factor: excessive stress

Risk for Loneliness: Risk factor: difficulty developing relationships with other people

Risk for Self-Mutilation: Risk factor: autistic state

Risk for Other-Directed Violence: Risk factors: frequent destructive rages toward others secondary to extreme response to changes in routine, fear of harmless things

Risk for Self-Directed Violence: Risk factors: frequent destructive rages toward self, secondary to extreme response to changes in routine, fear of harmless things

See Child with Chronic Condition

Autonomic Dysreflexia

Autonomic Dysreflexia r/t bladder distention, bowel distention, noxious stimuli

Risk for Autonomic Dysreflexia: Risk factors: bladder distention, bowel distention, noxious stimuli

Autonomic Hyperreflexia

See Autonomic Dysreflexia

B

Baby Care

Readiness for Enhanced Childbearing Process: demonstrates appropriate feeding and baby care techniques, along with attachment to infant and providing a safe environment

Anxiety r/t situational crisis, back injury

Ineffective Coping r/t situational crisis, back injury

Impaired Physical Mobility r/t pain

Acute Pain r/t back injury

Chronic Pain r/t back injury

Risk for Constipation: Risk factors: decreased activity, side effect of pain medication

Risk for Disuse Syndrome: Risk factor: severe pain

Readiness for Enhanced Knowledge: expresses an interest in learning

Bacteremia

Risk for Infection: Risk factor: compromised immune system

Risk for Shock: Risk factor: development of systemic inflammatory response from presence of bacteria in bloodstream

B

Balanced Energy Field

Imbalanced Energy Field (See **Energy Field, Imbalanced,** Section III)

Barrel Chest

See Aging (if appropriate); COPD (Chronic Obstructive Pulmonary Disease)

Bathing/Hygiene Problems

Impaired Mobility r/t chronic physically limiting condition

Self-Neglect (See **Self-Neglect,** Section III)

Bathing Self-Care Deficit (See **Self-Care Deficit, bathing,** Section III)

Battered Child Syndrome

Dysfunctional Family Processes r/t inadequate coping skills

Sleep Deprivation r/t prolonged psychological discomfort

Chronic Sorrow r/t situational crises

Risk for Post-Trauma Syndrome: Risk factors: physical abuse, incest, rape, molestation

Risk for Self-Mutilation: Risk factors: feelings of rejection, dysfunctional family

Risk for Suicidal Behavior: Risk factor: childhood abuse

See Child Abuse

Battered Person

See Abuse, Spouse, Parent, or Significant Other

Bedbugs, Infestation

Ineffective Home Maintenance Behaviors r/t deficient knowledge regarding prevention of bedbug infestation

Impaired Skin Integrity r/t bites of bedbugs

See Pruritus

Bed Mobility, Impaired

Impaired Bed Mobility (See **Mobility, Bed, Impaired,** Section III)

Bed Rest, Prolonged

Decreased Diversional Activity Engagement r/t prolonged bed rest

Impaired Bed Mobility r/t neuromuscular impairment

Social Isolation r/t prolonged bed rest

Risk for Chronic Functional Constipation: Risk factor: insufficient physical activity

Risk for Disuse Syndrome: Risk factor: prolonged immobility

Risk for Frail Elderly Syndrome: Risk factor: prolonged immobility

Risk for Loneliness: Risk factor: prolonged bed rest

Risk for Overweight: Risk factor: energy expenditure below energy intake

Risk for Pressure Ulcer: Risk factor: prolonged immobility

Risk for Thrombosis: Risk factor: prolonged immobility

Bedsores

See Pressure Ulcer

Bedwetting

Ineffective Health Maintenance Behaviors r/t unachieved developmental level, neuromuscular immaturity, diseases of the urinary system

Bell's Palsy

Disturbed Body Image r/t loss of motor control on one side of face

Imbalanced Nutrition: Less than Body Requirements r/t difficulty with chewing

Acute Pain r/t inflammation of facial nerve

Risk for Injury (Eye): Risk factors: decreased tears, decreased blinking of eye

Readiness for Enhanced Knowledge: expresses an interest in learning

Benign Prostatic Hypertrophy

See BPH (Benign Prostatic Hypertrophy); Prostatic Hypertrophy

Bereavement

Maladaptive Grieving r/t loss of significant person

Insomnia r/t grief

Risk for Maladaptive Grieving: Risk factor: emotional instability, lack of social support

Risk for Spiritual Distress: Risk factor: death of a loved one

Biliary Atresia

Anxiety r/t surgical intervention, possible liver transplantation

Impaired Comfort r/t inflammation of skin, itching

Imbalanced Nutrition: Less than Body Requirements r/t decreased absorption of fat and fat-soluble vitamins, poor feeding

Risk for Bleeding: Risk factors: vitamin K deficiency, altered clotting mechanisms

Ineffective Breathing Pattern r/t enlarged liver, development of ascites

Risk for Impaired Skin Integrity: Risk factor: pruritus

See Child with Chronic Condition; Cirrhosis; Hospitalized Child

Biliary Calculus

See Cholelithiasis

Biliary Obstruction

See Jaundice

Bilirubin Elevation in Neonate

See Hyperbilirubinemia, Neonatal

Biopsy

Fear r/t outcome of biopsy

Readiness for Enhanced Knowledge: expresses an interest in learning

Bioterrorism

Contamination r/t exposure to bioterrorism

Risk for Infection: Risk factor: exposure to harmful biological agent

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Risk for Post-Trauma Syndrome: Risk factor: perception of event of bioterrorism

Bipolar Disorder I (Most Recent Episode, Depressed or Manic)

Ineffective Activity Planning r/t unrealistic perception of events

Fatigue r/t psychological demands

Risk-Prone Health Behavior: Risk factor: low state of optimism

Ineffective Health Maintenance Behaviors r/t lack of ability to make good judgments regarding ways to obtain help

Self-Care Deficit: Specify r/t depression, cognitive impairment

Chronic Low Self-Esteem r/t repeated unmet expectations

Social Isolation r/t ineffective coping

Risk for Maladaptive Grieving: Risk factor: lack of previous resolution of former grieving response

Risk for Loneliness: Risk factors: stress, conflict

Risk for Spiritual Distress: Risk factor: mental illness

Risk for Suicidal Behavior: Risk factors: psychiatric disorder, poor support system

See Depression (Major Depressive Disorder); Manic Disorder, Bipolar I

Birth Asphyxia

See Asphyxia, Birth

Birth Control

See Contraceptive Method

Bladder Cancer

Urinary Retention r/t clots obstructing urethra

See Cancer; TURP (Transurethral Resection of the Prostate)

Bladder Distention

Urinary Retention r/t high urethral pressure caused by weak detrusor, inhibition of reflex arc, blockage, strong sphincter

Bladder Training

Disturbed Body Image r/t difficulty maintaining control of urinary elimination

Disability-Associated Urinary Incontinence r/t altered environment; sensory, cognitive, mobility deficit

Stress Urinary Incontinence r/t degenerative change in pelvic muscles and structural supports

Urge Urinary Incontinence r/t decreased bladder capacity, increased urine concentration, overdistention of bladder

Readiness for Enhanced Knowledge: expresses an interest in learning

Bladder Training, Child

See Toilet Training

Bleeding Tendency

Risk for Bleeding (See **Bleeding, Risk for,** Section III)

Risk for Delayed Surgical Recovery: Risk factor: bleeding tendency

Blepharoplasty

Disturbed Body Image r/t effects of surgery

Readiness for Enhanced Knowledge: expresses an interest in learning

Blindness

Interrupted Family Processes r/t shift in health status of family member (change in visual acuity)

Ineffective Home Maintenance Behaviors r/t decreased vision

Ineffective Role Performance r/t alteration in health status (change in visual acuity)

Self-Care Deficit: Specify r/t inability to see to be able to perform activities of daily living

Risk for Injury: Risk factor: sensory dysfunction

Readiness for Enhanced Knowledge: expresses an interest in learning

Blood Disorder

Ineffective Protection r/t abnormal blood profile

Risk for Bleeding: Risk factor: abnormal blood profile

See ITP (Idiopathic Thrombocytopenic Purpura); Hemophilia; Lacerations; Shock, Hypovolemic

Blood Glucose Control

Risk for Unstable Blood Glucose Level (See **Glucose Level, Blood, Unstable, Risk for,** Section III)

Blood Pressure Alteration

See Hypotension; HTN (Hypertension)

(See **Unstable Blood Pressure, Risk for,** Section III)

Blood Transfusion

Anxiety r/t possibility of harm from transfusion

See Anemia

Body Dysmorphic Disorder

Anxiety r/t perceived defect of body

Disturbed Body Image r/t over-involvement in physical appearance

Chronic Low Self-Esteem r/t lack of self-valuing because of perceived body defects

Social Isolation r/t distancing self from others because of perceived self-body defects

Risk for Suicidal Behavior: Risk factor: perceived defects of body affecting self-valuing and hopes

Body Image Change

Disturbed Body Image (See **Body Image, Disturbed,** Section III)

Body Temperature, Altered

Ineffective Thermoregulation (See **Thermoregulation, Ineffective,** Section III)

Bone Marrow Biopsy

Fear r/t unknown outcome of results of biopsy

Acute Pain r/t bone marrow aspiration

Readiness for Enhanced Knowledge: expresses an interest in learning

See Disease Necessitating Bone Marrow Biopsy (e.g., Leukemia)

Borderline Personality Disorder

Ineffective Activity Planning r/t unrealistic perception of events

Anxiety r/t perceived threat to self-concept

Defensive Coping r/t difficulty with relationships, inability to accept blame for own behavior

Ineffective Coping r/t use of maladjusted defense mechanisms (e.g., projection, denial)

Powerlessness r/t lifestyle of helplessness

Social Isolation r/t immature interests

Ineffective Family Health Self-Management r/t manipulative behavior of client

Risk for Caregiver Role Strain: Risk factors: inability of care receiver to accept criticism, care receiver taking advantage of others to meet own needs or having unreasonable expectations

Risk for Self-Mutilation: Risk factors: ineffective coping, feelings of self-hatred

Risk for Spiritual Distress: Risk factor: poor relationships associated with abnormal behaviors

Risk for Self-Directed Violence: Risk factors: feelings of need to punish self, manipulative behavior

Boredom

Decreased Diversional Activity Engagement r/t environmental lack of diversional activity

Impaired Mood Regulation r/t emotional instability

Social Isolation r/t altered state of wellness

Botulism

Deficient Fluid Volume r/t profuse diarrhea

Readiness for Enhanced Knowledge: expresses an interest in learning

Bowel Incontinence

Impaired Bowel Continence r/t decreased awareness of need to defecate, loss of sphincter control, fecal impaction

Readiness for Enhanced Knowledge: expresses an interest in learning

Bowel Obstruction

Constipation r/t decreased motility, intestinal obstruction

Deficient Fluid Volume r/t inadequate fluid volume intake, fluid loss in bowel

Imbalanced Nutrition: Less than Body Requirements r/t nausea, vomiting

Acute Pain r/t pressure from distended abdomen

Bowel Resection

See Abdominal Surgery

Bowel Sounds, Absent or Diminished

Constipation r/t decreased or absent peristalsis

Deficient Fluid Volume r/t inability to ingest fluids, loss of fluids in bowel

Delayed Surgical Recovery r/t inability to obtain adequate nutritional status

Risk for Dysfunctional Gastrointestinal Motility (See **Gastrointestinal Motility, Dysfunctional, Risk for,** Section III)

Bowel Sounds, Hyperactive

Diarrhea r/t increased gastrointestinal motility

Bowel Training

Impaired Bowel Continence r/t loss of control of rectal sphincter

Readiness for Enhanced Knowledge: expresses an interest in learning

Bowel Training, Child

See Toilet Training

BPH (Benign Prostatic Hypertrophy)

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding self-care with prostatic hypertrophy

Insomnia r/t nocturia

Urinary Retention r/t obstruction of urethra

Risk for Urge Urinary Incontinence: Risk factors: detrusor muscle instability with impaired contractility, involuntary sphincter relaxation

Risk for Infection: Risk factors: urinary residual after voiding, bacterial invasion of bladder

Readiness for Enhanced Knowledge: expresses an interest in learning

See Prostatic Hypertrophy

Bradycardia

Decreased Cardiac Output r/t slow heart rate supplying inadequate amount of blood for body function

Risk for Ineffective Cerebral Tissue Perfusion: Risk factors: decreased cardiac output secondary to bradycardia, vagal response

Readiness for Enhanced Knowledge: expresses an interest in learning

Bradypnea

Ineffective Breathing Pattern r/t neuromuscular impairment, pain, musculoskeletal impairment, perception or cognitive impairment, anxiety, fatigue or decreased energy, effects of drugs

See Sleep Apnea (See **Airway Clearance, Ineffective,** Section III)

Brain Injury

Risk for Ineffective Thermoregulation: Risk factor: posttraumatic inflammation or infection

See Intracranial Pressure, Increased

Brain Surgery

See Craniectomy/Craniotomy

Brain Tumor

Acute Confusion r/t pressure from tumor

Fear r/t threat to well-being

Maladaptive Grieving r/t potential loss of physiological-psychosocial well-being

Acute Pain r/t pressure from tumor

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Vision Loss r/t tumor growth compressing optic nerve and/or brain tissue

Risk for Injury: Risk factors: sensory-perceptual alterations, weakness

Risk for Ineffective Thermoregulation: Risk factor: changes in metabolic activity of the brain

See Cancer; Chemotherapy; Child with Chronic Condition; Craniectomy/Craniotomy; Hospitalized Child; Radiation Therapy; Terminally Ill Child, Adolescent; Terminally Ill Child, Infant/Toddler; Terminally Ill Child, Preschool Child; Terminally Ill Child, School-Age Child/Preadolescent; Terminally Ill Child/Death of Child, Parent

Braxton Hicks Contractions

Decreased Activity Tolerance r/t increased contractions with increased gestation

Anxiety r/t uncertainty about beginning labor

Fatigue r/t lack of sleep

Stress Urinary Incontinence r/t increased pressure on bladder with contractions

Insomnia r/t contractions when lying down

Ineffective Sexuality Pattern r/t fear of contractions associated with loss of infant

Breast Biopsy

Fear r/t potential for diagnosis of cancer

Risk for Spiritual Distress: Risk factor: fear of diagnosis of cancer

Readiness for Enhanced Knowledge: expresses an interest in learning

Breast Cancer

Death Anxiety r/t diagnosis of cancer

Ineffective Coping r/t treatment, prognosis

Fear r/t diagnosis of cancer

Sexual Dysfunction r/t loss of body part, partner's reaction to loss

Chronic Sorrow r/t diagnosis of cancer, loss of body integrity

Risk for Spiritual Distress: Risk factor: fear of diagnosis of cancer

Readiness for Enhanced Health Literacy: expresses desire to enhance understanding of health information to make health care choices

Readiness for Enhanced Knowledge: expresses an interest in learning

See Cancer; Chemotherapy; Mastectomy; Radiation Therapy

Breast Examination, Self

See SBE (Self–Breast Examination)

Breast Lumps

Fear r/t potential for diagnosis of cancer

Readiness for Enhanced Knowledge: expresses an interest in learning

Breast Pumping

Risk for Infection: Risk factors: possible contaminated breast pump, incomplete emptying of breast

Risk for Impaired Skin Integrity: Risk factor: high suction

Readiness for Enhanced Knowledge: expresses an interest in learning

Breastfeeding, Effective

Readiness for Enhanced Breastfeeding (See **Breastfeeding, Readiness for Enhanced,** Section III)

Breastfeeding, Ineffective

Ineffective Breastfeeding (See **Breastfeeding, Ineffective,** Section III)

See Ineffective Infant Suck-Swallow Response; Painful Breasts, Engorgement; Painful Breasts, Sore Nipples

Breastfeeding, Interrupted

Interrupted Breastfeeding (See **Breastfeeding, Interrupted,** Section III)

Breast Milk Production, Insufficient

Insufficient Breast Milk Production (See **Breast Milk Production, Insufficient,** Section III)

Breath Sounds, Decreased or Absent

See Atelectasis; Pneumothorax

Breathing Pattern Alteration

Ineffective Breathing Pattern r/t neuromuscular impairment, pain, musculoskeletal impairment, perception or cognitive impairment, anxiety, decreased energy or fatigue

Breech Birth

Fear: Maternal r/t danger to infant, self

Impaired Gas Exchange: Fetal r/t compressed umbilical cord

Risk for Aspiration: Fetal: Risk factor: birth of body before head

Risk for Impaired Tissue Integrity: Fetal: Risk factor: difficult birth

Risk for Impaired Tissue Integrity: Maternal: Risk factor: difficult birth

Bronchitis

Ineffective Airway Clearance r/t excessive thickened mucus secretion

Readiness for Enhanced Health Self-Management: wishes to stop smoking

Readiness for Enhanced Knowledge: expresses an interest in learning

Bronchopulmonary Dysplasia

Decreased Activity Tolerance r/t imbalance between oxygen supply and demand

Excess Fluid volume r/t sodium and water retention

Imbalanced Nutrition: Less than Body Requirements r/t poor feeding, increased caloric needs as a result of increased work of breathing

See Child with Chronic Condition; Hospitalized Child; Respiratory Conditions of the Neonate

Bronchoscopy

Risk for Aspiration: Risk factor: temporary loss of gag reflex

Risk for Injury: Risk factors: complication of pneumothorax, laryngeal edema, hemorrhage (if biopsy done)

Bruits, Carotid

Risk for Ineffective Cerebral Tissue Perfusion: Risk factors: interruption of carotid blood flow to brain

Bryant's Traction

See Traction and Casts

Buck's Traction

See Traction and Casts

Buerger's Disease

See Peripheral Vascular Disease (PVD)

Bulimia

Disturbed Body Image r/t misperception about actual appearance, body weight

Compromised Family Coping r/t chronically unresolved feelings of guilt, anger, hostility

Defensive Coping r/t eating disorder

Diarrhea r/t laxative abuse

Fear r/t food ingestion, weight gain

Imbalanced Nutrition: Less than Body Requirements r/t induced vomiting, excessive exercise, laxative abuse

Ineffective Adolescent Eating Dynamics r/t overeating, leading to purge

Powerlessness r/t urge to purge self after eating

Chronic Low Self-Esteem r/t lack of positive feedback

See Maturational Issues, Adolescent

Bullying

Anxiety r/t specific or nonspecific threat to self

Impaired Social Interaction r/t dysfunctional interactions with others

Fear r/t perceived threat to self

Risk for Compromised Human Dignity: Risk factors: dehumanizing treatment, humiliation

Risk for Other-Directed Violence: Risk factors: social isolation, unresolved interpersonal conflicts

Risk for Powerlessness: Risk factor: ineffective coping strategies

Risk for Impaired Resilience: Risk factor: insufficient familial and social support

Risk for Self-Directed violence: Risk factors: unresolved interpersonal conflicts, social isolation

Risk for Chronic Low Self-Esteem: Risk factors: ineffective coping strategies, absence of sense of belonging, inadequate respect from others

Bunion

Readiness for Enhanced Knowledge: expresses an interest in learning

Bunionectomy

Impaired physical Mobility r/t sore foot

Impaired Walking r/t pain associated with surgery

Risk for Surgical Site Infection: Risk factors: surgical incision

Readiness for Enhanced Knowledge: expresses an interest in learning

Burn Risk

Risk for Thermal Injury (See **Thermal Injury, Risk for,** Section III)

Burns

Anxiety r/t burn injury, treatments

Disturbed Body Image r/t altered physical appearance

Decreased Diversional Activity Engagement r/t long-term hospitalization

Fear r/t pain from treatments, possible permanent disfigurement

Deficient Fluid Volume r/t loss of protective skin

Maladaptive Grieving r/t loss of bodily function, loss of future hopes and plans

Hypothermia r/t impaired skin integrity

Impaired Physical Mobility r/t pain, musculoskeletal impairment, contracture formation

Imbalanced Nutrition: Less than Body Requirements r/t increased metabolic needs, anorexia, protein and fluid loss

Acute Pain r/t burn injury, treatments

Chronic Pain r/t burn injury, treatments

Ineffective Peripheral Tissue Perfusion r/t circumferential burns, impaired arterial/venous circulation

Post-Trauma Syndrome r/t life-threatening event

Impaired Skin Integrity r/t injury of skin

Delayed Surgical Recovery r/t ineffective tissue perfusion

Risk for Ineffective Airway Clearance: Risk factors: potential tracheobronchial obstruction, edema

Risk for Deficient Fluid Volume: Risk factors: loss from skin surface, fluid shift

Risk for Infection: Risk factors: loss of intact skin, trauma, invasive sites

Risk for Peripheral Neurovascular Dysfunction: Risk factor: eschar formation with circumferential burn

Risk for Post-Trauma Syndrome: Risk factors: perception, duration of event that caused burns

Risk for Ineffective Thermoregulation: Risk factor: disruption of skin integrity

Readiness for Enhanced Knowledge: expresses an interest in learning

See Hospitalized Child; Safety, Childhood

Bursitis

Impaired Physical Mobility r/t inflammation in joint

Acute Pain r/t inflammation in joint

Bypass Graft

See Coronary Artery Bypass Grafting (CABG)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

C

CABG (Coronary Artery Bypass Grafting)

See Coronary Artery Bypass Grafting (CABG)

Cachexia

Frail Elderly Syndrome r/t fatigue, feeding self-care deficit

Imbalanced Nutrition: Less than Body Requirements r/t inability to ingest food because of physiological factors

Risk for Infection: Risk factor: inadequate nutrition

Calcium Alteration

See Hypercalcemia; Hypocalcemia

Cancer

Decreased Activity Tolerance r/t side effects of treatment, weakness from cancer

Death Anxiety r/t unresolved issues regarding dying

Disturbed Body Image r/t side effects of treatment, cachexia

Decisional Conflict r/t selection of treatment choices, continuation or discontinuation of treatment, "do not resuscitate" decision

Constipation r/t side effects of medication, altered nutrition, decreased activity

Compromised Family Coping r/t prolonged disease or disability progression that exhausts supportive ability of significant others

Ineffective Coping r/t personal vulnerability in situational crisis, terminal illness

Ineffective Denial r/t complicated grieving process

Fear r/t serious threat to well-being

Maladaptive Grieving r/t potential loss of significant others, high risk for infertility

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding prescribed treatment

Hopelessness r/t loss of control, terminal illness

Insomnia r/t anxiety, pain

Impaired Physical Mobility r/t weakness, neuromusculoskeletal impairment, pain

Imbalanced Nutrition: Less than Body Requirements r/t loss of appetite, difficulty swallowing, side effects of chemotherapy, obstruction by tumor

Impaired Oral Mucous Membrane Integrity r/t chemotherapy, effects of radiation, oral pH changes, decreased oral secretions

Chronic Pain r/t metastatic cancer

Powerlessness r/t treatment, progression of disease

Ineffective Protection r/t cancer suppressing immune system

Ineffective Role Performance r/t change in physical capacity, inability to resume prior role

Self-Care Deficit: Specify r/t pain, intolerance to activity, decreased strength

Impaired Skin Integrity r/t immunological deficit, immobility

Social Isolation r/t hospitalization, lifestyle changes

Chronic Sorrow r/t chronic illness of cancer

Spiritual Distress r/t test of spiritual beliefs

Risk for Bleeding: Risk factor: bone marrow depression from chemotherapy

Risk for Disuse Syndrome: Risk factors: immobility, fatigue

Risk for Ineffective Home Maintenance Behaviors: Risk factor: lack of familiarity with community resources

Risk for Infection: Risk factor: inadequate immune system

Risk for Impaired Resilience: Risk factors: multiple stressors, pain, chronic illness

Risk for Spiritual Distress: Risk factor: physical illness of cancer

Readiness for Enhanced Knowledge: expresses an interest in learning

Readiness for enhanced spiritual well-being: desire for harmony with self, others, higher power, God, when faced with serious illness

See Chemotherapy; Child with Chronic Condition; Hospitalized Child; Leukemia; Radiation Therapy; Terminally Ill Child, Adolescent; Terminally Ill Child, Infant/Toddler; Terminally Ill Child, Preschool Child; Terminally Ill Child, School-Age Child/Preadolescent; Terminally Ill Child/Death of Child, Parent

Candidiasis, Oral

Readiness for Enhanced Knowledge: expresses an interest in learning

Impaired Oral Mucous Membrane Integrity r/t overgrowth of infectious agent, depressed immune function

Acute Pain r/t oral condition

Capillary Refill Time, Prolonged

Impaired Gas Exchange r/t ventilation perfusion imbalance

Ineffective Peripheral Tissue Perfusion r/t interruption of arterial flow

See Shock, Hypovolemic

Carbon Monoxide Poisoning

See Smoke Inhalation

Cardiac Arrest

Post-Trauma Syndrome r/t experiencing serious life event

See Dysrhythmia; MI (Myocardial Infarction)

Cardiac Catheterization

Fear r/t invasive procedure, uncertainty of outcome of procedure

Risk for Injury: Hematoma: Risk factor: invasive procedure

Risk for Decreased Cardiac Tissue Perfusion: Risk factors: ventricular ischemia, dysrhythmia

Risk for Peripheral Neurovascular Dysfunction: Risk factor: vascular obstruction

Risk for Impaired Tissue Integrity: Risk factor: invasive procedure

Readiness for Enhanced Knowledge: expresses an interest in learning postprocedure care, treatment, and prevention of coronary artery disease

C

Cardiac Disorders in Pregnancy

Decreased Activity Tolerance r/t cardiac pathophysiology, increased demand for cardiac output because of pregnancy, weakness, fatigue

Death Anxiety r/t potential danger of condition

Compromised Family Coping r/t prolonged hospitalization or maternal incapacitation that exhausts supportive capacity of significant others

Ineffective Coping r/t personal vulnerability

Interrupted Family Processes r/t hospitalization, maternal incapacitation, changes in roles

Fatigue r/t physiological, psychological, and emotional demands

Fear r/t potential maternal effects, potential poor fetal or maternal outcome

Powerlessness r/t illness-related regimen

Ineffective Role Performance r/t changes in lifestyle, expectations from disease process with superimposed pregnancy

Situational Low Self-Esteem r/t situational crisis, pregnancy

Social Isolation r/t limitations of activity, bed rest or hospitalization, separation from family and friends

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: strain on compromised heart from work of pregnancy, delivery

Risk for Imbalanced Fluid Volume: Risk factor: sudden changes in circulation after delivery of placenta, compromised regulatory mechanism with increased afterload, preload, circulating blood volume

Risk for Impaired Gas Exchange: Risk factor: pulmonary edema

Risk for Disturbed Maternal–Fetal Dyad: Risk factor: compromised oxygen transport

Risk for impaired Resilience: Risk factors: multiple stressors, fear

Risk for Spiritual Distress: Risk factor: fear of diagnosis for self and infant

Readiness for Enhanced Knowledge: expresses an interest in learning

Cardiac Dysrhythmia

See Dysrhythmia

Cardiac Output, Decreased

Decreased Cardiac Output r/t cardiac dysfunction

Decreased Cardiac Output (See **Cardiac Output, Decreased,** Section III)

Risk for Decreased Cardiac Output (See **Cardiac Output, Risk for Decreased,** Section III)

Cardiac Tamponade

Decreased Cardiac Output r/t fluid in pericardial sac

See Pericarditis

Cardiogenic Shock

See Shock, Cardiogenic

Caregiver Role Strain

Caregiver Role Strain (See **Caregiver Role Strain,** Section III)

Risk for Impaired Resilience: Risk factor: stress of prolonged caregiving

Carious Teeth

See Cavities in Teeth

Carotid Endarterectomy

Fear r/t surgery in vital area

Risk for Ineffective Airway Clearance: Risk factor: hematoma compressing trachea

Risk for Bleeding: Risk factor: possible hematoma formation, trauma to region

Risk for Ineffective Cerebral Tissue Perfusion: Risk factors: hemorrhage, clot formation

Readiness for Enhanced Knowledge: expresses an interest in learning

Carpal Tunnel Syndrome

Impaired Physical Mobility r/t neuromuscular impairment

Chronic Pain r/t unrelieved pressure on median nerve

Self-Care Deficit: Bathing, Dressing, Feeding r/t pain

Carpopedal Spasm

See Hypocalcemia

Casts

Decreased Diversional Activity Engagement r/t physical limitations from cast

Impaired Physical Mobility r/t limb immobilization

Self-Care Deficit: Bathing, Dressing, Feeding r/t presence of cast(s) on upper extremities

Self-Care Deficit: Toileting r/t presence of cast(s) on lower extremities

Impaired Walking r/t cast(s) on lower extremities, fracture of bones

Risk for Peripheral Neurovascular Dysfunction: Risk factors: mechanical compression from cast, trauma from fracture

Risk for Impaired Skin Integrity: Risk factor: unrelieved pressure on skin from cast

Readiness for Enhanced Knowledge: expresses an interest in learning

See Traction and Casts

Cataract Extraction

Anxiety r/t threat of permanent vision loss, surgical procedure

Vision Loss r/t edema from surgery (see Appendix E on Evolve)

Risk for Injury: Risk factors: increased intraocular pressure, accommodation to new visual field

Readiness for Enhanced Knowledge: expresses an interest in learning

Catatonic Schizophrenia

Impaired Verbal Communication r/t cognitive impairment

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Impaired Memory r/t cognitive impairment

Impaired Physical Mobility r/t cognitive impairment, maintenance of rigid posture, inappropriate or bizarre postures

Imbalanced Nutrition: Less than Body Requirements r/t decrease in outside stimulation, loss of perception of hunger, resistance to instructions to eat

Social Isolation r/t inability to communicate, immobility

See Schizophrenia

Catheterization, Urinary

Risk for Infection: Risk factor: invasive procedure

Readiness for Enhanced Knowledge: expresses an interest in learning

Cavities in Teeth

Impaired Dentition r/t ineffective oral hygiene, barriers to self-care, economic barriers to professional care, nutritional deficits, dietary habits

Celiac Disease

Diarrhea r/t malabsorption of food, immune effects of gluten on gastrointestinal system

Imbalanced Nutrition: Less than Body Requirements r/t malabsorption caused by immune effects of gluten

Readiness for Enhanced Knowledge: expresses an interest in learning

Cellulitis

Acute Pain r/t inflammatory changes in tissues from infection

Impaired Tissue Integrity r/t inflammatory process damaging skin and underlying tissue

Ineffective Peripheral Tissue Perfusion r/t edema of extremities

Risk for Vascular Trauma: Risk factor: infusion of antibiotics

Readiness for Enhanced Knowledge: expresses an interest in learning

Cellulitis, Periorbital

Acute Pain r/t edema and inflammation of skin/tissues

Impaired Skin Integrity r/t inflammation or infection of skin, tissues

Vision Loss r/t decreased visual field secondary to edema of eyelids (see Appendix E on Evolve)

Readiness for Enhanced Knowledge: expresses an interest in learning

See Hospitalized Child

Central Line Insertion

Risk for Infection: Risk factor: invasive procedure

Risk for Vascular Trauma (See **Vascular Trauma, Risk for,** Section III)

Readiness for Enhanced Knowledge: expresses an interest in learning

Cerebral Aneurysm

See Craniectomy/Craniotomy; Intracranial Pressure, Increased; Subarachnoid Hemorrhage

Cerebral Palsy

Impaired Verbal Communication r/t impaired ability to articulate or speak words because of facial muscle involvement

Decreased Diversional Activity Engagement r/t physical impairments, limitations on ability to participate in recreational activities

Impaired Physical Mobility r/t spasticity, neuromuscular impairment or weakness

Imbalanced Nutrition: Less than Body Requirements r/t spasticity, feeding or swallowing difficulties

Self-Care Deficit: Specify r/t neuromuscular impairments, sensory deficits

Impaired Social Interaction r/t impaired communication skills, limited physical activity, perceived differences from peers

Chronic Sorrow r/t presence of chronic disability

Risk for Adult Falls: Risk factor: impaired physical mobility

Risk for Child Falls: Risk factor: impaired physical mobility

Risk for Injury: Risk factors: muscle weakness, inability to control spasticity

Risk for Impaired Parenting: Risk factor: caring for child with overwhelming needs resulting from chronic change in health status

Risk for Spiritual Distress: Risk factor: psychological stress associated with chronic illness

See Child with Chronic Condition

Cerebral Perfusion

Risk for Ineffective Cerebral Tissue Perfusion (See **Cerebral Tissue Perfusion, Ineffective, Risk for,** Section III)

Cerebrovascular Accident (CVA)

See CVA (Cerebrovascular Accident)

Cervicitis

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding care and prevention of condition

Ineffective Sexuality Pattern r/t abstinence during acute stage

Risk for Infection: Risk factors: spread of infection, recurrence of infection

Cesarean Delivery

Disturbed Body Image r/t surgery, unmet expectations for childbirth

Interrupted Family Processes r/t unmet expectations for childbirth

Fear r/t perceived threat to own well-being, outcome of birth

Impaired Physical Mobility r/t pain

Acute Pain r/t surgical incision

Ineffective Role Performance r/t unmet expectations for childbirth

Situational Low Self-Esteem r/t inability to deliver child vaginally

Risk for Bleeding: Risk factor: surgery

Risk for Imbalanced Fluid Volume: Risk factors: loss of blood, fluid shifts

Risk for Surgical Site Infection: Risk factor: surgical incision

Risk for Urinary Retention: Risk factor: regional anesthesia

Readiness for Enhanced Childbearing Process: a pattern of preparing for, maintaining, and strengthening care of newborn

Readiness for Enhanced Knowledge: expresses an interest in learning

Chemical Dependence

See Alcoholism; Substance Abuse

Chemotherapy

Death Anxiety r/t chemotherapy not accomplishing desired results

Disturbed Body Image r/t loss of weight, loss of hair

Fatigue r/t disease process, anemia, drug effects

Nausea r/t effects of chemotherapy

Imbalanced Nutrition: Less than Body Requirements r/t side effects of chemotherapy

Impaired Oral Mucous Membrane Integrity r/t effects of chemotherapy

Ineffective Protection r/t suppressed immune system, decreased platelets

Risk for Bleeding: Risk factors: tumor eroding blood vessel, stress effects on gastrointestinal system

Risk for Infection: Risk factor: immunosuppression

Risk for Vascular Trauma: Risk factor: infusion of irritating medications

Readiness for Enhanced Knowledge: expresses an interest in learning

See Cancer

Chest Pain

Fear r/t potential threat of death

Acute Pain r/t myocardial injury, ischemia

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: ventricular ischemia

See Angina; MI (Myocardial Infarction)

Chest Tubes

Ineffective Breathing Pattern r/t asymmetrical lung expansion secondary to pain

Impaired Gas Exchange r/t decreased functional lung tissue

Acute Pain r/t presence of chest tubes, injury

Risk for Injury: Risk factor: presence of invasive chest tube

Cheyne-Stokes Respiration

Ineffective Breathing pattern r/t critical illness

Chickenpox

See Communicable Diseases, Childhood

Child Abuse

Interrupted Family Processes r/t inadequate coping skills

Fear r/t threat of punishment for perceived wrongdoing

Insomnia r/t hypervigilance, fear

Imbalanced Nutrition: Less than Body Requirements r/t inadequate caretaking

Acute Pain r/t physical injuries

Impaired Parenting r/t psychological impairment, physical or emotional abuse of parent, substance abuse, unrealistic expectations of child

Ineffective Child Eating Dynamics r/t hostile parental relationship

Post-Trauma Syndrome r/t physical abuse, incest, rape, molestation

Chronic Low Self-Esteem r/t lack of positive feedback, excessive negative feedback

Impaired Skin Integrity r/t altered nutritional state, physical abuse

Social Isolation: Family Imposed r/t fear of disclosure of family dysfunction and abuse

Risk for Poisoning: Risk factors: inadequate safeguards, lack of proper safety precautions, accessibility of illicit substances because of impaired home maintenance

Risk for Suffocation: Risk factors: unattended child, unsafe environment

Risk for Physical Trauma: Risk factors: inadequate precautions, cognitive or emotional difficulties

Childbearing Problems

Ineffective Childbearing Process (See **Childbearing Process, Ineffective,** Section III)

Risk for Ineffective Childbearing Process (See **Childbearing Process, Risk for Ineffective,** Section III)

Child Neglect

See Child Abuse; Failure to Thrive

Child with Chronic Condition

Decreased Activity Tolerance r/t fatigue associated with chronic illness

Compromised Family Coping r/t prolonged overconcern for child; distortion of reality regarding child's health problem, including extreme denial about its existence or severity

Disabled Family Coping r/t prolonged disease or disability progression that exhausts supportive capacity of significant others

Ineffective Coping: Child r/t situational or maturational crises

Decisional Conflict r/t treatment options, conflicting values

Decreased Diversional Activity Engagement r/t immobility, monotonous environment, frequent or lengthy treatments, reluctance to participate, self-imposed social isolation

Interrupted Family Processes r/t intermittent situational crisis of illness, disease, hospitalization

Ineffective Health Maintenance Behaviors r/t exhausting family resources (finances, physical energy, support systems)

Ineffective Home Maintenance Behaviors r/t overtaxed family members (e.g., exhausted, anxious)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Hopelessness: Child r/t prolonged activity restriction, long-term stress, lack of involvement in or passively allowing care as a result of parental overprotection

Insomnia: Child or Parent r/t time-intensive treatments, exacerbation of condition, 24-hour care needs

Deficient Knowledge r/t knowledge or skill acquisition regarding health practices, acceptance of limitations, promotion of maximal potential of child, self-actualization of rest of family

Imbalanced Nutrition: Less than Body Requirements r/t anorexia, fatigue from physical exertion

Risk for Overweight r/t effects of steroid medications on appetite

Chronic Pain r/t physical, biological, chemical, or psychological factors

Powerlessness: Child r/t health care environment, illness-related regimen, lifestyle of learned helplessness

Parental Role Conflict r/t separation from child as a result of chronic illness, home care of child with special needs, interruptions of family life resulting from home care regimen

Chronic Low Self-Esteem r/t actual or perceived differences; peer acceptance; decreased ability to participate in physical, school, and social activities

Ineffective Sexuality Pattern: Parental r/t disrupted relationship with sexual partner

Impaired Social Interaction r/t developmental lag or delay, perceived differences

Social Isolation: Family r/t actual or perceived social stigmatization, complex care requirements

Chronic Sorrow r/t developmental stages and missed opportunities or milestones that bring comparisons with social or personal norms, unending caregiving as reminder of loss

Risk for Delayed Child Development: Risk factor: chronic illness

Risk for Infection: Risk factor: debilitating physical condition

Risk for Impaired Parenting: Risk factors: impaired or disrupted bonding, caring for child with perceived overwhelming care needs

Readiness for Enhanced Family Coping: impact of crisis on family values, priorities, goals, or relationships; changes in family choices to optimize wellness

Childbirth

Readiness for Enhanced Childbearing Process (See **Childbearing Process, Readiness for Enhanced,** Section III)

See Labor, Normal; Postpartum, Normal Care

Childhood Obesity

Obesity r/t disordered eating behaviors

Risk for Unstable Blood Glucose Level: Risk factor: excessive weight gain

Risk for Metabolic Syndrome: Risk factors: obesity, sedentary lifestyle

Readiness for Enhanced Exercise Engagement: expresses desire to engage in regular exercise

Readiness for Enhanced Knowledge: expresses desire to make healthier nutrition choices

Chills

Hyperthermia r/t infectious process

Chlamydia Infection

See STD (Sexually Transmitted Disease)

Chloasma

Disturbed Body Image r/t change in skin color

Choking or Coughing with Eating

Impaired Swallowing r/t neuromuscular impairment

Risk for Aspiration: Risk factors: depressed cough and gag reflexes

Cholecystectomy

Imbalanced Nutrition: Less than Body Requirements r/t high metabolic needs, decreased ability to digest fatty foods

Acute Pain r/t trauma from surgery

Risk for Deficient Fluid Volume: Risk factors: restricted intake, nausea, vomiting

Risk for Surgical Site Infection: Risk factor: invasive procedure

Readiness for Enhanced Knowledge: expresses an interest in learning

See Abdominal Surgery

Cholelithiasis

Nausea r/t obstruction of bile

Imbalanced Nutrition: Less than Body Requirements r/t anorexia, nausea, vomiting

Acute Pain r/t obstruction of bile flow, inflammation in gallbladder

Readiness for Enhanced Knowledge: expresses an interest in learning

Chorioamnionitis

Anxiety r/t threat to self and infant

Maladaptive Grieving r/t guilt about potential loss of ideal pregnancy and birth

Hyperthermia r/t infectious process

Situational Low Self-Esteem r/t guilt about threat to infant's health

Risk for Infection: Risk factors: infection transmission from mother to fetus; infection in fetal environment

Chronic Confusion

See Confusion, Chronic

Chronic Functional Constipation

(See **Constipation, Chronic Functional,** Section III)

(See **Constipation, Chronic Functional, Risk for,** Section III)

Chronic Lymphocytic Leukemia

See Cancer; Chemotherapy; Leukemia

C

Chronic Obstructive Pulmonary Disease (COPD)

See COPD (Chronic Obstructive Pulmonary Disease)

Chronic Pain

See Pain Management, Chronic

Chronic Renal Failure (Chronic Renal Disease)

See Renal Failure

Chvostek's Sign

See Hypocalcemia

Circumcision

Acute Pain r/t surgical intervention

Risk for Bleeding: Risk factor: surgical trauma

Risk for Infection: Risk factor: surgical wound

Readiness for Enhanced Knowledge: Parent: expresses an interest in learning

Cirrhosis

Chronic Confusion r/t chronic organic disorder with increased ammonia levels, substance abuse

Defensive Coping r/t inability to accept responsibility to stop substance abuse

Fatigue r/t malnutrition

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding correlation between lifestyle habits and disease process

Nausea r/t irritation to gastrointestinal system

Imbalanced Nutrition: Less than Body Requirements r/t loss of appetite, nausea, vomiting

Chronic Pain r/t liver enlargement

Chronic Low Self-Esteem r/t chronic illness

Chronic Sorrow r/t presence of chronic illness

Risk for Bleeding: Risk factors: impaired blood coagulation, bleeding from portal hypertension

Risk for Injury: Risk factors: substance intoxication, potential delirium tremens

Risk for Impaired Oral Mucous Membrane Integrity: Risk factors: altered nutrition, inadequate oral care

Risk for Impaired Skin Integrity: Risk factors: altered nutritional state, altered metabolic state

Cleft Lip/Cleft Palate

Ineffective Airway Clearance r/t common feeding and breathing passage, postoperative laryngeal, incisional edema

Ineffective Breastfeeding r/t infant anomaly

Impaired Verbal Communication r/t inadequate palate function, possible hearing loss from infected eustachian tubes

Fear: Parental r/t special care needs, surgery

Maladaptive Grieving r/t loss of perfect child

Ineffective Infant Feeding Dynamics r/t fear resulting in inadequate feeding

Ineffective Infant Suck-Swallow Response r/t cleft lip, cleft palate

Impaired Physical Mobility r/t imposed restricted activity, use of elbow restraints

Impaired Oral Mucous Membrane Integrity r/t surgical correction

Acute Pain r/t surgical correction, elbow restraints

Impaired Skin Integrity r/t incomplete joining of lip, palate ridges

Chronic Sorrow r/t birth of child with congenital defect

Risk for Aspiration: Risk factor: common feeding and breathing passage

Risk for Disturbed Body Image: Risk factors: disfigurement, speech impediment

Risk for Deficient Fluid Volume: Risk factor: inability to take liquids in usual manner

Risk for Infection: Risk factors: invasive procedure, disruption of eustachian tube development, aspiration

Readiness for Enhanced Knowledge: Parent: expresses an interest in learning

Clotting Disorder

Fear r/t threat to well-being

Risk for Bleeding: Risk factor: impaired clotting

Readiness for Enhanced Knowledge: expresses an interest in learning

See Anticoagulant Therapy; DIC (Disseminated Intravascular Coagulation); Hemophilia

Cocaine Baby

See Neonatal Abstinence Syndrome

Codependency

Caregiver Role Strain r/t codependency

Impaired Verbal Communication r/t psychological barriers

Ineffective Coping r/t inadequate support systems

Decisional Conflict r/t support system deficit

Ineffective Denial r/t unmet self-needs

Powerlessness r/t lifestyle of helplessness

Cold, Viral

See Infectious Processes

Colectomy

Constipation r/t decreased activity, decreased fluid intake

Imbalanced Nutrition: Less than Body Requirements r/t high metabolic needs, decreased ability to ingest or digest food

Acute Pain r/t recent surgery

Risk for Surgical Site Infection: Risk factor: invasive procedure

Readiness for Enhanced Knowledge: expresses an interest in learning

See Abdominal Surgery

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Colitis

Diarrhea r/t inflammation in colon

Deficient Fluid Volume r/t frequent stools

Acute Pain r/t inflammation in colon

Readiness for Enhanced Knowledge: expresses an interest in learning

See Crohn's Disease; Inflammatory Bowel Disease (Child and Adult)

Collagen Disease

See specific disease (e.g., Lupus Erythematosus; JRA [Juvenile Rheumatoid Arthritis]); Congenital Heart Disease/Cardiac Anomalies

Colostomy

Disturbed Body Image r/t presence of stoma, daily care of fecal material

Ineffective Sexuality Pattern r/t altered body image, self-concept

Social Isolation r/t anxiety about appearance of stoma and possible leakage of stool

Risk for Constipation: Risk factor: inappropriate diet

Risk for Diarrhea: Risk factor: inappropriate diet

Risk for Impaired Skin Integrity: Risk factor: irritation from bowel contents

Readiness for Enhanced Knowledge: expresses an interest in learning

Colporrhaphy, Anterior

See Vaginal Hysterectomy

Coma

Death Anxiety: Significant Others r/t unknown outcome of coma state

Interrupted Family Processes r/t illness or disability of family member

Disability-Associated Urinary Incontinence r/t presence of comatose state

Self-Care Deficit r/t neuromuscular impairment

Ineffective Family Health Self-Management r/t complexity of therapeutic regimen

Risk for Aspiration: Risk factors: impaired swallowing, loss of cough or gag reflex

Risk for Disuse Syndrome: Risk factor: altered level of consciousness impairing mobility

Risk for Dry Mouth: Risk factor: inability to perform own oral care

Risk for Hypothermia: Risk factors: inactivity, possible pharmaceutical agents, possible hypothalamic injury

Risk for Injury: Risk factor: potential seizure activity

Risk for Corneal Injury: Risk factor: suppressed corneal reflex

Risk for Urinary Tract Injury: Risk factor: long-term use of urinary catheter

Risk for Impaired Oral Mucous Membrane Integrity: Risk factors: dry mouth, inability to do own mouth care

Risk for Pressure Ulcer: Risk factor: prolonged immobility

Risk for Impaired Skin Integrity: Risk factor: immobility

Risk for Spiritual Distress: Significant Others: Risk factors: loss of ability to relate to loved one, unknown outcome of coma

Risk for Impaired Tissue Integrity: Risk factor: impaired physical mobility

See Head Injury; Subarachnoid Hemorrhage; Intracranial Pressure, Increased

Comfort, Loss of

Impaired Comfort (See **Comfort, Impaired,** Section III)

Readiness for Enhanced Comfort (See **Comfort, Readiness for Enhanced,** Section III)

Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice, Impetigo)

Impaired Comfort r/t pruritus, inflammation or infection of skin, subdermal organisms

Decreased Diversional Activity Engagement r/t imposed isolation from peers, disruption in usual play activities, fatigue, activity intolerance

Ineffective Health Maintenance Behaviors r/t nonadherence to appropriate immunization schedules, lack of prevention of transmission of infection

Acute Pain r/t impaired skin integrity, edema

Risk for Infection: Transmission to Others: Risk factor: contagious organisms

See Meningitis/Encephalitis; Respiratory Infections, Acute Childhood

Communication

Readiness for Enhanced Communication (See **Communication, Readiness for Enhanced,** Section III)

Communication Problems

Impaired Verbal Communication (See **Communication, Verbal, Impaired,** Section III)

Community Coping

Ineffective Community Coping (See **Coping, Community, Ineffective,** Section III)

Readiness for Enhanced Community Coping: community sense of power to manage stressors, social supports available, resources available for problem solving

Community Health Problems

Deficient community Health (See **Health, Deficient, Community,** Section III)

Companion Animal

Anxiety r/t environmental and personal stressors

Impaired Comfort r/t insufficient environmental control

Compartment Syndrome

Fear r/t possible loss of limb, damage to limb

Acute Pain r/t pressure in compromised body part

Ineffective Peripheral Tissue Perfusion r/t increased pressure within compartment

C

Compulsion

See OCD (Obsessive-Compulsive Disorder)

Conduction Disorders (Cardiac)

See Dysrhythmia

Confusion, Acute

Acute Confusion r/t older than 70 years of age with hospitalization, alcohol abuse, delirium, dementia, substance abuse

Frail Elderly Syndrome r/t impaired memory

Risk for Acute Confusion: Risk factor: alteration in level of consciousness

Confusion, Chronic

Chronic Confusion r/t dementia, Korsakoff's psychosis, multi-infarct dementia, cerebrovascular accident, head injury

Frail Elderly Syndrome r/t impaired memory

Impaired Memory r/t fluid and electrolyte imbalance, neurological disturbances, excessive environmental disturbances, anemia, acute or chronic hypoxia, decreased cardiac output

Impaired Mood Regulation r/t emotional instability

See Alzheimer's Disease; Dementia

Congenital Heart Disease/Cardiac Anomalies

Decreased Activity Tolerance r/t fatigue, generalized weakness, lack of adequate oxygenation

Ineffective Breathing Pattern r/t pulmonary vascular disease

Decreased Cardiac Output r/t cardiac dysfunction

Excess Fluid Volume r/t cardiac dysfunction, side effects of medication

Impaired Gas Exchange r/t cardiac dysfunction, pulmonary congestion

Imbalanced Nutrition: Less than Body Requirements r/t fatigue, generalized weakness, inability of infant to suck and feed, increased caloric requirements

Risk for Deficient Fluid Volume: Risk factor: side effects of diuretics

Risk for Disorganized Infant Behavior: Risk factor: invasive procedures

Risk for Poisoning: Risk factor: potential toxicity of cardiac medications

Risk for Ineffective Thermoregulation: Risk factor: neonatal age

See Child with Chronic Condition; Hospitalized Child

Congestive Heart Failure (CHF)

See Heart Failure

Conjunctivitis

Acute Pain r/t inflammatory process

Vision Loss r/t change in visual acuity resulting from inflammation

Consciousness, Altered Level of

Acute Confusion r/t alcohol abuse, delirium, dementia, drug abuse, head injury

Chronic Confusion r/t multi-infarct dementia, Korsakoff's psychosis, head injury, cerebrovascular accident, neurological deficit

Disability-Associated Urinary Incontinence r/t neurological dysfunction

Impaired Memory r/t neurological disturbances

Self-Care Deficit: Specify r/t neuromuscular impairment

Risk for Aspiration: Risk factors: impaired swallowing, loss of cough or gag reflex

Risk for Disuse Syndrome: Risk factor: impaired mobility resulting from altered level of consciousness

Risk for Dry Mouth: Risk factor: inability to perform own oral care

Risk for Falls: Risk factor: diminished mental status

Risk for Impaired Oral Mucous Membrane Integrity: Risk factors: dry mouth, interrupted oral care

Risk for Ineffective Cerebral Tissue Perfusion: Risk factors: increased intracranial pressure, altered cerebral perfusion

Risk for Impaired Skin Integrity: Risk factor: immobility

See Coma; Head Injury; Subarachnoid Hemorrhage; Intracranial Pressure, Increased

Constipation

Constipation (See **Constipation,** Section III)

Constipation, Chronic Functional

Constipation (See **Constipation, Chronic Functional,** Section III)

Constipation, Perceived

Perceived Constipation (See **Perceived Constipation,** Section III)

Constipation, Risk for

Risk for Constipation (See **Constipation, Risk for,** Section III)

Risk for chronic functional Constipation (See **Constipation, Chronic Functional, Risk for,** Section III)

Contamination

Contamination (See **Contamination,** Section III)

Risk for Contamination (See **Contamination, Risk for,** Section III)

Continent Ileostomy (Kock Pouch)

Ineffective Coping r/t stress of disease, exacerbations caused by stress

Imbalanced Nutrition: Less than Body Requirements r/t malabsorption from disease process

Risk for Injury: Risk factors: failure of valve, stomal cyanosis, intestinal obstruction

Readiness for Enhanced Knowledge: expresses an interest in learning

See Abdominal Surgery; Crohn's Disease

Contraceptive Method

Decisional Conflict: Method of Contraception r/t unclear personal values or beliefs, lack of experience or interference with

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

decision-making, lack of relevant information, support system deficit

Ineffective Sexuality Pattern r/t fear of pregnancy

Readiness for Enhanced Health Self-Management: requesting information about available and appropriate birth control methods

Convulsions

Anxiety r/t concern over controlling convulsions

Impaired Memory r/t neurological disturbance

Risk for Aspiration: Risk factor: impaired swallowing

Risk for Injury: Risk factor: seizure activity

Readiness for Enhanced Knowledge: expresses an interest in learning

See Seizure Disorders, Adult; Seizure Disorders, Childhood

COPD (Chronic Obstructive Pulmonary Disease)

Decreased Activity Tolerance r/t imbalance between oxygen supply and demand

Ineffective Airway Clearance r/t bronchoconstriction, increased mucus, ineffective cough, infection

Anxiety r/t breathlessness, change in health status

Death Anxiety r/t seriousness of medical condition, difficulty being able to "catch breath," feeling of suffocation

Interrupted Family Processes r/t role changes

Impaired Gas Exchange r/t ventilation-perfusion inequality

Ineffective Health Self-Management (See **Health Management, Ineffective,** Section III)

Imbalanced Nutrition: Less than Body Requirements r/t decreased intake because of dyspnea, unpleasant taste in mouth left by medications, increased need for calories from work of breathing

Powerlessness r/t progressive nature of disease

Self-Care Deficit r/t fatigue from the increased work of breathing

Chronic Low Self-Esteem r/t chronic illness

Sleep Deprivation r/t breathing difficulties when lying down

Impaired Social Interaction r/t social isolation because of oxygen use, activity intolerance

Chronic Sorrow r/t presence of chronic illness

Risk for Infection: Risk factor: stasis of respiratory secretions

Readiness for Enhanced Health Self-Management (See **Health Management, Readiness for Enhanced,** Section III)

Coping

Readiness for Enhanced Coping (See **Coping, Readiness for Enhanced,** Section III)

Risk for Complicated Immigration Transition: Risk factors: insufficient knowledge about the process to access resources in the host country, insufficient social support in the host country, overt discrimination

Coping Problems

Compromised Family Coping (See **Coping, Compromised Family,** Section III)

Defensive Coping (See **Coping, Defensive,** Section III)

Disabled Family Coping (See **Coping, Disabled Family,** Section III)

Ineffective Coping (See **Coping, Ineffective,** Section III)

Ineffective Community Coping (See **Coping, Ineffective Community,** Section III)

Corneal Injury

Risk for Corneal Injury (See **Corneal Injury, Risk for,** Section III)

Corneal Reflex, Absent

Risk for Injury: Risk factors: accidental corneal abrasion, drying of cornea

Corneal Transplant

Risk for Surgical Site Infection: Risk factors: invasive procedure, surgery

Readiness for Enhanced Health Self-Management: describes need to rest and avoid strenuous activities during healing phase

Coronary Artery Bypass Grafting (CABG)

Decreased Cardiac Output r/t dysrhythmia, depressed cardiac function, change in preload, contractility or afterload

Fear r/t outcome of surgical procedure

Deficient Fluid Volume r/t intraoperative blood loss, use of diuretics in surgery

Acute Pain r/t traumatic surgery

Risk for Perioperative Positioning Injury: Risk factors: hypothermia, extended supine position

Risk for Surgical Site Infection: Risk factor: surgical incision

Risk for Impaired Tissue Integrity: Risk factor: surgical procedure

Readiness for Enhanced Knowledge: expresses an interest in learning

Costovertebral Angle Tenderness

See Kidney Stone; Pyelonephritis

Cough, Ineffective

Ineffective Airway Clearance r/t decreased energy, fatigue, normal aging changes

See Bronchitis; COPD (Chronic Obstructive Pulmonary Disease); Pulmonary Edema

Crackles in Lungs, Coarse

Ineffective Airway Clearance r/t excessive secretions in airways, ineffective cough

See Heart Failure; Pneumonia; Pulmonary Edema

Crackles in Lungs, Fine

Ineffective Breathing Pattern r/t fatigue, surgery, decreased energy

See Bronchitis or Pneumonia (if from pulmonary infection); Congestive Heart Failure (CHF) (if cardiac in origin); Infection, Potential for

Craniectomy/Craniotomy

Frail Elderly Syndrome r/t alteration in cognition

Fear r/t threat to well-being

Impaired Memory r/t neurological surgery

Acute Pain r/t recent brain surgery, increased intracranial pressure

Risk for Ineffective Cerebral Tissue Perfusion: Risk factors: cerebral edema, increased intracranial pressure

Risk for Injury: Risk factor: potential confusion

See Coma (if relevant)

Crepitation, Subcutaneous

See Pneumothorax

Crisis

Anxiety r/t threat to or change in environment, health status, interaction patterns, situation, self-concept, or role functioning; threat of death of self or significant other

Death Anxiety r/t feelings of hopelessness associated with crisis

Compromised Family Coping r/t situational or developmental crisis

Ineffective Coping r/t situational or maturational crisis

Fear r/t crisis situation

Maladaptive Grieving r/t potential significant loss

Impaired Resilience r/t onset of crisis

Situational Low Self-Esteem r/t perception of inability to handle crisis

Stress Overload (See **Stress Overload,** Section III)

Risk for Spiritual Distress: Risk factors: physical or psychological stress, natural disasters, situational losses, maturational losses

Crohn's Disease

Anxiety r/t change in health status

Ineffective Coping r/t repeated episodes of diarrhea

Diarrhea r/t inflammatory process

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding management of disease

Imbalanced Nutrition: Less than Body Requirements r/t diarrhea, altered ability to digest and absorb food

Acute Pain r/t increased peristalsis

Powerlessness r/t chronic disease

Risk for Deficient Fluid Volume: Risk factor: abnormal fluid loss with diarrhea

Croup

See Respiratory Infections, Acute Childhood (Croup, Epiglottitis, Pertussis, Pneumonia, Respiratory)

Cryosurgery for Retinal Detachment

See Retinal Detachment

Cushing's Syndrome

Decreased Activity Tolerance r/t fatigue, weakness

Disturbed Body Image r/t change in appearance from disease process

Excess Fluid Volume r/t failure of regulatory mechanisms

Sexual Dysfunction r/t loss of libido

Impaired Skin Integrity r/t thin vulnerable skin from effects of increased cortisol

Risk for Infection: Risk factor: suppression of immune system caused by increased cortisol levels

Risk for Injury: Risk factors: decreased muscle strength, brittle bones

Readiness for Enhanced Knowledge: expresses an interest in learning

Cuts (Wounds)

See Lacerations

CVA (Cerebrovascular Accident)

Anxiety r/t situational crisis, change in physical or emotional condition

Disturbed Body Image r/t chronic illness, paralysis

Caregiver Role Strain r/t cognitive problems of care receiver, need for significant home care

Impaired Verbal Communication r/t pressure damage, decreased circulation to brain in speech center informational sources

Chronic Confusion r/t neurological changes

Constipation r/t decreased activity

Ineffective Coping r/t disability

Interrupted Family Processes r/t illness, disability of family member

Frail Elderly Syndrome r/t alteration in cognitive functioning

Maladaptive Grieving r/t loss of health

Ineffective Home Maintenance Behaviors r/t neurological disease affecting ability to perform activities of daily living

Disability-Associated Urinary Incontinence r/t neurological dysfunction

Impaired Memory r/t neurological disturbances

Impaired Physical Mobility r/t loss of balance and coordination

Unilateral Neglect r/t disturbed perception from neurological damage

Self-Care Deficit: Specify r/t decreased strength and endurance, paralysis

Impaired Social interaction r/t limited physical mobility, limited ability to communicate

Impaired Swallowing r/t neuromuscular dysfunction

Impaired Transfer Ability r/t limited physical mobility

Vision Loss r/t pressure damage to visual centers in the brain (*see Appendix E on Evolve*)

Impaired Walking r/t loss of balance and coordination

Risk for Aspiration: Risk factors: impaired swallowing, loss of gag reflex

Risk for Chronic Functional Constipation: Risk factor: immobility

Risk for Disuse Syndrome: Risk factor: paralysis

Risk for Adult Falls: Risk factor: paralysis, decreased balance

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Risk for Injury: Risk factors: vision loss, decreased tissue perfusion with loss of sensation

Risk for Ineffective Cerebral Tissue Perfusion: Risk factor: clot, emboli, or hemorrhage from cerebral vessel

Risk for Impaired Skin Integrity: Risk factor: immobility

Readiness for Enhanced Knowledge: expresses an interest in learning

Cyanosis, Central with Cyanosis of Oral Mucous Membranes

Impaired Gas Exchange r/t alveolar-capillary membrane changes

Cyanosis, Peripheral with Cyanosis of Nail Beds

Ineffective Peripheral Tissue Perfusion r/t interruption of arterial flow, severe vasoconstriction, cold temperatures

Cystic Fibrosis

Decreased Activity Tolerance r/t imbalance between oxygen supply and demand

Ineffective Airway Clearance r/t increased production of thick mucus

Anxiety r/t dyspnea, oxygen deprivation

Disturbed Body Image r/t changes in physical appearance, treatment of chronic lung disease (clubbing, barrel chest, home oxygen therapy)

Impaired Gas Exchange r/t ventilation-perfusion imbalance

Ineffective Home Maintenance Behaviors r/t extensive daily treatment, medications necessary for health

Imbalanced Nutrition: Less than Body Requirements r/t anorexia; decreased absorption of nutrients, fat; increased work of breathing

Chronic Sorrow r/t presence of chronic disease

Risk for Caregiver Role Strain: Risk factors: illness severity of care receiver, unpredictable course of illness

Risk for Deficient Fluid Volume: Risk factors: decreased fluid intake, increased work of breathing

Risk for Infection: Risk factors: thick, tenacious mucus; harboring of bacterial organisms; immunocompromised state

Risk for Spiritual Distress: Risk factor: presence of chronic disease

See Child with Chronic Condition; Hospitalized Child; Terminally Ill Child, Adolescent; Terminally Ill Child, Infant/Toddler; Terminally Ill Child, Preschool Child; Terminally Ill Child, School-Age Child/Preadolescent; Terminally Ill Child/Death of Child, Parent

Cystitis

Acute Pain: Dysuria r/t inflammatory process in bladder and urethra

Impaired Urinary Elimination: Frequency r/t urinary tract infection

Urge Urinary Incontinence: Risk factor: infection in bladder

Readiness for Enhanced Knowledge: expresses an interest in learning

Cystocele

Stress Urinary Incontinence r/t prolapsed bladder

Readiness for Enhanced Knowledge: expresses an interest in learning

Cystoscopy

Urinary Retention r/t edema in urethra obstructing flow of urine

Risk for Infection: Risk factor: invasive procedure

Readiness for Enhanced Knowledge: expresses an interest in learning

D

Deafness

Impaired Verbal Communication r/t impaired hearing

Hearing Loss r/t alteration in sensory reception, transmission, integration

Risk for Injury: Risk factor: alteration in sensory perception

Death

Risk for Sudden Infant Death (See **Sudden Infant Death, Risk for,** Section III)

Death, Oncoming

Death Anxiety r/t unresolved issues surrounding dying

Compromised Family Coping r/t client's inability to provide support to family

Ineffective Coping r/t personal vulnerability

Fear r/t threat of death

Maladaptive Grieving r/t loss of significant other

Powerlessness r/t effects of illness, oncoming death

Social Isolation r/t altered state of wellness

Spiritual Distress r/t intense suffering

Readiness for Enhanced Spiritual Well-Being: desire of client and family to be in harmony with each other, higher power, God

See Terminally Ill Child, Adolescent; Terminally Ill Child, Infant/Toddler; Terminally Ill Child, Preschool Child; Terminally Ill Child, School-Age Child/Preadolescent; Terminally Ill Child/Death of Child, Parent

Decisions, Difficulty Making

Decisional Conflict r/t support system deficit, perceived threat to value system, multiple or divergent sources of information, lack of relevant information, unclear personal values or beliefs

Risk for Impaired Emancipated Decision-Making: Risk factor: insufficient self-confidence in decision-making

Readiness for Enhanced Decision-Making (See **Decision-Making, Readiness for Enhanced,** Section III)

Decubitus Ulcer

See Pressure Ulcer; Pressure Injury

D

Deep Vein Thrombosis (DVT)

See DVT (Deep Vein Thrombosis); Venous Thromboembolism

Defensive Behavior

Defensive Coping r/t nonacceptance of blame, denial of problems or weakness

Ineffective Denial r/t inability to face situation realistically

Dehiscence, Abdominal

Fear r/t threat of death, severe dysfunction

Acute Pain r/t stretching of abdominal wall

Impaired Skin Integrity r/t altered circulation, malnutrition, opening in incision

Delayed Surgical Recovery r/t altered circulation, malnutrition, opening in incision

Impaired Tissue Integrity r/t exposure of abdominal contents to external environment

Risk for Deficient Fluid Volume: Risk factor: altered circulation associated with opening of wound and exposure of abdominal contents

Risk for Surgical Site Infection: Risk factors: loss of skin integrity, open surgical wound

Dehydration

Deficient Fluid Volume r/t active fluid volume loss

Impaired Oral Mucous Membrane Integrity r/t decreased salivation, fluid deficit

Risk for Chronic Functional Constipation: Risk factor: decreased fluid volume

Risk for Dry Mouth: Risk factor: decreased fluid volume

Risk for Ineffective Thermoregulation: Risk factor: decreased fluid volume

Risk for Unstable Blood Pressure: Risk factor: hypotension caused by insufficient fluid volume

See Burns; Heat Stroke; Vomiting; Diarrhea

Delirium

Acute Confusion r/t effects of medication, response to hospitalization, alcohol abuse, substance abuse, sensory deprivation or overload, infection, polypharmacy

Impaired Memory r/t delirium

Sleep Deprivation r/t sustained inadequate sleep hygiene

Risk for Injury: Risk factor: altered level of consciousness

Delirium Tremens (DT)

See Alcohol Withdrawal

Delivery

See Labor, Normal

Delusions

Impaired Verbal Communication r/t psychological impairment, delusional thinking

Acute Confusion r/t alcohol abuse, delirium, dementia, substance abuse

Ineffective Coping r/t distortion and insecurity of life events

Fear r/t content of intrusive thoughts

Risk for Other-Directed Violence: Risk factor: delusional thinking

Risk for Self-Directed Violence: Risk factor: delusional thinking

Dementia

Chronic Confusion r/t neurological dysfunction

Interrupted Family Processes r/t disability of family member

Frail Elderly Syndrome r/t alteration in cognitive functioning

Ineffective Home Maintenance Behaviors r/t inadequate support system, neurological dysfunction

Imbalanced Nutrition: Less than Body Requirements r/t neurological impairment

Disability-Associated Urinary Incontinence r/t neurological dysfunction

Insomnia r/t neurological impairment, naps during the day

Impaired Physical Mobility r/t alteration in cognitive function

Self-Neglect r/t cognitive impairment

Self-Care Deficit: Specify r/t psychological or neuromuscular impairment

Chronic Sorrow: Significant Other r/t chronic long-standing disability, loss of mental function

Impaired Swallowing r/t neuromuscular changes associated with long-standing dementia

Risk for Caregiver Role Strain: Risk factors: number of caregiving tasks, duration of caregiving required

Risk for Chronic Functional Constipation: Risk factor: decreased fluid intake

Risk for Adult Falls: Risk factor: diminished mental status

Risk for Frail Elderly Syndrome: Risk factors: cognitive impairment

Risk for Injury: Risk factors: confusion, decreased muscle coordination

Risk for Impaired Skin Integrity: Risk factors: altered nutritional status, immobility

Denial of Health Status

Ineffective Denial r/t lack of perception about the health status effects of illness

Ineffective Health Self-Management r/t denial of seriousness of health situation

Dental Caries

Impaired Dentition r/t ineffective oral hygiene, barriers to self-care, economic barriers to professional care, nutritional deficits, dietary habits

Ineffective Health Maintenance Behaviors r/t lack of knowledge regarding prevention of dental disease

Depression (Major Depressive Disorder)

Death Anxiety r/t feelings of lack of self-worth

Constipation r/t inactivity, decreased fluid intake

Fatigue r/t psychological demands

Ineffective Health Maintenance Behaviors r/t lack of ability to make good judgments regarding ways to obtain help

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Hopelessness r/t feeling of abandonment, long-term stress

Impaired Mood Regulation r/t emotional instability

Insomnia r/t inactivity

Self-Neglect r/t depression, cognitive impairment

Powerlessness r/t pattern of helplessness

Chronic Low Self-Esteem r/t repeated unmet expectations

Sexual Dysfunction r/t loss of sexual desire

Social Isolation r/t ineffective coping

Chronic Sorrow r/t unresolved grief

Risk for Maladaptive Grieving: Risk factor: lack of previous resolution of former grieving response

Risk for Suicidal Behavior: Risk factor: grieving, hopelessness

Dermatitis

Anxiety r/t situational crisis imposed by illness

Impaired Comfort r/t itching

Impaired Skin Integrity r/t side effect of medication, allergic reaction

Readiness for Enhanced Knowledge: expresses an interest in learning

See Itching

Despondency

Hopelessness r/t long-term stress

See Depression (Major Depressive Disorder)

Destructive Behavior Toward Others

Risk-Prone Health Behavior r/t intense emotional state

Ineffective Coping r/t situational crises, maturational crises, disturbance in pattern of appraisal of threat

Risk for Other-Directed Violence (See **Violence, Other-Directed, Risk for,** Section III)

Developmental Concerns

Risk for Delayed Child Development: Risk factor: growth and development lag

Risk for Delayed Infant Motor Development: Risk factor: growth and development lag

Diabetes in Pregnancy

See Gestational Diabetes (Diabetes in Pregnancy)

Diabetes Insipidus

Deficient Fluid Volume r/t inability to conserve fluid

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding care of disease, importance of medications

Diabetes Mellitus

Ineffective Health Maintenance Behaviors r/t complexity of therapeutic regimen

Ineffective Health Self-Management (See **Health Management, Ineffective,** Section III)

Imbalanced Nutrition: Less than Body Requirements r/t inability to use glucose (type 1 [insulin-dependent] diabetes)

Risk for Overweight: Risk factor: excessive intake of nutrients (type 2 diabetes)

Ineffective Peripheral Tissue Perfusion r/t impaired arterial circulation

Powerlessness r/t perceived lack of personal control

Sexual Dysfunction r/t neuropathy associated with disease

Vision Loss r/t ineffective tissue perfusion of retina

Risk for Unstable Blood Glucose Level (See **Glucose Level, Blood, Unstable, Risk for,** Section III)

Risk for Infection: Risk factors: hyperglycemia, impaired healing, circulatory changes

Risk for Injury: Risk factors: hypoglycemia or hyperglycemia from failure to consume adequate calories, failure to take insulin

Risk for Dysfunctional Gastrointestinal Motility: Risk factor: complication of diabetes

Risk for Metabolic Syndrome: Risk factor: complication of diabetes

Risk for Impaired Skin Integrity: Risk factor: loss of pain perception in extremities

Risk for Delayed Surgical Recovery: Risk factor: impaired healing due to circulatory changes

Readiness for Enhanced Health Literacy: expresses desire to enhance understanding of health information to make health care choices

Readiness for Enhanced Health Self-Management (See **Health Self-Management, Readiness for Enhanced,** Section III)

Readiness for Enhanced Knowledge: expresses an interest in learning

See Hyperglycemia; Hypoglycemia

Diabetes Mellitus, Juvenile (Insulin-Dependent Diabetes Mellitus Type 1)

Risk-Prone Health Behavior r/t inadequate comprehension, inadequate social support, low self-efficacy, impaired adjustment attributable to adolescent maturational crises

Disturbed Body Image r/t imposed deviations from biophysical and psychosocial norm, perceived differences from peers

Impaired Comfort r/t insulin injections, peripheral blood glucose testing

Ineffective Health Maintenance Behaviors r/t inadequate trust in health care professional, ineffective communication skills, ineffective coping strategies, ineffective family coping

Imbalanced Nutrition: Less than Body Requirements r/t inability of body to adequately metabolize and use glucose and nutrients, increased caloric needs of child to promote growth and physical activity participation with peers

Risk for Metabolic Syndrome: Risk factor: complication of diabetes

Readiness for Enhanced Knowledge: expresses an interest in learning

See Diabetes Mellitus; Child with Chronic Condition; Hospitalized Child

Diabetic Coma

Acute Confusion r/t hyperglycemia, presence of excessive metabolic acids

Deficient Fluid Volume r/t hyperglycemia resulting in polyuria

Ineffective Health Self-Management r/t lack of understanding of preventive measures, adequate blood glucose control

Risk for Unstable Blood Glucose Level (See **Glucose Level, Blood, Unstable, Risk for,** Section III)

Risk for Infection: Risk factors: hyperglycemia, changes in vascular system

See Diabetes Mellitus

Diabetic Ketoacidosis

See Ketoacidosis, Diabetic

Diabetic Neuropathy

See Neuropathy, Peripheral

Diabetic Retinopathy

Maladaptive Grieving r/t loss of vision

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding preserving vision with treatment if possible, use of low-vision aids

See Vision Impairment; Blindness

Dialysis

See Hemodialysis; Peritoneal Dialysis

Diaphragmatic Hernia

See Hiatal Hernia

Diarrhea

Diarrhea r/t infection, change in diet, gastrointestinal disorders, stress, medication effect, impaction

Deficient Fluid Volume r/t excessive loss of fluids in liquid stools

Risk for Electrolyte Imbalance: Risk factor: effect of loss of electrolytes from frequent stools

DIC (Disseminated Intravascular Coagulation)

Fear r/t threat to well-being

Deficient Fluid Volume: Hemorrhage r/t depletion of clotting factors

Risk for Bleeding: Risk factors: microclotting within vascular system, depleted clotting factors

Digitalis Toxicity

Decreased Cardiac Output r/t drug toxicity affecting cardiac rhythm, rate

Ineffective Health Self-Management r/t deficient knowledge regarding action, appropriate method of administration of digitalis

Dignity, Loss of

Risk for Compromised Human Dignity (See **Human Dignity, Compromised, Risk for,** Section III)

Dilation and Curettage (D&C)

Acute Pain r/t uterine contractions

Risk for Bleeding: Risk factor: surgical procedure

Risk for Surgical Site Infection: Risk factor: surgical procedure

Ineffective Sexuality Pattern r/t painful coitus, fear associated with surgery on genital area

Readiness for Enhanced Knowledge: expresses an interest in learning

Dirty Body (for Prolonged Period)

Self-Neglect r/t mental illness, substance abuse, cognitive impairment

Discharge Planning

Ineffective Home Maintenance Behaviors r/t family member's disease or injury interfering with home maintenance

Deficient Knowledge r/t lack of exposure to information for home care

Relocation Stress Syndrome: Risk factors: insufficient predeparture counseling, insufficient support system, unpredictability of experience

Readiness for Enhanced Health Literacy: expresses desire to enhance understanding of health information to make health care choices

Readiness for Enhanced Knowledge: expresses an interest in learning

Discomforts of Pregnancy

Disturbed Body Image r/t pregnancy-induced body changes

Impaired Comfort r/t enlarged abdomen, swollen feet

Fatigue r/t hormonal, metabolic, body changes

Stress Urinary Incontinence r/t enlarged uterus, fetal movement

Insomnia r/t psychological stress, fetal movement, muscular cramping, urinary frequency, shortness of breath

Nausea r/t hormone effect

Acute Pain: Headache r/t hormonal changes of pregnancy

Acute Pain: Leg Cramps r/t nerve compression, calcium/phosphorus/potassium imbalance

Risk for Constipation: Risk factors: decreased intestinal motility, inadequate fiber in diet

Risk for Injury: Risk factors: faintness and/or syncope caused by vasomotor lability or postural hypotension, venous stasis in lower extremities

Dislocation of Joint

Acute Pain r/t dislocation of a joint

Self-Care Deficit r/t inability to use a joint

Risk for Injury: Risk factor: unstable joint

Dissecting Aneurysm

Fear r/t threat to well-being

See Abdominal Surgery; Aneurysm, Abdominal Aortic Repair

Disseminated Intravascular Coagulation (DIC)

See DIC (Disseminated Intravascular Coagulation)

Dissociative Identity Disorder (Not Otherwise Specified)

Anxiety r/t psychosocial stress

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Ineffective Coping r/t personal vulnerability in crisis of accurate self-perception

Disturbed Personal Identity r/t inability to distinguish self-caused by multiple personality disorder, depersonalization, disturbance in memory

Impaired Memory r/t altered state of consciousness

See Multiple Personality Disorder (Dissociative Identity Disorder)

Distress

Anxiety r/t situational crises, maturational crises

Death Anxiety r/t denial of one's own mortality or impending death

Disuse Syndrome, Potential to Develop

Risk for Disuse Syndrome: Risk factors: paralysis, mechanical immobilization, prescribed immobilization, severe pain, altered level of consciousness

Diversional Activity Engagement, Lack of

Decreased Diversional Activity Engagement r/t environmental lack of diversional activity as in frequent hospitalizations, lengthy treatments

Diverticulitis

Constipation r/t dietary deficiency of fiber and roughage

Diarrhea r/t increased intestinal motility caused by inflammation

Deficient Knowledge r/t diet needed to control disease, medication regimen

Imbalanced Nutrition: Less than Body Requirements r/t loss of appetite

Acute Pain r/t inflammation of bowel

Risk for Deficient Fluid Volume: Risk factor: diarrhea

Dizziness

Decreased Cardiac Output r/t alteration in heart rate and rhythm, altered stroke volume

Deficient Knowledge r/t actions to take to prevent or modify dizziness and prevent falls

Impaired Physical Mobility r/t dizziness

Risk for Adult Falls: Risk factor: difficulty maintaining balance

Risk for Ineffective Cerebral Tissue Perfusion: Risk factor: interruption of cerebral arterial blood flow

Domestic Violence

Impaired Verbal Communication r/t psychological barriers of fear

Compromised Family Coping r/t abusive patterns

Defensive Coping r/t low self-esteem

Disturbed Family Identity Syndrome r/t domestic violence

Dysfunctional Family Processes r/t inadequate coping skills

Fear r/t threat to self-concept, situational crisis of abuse

Insomnia r/t psychological stress

Post-Trauma Syndrome r/t history of abuse

Powerlessness r/t lifestyle of helplessness

Situational Low Self-Esteem r/t negative family interactions

Risk for Compromised Resilience: Risk factor: effects of abuse

Risk for Other-Directed Violence: Risk factor: history of abuse

Down Syndrome

See Child with Chronic Condition; Intellectual Disability

Dress Self (Inability to)

Dressing Self-Care Deficit r/t intolerance to activity, decreased strength and endurance, pain, discomfort, perceptual or cognitive impairment, neuromuscular impairment, musculoskeletal impairment, depression, severe anxiety

Dribbling of Urine

Urinary Retention r/t degenerative changes in pelvic muscles and urinary structures

Stress Urinary Incontinence r/t degenerative changes in pelvic muscles and urinary structures

Drooling

Impaired Swallowing r/t neuromuscular impairment, mechanical obstruction

Risk for Aspiration: Risk factor: impaired swallowing

Dropout from School

Impaired Resilience (See **Resilience, Individual, Impaired,** Section III)

Anxiety r/t conflict about life goals

Ineffective Coping r/t inadequate resources

Drug Abuse

See Substance Abuse

Drug Withdrawal

See Acute Substance Withdrawal Syndrome

Dry Eye

Risk for Dry Eye: Risk factors (See **Dry Eye, Risk for,** Section III)

Risk for Corneal Injury: Risk factor: suppressed corneal reflex

Readiness for Enhanced Knowledge: expresses an interest in learning

See Conjunctivitis; Keratoconjunctivitis Sicca (Dry Eye Syndrome)

Dry Mouth

Risk for Dry Mouth: Risk factors (See **Dry Mouth, Risk for,** Section III)

Risk for Impaired Oral Mucous Membrane Integrity: Risk factor: reduced quality or quantity of saliva caused by decreased fluid volume

DT (Delirium Tremens)

See Alcohol Withdrawal

DVT (Deep Vein Thrombosis)

Constipation r/t inactivity, bed rest

Impaired Physical Mobility r/t pain in extremity

Acute Pain r/t vascular inflammation, edema

Ineffective Peripheral Tissue Perfusion r/t deficient knowledge of aggravating factors

Delayed Surgical Recovery r/t impaired physical mobility

Readiness for Enhanced Knowledge: expresses an interest in learning

Risk for Ineffective Thermoregulation: Risk factor: inactivity

See Anticoagulant Therapy; Venous Thromboembolism, Risk for (See Section III)

D

Dying Client

See Terminally Ill Adult; Terminally Ill Adolescent; Terminally Ill Child, Infant/Toddler; Terminally Ill Child, Preschool Child; Terminally Ill Child, School-Age Child/Preadolescent; Terminally Ill Child/Death of Child, Parent

Dysfunctional Eating Pattern

Imbalanced Nutrition: Less than Body Requirements r/t psychological factors

Risk for Overweight: Risk factor: psychological factors

See Anorexia Nervosa; Bulimia; Maturational Issues, Adolescent; Obesity

Dysfunctional Family Unit

See Family Problems

Dysfunctional Ventilatory Weaning

Dysfunctional Ventilatory Weaning Response r/t physical, psychological, situational factors

Dysmenorrhea

Nausea r/t prostaglandin effect

Acute Pain r/t cramping from hormonal effects

Readiness for Enhanced Knowledge: expresses an interest in learning

Dyspareunia

Sexual Dysfunction r/t lack of lubrication during intercourse, alteration in reproductive organ function

Dyspepsia

Anxiety r/t pressures of personal role

Acute Pain r/t gastrointestinal disease, consumption of irritating foods

Readiness for Enhanced Knowledge: expresses an interest in learning

Dysphagia

Impaired Swallowing r/t neuromuscular impairment

Risk for Aspiration: Risk factor: loss of gag or cough reflex

Dysphasia

Impaired Verbal Communication r/t decrease in circulation to brain

Impaired Social Interaction r/t difficulty in communicating

Dyspnea

Decreased Activity Tolerance r/t imbalance between oxygen supply and demand

Ineffective Breathing Pattern r/t compromised cardiac or pulmonary function, decreased lung expansion, neurological impairment affecting respiratory center, extreme anxiety

Fear r/t threat to state of well-being, potential death

Impaired Gas Exchange r/t alveolar-capillary damage

Insomnia r/t difficulty breathing, positioning required for effective breathing

Sleep Deprivation r/t ineffective breathing pattern

Dysrhythmia

Decreased Activity Tolerance r/t decreased cardiac output

Decreased Cardiac Output r/t alteration in heart rate, rhythm

Fear r/t threat of death, change in health status

Risk for Ineffective Cerebral Tissue Perfusion: Risk factor: decreased blood supply to the brain from dysrhythmia

Risk for Unstable Blood Pressure r/t cardiac arrhythmia and electrolyte imbalance

Readiness for Enhanced Knowledge: expresses an interest in learning

Dysthymic Disorder

Ineffective Coping r/t impaired social interaction

Ineffective Health Maintenance Behaviors r/t inability to make good judgments regarding ways to obtain help

Insomnia r/t anxious thoughts

Chronic Low Self-Esteem r/t repeated unmet expectations

Ineffective Sexuality Pattern r/t loss of sexual desire

Social Isolation r/t ineffective coping

See Depression (Major Depressive Disorder)

Dystocia

Anxiety r/t difficult labor, deficient knowledge regarding normal labor pattern

Ineffective Coping r/t situational crisis

Fatigue r/t prolonged labor

Maladaptive Grieving r/t loss of ideal labor experience

Acute Pain r/t difficult labor, medical interventions

Powerlessness r/t perceived inability to control outcome of labor

Risk for Bleeding: Risk factor: hemorrhage secondary to uterine atony

Risk for Ineffective Cerebral Tissue Perfusion (Fetal): Risk factor: difficult labor and birth

Risk for Infection: Risk factor: prolonged rupture of membranes

Risk for Impaired Tissue Integrity (Maternal and Fetal): Risk factor: difficult labor

Dysuria

Impaired Urinary Elimination r/t infection/inflammation of the urinary tract

Risk for Urge Urinary Incontinence: Risk factor: detrusor hyperreflexia from infection in the urinary tract

Acute Pain r/t infection/inflammation of the urinary tract

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

E

Ear Surgery

Acute Pain r/t edema in ears from surgery

Hearing Loss r/t invasive surgery of ears, dressings

Risk for Delayed Child Development: Risk factor: hearing impairment

Risk for Adult Falls: Risk factor: dizziness from excessive stimuli to vestibular apparatus

Readiness for Enhanced Knowledge: expresses an interest in learning

See Hospitalized Child

Earache

Acute Pain r/t trauma, edema, infection

Hearing Loss r/t altered sensory reception, transmission

Eating Dynamics, Adolescent

Imbalanced Nutrition: Less than Body Requirements r/t negative perception of one's body

Ineffective Adolescent Eating Dynamics r/t altered family dynamics, eating disorder, excessive stress

Risk for Overweight: Risk factor: media influence resulting in unhealthy choices, insufficient interest in physical activity

Readiness for Enhanced Health Literacy: expresses desire to learn to make healthy food choices

Eating Dynamics, Child

Imbalanced Nutrition: Less than Body Requirements r/t excessive of parental control over quantity and choices of foods

Ineffective Child Eating Dynamics r/t bribing child to eat, forcing child to eat

Risk for Delayed Child Development: Risk factor: inadequate nutrition to meet metabolic needs for normal development

Risk for Overweight: Risk factors: unhealthy choices, frequent snacking, low physical activity

Eating Dynamics, Infant

See Feeding Dynamics, Infant

Eclampsia

Interrupted Family Processes r/t unmet expectations for pregnancy and childbirth

Fear r/t threat of well-being to self and fetus

Risk for Aspiration: Risk factor: seizure activity

Risk for Ineffective Cerebral Tissue Perfusion: Fetal: Risk factor: uteroplacental insufficiency

Risk for Imbalanced Fluid Volume: Risk factor: decreased urine output as a result of renal dysfunction

Risk for unstable Blood Pressure: Risk factor: hypertension caused by excess fluid volume

ECMO (Extracorporeal Membrane Oxygenator)

Death Anxiety r/t emergency condition, hemorrhage

Decreased Cardiac Output r/t altered contractility of the heart

Impaired Gas Exchange (See **Gas Exchange, Impaired,** Section III)

See Respiratory Conditions of the Neonate

ECT (Electroconvulsive Therapy)

Decisional Conflict r/t lack of relevant information

Fear r/t real or imagined threat to well-being

Impaired Memory r/t effects of treatment

See Depression (Major Depressive Disorder)

Ectopic Pregnancy

Death Anxiety r/t emergency condition, hemorrhage

Disturbed Body Image r/t negative feelings about body and reproductive functioning

Fear r/t threat to self, surgery, implications for future pregnancy

Acute Pain r/t stretching or rupture of implantation site

Ineffective Role Performance r/t loss of pregnancy

Situational Low Self-Esteem r/t loss of pregnancy, inability to carry pregnancy to term

Chronic Sorrow r/t loss of pregnancy, potential loss of fertility

Risk for Bleeding: Risk factor: possible rupture of implantation site, surgical trauma

Risk for Ineffective Coping: Risk factor: loss of pregnancy

Risk for Interrupted Family Processes: Risk factor: situational crisis

Risk for Infection: Risk factors: traumatized tissue, surgical procedure

Risk for Spiritual Distress: Risk factor: grief process

Eczema

Disturbed Body Image r/t change in appearance from inflamed skin

Impaired Comfort: Pruritus r/t inflammation of skin

Impaired Skin Integrity r/t side effect of medication, allergic reaction

Readiness for Enhanced Knowledge: expresses an interest in learning

ED (Erectile Dysfunction)

See Erectile Dysfunction (ED); Impotence

Edema

Excess Fluid Volume r/t excessive fluid intake, cardiac dysfunction, renal dysfunction, loss of plasma proteins

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding treatment of edema

Risk for Impaired Skin Integrity: Risk factors: impaired circulation, fragility of skin

See Heart Failure; Renal Failure

Elder Abuse

See Abuse, Spouse, Parent, or Significant Other

Elderly

See Aging; Frail Elderly Syndrome

Electroconvulsive Therapy

See ECT (Electroconvulsive Therapy)

Electrolyte Imbalance

Risk for Electrolyte Imbalance (See **Electrolyte Imbalance, Risk for,** Section III)

Risk for Unstable Blood Pressure: Risk factor: fluid volume changes

Emaciated Person

Frail Elderly Syndrome r/t living alone, malnutrition, alteration in cognitive functioning

Imbalanced Nutrition: Less than Body Requirements r/t inability to ingest food, digest food, absorb nutrients because of biological, psychological, economic factors

Emancipated Decision-Making, Impaired

Risk for Impaired Emancipated Decision-Making: Risk factor: inability or unwillingness to verbalize needs and wants

Readiness for Enhanced Emancipated Decision-Making: expresses desire to enhance decision-making process

Embolectomy

Fear r/t threat of great bodily harm from embolus

Ineffective Peripheral Tissue Perfusion r/t presence of embolus

Risk for Bleeding: Risk factors: postoperative complication, surgical area

See Surgery, Postoperative Care

Emboli

See Pulmonary Embolism (PE)

Embolism in Leg or Arm

Ineffective Peripheral Tissue Perfusion r/t arterial/venous obstruction from clot

See DVT (Deep Vein Thrombosis); Risk for Thrombosis

Emesis

Nausea (See **Nausea,** Section III)

See Vomiting

Emotional Problems

See Coping Problems

Empathy

Readiness for Enhanced Community Coping: social supports, being available for problem solving

Readiness for Enhanced Family Coping: basic needs met, desire to move to higher level of health

Readiness for Enhanced Spiritual Well-Being: desire to establish interconnectedness through spirituality

Emphysema

See COPD (Chronic Obstructive Pulmonary Disease)

Emptiness

Social Isolation r/t inability to engage in satisfying personal relationships

Chronic Sorrow r/t unresolved grief

Spiritual Distress r/t separation from religious or cultural ties

Encephalitis

See Meningitis/Encephalitis

Endocardial Cushion Defect

See Congenital Heart Disease/Cardiac Anomalies

Endocarditis

Decreased Activity Tolerance r/t reduced cardiac reserve, prescribed bed rest

Decreased Cardiac Output r/t inflammation of lining of heart and change in structure of valve leaflets, increased myocardial workload

Risk for Imbalanced Nutrition: Less than Body Requirements: Risk factors: fever, hypermetabolic state associated with fever

Risk for Ineffective Cerebral Tissue Perfusion: Risk factor: possible presence of emboli in cerebral circulation

Risk for Ineffective Peripheral Tissue Perfusion: Risk factor: possible presence of emboli in peripheral circulation

Readiness for Enhanced Knowledge: expresses an interest in learning

Endometriosis

Maladaptive Grieving r/t possible infertility

Nausea r/t prostaglandin effect

Acute Pain r/t onset of menses with distention of endometrial tissue

Sexual Dysfunction r/t painful intercourse

Readiness for Enhanced Knowledge: expresses an interest in learning

Endometritis

Anxiety r/t, fear of unknown

Ineffective Thermoregulation r/t infectious process

Acute Pain r/t infectious process in reproductive tract

Readiness for Enhanced Knowledge: expresses an interest in learning

Enuresis

Ineffective Health Maintenance Behaviors r/t unachieved developmental task, neuromuscular immaturity, diseases of urinary system

See Toilet Training

Environmental Interpretation Problems

See Chronic Confusion

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Epididymitis

Anxiety r/t situational crisis, pain, threat to future fertility

Acute Pain r/t inflammation in scrotal sac

Ineffective Sexuality Pattern r/t edema of epididymis and testes

Readiness for Enhanced Knowledge: expresses an interest in learning

Epiglottitis

See Respiratory Infections, Acute Childhood (Croup, Epiglottitis, Pertussis, Pneumonia, Respiratory Syncytial Virus)

Epilepsy

Anxiety r/t threat to role functioning

Ineffective Health Self-Management r/t deficient knowledge regarding seizure control

Impaired Memory r/t seizure activity

Risk for Aspiration: Risk factors: impaired swallowing, excessive secretions

Risk for Injury: Risk factor: environmental factors during seizure

Readiness for Enhanced Knowledge: expresses an interest in learning

See Seizure Disorders, Adult; Seizure Disorders, Childhood (Epilepsy, Febrile Seizures, Infantile Spasms)

Episiotomy

Anxiety r/t fear of pain

Disturbed Body Image r/t fear of resuming sexual relations

Impaired Physical Mobility r/t pain, swelling, tissue trauma

Acute Pain r/t tissue trauma

Sexual Dysfunction r/t altered body structure, tissue trauma

Impaired Skin Integrity r/t perineal incision

Risk for Infection: Risk factor: tissue trauma

Epistaxis

Fear r/t large amount of blood loss

Risk for Deficient Fluid Volume: Risk factor: excessive blood loss

Epstein-Barr Virus

See Mononucleosis

Erectile Dysfunction (ED)

Situational Low Self-Esteem r/t physiological crisis, inability to practice usual sexual activity

Sexual Dysfunction r/t altered body function

Readiness for Enhanced Knowledge: information regarding treatment for erectile dysfunction

See Impotence

Escherichia coli Infection

Fear r/t serious illness, unknown outcome

Deficient Knowledge r/t how to prevent disease; care of self with serious illness

See Gastroenteritis; Gastroenteritis, Child; Hospitalized Child

Esophageal Varices

Fear r/t threat of death from hematemesis

Risk for Bleeding: Risk factors: portal hypertension, distended variceal vessels that can easily rupture

See Cirrhosis

Esophagitis

Acute Pain r/t inflammation of esophagus

Readiness for Enhanced Knowledge: expresses an interest in learning

Evisceration

See Dehiscence, Abdominal

Exhaustion

Impaired Resilience (See **Resilience, Individual, Impaired,** Section III)

Disturbed Sleep Pattern (See **Sleep Pattern, Disturbed,** Section III)

Exposure to Hot or Cold Environment

Hyperthermia r/t exposure to hot environment, abnormal reaction to anesthetics

Hypothermia r/t exposure to cold environment

Risk for Ineffective Thermoregulation: Risk factors: extremes of environmental temperature, inappropriate clothing for environmental temperature

External Fixation

Disturbed Body Image r/t trauma, change to affected part

Risk for Infection: Risk factor: presence of pins inserted into bone

See Fracture

Extracorporeal Membrane Oxygenator (ECMO)

See ECMO (Extracorporeal Membrane Oxygenator)

Eye Discomfort

Risk for Dry Eye (See **Eye, Dry, Risk for,** Section III)

Risk for Corneal Injury: Risk factors: exposure of the eyeball, blinking less than five times per minute

Eye Surgery

Anxiety r/t possible loss of vision

Self-Care Deficit: Specify r/t impaired vision

Vision Loss r/t surgical procedure, eye pathology

Risk for Injury: Risk factor: impaired vision

Readiness for Enhanced Knowledge: expresses an interest in learning

See Hospitalized Child

F

Failure to Thrive, Child

Disorganized Infant Behavior (See **Infant Behavior, Disorganized,** Section III)

Ineffective Child Eating Dynamics r/t lack of knowledge or resources regarding nutritional needs of child

Ineffective Infant Feeding Dynamics r/t lack of knowledge regarding nutritional needs of infant

Ineffective Infant Suck-Swallow Response r/t unsatisfactory sucking behavior

Insomnia r/t inconsistency of caretaker; lack of quiet, consistent environment

Imbalanced Nutrition: Less than Body Requirements r/t inadequate type or amounts of food for infant or child, inappropriate feeding techniques

Impaired Parenting r/t lack of parenting skills, inadequate role modeling

Chronic Low Self-Esteem: Parental r/t feelings of inadequacy, support system deficiencies, inadequate role model

Social Isolation r/t limited support systems, self-imposed situation

Risk for Impaired Attachment: Risk factor: inability of parents to meet infant's needs

Readiness for Enhanced Knowledge: parent expresses willingness to learn how to meet infant/child nutritional needs

Falls, Risk for

Risk for Adult Falls (See **Adult Falls, Risk for,** Section III)

Risk for Child Falls (See **Child Falls, Risk for,** Section III)

Family Problems

Compromised Family Coping (See **Coping, Family, Compromised,** Section III)

Disabled Family Coping (See **Coping, Family, Disabled,** Section III)

Interrupted Family Processes r/t situation transition and/or crises, developmental transition and/or crises

Ineffective Family Health Self-Management (See **Family Health Management, Ineffective,** Section III)

Readiness for Enhanced Family Coping: needs sufficiently gratified, adaptive tasks effectively addressed to enable goals of self-actualization to surface

Family Process

Dysfunctional Family Processes (See **Family Processes, Dysfunctional,** Section III)

Interrupted Family Processes (See **Family Processes, Interrupted,** Section III)

Readiness for Enhanced Family Processes (See **Family Processes, Readiness for Enhanced,** Section III)

Readiness for Enhanced Relationship (See **Relationship, Readiness for Enhanced,** Section III)

Fatigue

Fatigue (See **Fatigue,** Section III)

Fear

Death Anxiety r/t fear of death

Fear r/t identifiable physical or psychological threat to person

Febrile Seizures

See Seizure Disorders, Childhood (Epilepsy, Febrile Seizures, Infantile Spasms)

Fecal Impaction

See Impaction of Stool

(See **Constipation,** Section III)

(See **Constipation, Chronic Functional,** Section III)

Fecal Incontinence

Impaired Bowel Continence r/t neurological impairment, gastrointestinal disorders, anorectal trauma, weakened perineal muscles

Feeding Dynamics, Infant

Ineffective Infant Eating Dynamics r/t inappropriate transition to sold foods

Ineffective Infant Suck-Swallow Response r/t unsatisfactory sucking behavior

Risk for Caregiver Role Strain: Risk factor: fatigue leading to ineffective or insufficient feeding

Risk for Impaired Attachment: Risk factor: inability physically or psychologically to meet nutritional needs of newborn

Risk for Impaired Parenting: Risk factors: stress, sleep deprivation, insufficient knowledge, and/or social isolation

Readiness for Enhanced Health Literacy: expresses a desire to enhance knowledge of appropriate feeding dynamics for each developmental stage (See **Ineffective Feeding Dynamics, Infant,** Section III)

Feeding Problems, Newborn

Ineffective Breastfeeding (See **Breastfeeding, Ineffective,** Section III)

Ineffective Infant Feeding Dynamics r/t attachment issues, lack of knowledge of appropriate methods of feeding infant for each stage of development

Ineffective Infant Suck-Swallow Response r/t unsatisfactory sucking behavior

Insufficient Breast Milk Production (See **Breast Milk Production, Insufficient,** Section III)

Disorganized Infant Behavior r/t prematurity, immature neurological system

Ineffective Infant Feeding Dynamics r/t parental lack of knowledge of appropriate feeding methods for each stage of development

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Ineffective Infant Feeding Pattern r/t prematurity, neurological impairment or delay, oral hypersensitivity, prolonged nothing-by-mouth status

Impaired Swallowing r/t prematurity

Neonatal Abstinence Syndrome: At-risk population: in utero substance exposure secondary to maternal substance use

Nipple-Areolar Complex Injury r/t maternal impatience with breastfeeding process

Risk for Deficient Fluid Volume: Risk factor: inability to take in adequate amount of fluids

Female Genital Mutilation

Acute Pain r/t traumatic surgical procedure

Anxiety r/t situational crisis

Disturbed Body Image r/t scarring, changes in body function

Fear r/t threat to well-being

Powerlessness r/t absence of control of decision-making

Impaired Skin Integrity r/t traumatic surgical procedure

Impaired Tissue Integrity r/t wound, potential for infection

Risk for Compromised Human Dignity: Risk factor: dehumanizing treatment

Risk for Infection: Risk factor: invasive procedure

Risk for Post-Trauma Syndrome: Risk factor: experiencing traumatic surgery

Risk for Chronic Low Self-Esteem: Risk factor: cultural incongruence (See **Female Genital Mutilation, Risk for,** Section III)

Femoral Popliteal Bypass

Anxiety r/t threat to or change in health status

Acute Pain r/t surgical trauma, edema in surgical area

Ineffective Peripheral Tissue Perfusion r/t impaired arterial circulation

Risk for Bleeding: Risk factor: surgery on arteries

Risk for Surgical Site Infection: Risk factor: invasive procedure

Fetal Alcohol Syndrome

See Neonatal Abstinence Syndrome

Fetal Distress/Nonreassuring Fetal Heart Rate Pattern

Fear r/t threat to fetus

Ineffective Peripheral Tissue Perfusion: fetal r/t interruption of umbilical cord blood flow

Fever

Ineffective Thermoregulation r/t infectious process

Fibrocystic Breast Disease

See Breast Lumps

Filthy Home Environment

Ineffective Home Maintenance Behaviors (See **Home Maintenance Behaviors, Ineffective,** Section III)

Self-Neglect r/t mental illness, substance abuse, cognitive impairment

Financial Crisis in the Home Environment

Ineffective Home Maintenance Behaviors r/t insufficient finances

Fistulectomy

See Hemorrhoidectomy

Flail Chest

Ineffective Breathing Pattern r/t chest trauma

Fear r/t difficulty breathing

Impaired Gas Exchange r/t loss of effective lung function

Impaired Spontaneous Ventilation r/t paradoxical respirations

Flashbacks

Post-Trauma Syndrome r/t catastrophic event

Flat Affect

Hopelessness r/t prolonged activity restriction creating isolation, failing or deteriorating physiological condition, long-term stress, abandonment, lost belief in transcendent values or higher power or God

Risk for Loneliness: Risk factors: social isolation, lack of interest in surroundings

See Depression (Major Depressive Disorder); Dysthymic Disorder

Fluid Volume Deficit

Deficient Fluid Volume r/t active fluid loss, vomiting, diarrhea, failure of regulatory mechanisms

Risk for Shock: Risk factors: hypovolemia, sepsis, systemic inflammatory response syndrome (SIRS)

Risk for Unstable Blood Pressure: Risk factor: hypotension, excessive loss or insufficient intake of fluid

Fluid Volume Excess

Excess Fluid Volume r/t compromised regulatory mechanism, excess sodium intake

Risk for Unstable Blood Pressure: Risk factor: hypertension, excessive intake or retention of fluid

Fluid Volume Imbalance, Risk for

Risk for Imbalanced Fluid Volume: Risk factor: major invasive surgeries

Food Allergies

Diarrhea r/t immune effects of offending food on gastrointestinal system

Risk for Allergy Reaction: Risk factor: specific foods

Readiness for Enhanced Knowledge: expresses an interest in learning

See Anaphylactic Shock

F

Foodborne Illness

Diarrhea r/t infectious material in gastrointestinal tract

Deficient Fluid Volume r/t active fluid loss from vomiting and diarrhea

Deficient Knowledge r/t care of self with serious illness, prevention of further incidences of foodborne illness

Nausea r/t contamination irritating stomach

Risk for Dysfunctional Gastrointestinal Motility: Risk factor: contaminated food

See Gastroenteritis; Gastroenteritis, Child; Hospitalized Child; Escherichia coli *Infection*

Food Intolerance

Risk for Dysfunctional Gastrointestinal Motility: Risk factor: food intolerance

Foreign Body Aspiration

Ineffective Airway Clearance r/t obstruction of airway

Ineffective Health Maintenance Behaviors r/t parental deficient knowledge regarding high-risk items

Risk for Suffocation: Risk factor: inhalation of small objects

See Safety, Childhood

Formula Feeding of Infant

Maladaptive Grieving: Maternal r/t loss of desired breastfeeding experience

Ineffective Infant Feeding Dynamics r/t lack of knowledge of appropriate methods of feeding infant for each stage of development

Ineffective Infant Suck-Swallow Response r/t unsatisfactory sucking behavior

Risk for Constipation: Infant: Risk factor: iron-fortified formula

Risk for Infection: Infant: Risk factors: lack of passive maternal immunity, supine feeding position, contamination of formula

Readiness for Enhanced Knowledge: expresses an interest in learning

Fracture

Decreased Diversional Activity Engagement r/t immobility

Impaired Physical Mobility r/t limb immobilization

Acute Pain r/t muscle spasm, edema, trauma

Post-Trauma Syndrome r/t catastrophic event

Impaired Walking r/t limb immobility

Risk for Ineffective Peripheral Tissue Perfusion: Risk factors: immobility, presence of cast

Risk for Peripheral Neurovascular Dysfunction: Risk factors: mechanical compression, treatment of fracture

Risk for Impaired Skin Integrity: Risk factors: immobility, presence of cast

Risk for Thrombosis: Risk factors: trauma, immobility

Readiness for Enhanced Knowledge: expresses an interest in learning

Fractured Hip

See Hip Fracture

Frail Elderly Syndrome

Decreased Activity Tolerance r/t sensory changes

Risk for Frail Elderly Syndrome (See **Frail Elderly Syndrome, Risk for,** Section III)

Risk for Injury: Risk factors: impaired vision, impaired gait

Risk for Powerlessness: Risk factor: inability to maintain independence

Frequency of Urination

Stress Urinary Incontinence r/t degenerative change in pelvic muscles and structural support

Urge Urinary Incontinence r/t decreased bladder capacity, irritation of bladder stretch receptors causing spasm, alcohol, caffeine, increased fluids, increased urine concentration, overdistended bladder

Impaired Urinary Elimination r/t urinary tract infection

Urinary Retention r/t high urethral pressure caused by weak detrusor, inhibition of reflex arc, strong sphincter, blockage

Friendship

Readiness for Enhanced Relationship: expresses desire to enhance communication between partners

Frostbite

Acute Pain r/t decreased circulation from prolonged exposure to cold

Ineffective Peripheral Tissue Perfusion r/t damage to extremities from prolonged exposure to cold

Impaired Tissue Integrity r/t freezing of skin and tissues

Risk for Ineffective Thermoregulation: Risk factor: prolonged exposure to cold

See Hypothermia

Frothy Sputum

See CHF (Congestive Heart Failure); Pulmonary Edema; Seizure Disorders, Adult; Seizure Disorders, Childhood (Epilepsy, Febrile Seizures, Infantile Spasms)

Fusion, Lumbar

Anxiety r/t fear of surgical procedure, possible recurring problems

Impaired Physical Mobility r/t limitations from surgical procedure, presence of brace

Acute Pain r/t discomfort at bone donor site, surgical operation

Risk for Injury: Risk factor: improper body mechanics

Risk for Perioperative Positioning Injury: Risk factor: immobilization during surgery

Readiness for Enhanced Knowledge: expresses an interest in learning

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

G

Gag Reflex, Depressed or Absent

Impaired Swallowing r/t neuromuscular impairment

Risk for Aspiration: Risk factors: depressed cough or gag reflex

Gallop Rhythm

Decreased Cardiac Output r/t decreased contractility of heart

Gallstones

See Cholelithiasis

Gang Member

Impaired Resilience (See **Resilience, Individual, Impaired,** Section III)

Gangrene

Fear r/t possible loss of extremity

Ineffective Peripheral Tissue Perfusion r/t obstruction of arterial flow

See Diabetes Mellitus; Peripheral Vascular Disease

Gas Exchange, Impaired

Impaired Gas Exchange r/t ventilation-perfusion imbalance

Dysfunctional Ventilatory Weaning Response r/t psychomotor agitation

Gastric Ulcer

See GI Bleed (Gastrointestinal Bleeding); Ulcer, Peptic (Duodenal or Gastric)

Gastritis

Imbalanced Nutrition: Less than Body Requirements r/t vomiting, inadequate intestinal absorption of nutrients, restricted dietary regimen

Acute Pain r/t inflammation of gastric mucosa

Risk for Deficient Fluid Volume: Risk factors: excessive loss from gastrointestinal tract from vomiting, decreased intake

Gastroenteritis

Diarrhea r/t infectious process involving intestinal tract

Deficient Fluid Volume r/t excessive loss from gastrointestinal tract from diarrhea, vomiting

Nausea r/t irritation to gastrointestinal system

Imbalanced Nutrition: Less than Body Requirements r/t vomiting, inadequate intestinal absorption of nutrients, restricted dietary intake

Acute Pain r/t increased peristalsis causing cramping

Risk for Electrolyte Imbalance: Risk factor: loss of gastrointestinal fluids high in electrolytes

Readiness for Enhanced Knowledge: expresses an interest in learning

See Gastroenteritis, Child

Gastroenteritis, Child

Impaired Skin Integrity: Diaper Rash r/t acidic excretions on perineal tissues

Readiness for Enhanced Knowledge: expresses an interest in learning

Acute Pain r/t increased peristalsis causing cramping

See Gastroenteritis; Hospitalized Child

Gastroesophageal Reflux Disease (GERD)

Ineffective Airway Clearance r/t reflux of gastric contents into esophagus and tracheal or bronchial tree

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding antireflux regimen (e.g., positioning, change in diet)

Acute Pain r/t irritation of esophagus from gastric acids

Risk for Aspiration: Risk factor: entry of gastric contents in tracheal or bronchial tree

Gastroesophageal Reflux, Child

Ineffective Airway Clearance r/t reflux of gastric contents into esophagus and tracheal or bronchial tree

Anxiety: Parental r/t possible need for surgical intervention

Deficient Fluid Volume r/t persistent vomiting

Imbalanced Nutrition: Less than Body Requirements r/t poor feeding, vomiting

Risk for Aspiration: Risk factor: entry of gastric contents in tracheal or bronchial tree

Risk for Impaired Parenting: Risk factors: disruption in bonding as a result of irritable or inconsolable infant; lack of sleep for parents

Readiness for Enhanced Knowledge: expresses an interest in learning

See Child with Chronic Condition; Hospitalized Child

Gastrointestinal Bleeding (GI Bleed)

See GI Bleed (Gastrointestinal Bleeding)

Gastrointestinal Hemorrhage

See GI Bleed (Gastrointestinal Bleeding)

Gastrointestinal Surgery

Risk for Injury: Risk factor: inadvertent insertion of nasogastric tube through gastric incision line

See Abdominal Surgery

Gastroschisis/Omphalocele

Ineffective Airway Clearance r/t complications of anesthetic effects

Impaired Gas Exchange r/t effects of anesthesia, subsequent atelectasis

Maladaptive Grieving r/t threatened loss of infant, loss of perfect birth or infant because of serious medical condition

Risk for Deficient Fluid Volume: Risk factors: inability to feed because of condition, subsequent electrolyte imbalance

Risk for Infection: Risk factor: disrupted skin integrity with exposure of abdominal contents

Risk for Injury: Risk factors: disrupted skin integrity, ineffective protection

Gastrostomy

Risk for Impaired Skin Integrity: Risk factor: presence of gastric contents on skin

See Tube Feeding

Gender Dysphoria

Anxiety r/t conflict between physical (assigned) gender and gender they identify with

Decisional Conflict r/t uncertainty about choices regarding gender reassignment

Disturbed Body Image r/t alteration in self-perception, inability to identify with own body

Ineffective Denial r/t insufficient emotional support

Fear r/t victimization

Disturbed Personal Identity r/t gender confusion

Ineffective Sexuality Pattern r/t conflict surrounding gender identity

Risk for Compromised Human Dignity: Risk factor: cultural incongruence, humiliation

Readiness for Enhanced Decision-Making: expresses desire to enhance understanding of choices for decision-making

Genital Herpes

See Herpes Simplex II

Genital Warts

See STD (Sexually Transmitted Disease)

GERD

See Gastroesophageal Reflux Disease (GERD)

Gestational Diabetes (Diabetes in Pregnancy)

Anxiety r/t threat to self and/or fetus

Impaired Nutrition: Less than Body Requirements r/t decreased insulin production and glucose uptake in cells

Risk for Overweight: Fetal r/t excessive glucose uptake

Impaired Nutrition: More than Body Requirements: Fetal r/t excessive glucose uptake

Risk for Unstable Blood Glucose: Risk factor: excessive intake of carbohydrates

Risk for Disturbed Maternal–Fetal Dyad: Risk factor: impaired glucose metabolism

Risk for Impaired Tissue Integrity: Fetal: Risk factors: large infant, congenital defects, birth injury

Risk for Impaired Tissue Integrity: Maternal: Risk factor: delivery of large infant

Readiness for Enhanced Knowledge: expresses an interest in learning

See Diabetes Mellitus

GI Bleed (Gastrointestinal Bleeding)

Fatigue r/t loss of circulating blood volume, decreased ability to transport oxygen

Fear r/t threat to well-being, potential death

Deficient Fluid Volume r/t gastrointestinal bleeding, hemorrhage

Imbalanced Nutrition: Less than Body Requirements r/t nausea, vomiting

Acute Pain r/t irritated mucosa from acid secretion

Risk for Ineffective Coping: Risk factors: personal vulnerability in crisis, bleeding, hospitalization

Readiness for Enhanced Knowledge: expresses an interest in learning

Gingivitis

Impaired Oral Mucous Membrane Integrity r/t ineffective oral hygiene

Glaucoma

Deficient Knowledge r/t treatment and self-care for disease

See Vision Impairment

Glomerulonephritis

Excess Fluid Volume r/t renal impairment

Imbalanced Nutrition: Less than Body Requirements r/t anorexia, restrictive diet

Acute Pain r/t edema of kidney

Readiness for Enhanced Knowledge: expresses an interest in learning

Gluten Allergy

See Celiac Disease

Gonorrhea

Acute Pain r/t inflammation of reproductive organs

Risk for Infection: Risk factor: spread of organism throughout reproductive organs

Readiness for Enhanced Knowledge: expresses an interest in learning

See STD (Sexually Transmitted Disease)

Gout

Impaired Physical Mobility r/t musculoskeletal impairment

Chronic Pain r/t inflammation of affected joint

Readiness for Enhanced Knowledge: expresses an interest in learning

Grandiosity

Defensive Coping r/t inaccurate perception of self and abilities

Grand Mal Seizure

See Seizure Disorders, Adult; Seizure Disorders, Childhood (Epilepsy, Febrile Seizures, Infantile Spasms)

Grandparents Raising Grandchildren

Anxiety r/t change in role status

Decisional Conflict r/t support system deficit

Parental Role Conflict r/t change in parental role

Compromised Family Coping r/t family role changes

Interrupted Family Processes r/t family roles shift

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Ineffective Role Performance r/t role transition, aging

Ineffective Family Health Self-Management r/t excessive demands on individual or family

Risk for Impaired Parenting: Risk factor: role strain

Risk for Powerlessness: Risk factors: role strain, situational crisis, aging

Risk for Spiritual Distress: Risk factor: life change

Readiness for Enhanced Parenting: physical and emotional needs of children are met

Graves' Disease

See Hyperthyroidism

Grieving, Maladaptive

Complicated Grieving r/t expected or sudden death of a significant other with whom there was a volatile relationship, emotional instability, lack of social support

Risk for Maladaptive Grieving: Risk factors: death of a significant other with whom there was a volatile relationship, emotional instability, lack of social support

Groom Self (Inability to)

Bathing Self-Care Deficit (See **Self-Care Deficit, Bathing,** Section III)

Dressing Self-Care Deficit (See **Self-Care Deficit, Dressing,** Section III)

Growth and Development Lag

See Failure to Thrive, Child

Guillain-Barré Syndrome

Dysfunctional Ventilatory Weaning Response r/t fatigue

Impaired Spontaneous Ventilation r/t weak respiratory muscles

Risk for Aspiration: Risk factors: ineffective cough; depressed gag reflex

See Neurological Disorders

Guilt

Maladaptive Grieving r/t potential loss of significant person, animal, prized material possession, change in life role

Impaired Resilience (See **Resilience, Individual, Impaired,** Section III)

Situational Low Self-Esteem r/t unmet expectations of self

Risk for Maladaptive Grieving: Risk factors: actual loss of significant person, animal, prized material possession, change in life role

Risk for Post-Trauma Syndrome: Risk factor: exaggerated sense of responsibility for traumatic event

Readiness for Enhanced Spiritual Well-Being: desire to be in harmony with self, others, higher power or God

H

Hair Loss

Disturbed Body Image r/t psychological reaction to loss of hair

Imbalanced Nutrition: Less than Body Requirements r/t inability to ingest food because of biological, psychological, economic factors

Halitosis

Impaired Dentition r/t ineffective oral hygiene

Impaired Oral Mucous Membrane Integrity r/t ineffective oral hygiene

Hallucinations

Anxiety r/t threat to self-concept

Acute Confusion r/t alcohol abuse, delirium, dementia, mental illness, substance abuse

Ineffective Coping r/t distortion and insecurity of life events

Risk for Self-Mutilation: Risk factor: command hallucinations

Risk for Other-Directed Violence: Risk factors: catatonic excitement, manic excitement, rage or panic reactions, response to violent internal stimuli

Risk for Self-Directed Violence: Risk factors: catatonic excitement, manic excitement, rage or panic reactions, response to violent internal stimuli

Headache

Acute Pain r/t lack of knowledge of pain control techniques or methods to prevent headaches

Ineffective Health Self-Management r/t lack of knowledge, identification, elimination of aggravating factors

Head Injury

Ineffective Breathing Pattern r/t pressure damage to breathing center in brainstem

Acute Confusion r/t increased intracranial pressure

Risk for Ineffective Cerebral Tissue Perfusion: Risk factors: effects of increased intracranial pressure, trauma to brain

See Neurological Disorders

Health Behavior, Risk-Prone

Risk-Prone Health Behavior: Risk factors (See **Health Behavior, Risk-Prone,** Section III)

Risk for Metabolic Syndrome r/t obesity

Health Maintenance Problems

Ineffective Health Maintenance Behaviors (See **Health Maintenance Behaviors, Ineffective,** Section III)

Ineffective Health Self-Management (See **Health Self-Management, Ineffective,** Section III)

Health-Seeking Person

Readiness for Enhanced Health literacy (See **Health Literacy, Readiness for Enhanced,** Section III)

Readiness for Enhanced Health Self-Management (See **Health Self-Management, Readiness for Enhanced,** Section III)

Hearing Impairment

Impaired Verbal Communication r/t inability to hear own voice

Hearing Loss (see Appendix E on Evolve)

Social Isolation r/t difficulty with communication

Heart Attack

See MI (Myocardial Infarction)

Heartburn

Nausea r/t gastrointestinal irritation

Acute Pain: Heartburn r/t inflammation of stomach and esophagus

Risk for Imbalanced Nutrition: Less than Body Requirements: Risk factor: pain after eating

Readiness for Enhanced Knowledge: expresses an interest in learning

See Gastroesophageal Reflux Disease (GERD)

Heart Failure

Decreased Activity Tolerance r/t weakness, fatigue, shortness of breath

Decreased Cardiac Output r/t impaired cardiac function, increased preload, decreased contractility, increased afterload

Constipation r/t activity intolerance

Fatigue r/t disease process with decreased cardiac output

Fear r/t threat to one's own well-being

Excess Fluid Volume r/t impaired excretion of sodium and water

Impaired Gas Exchange r/t excessive fluid in interstitial space of lungs

Powerlessness r/t illness-related regimen

Risk for Shock (Cardiogenic): Risk factors: decreased contractility of heart, increased afterload

Readiness for Enhanced Health Management (See **Health Management, Readiness for Enhanced,** Section III)

See Child with Chronic Condition; Congenital Heart Disease/Cardiac Anomalies; Hospitalized Child

Heart Surgery

See Coronary Artery Bypass Grafting (CABG)

Heat Stroke

Deficient Fluid Volume r/t profuse diaphoresis from high environmental temperature

Hyperthermia r/t vigorous activity, high environmental temperature, inappropriate clothing

Hematemesis

See GI Bleed (Gastrointestinal Bleeding)

Hematuria

See Kidney Stone; UTI (Urinary Tract Infection)

Hemianopia

Anxiety r/t change in vision

Unilateral Neglect r/t effects of disturbed perceptual abilities

Risk for Injury: Risk factor: disturbed sensory perception

Hemiplegia

Anxiety r/t change in health status

Disturbed Body Image r/t functional loss of one side of body

Impaired Physical Mobility r/t loss of neurological control of involved extremities

Self-Care Deficit: Specify r/t neuromuscular impairment

Impaired Sitting r/t partial paralysis

Impaired Standing r/t partial paralysis

Impaired Transfer Ability r/t partial paralysis

Unilateral Neglect r/t effects of disturbed perceptual abilities

Impaired Walking r/t loss of neurological control of involved extremities

Risk for Adult Falls: Risk factor: impaired mobility

Risk for Impaired Skin Integrity: Risk factors: alteration in sensation, immobility; pressure over bony prominence

See CVA (Cerebrovascular Accident)

Hemodialysis

Ineffective Coping r/t situational crisis

Interrupted Family Processes r/t changes in role responsibilities as a result of therapy regimen

Excess Fluid Volume r/t renal disease with minimal urine output

Powerlessness r/t treatment regimen

Risk for Caregiver Role Strain: Risk factor: complexity of care receiver treatment

Risk for Electrolyte Imbalance: Risk factor: effect of metabolic state on renal function

Risk for deficient Fluid Volume: Risk factor: excessive removal of fluid during dialysis

Risk for Infection: Risk factors: exposure to blood products, risk for developing hepatitis B or C, impaired immune system

Risk for Injury: Risk factors: clotting of blood access, abnormal surface for blood flow

Risk for Impaired Tissue Integrity: Risk factor: mechanical factor associated with fistula formation

Readiness for Enhanced Knowledge: expresses an interest in learning

See Renal Failure; Renal Failure, Child with Chronic Condition

Hemodynamic Monitoring

Risk for Infection: Risk factor: invasive procedure

Risk for Injury: Risk factors: inadvertent wedging of catheter, dislodgment of catheter, disconnection of catheter

Risk for Impaired Tissue Integrity: Risk factor: invasive procedure

See Shock, Cardiogenic; Shock, Hypovolemic; Shock, Septic

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Hemolytic Uremic Syndrome

Fatigue r/t decreased red blood cells

Fear r/t serious condition with unknown outcome

Deficient Fluid Volume r/t vomiting, diarrhea

Nausea r/t effects of uremia

Risk for Injury: Risk factors: decreased platelet count, seizure activity

Risk for Impaired Skin Integrity: Risk factor: diarrhea

See Hospitalized Child; Renal Failure, Acute/Chronic, Child

Hemophilia

Fear r/t high risk for AIDS infection from contaminated blood products

Impaired Physical Mobility r/t pain from acute bleeds, imposed activity restrictions, joint pain

Acute Pain r/t bleeding into body tissues

Risk for Bleeding: Risk factors: deficient clotting factors, child's developmental level, age-appropriate play, inappropriate use of toys or sports equipment

Readiness for Enhanced Knowledge: expresses an interest in learning

See Child with Chronic Condition; Hospitalized Child; Maturational Issues, Adolescent

Hemoptysis

Fear r/t serious threat to well-being

Risk for Ineffective Airway Clearance: Risk factor: obstruction of airway with blood and mucus

Risk for Deficient Fluid Volume: Risk factor: excessive loss of blood

Hemorrhage

Fear r/t threat to well-being

Deficient Fluid Volume r/t massive blood loss

See Hypovolemic Shock

Hemorrhoidectomy

Anxiety r/t embarrassment, need for privacy

Constipation r/t fear of pain with defecation

Acute Pain r/t surgical procedure

Urinary Retention r/t pain, anesthetic effect

Risk for Bleeding: Risk factors: inadequate clotting, trauma from surgery

Readiness for Enhanced Knowledge: expresses an interest in learning

Hemorrhoids

Impaired Comfort r/t itching in rectal area

Constipation r/t painful defecation, poor bowel habits

Impaired Sitting r/t pain and pressure

Readiness for Enhanced Knowledge: expresses an interest in learning

Hemothorax

Deficient Fluid Volume r/t blood in pleural space

See Pneumothorax

Hepatitis

Decreased Activity Tolerance r/t weakness or fatigue caused by infection

Decreased Diversional Activity Engagement r/t isolation

Fatigue r/t infectious process, altered body chemistry

Imbalanced Nutrition: Less than Body Requirements r/t anorexia, impaired use of proteins and carbohydrates

Acute Pain r/t edema of liver, bile irritating skin

Social Isolation r/t treatment-imposed isolation

Risk for Imbalanced Fluid Volume: Risk factor: excessive loss of fluids from vomiting and diarrhea

Readiness for Enhanced Knowledge: expresses an interest in learning

Hernia

See Hiatal Hernia; Inguinal Hernia Repair

Herniated Disk

See Low Back Pain

Herniorrhaphy

See Inguinal Hernia Repair

Herpes in Pregnancy

Fear r/t threat to fetus, impending surgery

Situational Low Self-Esteem r/t threat to fetus as a result of disease process

Risk for Infection: Infant: Risk factors: transplacental transfer during primary herpes, exposure to active herpes during birth process

See Herpes Simplex II

Herpes Simplex I

Impaired Oral Mucous Membrane Integrity r/t inflammatory changes in mouth

Herpes Simplex II

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding treatment, prevention, spread of disease

Acute Pain r/t active herpes lesion

Situational Low Self-Esteem r/t expressions of shame or guilt

Sexual Dysfunction r/t disease process

Impaired Tissue Integrity r/t active herpes lesion

Impaired Urinary Elimination r/t pain with urination

Herpes Zoster

See Shingles

HHNS (Hyperosmolar Hyperglycemic Nonketotic Syndrome)

See Hyperosmolar Hyperglycemic Nonketotic Syndrome (HHNS)

Hiatal Hernia

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding care of disease

Nausea r/t effects of gastric contents in esophagus

Imbalanced Nutrition: Less than Body Requirements r/t pain after eating

Acute Pain r/t gastroesophageal reflux

Hip Fracture

Acute Confusion r/t sensory overload, sensory deprivation, medication side effects, advanced age, pain

Constipation r/t immobility, opioids, anesthesia

Fear r/t outcome of treatment, future mobility, present helplessness

Impaired Physical Mobility r/t surgical incision, temporary absence of weight bearing, pain when walking

Acute Pain r/t injury, surgical procedure, movement

Powerlessness r/t health care environment

Self-Care Deficit: Specify r/t musculoskeletal impairment

Impaired Transfer Ability r/t immobilization of hip

Impaired Walking r/t temporary absence of weight bearing

Risk for Bleeding: Risk factors: postoperative complication, surgical blood loss

Risk for Surgical Site Infection: Risk factor: invasive procedure

Risk for Injury: Risk factors: activities such as greater than 90-degree flexion of hips that can result in dislodged prosthesis, unsteadiness when ambulating

Risk for Perioperative Positioning Injury: Risk factors: immobilization, muscle weakness, emaciation

Risk for Peripheral Neurovascular Dysfunction: Risk factors: trauma, vascular obstruction, fracture

Risk for Impaired Skin Integrity: Risk factor: immobility

Risk for Thrombosis: Risk factors: immobility, trauma

Hip Replacement

See Total Joint Replacement (Total Hip/Total Knee/Shoulder)

Hirschsprung's Disease

Constipation: Bowel Obstruction r/t inhibited peristalsis as a result of congenital absence of parasympathetic ganglion cells in distal colon

Maladaptive Grieving r/t loss of perfect child, birth of child with congenital defect even though child expected to be normal within 2 years

Imbalanced Nutrition: Less than Body Requirements r/t anorexia, pain from distended colon

Acute Pain r/t distended colon, incisional postoperative pain

Impaired Skin Integrity r/t stoma, potential skin care problems associated with stoma

Readiness for Enhanced Knowledge: expresses an interest in learning

See Hospitalized Child

Hirsutism

Disturbed Body Image r/t excessive hair

Hitting Behavior

Acute Confusion r/t dementia, alcohol abuse, drug abuse, delirium

Risk for Other-Directed Violence (See **Violence, Other-Directed, Risk for,** Section III)

HIV (Human Immunodeficiency Virus)

Fear r/t possible death

Ineffective Protection r/t depressed immune system

Readiness for Enhanced Health Literacy: expresses desire to enhance understanding of health information to make health care choices

See AIDS (Acquired Immunodeficiency Syndrome)

Hodgkin's Disease

See Anemia; Cancer; Chemotherapy

Homelessness

Ineffective Home Maintenance Behaviors r/t impaired cognitive or emotional functioning, inadequate support system, insufficient finances

Home Maintenance Problems

Ineffective Home Maintenance Behaviors (See **Home Maintenance, Impaired,** Section III)

Self-Neglect r/t mental illness, substance abuse, cognitive impairment

Powerlessness r/t interpersonal interactions

Risk for Physical Trauma: Risk factor: being in high-crime neighborhood

Hope

Readiness for Enhanced Hope (See **Hope, Readiness for Enhanced,** Section III)

Hopelessness

Hopelessness (See **Hopelessness,** Section III)

Hospitalized Child

Decreased Activity Tolerance r/t fatigue associated with acute illness

Anxiety: Separation: Child r/t familiar surroundings and separation from family and friends

Compromised Family Coping r/t possible prolonged hospitalization that exhausts supportive capacity of significant people

Ineffective Coping: Parent r/t possible guilt regarding hospitalization of child, parental inadequacies

Decreased Diversional Activity Engagement r/t immobility, monotonous environment, frequent or lengthy treatments, reluctance to participate, therapeutic isolation, separation from peers

Interrupted Family Processes r/t situational crisis of illness, disease, hospitalization

Fear r/t deficient knowledge or maturational level with fear of unknown, mutilation, painful procedures, surgery

Hopelessness: Child r/t prolonged activity restriction, uncertain prognosis

Insomnia: Child or Parent r/t 24-hour care needs of hospitalization

Acute Pain r/t treatments, diagnostic or therapeutic procedures, disease process

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Powerlessness: Child r/t health care environment, illness-related regimen

Risk for Impaired Attachment: Risk factor: separation

Risk for Injury: Risk factors: unfamiliar environment, developmental age, lack of parental knowledge regarding safety (e.g., side rails, IV site/pole)

Risk for Imbalanced Nutrition: Less than Body Requirements: Risk factors: anorexia, absence of familiar foods, cultural preferences

Readiness for Enhanced Family Coping: impact of crisis on family values, priorities, goals, relationships in family

See Child with Chronic Condition

Hostile Behavior

Risk for Other-Directed Violence: Risk factor: antisocial personality disorder

HTN (Hypertension)

Ineffective Health Self-Management (See **Health Management, Ineffective,** Section III)

Readiness for Enhanced Health Self-Management (See **Health Management, Readiness for Enhanced,** Section III)

Risk for Overweight: Risk factor: lack of knowledge of relationship between diet and disease process

Human Energy Field

Energy Field, Imbalanced (See **Imbalanced Energy Field,** Section III)

Humiliating Experience

Risk for Compromised Human Dignity (See **Human Dignity, Compromised, Risk for,** Section III)

Huntington's Disease

Decisional Conflict r/t whether to have children

See Neurological Disorders

Hydrocele

Acute Pain r/t severely enlarged hydrocele

Ineffective Sexuality Pattern r/t recent surgery on area of scrotum

Hydrocephalus

Decisional Conflict r/t unclear or conflicting values regarding selection of treatment modality

Interrupted Family processes r/t situational crisis

Imbalanced Nutrition: Less than Body Requirements r/t inadequate intake as a result of anorexia, nausea, vomiting, feeding difficulties

Risk for Infection: Risk factor: sequelae of invasive procedure (shunt placement)

Risk for Ineffective Cerebral Tissue Perfusion: Risk factors: interrupted flow, hypervolemia of cerebral ventricles

Risk for Adult Falls: Risk factors: acute illness, alteration in cognitive functioning

See Normal Pressure Hydrocephalus (NPH); Child with Chronic Condition; Hospitalized Child; Premature Infant (Child); Premature Infant (Parent)

Hygiene, Inability to Provide Own

Frail Elderly Syndrome r/t living alone

Self-Neglect (See **Self-Neglect,** Section III)

Bathing Self-Care Deficit (See **Self-Care Deficit, Bathing,** Section III)

Hyperactive Syndrome

Decisional Conflict r/t multiple or divergent sources of information regarding education, nutrition, medication regimens; willingness to change own food habits; limited resources

Parental Role Conflict: When Siblings Present r/t increased attention toward hyperactive child

Compromised Family Coping r/t unsuccessful strategies to control excessive activity, behaviors, frustration, anger

Ineffective Impulse Control r/t disorder of development, environment that might cause frustration or irritation

Ineffective Role Performance: Parent r/t stressors associated with dealing with hyperactive child, perceived or projected blame for causes of child's behavior, unmet needs for support or care, lack of energy to provide for those needs

Chronic Low Self-Esteem r/t inability to achieve socially acceptable behaviors; frustration; frequent reprimands, punishment, or scolding for uncontrolled activity and behaviors; mood fluctuations and restlessness; inability to succeed academically; lack of peer support

Impaired Social Interaction r/t impulsive and overactive behaviors, concomitant emotional difficulties, distractibility and excitability

Risk for Impaired Parenting: Risk factor: disruptive or uncontrollable behaviors of child

Risk for Other-Directed Violence: Parent or Child: Risk factors: frustration with disruptive behavior, anger, unsuccessful relationships

Hyperbilirubinemia, Neonatal

Anxiety: Parent r/t threat to infant, unknown future

Parental Role Conflict r/t interruption of family life because of care regimen

Neonatal Hyperbilirubinemia r/t abnormal breakdown of red blood cells following birth

Imbalanced Nutrition: Less than Body Requirements: Infant r/t disinterest in feeding because of jaundice-related lethargy

Risk for Injury: Infant: Risk factors: kernicterus, phototherapy lights

Risk for Ineffective Thermoregulation: Risk factor: phototherapy

Readiness for Enhanced Health Self-Management: Parent: expresses desire to manage treatment: assessment of jaundice when infant is discharged from the hospital, when to call the physician, and possible preventive measures such as frequent breastfeeding (See **Neonatal Hyperbilirubinemia, Risk for,** Section III)

Hypercalcemia

Decreased Cardiac Output r/t bradydysrhythmia

Impaired Physical Mobility r/t decreased muscle tone

Imbalanced Nutrition: Less than Body Requirements r/t gastrointestinal manifestations of hypercalcemia (nausea, anorexia, ileus)

Risk for Disuse Syndrome: Risk factor: comatose state impairing mobility

Hypercapnia

Fear r/t difficulty breathing

Impaired Gas Exchange r/t ventilation-perfusion imbalance, retention of carbon dioxide

See ARDS (Adult Respiratory Distress Syndrome); COPD (Chronic Obstructive Pulmonary Disorder); Sleep Apnea

Hyperemesis Gravidarum

Anxiety r/t threat to self and infant, hospitalization

Deficient Fluid Volume r/t excessive vomiting

Ineffective Home Maintenance Behaviors r/t chronic nausea, inability to function

Nausea r/t hormonal changes of pregnancy

Imbalanced Nutrition: Less than Body Requirements r/t excessive vomiting

Powerlessness r/t health care regimen

Social Isolation r/t hospitalization

Risk for Electrolyte Imbalance: Risk factor: vomiting

Hyperglycemia

Ineffective Health Self-Management r/t complexity of therapeutic regimen, decisional conflicts, economic difficulties, unsupportive family, insufficient cues to action, deficient knowledge, mistrust, lack of acknowledgment of seriousness of condition

Risk for Unstable Blood Glucose Level (See **Glucose Level, Blood, Unstable, Risk for,** Section III)

See Diabetes Mellitus

Hyperkalemia

Risk for Decreased Activity Tolerance: Risk factor: muscle weakness

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: abnormal electrolyte level affecting heart rate and rhythm

Risk for Excess Fluid Volume: Risk factor: untreated renal failure

Hypernatremia

Risk for Imbalanced Fluid Volume: Risk factors: abnormal water loss, inadequate water intake

Hyperosmolar Hyperglycemic Nonketotic Syndrome (HHNS)

Acute Confusion r/t dehydration, electrolyte imbalance

Deficient Fluid Volume r/t polyuria, hyperglycemia, inadequate fluid intake

Risk for Electrolyte Imbalance: Risk factor: effect of metabolic state on kidney function

Risk for Injury: Seizures: Risk factors: hyperosmolar state, electrolyte imbalance

See Diabetes Mellitus; Diabetes Mellitus, Juvenile (Insulin-Dependent Diabetes Mellitus Type 1)

Hyperphosphatemia

Deficient Knowledge r/t dietary changes needed to control phosphate levels

See Renal Failure

Hypersensitivity to Slight Criticism

Defensive Coping r/t situational crisis, psychological impairment, substance abuse

Hypertension (HTN)

See HTN (Hypertension)

Risk for Decreased Cardiac Output: Risk factors: decreased contractility and altered conductivity associated with myocardial damage

Risk for Unstable Blood Pressure (See **Unstable Blood Pressure, Risk for,** Section III)

Hyperthermia

Hyperthermia (See **Hyperthermia,** Section III)

Hyperthyroidism

Anxiety r/t increased stimulation, loss of control

Diarrhea r/t increased gastric motility

Insomnia r/t anxiety, excessive sympathetic discharge

Imbalanced Nutrition: Less than Body Requirements r/t increased metabolic rate, increased gastrointestinal activity

Risk for Injury: Eye Damage: Risk factor: protruding eyes without sufficient lubrication

Risk for Unstable Blood Pressure r/t hyperthyroidism

Readiness for Enhanced Knowledge: expresses an interest in learning

Hyperventilation

Ineffective Breathing Pattern r/t anxiety, acid-base imbalance

See Anxiety Disorder; Dyspnea; Heart Failure

Hypocalcemia

Decreased Activity Tolerance r/t neuromuscular irritability

Ineffective Breathing Pattern r/t laryngospasm

Imbalanced Nutrition: Less than Body Requirements r/t effects of vitamin D deficiency, renal failure, malabsorption, laxative use

Hypoglycemia

Acute Confusion r/t insufficient blood glucose to brain

Ineffective Health Self-Management r/t deficient knowledge regarding disease process, self-care

Imbalanced Nutrition: Less than Body Requirements r/t imbalance of glucose and insulin level

Risk for Unstable Blood Glucose Level (See **Glucose Level, Blood, Unstable, Risk for,** Section III)

See Diabetes Mellitus; Diabetes Mellitus, Juvenile (IDDM Type 1)

Hypokalemia

Decreased Activity Tolerance r/t muscle weakness

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: possible dysrhythmia from electrolyte imbalance

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Hypomagnesemia

Imbalanced Nutrition: Less than Body Requirements r/t deficient knowledge of nutrition, alcoholism

See Alcoholism

Hypomania

Insomnia r/t psychological stimulus

See Manic Disorder, Bipolar I

Hyponatremia

Acute Confusion r/t electrolyte imbalance

Excess Fluid Volume r/t excessive intake of hypotonic fluids

Risk for Injury: Risk factors: seizures, new onset of confusion

Hypoplastic Left Lung

See Congenital Heart Disease/Cardiac Anomalies

Hypotension

Decreased Cardiac Output r/t decreased preload, decreased contractility

Risk for Deficient Fluid Volume: Risk factor: excessive fluid loss

Risk for Ineffective Cerebral Tissue Perfusion: Risk factors: hypovolemia, decreased contractility, decreased afterload

Risk for Shock (See **Shock, Risk for,** Section III)

Risk for Unstable Blood Pressure (See **Unstable Blood Pressure, Risk for,** Section III)

See Dehydration; Heart Failure; MI (Myocardial Infarction)

Hypothermia

Hypothermia (See **Hypothermia,** Section III)

Risk for Hypothermia (See **Hypothermia, Risk for,** Section III)

Hypothyroidism

Decreased Activity Tolerance r/t muscular stiffness, shortness of breath on exertion

Constipation r/t decreased gastric motility

Impaired Gas Exchange r/t respiratory depression

Impaired Skin Integrity r/t edema, dry or scaly skin

Risk for Overweight: Risk factor: decreased metabolic process

Hypovolemic Shock

See Shock, Hypovolemic

Hypoxia

Acute Confusion r/t decreased oxygen supply to brain

Fear r/t breathlessness

Impaired Gas Exchange r/t altered oxygen supply, inability to transport oxygen

Risk for Shock (See **Shock, Risk for,** Section III)

Hysterectomy

Constipation r/t opioids, anesthesia, bowel manipulation during surgery

Ineffective Coping r/t situational crisis of surgery

Maladaptive Grieving r/t change in body image, loss of reproductive status

Acute Pain r/t surgical injury

Sexual Dysfunction r/t disturbance in self-concept

Urinary Retention r/t edema in area, anesthesia, opioids, pain

Risk for Bleeding: Risk factor: surgical procedure

Risk for Constipation: Risk factors: opioids, anesthesia, bowel manipulation during surgery

Risk for Ineffective Peripheral Tissue Perfusion: Risk factor: deficient knowledge of aggravating factors

Risk for Surgical Site Infection: Risk factor: invasive procedure

Readiness for Enhanced Knowledge: Expresses an interest in learning

See Surgery, Perioperative Care; Surgery, Preoperative Care; Surgery, Postoperative Care

I

IBS (Irritable Bowel Syndrome)

Constipation r/t low-residue diet, stress

Diarrhea r/t increased motility of intestines associated with disease process, stress

Ineffective Health Self-Management r/t deficient knowledge, powerlessness

Chronic Pain r/t spasms, increased motility of bowel

Risk for Electrolyte Imbalance: Risk factor: diarrhea

Readiness for Enhanced Health Self-Management: expresses desire to manage illness and prevent onset of symptoms

ICD (Implantable Cardioverter/Defibrillator)

Anxiety r/t possible dysrhythmia, threat of death

Decreased Cardiac Output r/t possible dysrhythmia

Readiness for Enhanced Knowledge: expresses an interest in learning

IDDM (Insulin-Dependent Diabetes Mellitus)

See Diabetes Mellitus

Identity Disturbance/Problems

Disturbed Personal Identity r/t situational crisis, psychological impairment, chronic illness, pain

Risk for Disturbed Personal Identity (See **Identity, Personal, Risk for Disturbed,** Section III)

Idiopathic Thrombocytopenic Purpura (ITP)

See ITP (Idiopathic Thrombocytopenic Purpura)

Ileal Conduit

Disturbed Body Image r/t presence of stoma

Ineffective Health Self-Management r/t new skills required to care for appliance and self

Ineffective Sexuality Pattern r/t altered body function and structure

Social Isolation r/t alteration in physical appearance, fear of accidental spill of urine

Risk for Latex Allergy Reaction: Risk factor: repeated exposures to latex associated with treatment and management of disease

Risk for Impaired Skin Integrity: Risk factor: difficulty obtaining tight seal of appliance

Readiness for Enhanced Knowledge: expresses an interest in learning

Ileostomy

Disturbed Body Image r/t presence of stoma

Diarrhea r/t dietary changes, alteration in intestinal motility

Deficient Knowledge r/t limited practice of stoma care, dietary modifications

Ineffective Sexuality Pattern r/t altered body function and structure

Social Isolation r/t alteration in physical appearance, fear of accidental spill of ostomy contents

Risk for Impaired Skin Integrity: Risk factors: difficulty obtaining tight seal of appliance, caustic drainage

Readiness for Enhanced Knowledge: expresses an interest in learning

Ileus

Deficient Fluid Volume r/t loss of fluids from vomiting, fluids trapped in bowel

Dysfunctional Gastrointestinal Motility r/t effects of surgery, decreased perfusion of intestines, medication effect, immobility

Nausea r/t gastrointestinal irritation

Acute Pain r/t pressure, abdominal distention

Readiness for Enhanced Knowledge: expresses an interest in learning

Immigration Transition, Risk for Complicated

Anxiety r/t changes in safety and security needs

Fear r/t unfamiliar environment, separation from support system, possible language barrier

Impaired Social Interaction r/t possible communication or sociocultural barriers

Risk for Loneliness: Risk factor: separation from support system

Risk for Powerlessness: Risk factor: insufficient social support

Risk for Relocation Stress Syndrome: Risk factors: insufficient support system, social isolation, and potential communication barriers

Risk for Impaired Resilience: Risk factor: decreased ability to adapt to adverse or changing situations

Readiness for Enhanced Coping: expresses desire to enhance social support

Readiness for Enhanced Knowledge: expresses a desire to become familiar with resources within their environment

Immobility

Ineffective Breathing Pattern r/t inability to deep breathe in supine position

Acute Confusion: Elderly r/t sensory deprivation from immobility

Constipation r/t immobility

Risk for Frail Elderly Syndrome: Risk factors: low physical activity, bed rest

Impaired Physical Mobility r/t medically imposed bed rest

Ineffective Peripheral Tissue Perfusion r/t interruption of venous flow

Powerlessness r/t forced immobility from health care environment

Impaired Walking r/t limited physical mobility, deconditioning of body

Risk for Disuse Syndrome: Risk factor: immobilization

Risk for Impaired Skin Integrity: Risk factors: pressure over bony prominences, shearing forces when moved; pressure from devices

Risk for Impaired Tissue Integrity: Risk factors: mechanical factors from pressure over bony prominences, shearing forces when moved; pressure from devices

Risk for Overweight: Risk factor: energy expenditure less than energy intake

Risk for Thrombosis: Risk factor: lack of physical activity

Readiness for Enhanced Knowledge: expresses an interest in learning

Immunization

(See **Readiness for Enhanced Health Literacy,** Section III)

(See **Readiness for Enhanced Health Self-Management,** Section III)

Immunosuppression

Risk for Infection: Risk factors: immunosuppression; exposure to disease outbreak

Impaired Social Interaction r/t therapeutic isolation

Impaction of Stool

Constipation r/t decreased fluid intake, less than adequate amounts of fiber and bulk-forming foods in diet, medication effect, or immobility

Impaired Sitting

Impaired Physical Mobility r/t musculoskeletal, cognitive, or neuromuscular disorder

Impaired Standing

Decreased Activity Tolerance r/t insufficient physiological or psychological energy

Powerlessness r/t loss of function

Imperforate Anus

Anxiety r/t ability to care for newborn

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Deficient Knowledge r/t home care for newborn

Impaired Skin Integrity r/t pruritus

Impetigo

Impaired Skin Integrity r/t infectious disease

Readiness for Enhanced Knowledge: expresses an interest in learning

See Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice)

Implantable Cardioverter/Defibrillator (ICD)

See ICD (Implantable Cardioverter/Defibrillator)

Impotence

Situational Low Self-Esteem r/t physiological crisis, inability to practice usual sexual activity

Sexual Dysfunction r/t altered body function

Readiness for Enhanced Knowledge: treatment information for erectile dysfunction

See Erectile Dysfunction (ED)

Impulsiveness

Ineffective Impulse Control (See **Impulse Control, Ineffective,** Section III)

Inactivity

Decreased Activity Tolerance r/t imbalance between oxygen supply and demand, sedentary lifestyle, weakness, immobility

Hopelessness r/t deteriorating physiological condition, long-term stress, social isolation

Impaired Physical Mobility r/t intolerance to activity, decreased strength and endurance, depression, severe anxiety, musculoskeletal impairment, perceptual or cognitive impairment, neuromuscular impairment, pain, discomfort

Risk for Constipation: Risk factor: insufficient physical activity

Incompetent Cervix

See Premature Dilation of the Cervix (Incompetent Cervix)

Incontinence of Stool

Disturbed Body Image r/t inability to control elimination of stool

Impaired Bowel Continence r/t decreased awareness of need to defecate, loss of sphincter control

Toileting Self-Care Deficit r/t cognitive impairment, neuromuscular impairment, perceptual impairment, weakness

Situational Low Self-Esteem r/t inability to control elimination of stool

Risk for Impaired Skin Integrity: Risk factor: presence of stool

Incontinence of Urine

Disability-Associated Urinary Incontinence r/t altered environment; sensory, cognitive, or mobility deficits

Stress Urinary Incontinence (See **Incontinence, Urinary, Stress,** Section III)

Urge Urinary Incontinence (See **Incontinence, Urinary, Urge,** Section III)

Toileting Self-Care Deficit r/t cognitive impairment

Situational Low Self-Esteem r/t inability to control passage of urine

Risk for Impaired Skin Integrity: Risk factor: presence of urine on perineal skin

Indigestion

Nausea r/t gastrointestinal irritation

Imbalanced Nutrition: Less than Body Requirements r/t discomfort when eating

Induction of Labor

Anxiety r/t medical interventions, powerlessness

Decisional Conflict r/t perceived threat to idealized birth

Ineffective Coping r/t situational crisis of medical intervention in birthing process

Acute Pain r/t contractions

Situational Low Self-Esteem r/t inability to carry out normal labor

Risk for Injury: Maternal and Fetal: Risk factors: hypertonic uterus, potential prematurity of newborn

Readiness for Enhanced Family Processes: family support during induction of labor

Infant Apnea

See Premature Infant (Child); Respiratory Conditions of the Neonate; Sudden Infant Death Syndrome (SIDS)

Infant Behavior

Disorganized Infant Behavior r/t pain, oral/motor problems, feeding intolerance, environmental overstimulation, lack of containment or boundaries, prematurity, invasive or painful procedures

Risk for Disorganized Infant Behavior: Risk factors: pain, oral/motor problems, environmental overstimulation, lack of containment or boundaries

Readiness for Enhanced Organized Infant behavior: stable physiologic measures, use of some self-regulatory measures

Infant Care

Readiness for Enhanced Childbearing Process: a pattern of preparing for, maintaining, and strengthening care of newborn infant

Infant Feeding Dynamic, Ineffective

Ineffective Infant Feeding Dynamic r/t prematurity, neurological impairment or delay, oral hypersensitivity, prolonged nothing-by-mouth order

Infant of Diabetic Mother

Decreased Cardiac Output r/t cardiomegaly

Deficient Fluid Volume r/t increased urinary excretion and osmotic diuresis

Imbalanced Nutrition: Less than Body Requirements r/t hypotonia, lethargy, poor sucking, postnatal metabolic changes from hyperglycemia to hypoglycemia and hyperinsulinism

Risk for Impaired Gas Exchange: Risk factors: increased incidence of cardiomegaly, prematurity

Risk for Unstable Blood Glucose Level: Risk factor: metabolic change from hyperglycemia to hypoglycemia and hyperinsulinism

Risk for Disturbed Maternal–Fetal Dyad: Risk factor: impaired glucose metabolism

See Premature Infant (Child); Respiratory Conditions of the Neonate

Infant of Substance-Abusing Mother

See Neonatal Abstinence Syndrome

Infantile Polyarteritis

See Kawasaki Disease

Infection, Potential for

Risk for Infection (See **Infection, Risk for,** Section III)

Infectious Processes

Impaired Comfort r/t distressing symptoms

Diarrhea r/t gastrointestinal inflammation

Ineffective Health Maintenance Behaviors r/t knowledge deficit regarding transmission, symptoms, and treatment

Ineffective Health Self-Management r/t lack of knowledge regarding preventive immunizations

Ineffective Protection r/t inadequate nutrition, abnormal blood profiles, drug therapies, treatments

Impaired Social Interaction r/t therapeutic isolation

Risk for Electrolyte Imbalance: Risk factors: vomiting, diarrhea

Risk for Deficient Fluid Volume: Risk factors: vomiting, diarrhea, inadequate fluid intake

Risk for Infection: Risk factor: increased environmental exposure when in close proximity to infected persons

Risk for Surgical Site Infection r/t immunosuppression

Risk for Ineffective Thermoregulation: Risk factor: infectious process

Readiness for Enhanced Knowledge: expresses desire for information regarding prevention and treatment

Infertility

Ineffective Health Self-Management r/t deficient knowledge about infertility

Powerlessness r/t infertility

Chronic Sorrow r/t inability to conceive a child

Spiritual Distress r/t inability to conceive a child

Inflammatory Bowel Disease (Child and Adult)

Ineffective Coping r/t repeated episodes of diarrhea

Diarrhea r/t effects of inflammatory changes of the bowel

Deficient Fluid Volume r/t frequent and loose stools

Imbalanced Nutrition: Less than Body Requirements r/t anorexia, decreased absorption of nutrients from gastrointestinal tract

Acute Pain r/t abdominal cramping and anal irritation

Impaired Skin Integrity r/t frequent stools, development of anal fissures

Social Isolation r/t diarrhea

See Child with Chronic Condition; Crohn's Disease; Hospitalized Child; Maturational Issues, Adolescent

Influenza

See Infectious Processes

Inguinal Hernia Repair

Impaired Physical Mobility r/t pain at surgical site and fear of causing hernia to rupture

Acute Pain r/t surgical procedure

Urinary Retention r/t possible edema at surgical site

Risk for Surgical Site Infection: Risk factor: surgical procedure

Injury

Risk for Adult Falls: Risk factors: orthostatic hypotension, impaired physical mobility, diminished mental status

Risk for Child Falls: Risk factors: impaired physical mobility, diminished mental status

Risk for Injury: Risk factor: environmental conditions interacting with client's adaptive and defensive resources

Risk for Corneal Injury: Risk factors: blinking less than five times per minute, mechanical ventilation, pharmaceutical agent, prolonged hospitalization

Risk for Thermal Injury: Risk factors: cognitive impairment, inadequate supervision, developmental level

Risk for Urinary Tract Injury: Risk factor: inflammation and/or infection from long-term use of urinary catheter

Insomnia

(See **Insomnia,** Section III)

Insulin Shock

See Hypoglycemia

Intellectual Disability

Impaired Verbal Communication r/t developmental delay

Interrupted Family Processes r/t crisis of diagnosis and situational transition

Maladaptive Grieving r/t loss of perfect child, birth of child with congenital defect or subsequent head injury

Deficient Community Health r/t lack of programs to address developmental deficiencies

Ineffective Home Maintenance Behaviors r/t insufficient support systems

Self-Neglect r/t learning disability

Self-Care Deficit: Bathing, Dressing, Feeding, Toileting r/t perceptual or cognitive impairment

Self-Mutilation r/t inability to express tension verbally

Social Isolation r/t delay in accomplishing developmental tasks

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Spiritual Distress r/t chronic condition of child with special needs

Stress Overload r/t intense, repeated stressor (chronic condition)

Impaired Swallowing r/t neuromuscular impairment

Risk for Ineffective Activity Planning r/t inability to process information

Risk for Impaired Religiosity: Risk factor: social isolation

Risk for Self-Mutilation: Risk factors: separation anxiety, depersonalization

Readiness for Enhanced Family Coping: adaptation and acceptance of child's condition and needs

See Child with Chronic Condition; Safety, Childhood

Intermittent Claudication

Deficient Knowledge r/t lack of knowledge of cause and treatment of peripheral vascular diseases

Acute Pain r/t decreased circulation to extremities with activity

Ineffective Peripheral Tissue Perfusion r/t interruption of arterial flow

Risk for Injury: Risk factor: tissue hypoxia

Readiness for Enhanced Knowledge: prevention of pain and impaired circulation

See Peripheral Vascular Disease (PVD)

Internal Cardioverter/Defibrillator (ICD)

See ICD (Implantable Cardioverter/Defibrillator)

Internal Fixation

Impaired Walking r/t repair of fracture

Risk for Infection: Risk factors: traumatized tissue, broken skin

See Fracture

Interstitial Cystitis

Acute Pain r/t inflammatory process

Impaired Urinary Elimination r/t inflammation of bladder

Risk for Infection: Risk factor: suppressed inflammatory response

Readiness for Enhanced Knowledge: expresses an interest in learning

Intervertebral Disk Excision

See Laminectomy

Intestinal Obstruction

See Ileus; Bowel Obstruction

Intestinal Perforation

See Peritonitis

Intoxication

Anxiety r/t loss of control of actions

Acute Confusion r/t alcohol abuse

Ineffective Coping r/t use of mind-altering substances as a means of coping

Impaired Memory r/t effects of alcohol on mind

Risk for Aspiration: Risk factors: diminished mental status, vomiting

Risk for Adult Falls: Risk factor: diminished mental status

Risk for Other-Directed Violence: Risk factor: inability to control thoughts and actions

Intraaortic Balloon Counterpulsation

Anxiety r/t device providing cardiovascular assistance

Decreased Cardiac Output r/t heart dysfunction needing counterpulsation

Compromised Family Coping r/t seriousness of significant other's medical condition

Impaired Physical Mobility r/t restriction of movement because of mechanical device

Risk for Peripheral Neurovascular Dysfunction: Risk factors: vascular obstruction of balloon catheter, thrombus formation, emboli, edema

Risk for Infection: Risk factor: invasive procedure

Risk for Impaired Tissue Integrity: Risk factor: invasive procedure

Intracranial Pressure, Increased

Ineffective Breathing Pattern r/t pressure damage to breathing center in brainstem

Acute Confusion r/t increased intracranial pressure

Impaired Memory r/t neurological disturbance

Vision Loss r/t pressure damage to sensory centers in brain

Risk for Ineffective Cerebral Tissue Perfusion: Risk factors: body position, cerebral vessel circulation deficits

See Head Injury; Subarachnoid Hemorrhage

Intrauterine Growth Retardation

Anxiety: Maternal r/t threat to fetus

Ineffective Coping: Maternal r/t situational crisis, threat to fetus

Impaired Gas Exchange r/t insufficient placental perfusion

Imbalanced Nutrition: Less than Body Requirements r/t insufficient placenta

Situational Low Self-Esteem: Maternal r/t guilt about threat to fetus

Spiritual Distress r/t unknown outcome of fetus

Risk for Powerlessness: Risk factor: unknown outcome of fetus

Intravenous Therapy

Risk for Vascular Trauma: Risk factor: infusion of irritating chemicals

Intubation, Endotracheal or Nasogastric

Disturbed Body Image r/t altered appearance with mechanical devices

Impaired Verbal Communication r/t endotracheal tube

Imbalanced Nutrition: Less than Body Requirements r/t inability to ingest food because of the presence of tubes

Impaired Oral Mucous Membrane r/t presence of tubes

Acute Pain r/t presence of tube

Iodine Reaction with Diagnostic Testing

Risk for Adverse Reaction to Iodinated Contrast Media (See **Reaction to Iodinated Contrast Media, Risk for Adverse,** Section III)

Irregular Pulse

See Dysrhythmia

Irritable Bowel Syndrome (IBS)

See IBS (Irritable Bowel Syndrome)

Isolation

Impaired Resilience (See **Resilience, Individual, Impaired,** Section III)

Social Isolation (See **Social Isolation,** Section III)

Itching

See Pruritus

ITP (Idiopathic Thrombocytopenic Purpura)

Decreased Diversional Activity Engagement r/t activity restrictions, safety precautions

Ineffective Protection r/t decreased platelet count

Risk for Bleeding: Risk factors: decreased platelet count, developmental level, age-appropriate play

J

Jaundice

Imbalanced Nutrition: Less than Body Requirements r/t decreased appetite with liver disorder

Risk for Bleeding: Risk factor: impaired liver function

Risk for Impaired Liver Function: Risk factors: possible viral infection, medication effect

Risk for Impaired Skin Integrity: Risk factors: pruritus, itching

See Cirrhosis; Hepatitis

Jaundice, Neonatal

See Hyperbilirubinemia, Neonatal

Jaw Pain and Heart Attacks

See Angina; Chest Pain; MI (Myocardial Infarction)

Jaw Surgery

Deficient Knowledge r/t emergency care for wired jaws (e.g., cutting bands and wires), oral care

Imbalanced Nutrition: Less than Body Requirements r/t jaws wired closed, difficulty eating

Acute Pain r/t surgical procedure

Impaired Swallowing r/t edema from surgery

Risk for Aspiration: Risk factor: wired jaws

Jittery

Anxiety r/t unconscious conflict about essential values and goals, threat to or change in health status

Death Anxiety r/t unresolved issues relating to end of life

Risk for Post-Trauma Syndrome: Risk factors: occupation, survivor's role in event, inadequate social support

Jock Itch

Ineffective Health Self-Management r/t prevention and treatment of disorder

Impaired Skin Integrity r/t moisture and irritating or tight-fitting clothing

See Pruritus

Joint Dislocation

See Dislocation of Joint

Joint Pain

See Arthritis; Bursitis; JRA (Juvenile Rheumatoid Arthritis); Osteoarthritis; Rheumatoid Arthritis (RA)

Joint Replacement

Risk for Peripheral Neurovascular Dysfunction: Risk factor: orthopedic surgery

Risk for Impaired Tissue Integrity: Risk factor: invasive procedure

See Total Joint Replacement (Total Hip/Total Knee/Shoulder)

JRA (Juvenile Rheumatoid Arthritis)

Impaired Comfort r/t altered health status

Fatigue r/t chronic inflammatory disease

Impaired Physical Mobility r/t pain, restricted joint movement

Acute Pain r/t swollen or inflamed joints, restricted movement, physical therapy

Self-Care Deficit: feeding, bathing, dressing, toileting r/t restricted joint movement, pain

Risk for Compromised Human Dignity: Risk factors: perceived intrusion by clinicians, invasion of privacy

Risk for Injury: Risk factors: impaired physical mobility, splints, adaptive devices, increased bleeding potential from anti-inflammatory medications

Risk for Impaired Resilience: Risk factor: chronic condition

Risk for Situational Low Self-Esteem: Risk factor: disturbed body image

Risk for Impaired Skin Integrity: Risk factors: splints, adaptive devices

See Child with Chronic Condition; Hospitalized Child

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

K

Kaposi's Sarcoma

Risk for Maladaptive Grieving: Risk factor: loss of social support

Risk for Impaired Religiosity: Risk factors: illness/hospitalization, ineffective coping

Risk for Impaired Resilience: Risk factor: serious illness

See AIDS (Acquired Immunodeficiency Syndrome)

Kawasaki Disease

Anxiety: Parental r/t progression of disease, complications of arthritis, and cardiac involvement

Impaired Comfort r/t altered health status

Hyperthermia r/t inflammatory disease process

Imbalanced Nutrition: Less than Body Requirements r/t impaired oral mucous membrane integrity

Impaired Oral Mucous Membrane Integrity r/t inflamed mouth and pharynx; swollen lips that become dry, cracked, fissured

Acute Pain r/t enlarged lymph nodes; erythematous skin rash that progresses to desquamation, peeling, denuding of skin

Impaired Skin integrity r/t inflammatory skin changes

Risk for Imbalanced Fluid Volume: Risk factor: hypovolemia

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: cardiac involvement

Risk for Dry Mouth: Risk factor: decreased fluid intake

See Hospitalized Child

Keloids

Disturbed Body Image r/t presence of scar tissue at site of a healed skin injury

Readiness for Enhanced Health Self-Management: desire to have information to manage condition

Keratoconjunctivitis Sicca (Dry Eye Syndrome)

Risk for Dry Eye: Risk factors: aging, staring at a computer screen for long intervals

Risk for Infection: Risk factor: dry eyes that are more vulnerable to infection

Risk for Corneal Injury: Risk factors: dry eye, exposure of the eyeball

See Conjunctivitis

Keratoplasty

See Corneal Transplant

Ketoacidosis, Alcoholic

See Alcohol Withdrawal; Alcoholism

Ketoacidosis, Diabetic

Deficient Fluid Volume r/t excess excretion of urine, nausea, vomiting, increased respiration

Impaired Memory r/t fluid and electrolyte imbalance

Imbalanced Nutrition: Less than Body Requirements r/t body's inability to use nutrients

Risk for Unstable Blood Glucose Level: Risk factor: deficient knowledge of diabetes management (e.g., action plan)

Risk for Powerlessness: Risk factor: illness-related regimen

Risk for Impaired Resilience: Risk factor: complications of disease

See Diabetes Mellitus

Keyhole Heart Surgery

See MIDCAB (Minimally Invasive Direct Coronary Artery Bypass)

Kidney Disease Screening

Readiness for Enhanced Health Self-Management: seeks information for screening

Risk for Electrolyte Imbalance r/t renal dysfunction

Kidney Failure

See Renal Failure

Kidney Failure Acute/Chronic, Child

See Renal Failure, Acute/Chronic, Child

Kidney Failure, Nonoliguric

See Renal Failure, Nonoliguric

Kidney Stone

Acute Pain r/t obstruction from kidney calculi

Impaired Urinary Elimination: Urgency and Frequency r/t anatomical obstruction, irritation caused by stone

Risk for Infection: Risk factor: obstruction of urinary tract with stasis of urine

Readiness for Enhanced Knowledge: expresses an interest in learning about prevention of stones

Kidney Transplant

Ineffective Protection r/t immunosuppressive therapy

Readiness for Enhanced Decision-Making: expresses desire to enhance understanding of choices

Readiness for Enhanced Family Processes: adapting to life without dialysis

Readiness for Enhanced Health Self-Management: desire to manage the treatment and prevention of complications after transplantation

Readiness for Enhanced Spiritual Well-Being: heightened coping, living without dialysis

See Renal Failure, Kidney Transplantation, Donor; Kidney Transplantation, Recipient; Nephrectomy; Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Kidney Transplantation, Donor

Impaired Emancipated Decision-Making r/t harvesting of kidney from traumatized donor

Moral Distress r/t conflict among decision makers, end-of-life decisions, time constraints for decision-making

Spiritual Distress r/t grieving from loss of significant person

Risk for Surgical Site Infection: Risk factor: surgical procedure

Readiness for Enhanced Communication: expressing thoughts and feelings about situation

Readiness for Enhanced Family Coping: decision to allow organ donation

Readiness for Enhanced Emancipated Decision-Making: expresses desire to enhance understanding and meaning of choices

Readiness for Enhanced Resilience: decision to donate organs

Readiness for Enhanced Spirituality: inner peace resulting from allowance of organ donation

See Nephrectomy

Kidney Transplantation, Recipient

Anxiety r/t possible rejection, procedure

Ineffective Health Maintenance Behaviors r/t long-term home treatment after transplantation, diet, signs of rejection, use of medications

Deficient Knowledge r/t specific nutritional needs, possible paralytic ileus, fluid or sodium restrictions

Impaired Urinary Elimination r/t possible impaired renal function

Risk for Bleeding: Risk factor: surgical procedure

Risk for Infection: Risk factor: use of immunosuppressive therapy to control rejection

Risk for Surgical Site Infection: Risk factor: surgical procedure

Risk for Shock: Risk factor: possible hypovolemia

Risk for Spiritual Distress: Risk factor: obtaining transplanted kidney from someone's traumatic loss

Readiness for Enhanced Spiritual Well-Being: acceptance of situation

Kidney Tumor

See Wilms' Tumor

Kissing Disease

See Mononucleosis

Knee Replacement

See Total Joint Replacement (Total Hip/Total Knee/Shoulder)

Knowledge

Readiness for Enhanced Knowledge (See **Knowledge, Readiness for Enhanced,** Section III)

Knowledge, Deficient

Ineffective Health maintenance behaviors r/t lack of or significant alteration in communication skills (written, verbal, and/or gestural)

Deficient Knowledge (See **Knowledge, Deficient,** Section III)

Readiness for Enhanced Knowledge (See **Knowledge, Readiness for Enhanced,** Section III)

Kock Pouch

See Continent Ileostomy (Kock Pouch)

Korsakoff's Syndrome

Acute Confusion r/t alcohol abuse

Dysfunctional Family Processes r/t alcoholism as possible cause of syndrome

Impaired Memory r/t neurological changes associated with excessive alcohol intake

Self-Neglect r/t cognitive impairment from chronic alcohol abuse

Risk for Adult Falls: Risk factor: cognitive impairment from chronic alcohol abuse

Risk for Injury: Risk factors: sensory dysfunction, lack of coordination when ambulating from chronic alcohol abuse

Risk for Impaired Liver function: Risk factor: substance abuse (alcohol)

Risk for Imbalanced Nutrition: Less than Body Requirements: Risk factor: lack of adequate balanced intake from chronic alcohol abuse

L

Labor, Induction of

See Induction of Labor

Labor, Normal

Anxiety r/t fear of the unknown, situational crisis

Impaired Comfort r/t labor

Fatigue r/t childbirth

Deficient Knowledge r/t lack of preparation for labor

Labor Pain r/t uterine contractions, stretching of cervix and birth canal

Impaired Tissue Integrity r/t passage of infant through birth canal, episiotomy

Risk for Ineffective Childbearing Process (See **Childbearing Process,** Section III)

Risk for Adult Falls: Risk factors: excessive loss or shift in intravascular fluid volume, orthostatic hypotension

Risk for Deficient Fluid Volume: Risk factor: excessive loss of blood

Risk for Infection: Risk factors: multiple vaginal examinations, tissue trauma, prolonged rupture of membranes

Risk for Injury: Fetal: Risk factor: hypoxia

Risk for Post-Trauma Syndrome: Risk factors: trauma or violence associated with labor pains, medical or surgical interventions, history of sexual abuse

Readiness for Enhanced Childbearing Process: responds appropriately, is proactive, bonds with infant, uses support systems

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Risk for Nipple-Areolar Complex Injury: breast engorgement; inappropriate positioning of the mother during breastfeeding

Readiness for Enhanced Family Coping: significant other provides support during labor

Readiness for Enhanced Health Management: prenatal care and childbirth education birth process

Readiness for Enhanced Power: expresses readiness to enhance participation in choices regarding treatment during labor

Labor Pain

Labor Pain r/t uterine contractions, stretching of cervix and birth canal

Labyrinthitis

Ineffective Health Self-Management r/t delay in seeking treatment for respiratory and ear infections

Risk for Injury r/t dizziness

Readiness for Enhanced Health Management: management of episodes

See Ménière's Disease

Lacerations

Readiness for Enhanced Health Management: appropriate care of injury

Risk for Infection: Risk factor: broken skin

Risk for Physical Trauma: Risk factor: children playing with dangerous objects

Lactation

See Breastfeeding, Ineffective; Breastfeeding, Interrupted

Lactic Acidosis

Decreased Cardiac Output r/t altered heart rate/rhythm, preload, and contractility

Risk for Electrolyte Imbalance: Risk factor: impaired regulatory mechanism

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: hypoxia

Impaired Gas Exchange r/t ineffective breathing pattern, pain, ineffective airway clearance

See Ketoacidosis, Diabetic

Lactose Intolerance

Readiness for Enhanced Knowledge: interest in identifying lactose intolerance, treatment, and substitutes for milk products

See Abdominal Distention; Diarrhea

Laminectomy

Anxiety r/t change in health status, surgical procedure

Impaired Comfort r/t surgical procedure

Deficient Knowledge r/t appropriate postoperative and postdischarge activities

Impaired Physical Mobility r/t neuromuscular impairment

Acute Pain r/t localized inflammation and edema

Urinary Retention r/t competing sensory impulses, effects of opioids or anesthesia

Risk for Bleeding: Risk factor: surgery

Risk for Surgical Site Infection: Risk factor: invasive procedure, surgery

Risk for Perioperative Positioning Injury: Risk factor: prone position

See Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Language Impairment

See Speech Disorders

Laparoscopic Laser Cholecystectomy

See Cholecystectomy; Laser Surgery

Laparoscopy

Urge Urinary Incontinence r/t pressure on the bladder from gas

Acute Pain: Shoulder r/t gas irritating the diaphragm

Laparotomy

See Abdominal Surgery

Large Bowel Resection

See Abdominal Surgery

Laryngectomy

Ineffective Airway Clearance r/t surgical removal of glottis, decreased humidification

Death Anxiety r/t unknown results of surgery

Disturbed Body Image r/t change in body structure and function

Impaired Comfort r/t surgery

Impaired Verbal Communication r/t removal of larynx

Interrupted Family Processes r/t surgery, serious condition of family member, difficulty communicating

Grieving r/t loss of voice, fear of death

Ineffective Health Self-Management r/t deficient knowledge regarding self-care with laryngectomy

Imbalanced Nutrition: Less than Body Requirements r/t absence of oral feeding, difficulty swallowing, increased need for fluids

Impaired Oral Mucous Membrane r/t absence of oral feeding

Chronic Sorrow r/t change in body image

Impaired Swallowing r/t edema, laryngectomy tube

Risk for Electrolyte Imbalance: Risk factor: fluid imbalance

Risk for Maladaptive Grieving: Risk factors: loss, major life event

Risk for Compromised Human Dignity: Risk factor: inability to communicate

Risk for Surgical Site Infection: Risk factors: invasive procedure, surgery

Risk for Powerlessness: Risk factors: chronic illness, change in communication

Risk for Impaired Resilience: Risk factor: change in health status

Risk for Situational Low Self-Esteem: Risk factor: disturbed body image

Laser Surgery

Impaired Comfort r/t surgery

Constipation r/t laser intervention in vulval and perianal areas

Deficient Knowledge r/t preoperative and postoperative care associated with laser procedure

Acute Pain r/t heat from laser

Risk for Bleeding: Risk factor: surgery

Risk for Infection: Risk factor: delayed heating reaction of tissue exposed to laser

Risk for Injury: Risk factor: accidental exposure to laser beam

LASIK Eye Surgery (Laser-Assisted in Situ Keratomileusis)

Impaired Comfort r/t surgery

Decisional Conflict r/t decision to have surgery

Risk for Infection: Risk factor: invasive procedure/surgery

Readiness for Enhanced Health Management: surgical procedure preoperative and postoperative teaching and expectations

L

Latex Allergic Reaction

Latex Allergic Reaction (See **Latex Allergic Reaction,** Section III)

Risk for Latex Allergic Reaction (See **Latex Allergic Reaction, Risk for,** Section III)

Readiness for Enhanced Knowledge: prevention and treatment of exposure to latex products

Laxative Abuse

Perceived Constipation r/t health belief, faulty appraisal, impaired thought processes

Lead Poisoning

Contamination r/t flaking, peeling paint in presence of young children

Ineffective Home Maintenance Behaviors r/t presence of lead paint

Risk for Delayed Child Development: Risk factor: lead poisoning

Left Heart Catheterization

See Cardiac Catheterization

Legionnaires' Disease

Contamination r/t contaminated water in air-conditioning systems

See Pneumonia

Lens Implant

See Cataract Extraction; Vision Impairment

Lethargy/Listlessness

Frail Elderly Syndrome r/t alteration in cognitive function

Fatigue r/t decreased metabolic energy production

Insomnia r/t internal or external stressors

Risk for Ineffective Cerebral Tissue Perfusion: Risk factor: carbon dioxide retention and/or lack of oxygen supply to brain

Leukemia

Ineffective Protection r/t abnormal blood profile

Fatigue r/t abnormal blood profile and/or side effects of chemotherapy treatment

Risk for Imbalanced Fluid Volume: Risk factors: nausea, vomiting, bleeding, side effects of treatment

Risk for Infection: Risk factor: ineffective immune system

Risk for Impaired Resilience: Risk factor: serious illness

See Cancer; Chemotherapy

Leukopenia

Ineffective Protection r/t leukopenia

Risk for Infection: Risk factor: low white blood cell count

Level of Consciousness, Decreased

See Confusion, Acute; Confusion, Chronic

Lice

Impaired Comfort r/t inflammation, pruritus

Readiness for Enhanced Health Management: preventing and treating infestation

Ineffective Home Maintenance Behaviors r/t close unsanitary, overcrowded conditions

Self-Neglect r/t lifestyle

See Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice)

Lifestyle, Sedentary

Sedentary Lifestyle (See **Sedentary Lifestyle,** Section III)

Risk for Ineffective Peripheral Tissue Perfusion: Risk factor: lack of movement

Decreased Activity Tolerance: Related factor: impaired physical mobility

Lightheadedness

See Dizziness; Vertigo; Falls

Limb Reattachment Procedures

Anxiety r/t unknown outcome of reattachment procedure, use and appearance of limb

Disturbed Body Image r/t unpredictability of function and appearance of reattached body part

Grieving r/t unknown outcome of reattachment procedure

Spiritual Distress r/t anxiety about condition

Stress Overload r/t multiple coexisting stressors, physical demands

Risk for Bleeding: Risk factor: severed vessels

Risk for Perioperative Positioning Injury: Risk factor: immobilization

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Risk for Peripheral Neurovascular Dysfunction: Risk factors: trauma, orthopedic and neurovascular surgery, compression of nerves and blood vessels

Risk for Powerlessness: Risk factor: unknown outcome of procedure

Risk for Impaired Religiosity: Risk factors: suffering, hospitalization

See Surgery, Postoperative Care

Liposuction

Disturbed Body Image r/t dissatisfaction with unwanted fat deposits in body

Risk for Impaired Resilience: Risk factor: body image disturbance

Readiness for Enhanced Decision-Making: expresses desire to make decision regarding liposuction

Readiness for Enhanced Self-Concept: satisfaction with new body image

See Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Lithotripsy

Readiness for Enhanced Health Management: expresses desire for information related to procedure and aftercare and prevention of stones

See Kidney Stone

Liver Biopsy

Anxiety r/t procedure and results

Risk for Deficient Fluid Volume: Risk factor: hemorrhage from biopsy site

Risk for Infection: Risk factor: invasive procedure

Risk for Powerlessness: Risk factor: inability to control outcome of procedure

Liver Cancer

Risk for Bleeding: Risk factor: liver dysfunction

Risk for Adult Falls: Risk factor: confusion associated with liver dysfunction

Risk for Impaired Liver Function: Risk factor: disease process

Risk for Impaired Resilience: Risk factor: serious illness

See Cancer; Chemotherapy; Radiation Therapy

Liver Disease

See Cirrhosis; Hepatitis

Liver Function

Risk for Impaired Liver Function (See **Liver Function, Impaired, Risk for,** Section III)

Liver Transplant

Impaired Comfort r/t surgical pain

Decisional Conflict r/t acceptance of donor liver

Ineffective Protection r/t immunosuppressive therapy

Risk for Impaired Liver Function: Risk factors: possible rejection, infection

Readiness for Enhanced Family Processes: change in physical needs of family member

Readiness for Enhanced Health Management: desire to manage the treatment and prevention of complications after transplantation

Readiness for Enhanced Spiritual Well-Being: heightened coping

See Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Living Will

Moral Distress r/t end-of-life decisions

Readiness for Enhanced Decision-Making: expresses desire to enhance understanding of choices for decision-making

Readiness for Enhanced Relationship: shares information with others

Readiness for Enhanced Religiosity: request to meet with religious leaders or facilitators

Readiness for Enhanced Resilience: uses effective communication

Readiness for Enhanced Spiritual Well-Being: acceptance of and preparation for end of life

See Advance Directives

Lobectomy

See Thoracotomy

Loneliness

Spiritual Distress r/t loneliness, social alienation

Risk for Loneliness (See **Loneliness, Risk for,** Section III)

Risk for Impaired Religiosity: Risk factor: lack of social interaction

Readiness for Enhanced Hope: expresses desire to enhance interconnectedness with others

Readiness for Enhanced Relationship: expresses satisfaction with complementary relationship between partners

Loose Stools (Bowel Movements)

Diarrhea r/t increased gastric motility

Risk for Dysfunctional Gastrointestinal Motility (See **Gastrointestinal Motility, Dysfunctional, Risk for,** Section III)

See Diarrhea

Loss of Bladder Control

See Incontinence of Urine

Loss of Bowel Control

See Incontinence of Stool

Lou Gehrig's Disease

See Amyotrophic Lateral Sclerosis (ALS)

Low Back Pain

Impaired Comfort r/t back pain

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding self-care with back pain

Impaired Physical Mobility r/t back pain

Chronic Pain r/t degenerative processes, musculotendinous strain, injury, inflammation, congenital deformities

Urinary Retention r/t possible spinal cord compression

Risk for Powerlessness: Risk factor: living with chronic pain

Readiness for Enhanced Health Management: expresses desire for information to manage pain

Low Blood Glucose

See Hypoglycemia

Low Blood Pressure

See Hypotension

Lower GI Bleeding

See GI Bleed (Gastrointestinal Bleeding)

Lumbar Puncture

Anxiety r/t invasive procedure and unknown results

Deficient Knowledge r/t information about procedure

Acute Pain r/t possible loss of cerebrospinal fluid

Risk for Ineffective Cerebral Tissue Perfusion: Risk factor: treatment-related side effects

Risk for Infection: Risk factor: invasive procedure

Lumpectomy

Decisional Conflict r/t treatment choices

Readiness for Enhanced Knowledge: preoperative and postoperative care

Readiness for Enhanced Spiritual Well-Being: hope of benign diagnosis

See Cancer

Lung Cancer

See Cancer; Chemotherapy; Radiation Therapy; Thoracotomy

Lung Surgery

See Thoracotomy

Lupus Erythematosus

Disturbed Body Image r/t change in skin, rash, lesions, ulcers, mottled erythema

Fatigue r/t increased metabolic requirements

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding medication, diet, activity

Acute Pain r/t inflammatory process

Powerlessness r/t unpredictability of course of disease

Impaired Religiosity r/t ineffective coping with disease

Chronic Sorrow r/t presence of chronic illness

Spiritual Distress r/t chronicity of disease, unknown etiology

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: altered circulation

Risk for Impaired Resilience: Risk factor: chronic disease

Risk for Impaired Skin Integrity: Risk factors: chronic inflammation, edema, altered circulation

Lyme Disease

Impaired Comfort r/t inflammation

Fatigue r/t increased energy requirements

Deficient Knowledge r/t lack of information concerning disease, prevention, treatment

Acute Pain r/t inflammation of joints, urticaria, rash

Chronic Pain r/t chronic inflammation

Risk for Decreased Cardiac Output: Risk factor: dysrhythmia

Risk for Powerlessness: Risk factor: possible chronic condition

Lymphedema

Disturbed Body Image r/t change in appearance of body part with edema

Excess Fluid Volume r/t compromised regulatory system; inflammation, obstruction, or removal of lymph glands

Deficient Knowledge r/t management of condition

Risk for Infection: Risk factors: abnormal lymphatic system allowing stasis of fluids with decreased resistance to infection

Risk for Situational Low Self-Esteem: Risk factor: disturbed body image

Ineffective Lymphedema Self-Management r/t difficulty managing complex treatment regimen

Risk for Ineffective Lymphedema Self-Management: Risk factors: decreased perceived quality of life; inadequate commitment to a plan of action; unrealistic perception of susceptibility to sequelae

Lymphoma

See Cancer

M

Macular Degeneration

Anxiety r/t expressed insecurity with visual loss

Ineffective Coping r/t visual loss

Compromised Family Coping r/t deteriorating vision of family member

Risk-Prone Health Behavior r/t deteriorating vision while trying to maintain usual lifestyle

Hopelessness r/t deteriorating vision

Sedentary Lifestyle r/t visual loss

Self-Neglect r/t change in vision

Social Isolation r/t inability to drive because of visual changes

Risk for Falls: Risk factor: visual difficulties

Risk for Injury: Risk factor: inability to distinguish traffic lights and safety signs

Risk for Powerlessness: Risk factor: deteriorating vision

Risk for Impaired Religiosity: Risk factor: possible lack of transportation to church

Risk for Impaired Resilience: Risk factor: changing vision

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Readiness for Enhanced Health Management: appropriate choices of daily activities for meeting the goals of a treatment program

Magnetic Resonance Imaging (MRI)

See MRI (Magnetic Resonance Imaging)

Major Depressive Disorder

See Depression (Major Depressive Disorder)

Malabsorption Syndrome

Diarrhea r/t lactose intolerance, gluten sensitivity, resection of small bowel

Dysfunctional Gastrointestinal Motility r/t disease state

Deficient Knowledge r/t lack of information about diet and nutrition

Imbalanced Nutrition: Less than Body Requirements r/t inability of body to absorb nutrients because of physiological factors

Risk for Electrolyte Imbalance: Risk factors: hypovolemia, hyponatremia, hypokalemia

Risk for Imbalanced Fluid Volume: Risk factors: diarrhea, hypovolemia

See Abdominal Distention

Maladaptive Behavior

See Crisis; Post-Trauma Syndrome; Suicide Attempt

Malaise

See Fatigue

Malaria

Contamination r/t geographic area

Risk for Contamination: Risk factors: increased environmental exposure (not wearing protective clothing, not using insecticide or repellant on skin, clothing, and in room in areas in which infected mosquitoes are present); inadequate defense mechanisms (inappropriate use of prophylactic regimen)

Risk for Impaired Liver Function: Risk factor: complications of disease

Readiness for Enhanced Community Coping: uses resources available for problem-solving

Readiness for Enhanced Health Management: expresses desire to enhance immunization status/vaccination status

Readiness for Enhanced Resilience: immunization status

See Anemia

Male Infertility

See Erectile Dysfunction (ED); Infertility

Malignancy

See Cancer

Malignant Hypertension (Arteriolar Nephrosclerosis)

Decreased Cardiac Output r/t altered afterload, altered contractility

Fatigue r/t disease state, increased blood pressure

Excess Fluid Volume r/t decreased kidney function

Risk for Ineffective Cerebral Tissue Perfusion: Risk factor: elevated blood pressure damaging cerebral vessels

Risk for Acute Confusion: Risk factors: increased blood urea nitrogen or creatinine levels

Risk for Imbalanced Fluid Volume: Risk factors: hypertension, altered kidney function

Risk for Unstable Blood Pressure: Risk factor: damaged vessels due to disease process

Readiness for Enhanced Health Management: expresses desire to manage the illness, high blood pressure

Malignant Hyperthermia

Hyperthermia r/t anesthesia reaction associated with inherited condition

Readiness for Enhanced Health Management: knowledge of risk factors

Risk for Shock r/t deficient fluid volume

Malnutrition

Insufficient Breast Milk Production (See **Breast Milk, Insufficient Production,** Section III)

Frail Elderly Syndrome r/t undetected malnutrition

Deficient Knowledge r/t misinformation about normal nutrition, social isolation, lack of food preparation facilities

Imbalanced Nutrition: Less than Body Requirements r/t inability to ingest food, digest food, or absorb nutrients because of biological, psychological, or economic factors; institutionalization (i.e., lack of menu choices)

Ineffective Protection r/t inadequate nutrition

Ineffective Health Management r/t inadequate nutrition

Self-Neglect r/t inadequate nutrition

Risk for Powerlessness: Risk factor: possible inability to provide adequate nutrition

Mammography

Readiness for Enhanced Health Management: follows guidelines for screening

Readiness for Enhanced Resilience: responsibility for self-care

Manic Disorder, Bipolar I

Anxiety r/t change in role function

Ineffective Coping r/t situational crisis

Ineffective Denial r/t fear of inability to control behavior

Interrupted Family Processes r/t family member's illness

Risk-Prone Health Behavior r/t low self-efficacy

Ineffective Health Management r/t unpredictability of client, excessive demands on family, chronic illness, social support deficit

Ineffective Home Maintenance Behaviors r/t altered psychological state, inability to concentrate

Disturbed Personal Identity r/t manic state

Insomnia r/t constant anxious thoughts

Imbalanced Nutrition: Less than Body Requirements r/t lack of time and motivation to eat, constant movement

Impaired individual Resilience r/t psychological disorder

Ineffective Role Performance r/t impaired social interactions

Self-Neglect r/t manic state

Sleep Deprivation r/t hyperagitated state

Risk for Ineffective Activity Planning r/t inability to process information

Risk for Caregiver Role Strain: Risk factor: unpredictability of condition

Risk for Imbalanced Fluid Volume: Risk factor: hypovolemia

Risk for Powerlessness: Risk factor: inability to control changes in mood

Risk for Spiritual Distress: Risk factor: depression

Risk for Suicidal Behavior: Risk factor: bipolar disorder

Risk for Self-Directed Violence: Risk factors: hallucinations, delusions

Risk for Other-Directed Violence: Risk factor: pathologic intoxication

Readiness for Enhanced Hope: expresses desire to enhance problem-solving goals

Manipulative Behavior

Defensive Coping r/t superior attitude toward others

Ineffective Coping r/t inappropriate use of defense mechanisms

Self-Mutilation r/t use of manipulation to obtain nurturing relationship with others

Self-Neglect r/t maintaining control

Impaired Social Interaction r/t self-concept disturbance

Risk for Loneliness: Risk factor: inability to interact appropriately with others

Risk for Situational Low Self-Esteem: Risk factor: history of learned helplessness

Risk for Self-Mutilation: Risk factor: inability to cope with increased psychological or physiological tension in healthy manner

Marfan Syndrome

Decreased Cardiac Output r/t dilation of the aortic root, dissection or rupture of the aorta

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: heart-related complications from Marfan syndrome

Risk for Impaired Cardiovascular Function: Risk factor: heart-related valve disorders form Marfan syndrome

Readiness for Enhanced Health Management: describes reduction of risk factors

See Mitral Valve Prolapse; Scoliosis

Mastectomy

Disturbed Body Image r/t loss of sexually significant body part

Impaired Comfort r/t altered body image; difficult diagnosis

Death Anxiety r/t threat of mortality associated with breast cancer

Fatigue r/t increased metabolic requirements

Fear r/t change in body image, prognosis

Deficient Knowledge r/t self-care activities

Insomnia r/t impaired health status

Nausea r/t chemotherapy

Acute Pain r/t surgical procedure

Sexual Dysfunction r/t change in body image, fear of loss of femininity

Chronic Sorrow r/t disturbed body image, unknown long-term health status

Spiritual Distress r/t change in body image

Risk for Surgical Site Infection: Risk factors: surgical procedure, broken skin

Risk for Impaired Physical Mobility: Risk factors: nerve or muscle damage, pain

Risk for Post-Trauma Syndrome: Risk factors: loss of body part, surgical wounds

Risk for Powerlessness: Risk factor: fear of unknown outcome of procedure

Risk for Impaired Resilience: Risk factor: altered body image

See Cancer; Modified Radical Mastectomy; Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Mastitis

Anxiety r/t threat to self, concern over safety of milk for infant

Ineffective Breastfeeding r/t breast pain, conflicting advice from health care providers

Deficient Knowledge r/t antibiotic regimen, comfort measures

Acute Pain r/t infectious disease process, swelling of breast tissue

Ineffective Role Performance r/t change in capacity to function in expected role

Maternal Infection

Ineffective Protection r/t invasive procedures, traumatized tissue

See Postpartum, Normal Care

Maturational Issues, Adolescent

Ineffective Coping r/t maturational crises

Risk-Prone Health Behavior r/t inadequate comprehension, negative attitude toward health care

Interrupted Family Processes r/t developmental crises of adolescence resulting from challenge of parental authority and values, situational crises from change in parental marital status

Deficient Knowledge: Potential for Enhanced Health Maintenance r/t information misinterpretation, lack of education regarding age-related factors

Impaired Social Interaction r/t ineffective, unsuccessful, or dysfunctional interaction with peers

Social Isolation r/t perceived alteration in physical appearance, social values not accepted by dominant peer group

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Risk for Ineffective Activity Planning: Risk factor: unrealistic perception of personal competencies

Risk for Disturbed Personal Identity: Risk factor: maturational issues

Risk for Injury: Risk factor: thrill-seeking behaviors

Risk for Chronic Low Self-Esteem: Risk factor: lack of sense of belonging in peer group

Risk for Situational Low Self-Esteem: Risk factor: developmental changes

Readiness for Enhanced Communication: expressing willingness to communicate with parental figures

Readiness for Enhanced Relationship: expresses desire to enhance communication with parental figures

See Sexuality, Adolescent; Substance Misuse (if relevant)

Maze III Procedure

See Dysrhythmia; Open Heart Surgery

MD (Muscular Dystrophy)

See Muscular Dystrophy (MD)

Measles (Rubeola)

See Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice)

Meconium Aspiration

See Respiratory Conditions of the Neonate

Meconium Delayed

Risk for Neonatal Hyperbilirubinemia: Risk factor: delayed meconium

Medical Marijuana

Imbalanced Nutrition: Less than Body Requirements r/t eating disorder, appetite loss, effects of chemotherapy

Chronic Pain Syndrome r/t persistence of pain as a result of physical injury or condition

Nausea r/t effects of chemotherapy

Melanoma

Disturbed Body Image r/t altered pigmentation, surgical incision

Death Anxiety r/t threat of mortality associated with cancer

Fear r/t threat to well-being

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding self-care and treatment of melanoma

Acute Pain r/t surgical incision

Chronic Sorrow r/t disturbed body image, unknown long-term health status

Readiness for Enhanced Health Management: describes reduction of risk factors; protection from sunlight's ultraviolet rays

See Cancer

Melena

Fear r/t presence of blood in feces

Risk for Imbalanced Fluid volume: Risk factor: hemorrhage

See GI Bleed (Gastrointestinal Bleeding)

Memory Deficit

Impaired Memory (See **Memory, Impaired,** Section III)

Ménière's Disease

Risk for Injury: Risk factor: symptoms of disease

Readiness for Enhanced Health Management: expresses desire to manage illness

See Dizziness; Nausea; Vertigo

Meningitis/Encephalitis

Ineffective Airway Clearance r/t seizure activity

Impaired Comfort r/t altered health status

Excess Fluid Volume r/t increased intracranial pressure, syndrome of inappropriate secretion of antidiuretic hormone

Impaired Mobility r/t neuromuscular or central nervous system insult

Acute Pain r/t biological injury

Risk for Aspiration: Risk factor: seizure activity

Risk for Acute Confusion: Risk factor: infection of brain

Risk for Falls: Risk factors: neuromuscular dysfunction and confusion

Risk for Injury: Risk factor: seizure activity

Risk for Impaired Resilience: Risk factor: illness

Risk for Shock: Risk factor: infectious process

Risk for Ineffective Cerebral Tissue Perfusion: Risk factors: cerebral tissue edema and inflammation of meninges, increased intracranial pressure; infection

Risk for Ineffective Thermoregulation: Risk factor: infectious process

Risk for Unstable Blood Pressure r/t fluid shifts

See Hospitalized Child

Meningocele

See Neural Tube Defects

Menopause

Impaired Comfort r/t symptoms associated with menopause

Insomnia r/t hormonal shifts

Impaired Memory r/t change in hormonal levels

Sexual Dysfunction r/t menopausal changes

Ineffective Sexuality Pattern r/t altered body structure, lack of lubrication, lack of knowledge of artificial lubrication

Ineffective Thermoregulation r/t changes in hormonal levels

Risk for Urge Urinary Incontinence: Risk factor: changes in hormonal levels affecting bladder function

Risk for Overweight: Risk factor: change in metabolic rate caused by fluctuating hormone levels

Risk for Powerlessness: Risk factor: changes associated with menopause

Risk for Impaired Resilience: Risk factor: menopause

Risk for Situational Low Self-Esteem: Risk factors: developmental changes, menopause

Readiness for Enhanced Health Management: verbalized desire to manage menopause

Readiness for Enhanced Self-Care: expresses satisfaction with body image

Readiness for Enhanced Spiritual Well-Being: desire for harmony of mind, body, and spirit

Menorrhagia

Fear r/t loss of large amounts of blood

Risk for Deficient Fluid Volume: Risk factor: excessive loss of menstrual blood

Mental Illness

Defensive Coping r/t psychological impairment, substance misuse

Ineffective Coping r/t situational crisis, coping with mental illness

Compromised Family Coping r/t lack of available support from client

Disabled Family Coping r/t chronically unexpressed feelings of guilt, anxiety, hostility, or despair

Ineffective Denial r/t refusal to acknowledge abuse problem, fear of the social stigma of disease

Risk-Prone Health Behavior r/t low self-efficacy

Disturbed Personal Identity r/t psychoses

Ineffective Relationship r/t effects of mental illness in partner relationship

Chronic Sorrow r/t presence of mental illness

Stress Overload r/t multiple coexisting stressors

Ineffective Family Health Self-Management r/t chronicity of condition, unpredictability of client, unknown prognosis

Risk for Loneliness: Risk factor: social isolation

Risk for Powerlessness: Risk factor: lifestyle of helplessness

Risk for Impaired Resilience: Risk factor: chronic illness

Risk for Chronic Low Self-Esteem: Risk factor: presence of mental illness/repeated negative reinforcement

Metabolic Acidosis

See Ketoacidosis, Alcoholic; Ketoacidosis, Diabetic

Metabolic Alkalosis

Deficient Fluid Volume r/t fluid volume loss, vomiting, gastric suctioning, failure of regulatory mechanisms

Metabolic Imbalance Syndrome

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding basic health practice

Obesity r/t energy expenditure below energy intake

Risk for Unstable Blood Glucose Level: Risk factor: variations in serum glucose levels

Metastasis

See Cancer

Methicillin-Resistant *Staphylococcus aureus* (MRSA)

See MRSA (Methicillin-Resistant Staphylococcus aureus*)*

MI (Myocardial Infarction)

Decreased Activity Tolerance r/t imbalance between oxygen supply and demand

Anxiety r/t threat of death, possible change in role status

Death Anxiety r/t seriousness of medical condition

Constipation r/t decreased peristalsis from decreased physical activity, medication effect, change in diet

Ineffective Family Coping r/t spouse or significant other's fear of partner loss

Ineffective Denial r/t fear, deficient knowledge about heart disease

Interrupted Family Processes r/t crisis, role change

Fear r/t threat to well-being

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding self-care and treatment

Acute Pain r/t myocardial tissue damage from inadequate blood supply

Situational Low Self-Esteem r/t crisis of MI

Ineffective Sexuality Pattern r/t fear of chest pain, possibility of heart damage

Risk for Powerlessness: Risk factor: acute illness

Risk for Shock: Risk factors: hypotension, myocardial dysfunction, hypoxia

Risk for Spiritual Distress: Risk factor: physical illness

Risk for Decreased Cardiac Output: Risk factors: alteration in heart rate, rhythm, and contractility

Risk for Decreased Cardiac Tissue Perfusion: Risk factors: coronary artery spasm, hypertension, hypotension, hypoxia

Risk for Unstable Blood Pressure r/t cardiac dysrhythmia

Readiness for Enhanced Knowledge: expresses an interest in learning about condition

See Angioplasty, Coronary; Coronary Artery Bypass Grafting (CABG)

MIDCAB (Minimally Invasive Direct Coronary Artery Bypass)

Risk for Bleeding: Risk factor: surgery

Readiness for Enhanced Health Management: preoperative and postoperative care associated with surgery

Risk for Surgical Site Infection: Risk factor: surgical procedure

See Angioplasty, Coronary; Coronary Artery Bypass Grafting (CABG)

Midlife Crisis

Ineffective Coping r/t inability to deal with changes associated with aging

Powerlessness r/t lack of control over life situation

Spiritual Distress r/t questioning beliefs or value system

Risk for Disturbed Personal Identity: Risk factor: alteration in social roles

Risk for Chronic Low Self-Esteem: Risk factor: ineffective coping with loss

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Readiness for Enhanced Relationship: meets goals for lifestyle change

Readiness for Enhanced Spiritual Well-Being: desire to find purpose and meaning to life

Migraine Headache

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding prevention and treatment of headaches

Readiness for Enhanced Health Management: expresses desire to manage illness

Acute Pain: Headache r/t vasodilation of cerebral and extracerebral vessels

Risk for Impaired Resilience: Risk factors: chronic illness, disabling pain

Military Families, Personnel

Anxiety r/t apprehension and helplessness caused by uncertainty of family members' situation

Interrupted Family Processes r/t possible change in family roles, decrease in available emotional support

Relocation Stress Syndrome r/t unpredictability of experience, powerlessness, significant environmental change

Milk Intolerance

See Lactose Intolerance

Minimally Invasive Direct Coronary Artery Bypass (MIDCAB)

See MIDCAB (Minimally Invasive Direct Coronary Artery Bypass)

Miscarriage

See Pregnancy Loss

Mitral Stenosis

Decreased Activity Tolerance r/t imbalance between oxygen supply and demand

Anxiety r/t possible worsening of symptoms, activity intolerance, fatigue

Decreased Cardiac Output r/t incompetent heart valves, abnormal forward or backward blood flow, flow into a dilated chamber, flow through an abnormal passage between chambers

Fatigue r/t reduced cardiac output

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding self-care with disorder

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: incompetent heart valve

Risk for Infection: Risk factors: invasive procedure, risk for endocarditis

Mitral Valve Prolapse

Anxiety r/t symptoms of condition: palpitations, chest pain

Fatigue r/t abnormal catecholamine regulation, decreased intravascular volume

Fear r/t lack of knowledge about mitral valve prolapse, feelings of having heart attack

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding methods to relieve pain and treat dysrhythmia and shortness of breath, need for prophylactic antibiotics before invasive procedures

Acute Pain r/t mitral valve regurgitation

Risk for Ineffective Cerebral Tissue Perfusion: Risk factor: postural hypotension

Risk for Infection: Risk factor: invasive procedures

Risk for Powerlessness: Risk factor: unpredictability of onset of symptoms

Readiness for Enhanced Knowledge: expresses interest in learning about condition

Mobility, Impaired Bed

Impaired Bed Mobility (See **Mobility, Bed, Impaired,** Section III)

Mobility, Impaired Physical

Impaired Physical Mobility (See **Mobility, Physical, Impaired,** Section III)

Risk for Falls: Risk factor: impaired physical mobility

Mobility, Impaired Wheelchair

Impaired Wheelchair Mobility (See **Mobility, Wheelchair, Impaired,** Section III)

Modified Radical Mastectomy

Readiness for Enhanced Communication: willingness to enhance communication

See Mastectomy

Mononucleosis

Decreased Activity Tolerance r/t generalized weakness

Impaired Comfort r/t sore throat, muscle aches

Fatigue r/t disease state, stress

Ineffective Health Maintenance Behaviors r/t deficient knowledge concerning transmission and treatment of disease

Acute Pain r/t enlargement of lymph nodes, oropharyngeal edema

Impaired Swallowing r/t enlargement of lymph nodes, oropharyngeal edema

Risk for Injury: Risk factor: possible rupture of spleen

Risk for Loneliness: Risk factor: social isolation

Mood Disorders

Caregiver Role Strain r/t overwhelming needs of care receiver, unpredictability of mood alterations

Labile Emotional Control (See **Labile Emotional Control,** Section III)

Risk-Prone Health Behavior r/t hopelessness, altered locus of control

Impaired Mood Regulation (See **Mood Regulation, Impaired,** Section III)

Self-Neglect r/t inability to care for self

Social Isolation r/t alterations in mental status

Risk for Situational Low Self-Esteem: Risk factor: unpredictable changes in mood

Readiness for Enhanced Communication: expresses feelings

See specific disorder: Depression (Major Depressive Disorder); Dysthymic Disorder; Hypomania; Manic Disorder, Bipolar I

Moon Face

Disturbed Body Image r/t change in appearance from disease and medication(s)

Risk for Situational Low Self-Esteem: Risk factor: change in body image

See Cushing's Syndrome

Moral/Ethical Dilemmas

Impaired Emancipated Decision-Making r/t questioning personal values and belief, which alter decision

Moral Distress r/t conflicting information guiding moral or ethical decision-making

Risk for Powerlessness: Risk factor: lack of knowledge to make a decision

Risk for Spiritual Distress: Risk factor: moral or ethical crisis

Readiness for Enhanced Emancipated Decision-Making: expresses desire to enhance congruency of decisions with personal values and goals

Readiness for Enhanced Religiosity: requests assistance in expanding religious options

Readiness for Enhanced Resilience: vulnerable state

Readiness for Enhanced Spiritual Well-Being: request for interaction with others regarding difficult decisions

Morning Sickness

See Hyperemesis Gravidarum; Pregnancy, Normal

Motion Sickness

See Labyrinthitis

Mottling of Peripheral Skin

Ineffective Peripheral Tissue Perfusion r/t interruption of arterial flow, decreased circulating blood volume

Risk for Shock: Risk factor: inadequate circulation to perfuse body

Mourning

See Grieving

Mouth Lesions

See Mucous Membrane Integrity, Impaired Oral

MRI (Magnetic Resonance Imaging)

Anxiety r/t fear of being in closed spaces

Readiness for Enhanced Health Management: describes reduction of risk factors associated with exam

Deficient Knowledge r/t unfamiliarity with information resources; exam information

Readiness for Enhanced Knowledge: expresses interest in learning about exam

MRSA (Methicillin-Resistant *Staphylococcus aureus*)

Impaired Skin Integrity r/t infection

Delayed Surgical Recovery r/t infection

Ineffective Thermoregulation r/t severe infection stimulating immune system

Impaired Tissue Integrity r/t wound, infection

Risk for Loneliness: Risk factor: physical isolation

Risk for Impaired Resilience: Risk factor: illness

Risk for Shock: Risk factor: sepsis

MS (Multiple Sclerosis)

See Multiple Sclerosis

Mucocutaneous Lymph Node Syndrome

See Kawasaki Disease

Mucous Membrane Integrity, Impaired Oral

Impaired Oral Mucous Membrane Integrity (See **Oral Mucous Membrane Integrity, Impaired,** Section III)

Multi-Infarct Dementia

See Dementia

Multiple Gestations

Anxiety r/t uncertain outcome of pregnancy

Death Anxiety r/t maternal complications associated with multiple gestations

Insufficient Breast Milk Production r/t multiple births

Ineffective Childbearing Process r/t unavailable support system

Fatigue r/t physiological demands of a multifetal pregnancy and/or care of more than one infant

Ineffective Home Maintenance Behaviors r/t fatigue

Stress Urinary Incontinence r/t increased pelvic pressure

Insomnia r/t impairment of normal sleep pattern; parental responsibilities

Deficient Knowledge r/t caring for more than one infant

Neonatal Hyperbilirubinemia r/t feeding pattern not well established

Deficient Knowledge r/t caring for more than one infant

Imbalanced Nutrition: Less than Body Requirements r/t physiological demands of a multifetal pregnancy

Stress Overload r/t multiple coexisting stressors, family demands

Impaired Walking r/t increased uterine size

Risk for Ineffective Breastfeeding: Risk factors: lack of support, physical demands of feeding more than one infant

Risk for Delayed Child Development: Fetus: Risk factor: multiple gestations

Risk for Neonatal Hyperbilirubinemia: Risk factors: abnormal weight loss, prematurity, feeding pattern not well established

Readiness for Enhanced Childbearing Process: demonstrates appropriate care for infants and mother

Readiness for Enhanced Family Processes: family adapting to change with more than one infant

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Multiple Personality Disorder (Dissociative Identity Disorder)

Anxiety r/t loss of control of behavior and feelings

Disturbed Body Image r/t psychosocial changes

Defensive Coping r/t unresolved past traumatic events, severe anxiety

Ineffective Coping r/t history of abuse

Hopelessness r/t long-term stress

Disturbed Personal Identity r/t severe child abuse

Chronic Low Self-Esteem r/t rejection, failure

Risk for Self-Mutilation: Risk factor: need to act out to relieve stress

Readiness for Enhanced Communication: willingness to discuss problems associated with condition

See Dissociative Identity Disorder (Not Otherwise Specified)

Multiple Sclerosis (MS)

Ineffective Activity Planning r/t unrealistic perception of personal competence

Ineffective Airway Clearance r/t decreased energy or fatigue

Impaired Physical Mobility r/t neuromuscular impairment

Self-Neglect r/t functional impairment

Powerlessness r/t progressive nature of disease

Self-Care Deficit: Specify r/t neuromuscular impairment

Sexual Dysfunction r/t biopsychosocial alteration of sexuality

Chronic Sorrow r/t loss of physical ability

Spiritual Distress r/t perceived hopelessness of diagnosis

Urinary Retention r/t inhibition of the reflex arc

Risk for Disuse Syndrome: Risk factor: physical immobility

Risk for Injury: Risk factors: altered mobility, sensory dysfunction

Risk for Imbalanced Nutrition: Less than Body Requirements: Risk factors: impaired swallowing, depression

Risk for Powerlessness: Risk factor: chronic illness

Risk for Impaired Religiosity: Risk factor: illness

Risk for Thermal Injury: Risk factor: neuromuscular impairment

Readiness for Enhanced Health Management: expresses a desire to manage condition

Readiness for Enhanced Self-Care: expresses desire to enhance knowledge of strategies and responsibility for self-care

Readiness for Enhanced Spiritual Well-Being: struggling with chronic debilitating condition

See Neurological Disorders

Mumps

See Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice)

Murmurs

Decreased Cardiac Output r/t altered preload/afterload

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: incompetent valve

Risk for Fatigue: Risk factor: decreased cardiac output

Muscular Atrophy/Weakness

Risk for Disuse Syndrome: Risk factor: impaired physical mobility

Risk for Adult Falls: Risk factor: impaired physical mobility

Risk for Child Falls: Risk factor: impaired physical mobility

Muscular Dystrophy (MD)

Decreased Activity Tolerance r/t fatigue, muscle weakness

Ineffective Activity Planning r/t unrealistic perception of personal competence

Ineffective Airway Clearance r/t muscle weakness and decreased ability to cough

Constipation r/t immobility

Fatigue r/t increased energy requirements to perform activities of daily living

Impaired Physical Mobility r/t muscle weakness and development of contractures

Imbalanced Nutrition: Less than Body Requirements r/t impaired swallowing or chewing

Self-Care Deficit: Feeding, Bathing, Dressing, Toileting r/t muscle weakness and fatigue

Self-Neglect r/t functional impairment

Impaired Transfer Ability r/t muscle weakness

Impaired Swallowing r/t neuromuscular impairment

Impaired Walking r/t muscle weakness

Risk for Aspiration: Risk factor: impaired swallowing

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: hypoxia associated with cardiomyopathy

Risk for Disuse Syndrome: Risk factor: complications of immobility

Risk for Falls: Risk factor: muscle weakness

Risk for Infection: Risk factor: pooling of pulmonary secretions as a result of immobility and muscle weakness

Risk for Injury: Risk factors: muscle weakness and unsteady gait

Risk for Overweight: Risk factor: inactivity

Risk for Powerlessness: Risk factor: chronic condition

Risk for Impaired Religiosity: Risk factor: illness

Risk for Impaired Resilience: Risk factor: chronic illness

Risk for Situational Low Self-Esteem: Risk factor: presence of chronic condition

Risk for Impaired Skin Integrity: Risk factors: immobility, braces, or adaptive devices

Readiness for Enhanced Self-Concept: acceptance of strength and abilities

See Child with Chronic Condition; Hospitalized Child

MVC (Motor Vehicle Crash)

See Fracture; Head Injury; Injury; Pneumothorax

Myasthenia Gravis

Ineffective Airway Clearance r/t decreased ability to cough and swallow

Interrupted Family Processes r/t crisis of dealing with diagnosis

Fatigue r/t paresthesia, aching muscles, weakness of muscles

Impaired Physical Mobility r/t defective transmission of nerve impulses at the neuromuscular junction

Imbalanced Nutrition: Less than Body Requirements r/t difficulty eating and swallowing

Impaired Swallowing r/t neuromuscular impairment

Risk for Caregiver Role Strain: Risk factors: severity of illness of client, overwhelming needs of client

Risk for Impaired Religiosity: Risk factor: illness

Risk for Impaired Resilience: Risk factor: new diagnosis of chronic, serious illness

Readiness for Enhanced Spiritual Well-Being: heightened coping with serious illness

See Neurological Disorders

Mycoplasma Pneumonia

See Pneumonia

Myelocele

See Neural Tube Defects

Myelomeningocele

See Neural Tube Defects

Myocardial Infarction (MI)

See MI (Myocardial Infarction)

Myocarditis

Decreased Activity Tolerance r/t reduced cardiac reserve and prescribed bed rest

Decreased Cardiac Output r/t altered preload/afterload

Fear r/t dyspnea and reduced cardiac reserve

Deficient Knowledge r/t treatment of disease

Risk for Decreased Cardiac Tissue Perfusion: Risk factors: hypoxia, hypovolemia, cardiac tamponade

Readiness for Enhanced Knowledge: treatment of disease

See Heart Failure, if appropriate

Myringotomy

Fear r/t hospitalization, surgical procedure

Ineffective Health Maintenance r/t deficient knowledge regarding care after surgery

Acute Pain r/t surgical procedure

Risk for Surgical Site Infection: Risk factor: invasive procedure

See Ear Surgery

Myxedema

See Hypothyroidism

N

Narcissistic Personality Disorder

Defensive Coping r/t grandiose sense of self

Impaired Emancipated Decision-Making r/t lack of realistic problem-solving skills

Interrupted Family Processes r/t taking advantage of others to achieve own goals

Risk-Prone Health Behavior r/t low self-efficacy

Disturbed Personal Identity r/t psychological impairment

Ineffective Relationship r/t lack of mutual support/respect between partners

Impaired Individual Resilience r/t psychological disorders

Impaired Social Interaction r/t self-concept disturbance

Risk for Loneliness: Risk factors: emotional deprivation, social isolation

Narcolepsy

Anxiety r/t fear of lack of control over falling asleep

Disturbed Sleep Pattern r/t uncontrollable desire to sleep

Risk for Physical Trauma: Risk factor: falling asleep during potentially dangerous activity

Readiness for Enhanced Sleep: expresses willingness to enhance sleep

Narcotic Use

See Opioid Use (preferred terminology)

Nasogastric Suction

Impaired Oral Mucous Membrane Integrity r/t presence of nasogastric tube

Risk for Electrolyte Imbalance: Risk factor: loss of gastrointestinal fluids that contain electrolytes

Risk for Imbalanced Fluid Volume: Risk factor: loss of gastrointestinal fluids without adequate replacement

Risk for Dysfunctional Gastrointestinal Motility: Risk factor: decreased intestinal motility

Nausea

Nausea (See **Nausea,** Section III)

Near-Drowning

Ineffective Airway Clearance r/t aspiration of fluid

Aspiration r/t aspiration of fluid into lungs

Fear: Parental r/t possible death of child, possible permanent and debilitating sequelae

Impaired Gas Exchange r/t laryngospasm, holding breath, aspiration, inflammation

Maladaptive Grieving r/t potential death of child, unknown sequelae, guilt about accident

Ineffective Health Maintenance Behaviors r/t parental deficient knowledge regarding safety measures appropriate for age

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Hypothermia r/t central nervous system injury, prolonged submersion in cold water

Risk for Delayed Child Development: Risk factors: hypoxemia, cerebral anoxia

Risk for Maladaptive Grieving: Risk factors: potential death of child, unknown sequelae, guilt about accident

Risk for Infection: Risk factors: aspiration, invasive monitoring

Risk for Ineffective Cerebral Tissue Perfusion: Risk factor: hypoxia

Readiness for Enhanced Spiritual Well-Being: struggle with survival of life-threatening situation

See Child with Chronic Condition; Hospitalized Child; Safety, Childhood; Terminally Ill Child/Death of Child, Parent

Nearsightedness

Readiness for Enhanced Health Management: need for correction of myopia

Nearsightedness; Corneal Surgery

See LASIK Eye Surgery (Laser-Assisted in Situ Keratomileusis)

Neck Vein Distention

Decreased Cardiac Output r/t decreased contractility of heart resulting in increased preload

Excess Fluid Volume r/t excess fluid intake, compromised regulatory mechanisms

Risk for Thrombosis r/t blood coagulation disorders

See Congestive Heart Failure (CHF); Heart Failure

Necrosis, Kidney Tubular; Necrosis, Acute Tubular

See Renal Failure

Necrotizing Enterocolitis

Ineffective Breathing Pattern r/t abdominal distention, hypoxia

Diarrhea r/t infection

Impaired Bowel Continence r/t infection

Deficient Fluid Volume r/t vomiting, gastrointestinal bleeding

Neonatal Hyperbilirubinemia r/t feeding pattern not well established

Imbalanced Nutrition: Less than Body Requirements r/t decreased ability to absorb nutrients, decreased perfusion to gastrointestinal tract

Risk for Dysfunctional Gastrointestinal Motility: Risk factor: infection

Risk for Infection: Risk factors: bacterial invasion of gastrointestinal tract, invasive procedures

See Hospitalized Child; Premature Infant (Child)

Negative Feelings About Self

Chronic Low Self-Esteem r/t long-standing negative self-evaluation

Self-Neglect r/t negative feelings

Readiness for Enhanced Self-Concept: expresses willingness to enhance self-concept

Neglect, Unilateral

Unilateral Neglect (See **Unilateral Neglect,** Section III)

Neglectful Care of Family Member

Caregiver Role Strain r/t overwhelming care demands of family member, lack of social or financial support

Disabled Family Coping r/t highly ambivalent family relationships, lack of respite care

Interrupted Family Processes r/t situational transition or crisis

Deficient Knowledge r/t care needs

Impaired Individual Resilience r/t vulnerability from neglect

Risk for Compromised Human Dignity: Risk factor: inadequate participation in decision-making

Neonatal Abstinence Syndrome

Ineffective Airway Clearance r/t pooling of secretions from lack of adequate cough reflex, effects of viral or bacterial lower airway infection as a result of altered protective state

Interrupted Breastfeeding r/t use of drugs or alcohol by mother

Ineffective Childbearing Process r/t inconsistent prenatal health visits, suboptimal maternal nutrition, substance abuse

Impaired Comfort r/t irritability and inability to relax

Diarrhea r/t effects of withdrawal, increased peristalsis from hyperirritability

Disorganized Infant Behavior r/t exposure and/or withdrawal from toxic substances (alcohol or drugs), lack of attachment

Imbalanced Nutrition: Less than Body Requirements r/t feeding problems; uncoordinated or ineffective suck and swallow; effects of diarrhea, vomiting, or colic associated with maternal substance abuse

Impaired Parenting r/t impaired or absent attachment behaviors, inadequate support systems

Ineffective Infant Suck-Swallow Response r/t uncoordinated or ineffective sucking reflex, neurological delay

Disturbed Sleep Pattern r/t hyperirritability or hypersensitivity to environmental stimuli

Risk for Impaired Attachment: Risk factor: (parent) substance misuse, inability to meet infant's needs

Risk for Delayed Child Development: Risk factor: effects of prenatal substance abuse

Risk for Infection: Risk factor: stress effects of withdrawal

Risk for Disturbed Maternal–Fetal Dyad: Risk factor: substance abuse

Risk for Sudden Infant Death: Risk factor: prenatal illicit drug exposure

Risk for Ineffective Thermoregulation: Risk factor: immature nervous system

See Anomaly, Fetal/Newborn (Parent Dealing with); Cerebral Palsy; Child with Chronic Condition; Failure to Thrive; Hospitalized Child; Hyperactive Syndrome; Premature Infant/Child; Sudden Infant Death, Risk for

Neonatal Hyperbilirubinemia

Neonatal Hyperbilirubinemia (See **Neonatal Hyperbilirubinemia,** Section III)

Neonate

Readiness for Enhanced Childbearing Process: appropriate care of newborn

See Newborn, Normal; Newborn, Postmature; Newborn, Small for Gestational Age (SGA)

Neoplasm

Fear r/t possible malignancy

See Cancer

Nephrectomy

Anxiety r/t surgical recovery, prognosis

Ineffective Breathing Pattern r/t location of surgical incision

Constipation r/t lack of return of peristalsis

Acute Pain r/t incisional discomfort

Spiritual Distress r/t chronic illness

Risk for Bleeding: Risk factor: surgery

Risk for Imbalanced Fluid Volume: Risk factors: vascular losses, decreased intake

Risk for Surgical Site Infection: Risk factor: surgical procedure

Nephrostomy, Percutaneous

Acute Pain r/t invasive procedure

Impaired Urinary Elimination r/t nephrostomy tube

Risk for Infection: Risk factor: invasive procedure

Nephrotic Syndrome

Decreased Activity Tolerance r/t generalized edema

Disturbed Body Image r/t edematous appearance and side effects of steroid therapy

Excess Fluid Volume r/t edema resulting from oncotic fluid shift caused by serum protein loss and kidney retention of salt and water

Imbalanced Nutrition: Less than Body Requirements r/t anorexia, protein loss

Imbalanced Nutrition: More than Body Requirements r/t increased appetite attributable to steroid therapy

Social Isolation r/t edematous appearance

Risk for Infection: Risk factor: altered immune mechanisms caused by disease and effects of steroids

Risk for Impaired Skin Integrity: Risk factor: edema

See Child with Chronic Condition; Hospitalized Child

Neural Tube Defects (Meningocele, Myelomeningocele, Spina Bifida, Anencephaly)

Chronic Functional Constipation r/t immobility or less than adequate mobility

Maladaptive Grieving r/t loss of perfect child, birth of child with congenital defect

Mixed Urinary Incontinence r/t neurogenic impairment

Urge Urinary Incontinence r/t neurogenic impairment

Impaired Mobility r/t neuromuscular impairment

Chronic Low Self-Esteem r/t perceived differences, decreased ability to participate in physical and social activities at school

Impaired Skin Integrity r/t incontinence

Risk for Delayed Child Development: Risk factor: inadequate nutrition

Risk for Latex Allergic Reaction: Risk factor: multiple exposures to latex products

Risk for Imbalanced Nutrition: More than Body Requirements: Risk factors: diminished, limited, or impaired physical activity

Risk for Powerlessness: Risk factor: debilitating disease

Risk for Impaired Skin Integrity: Lower Extremities: Risk factor: decreased sensory perception

Readiness for Enhanced Family Coping: effective adaptive response by family members

Readiness for Enhanced Family Processes: family supports each other

See Child with Chronic Condition; Premature Infant (Child)

Neuralgia

See Trigeminal Neuralgia

Neuritis (Peripheral Neuropathy)

Decreased Activity Tolerance r/t pain with movement

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding self-care with neuritis

Acute Pain r/t stimulation of affected nerve endings, inflammation of sensory nerves

See Neuropathy, Peripheral

Neurogenic Bladder

Mixed Urinary Incontinence r/t neurological impairment

Urinary Retention r/t interruption in the lateral spinal tracts

Neurological Disorders

Ineffective Airway Clearance r/t perceptual or cognitive impairment, decreased energy, fatigue

Acute Confusion r/t dementia, alcohol abuse, drug abuse, delirium

Ineffective Coping r/t disability requiring change in lifestyle

Interrupted Family Processes r/t situational crisis, illness, or disability of family member

Maladaptive Grieving r/t loss of usual body functioning

Ineffective Home Maintenance Behaviors r/t client's or family member's disease

Risk for Corneal Injury: Risk factor: lack of spontaneous blink reflex

Impaired Memory r/t neurological disturbance

Impaired Physical Mobility r/t neuromuscular impairment

Imbalanced Nutrition: Less than Body Requirements r/t impaired swallowing, depression, difficulty feeding self

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Powerlessness r/t progressive nature of disease

Self-Care Deficit: Specify r/t neuromuscular dysfunction

Sexual Dysfunction r/t biopsychosocial alteration of sexuality

Social Isolation r/t altered state of wellness

Impaired Swallowing r/t neuromuscular dysfunction

Risk for Disuse Syndrome: Risk factors: physical immobility, neuromuscular dysfunction

Risk for Injury: Risk factors: altered mobility, sensory dysfunction, cognitive impairment

Risk for Ineffective Cerebral Tissue Perfusion: Risk factor: cerebral disease/injury

Risk for Impaired Religiosity: Risk factor: life transition

Risk for Impaired Skin Integrity: Risk factors: altered sensation, altered mental status, paralysis

See specific condition: Alcohol Withdrawal; Amyotrophic Lateral Sclerosis (ALS); CVA (Cerebrovascular Accident); Delirium; Dementia; Guillain-Barré Syndrome; Head Injury; Huntington's Disease; Spinal Cord Injury; Myasthenia Gravis; Muscular Dystrophy (MD); Parkinson's Disease

Neuropathy, Peripheral

Chronic Pain r/t damage to nerves in the peripheral nervous system as a result of medication side effects, vitamin deficiency, or diabetes

Ineffective Thermoregulation r/t decreased ability to regulate body temperature

Risk for Injury: Risk factors: lack of muscle control, decreased sensation

Risk for Impaired Skin Integrity: Risk factor: poor perfusion

Risk for Thermal Injury: Risk factor: nerve damage

See Peripheral Vascular Disease (PVD)

Neurosurgery

See Craniectomy/Craniotomy

Newborn, Normal

Breastfeeding r/t normal oral structure and gestational age greater than 34 weeks

Ineffective Thermoregulation r/t immaturity of neuroendocrine system

Risk for Sudden Infant Death: Risk factors: lack of knowledge regarding infant sleeping in prone or side-lying position, prenatal or postnatal infant smoke exposure, infant overheating or overwrapping, loose articles in the sleep environment

Risk for Infection: Risk factors: open umbilical stump, immature immune system

Risk for Injury: Risk factors: immaturity, need for caretaking

Readiness for Enhanced Childbearing Process: appropriate care of newborn

Readiness for Enhanced Organized Infant Behavior: demonstrates adaptive response to pain

Readiness for Enhanced Parenting: providing emotional and physical needs of infant

Newborn, Postmature

Hypothermia r/t depleted stores of subcutaneous fat

Impaired Skin Integrity r/t cracked and peeling skin as a result of decreased vernix

Risk for Ineffective Airway Clearance: Risk factor: meconium aspiration

Risk for Unstable Blood Glucose Level: Risk factor: depleted glycogen stores

Newborn, Small for Gestational Age (SGA)

Neonatal Hyperbilirubinemia r/t neonate age and difficulty feeding

Imbalanced Nutrition: Less than Body Requirements r/t history of placental insufficiency

Ineffective Thermoregulation r/t decreased brown fat, subcutaneous fat

Risk for Delayed Child Development: Risk factor: history of placental insufficiency

Risk for Injury: Risk factors: hypoglycemia, perinatal asphyxia, meconium aspiration

Risk for Sudden Infant Death: Risk factor: low birth weight

Nicotine Addiction

Risk-Prone Health behavior r/t smoking

Ineffective Health Maintenance Behaviors r/t lack of ability to make a judgment about smoking cessation

Risk for Impaired Skin Integrity: Risk factor: poor tissue perfusion associated with nicotine

Powerlessness r/t perceived lack of control over ability to give up nicotine

Readiness for Enhanced Emancipated Decision-Making: expresses desire to enhance understanding and meaning of choices

Readiness for Enhanced Health Literacy: expresses desire to enhance understanding of health information to make health care choices

Readiness for Enhanced Health Management: expresses desire to learn measures to stop smoking

NIDDM (Non–Insulin-Dependent Diabetes Mellitus)

Readiness for Enhanced Health Management: expresses desire for information on exercise and diet to manage diabetes

See Diabetes Mellitus

Nightmares

Post-Trauma Syndrome r/t disaster, war, epidemic, rape, assault, torture, catastrophic illness, or accident

Nipple Soreness

Impaired Comfort r/t physical condition

See Painful Breasts, Sore Nipples; Sore Nipples, Breastfeeding

Nocturia

Urge Urinary Incontinence r/t decreased bladder capacity, irritation of bladder stretch receptors causing spasm, alcohol,

caffeine, increased fluids, increased urine concentration, overdistention of bladder

Impaired Urinary Elimination r/t sensory motor impairment, urinary tract infection

Risk for Powerlessness: Risk factor: inability to control nighttime voiding

Nocturnal Myoclonus

See Restless Leg Syndrome; Stress

Nocturnal Paroxysmal Dyspnea

See PND (Paroxysmal Nocturnal Dyspnea)

Non–Insulin-Dependent Diabetes Mellitus (NIDDM)

See Diabetes Mellitus

Normal Pressure Hydrocephalus (NPH)

Impaired Verbal Communication r/t obstruction of flow of cerebrospinal fluid affecting speech

Acute Confusion r/t increased intracranial pressure caused by obstruction to flow of cerebrospinal fluid

Impaired Memory r/t neurological disturbance

Risk for Ineffective Cerebral Tissue Perfusion: Risk factor: fluid pressing on the brain

Risk for Adult Falls: Risk factor: unsteady gait as a result of obstruction of cerebrospinal fluid

Risk for Child Falls: Risk factor: unsteady gait as a result of obstruction of cerebrospinal fluid

NSTEMI (Non–ST-Elevation Myocardial Infarction)

See MI (Myocardial Infarction)

Nursing

See Breastfeeding, Effective; Breastfeeding, Ineffective; Breastfeeding, Interrupted, Nipple-Areolar Complex Injury

Nutrition

Readiness for Enhanced Nutrition (See **Nutrition, Readiness for Enhanced,** Section III)

Nutrition, Imbalanced

Imbalanced Nutrition: Less than Body Requirements (See **Nutrition: Less than Body Requirements, Imbalanced,** Section III)

Obesity (See **Obesity,** Section III)

Overweight (See **Overweight,** Section III)

Risk for Dry Mouth r/t depression

Risk for Overweight (See **Overweight, Risk for,** Section III)

Risk for Metabolic Syndrome r/t inadequate dietary habits

O

Obesity

Disturbed Body Image r/t eating disorder, excess weight

Risk-Prone Health Behavior r/t negative attitude toward health care

Obesity (See **Obesity,** Section III)

Chronic Low Self-Esteem r/t ineffective coping, overeating

Risk for Metabolic Syndrome: Risk factor: obesity

Risk for ineffective Peripheral Tissue Perfusion: Risk factor: sedentary lifestyle

Readiness for Enhanced Nutrition: expresses willingness to enhance nutrition

OBS (Organic Brain Syndrome)

See Organic Mental Disorders; Dementia

Obsessive-Compulsive Disorder (OCD)

See OCD (Obsessive-Compulsive Disorder)

Obstruction, Bowel

See Bowel Obstruction

Obstructive Sleep Apnea

Insomnia r/t blocked airway

Obesity r/t excessive intake related to metabolic need

See PND (Paroxysmal Nocturnal Dyspnea)

OCD (Obsessive-Compulsive Disorder)

Ineffective Activity Planning r/t unrealistic perception of events

Anxiety r/t threat to self-concept, unmet needs

Impaired Emancipated Decision-Making r/t inability to make a decision for fear of reprisal

Disabled Family Coping r/t family process being disrupted by client's ritualistic activities

Ineffective Coping r/t expression of feelings in an unacceptable way, ritualistic behavior

Risk-Prone Health behavior r/t inadequate comprehension associated with repetitive thoughts

Powerlessness r/t unrelenting repetitive thoughts to perform irrational activities

Impaired Individual Resilience r/t psychological disorder

Risk for Situational Low Self-Esteem: Risk factor: inability to control repetitive thoughts and actions

Occupational Injury

Fatigue r/t lack of sleep

Deficient Knowledge r/t inadequate training, improper use of equipment

Stress Overload r/t feelings of pressure

Risk for Occupational Injury (See **Risk for Occupational Injury,** Section III)

ODD (Oppositional Defiant Disorder)

Anxiety r/t feelings of anger and hostility toward authority figures

Ineffective Coping r/t lack of self-control or perceived lack of self-control

Disabled Family Coping r/t feelings of anger, hostility; defiant behavior toward authority figures

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Risk-Prone Health Behavior r/t multiple stressors associated with condition

Ineffective Impulse Control r/t anger/compunction to engage in disruptive behaviors

Chronic or Situational Low Self-Esteem r/t poor self-control and disruptive behaviors

Impaired Social Interaction r/t being touchy or easily annoyed, blaming others for own mistakes, constant trouble in school

Social Isolation r/t unaccepted social behavior

Ineffective Family Health Self-Management r/t difficulty in limit setting and managing oppositional behaviors

Risk for Ineffective Activity Planning: Risk factors: unrealistic perception of events, hedonism, insufficient social support

Risk for Impaired Parenting: Risk factors: children's difficult behaviors and inability to set limits

Risk for Powerlessness: Risk factor: inability to deal with difficult behaviors

Risk for Spiritual Distress: Risk factors: anxiety and stress in dealing with difficult behaviors

Risk for Other-Directed Violence: Risk factors: history of violence, threats of violence against others, history of antisocial behavior, history of indirect violence

Older Adult

See Aging

Oliguria

Deficient Fluid Volume r/t active fluid loss, failure of regulatory mechanism, inadequate intake

Risk for Electrolyte Imbalance r/t inadequate knowledge of modifiable factors

See Cardiac Output, Decreased; Renal Failure; Shock, Hypovolemic

Omphalocele

See Gastroschisis/Omphalocele

Oophorectomy

Risk for Ineffective Sexuality Pattern: Risk factor: altered body function

See Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

OPCAB (Off-Pump Coronary Artery Bypass)

See Angioplasty, Coronary; Coronary Artery Bypass Grafting (CABG)

Open Heart Surgery

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: cardiac surgery

See Coronary Artery Bypass Grafting (CABG); Dysrhythmia

Open Reduction of Fracture with Internal Fixation (Femur)

Anxiety r/t outcome of corrective procedure

Impaired Physical Mobility r/t postoperative position, abduction of leg, avoidance of acute flexion

Powerlessness r/t loss of control, unanticipated change in lifestyle

Risk for Surgical Site Infection: Risk factor: surgical procedure

Risk for Perioperative Positioning injury: Risk factor: immobilization

Risk for Peripheral Neurovascular Dysfunction: Risk factors: mechanical compression, orthopedic surgery, immobilization

Risk for Thrombosis: Risk factor: impaired mobility

See Surgery, Postoperative Care

Opioid Addiction

See Substance Abuse

Opioid Use

Acute Pain r/t physical injury or surgical procedure

Chronic Pain Syndrome r/t prolonged use of opioids

Risk for Constipation: Risk factor: effects of opioids on peristalsis

See Substance Abuse; Substance Withdrawal; Pain Management, Acute; Pain Management, Chronic

Opportunistic Infection

Delayed Surgical Recovery r/t abnormal blood profiles, impaired healing

Risk for Infection: Risk factor: abnormal blood profiles

See AIDS (Acquired Immunodeficiency Syndrome); HIV (Human Immunodeficiency Virus)

Oppositional Defiant Disorder (ODD)

See ODD (Oppositional Defiant Disorder)

Oral Mucous Membrane Integrity, Impaired

Impaired Oral Mucous Membrane Integrity (See **Oral Mucous Membrane Integrity, Impaired,** Section III)

Oral Thrush

Impaired Oral Mucous Membrane Integrity: Risk factors: effects of chemotherapy, radiotherapy, oral trauma, immune system disease

See Candidiasis, Oral

Orchitis

Readiness for Enhanced Health Self-Management: follows recommendations for mumps vaccination

See Epididymitis

Organic Mental Disorders

Chronic Confusion r/t progressive impairment in cognitive functioning

Frail Elderly Syndrome r/t alteration in cognitive function

Impaired Social Interaction r/t disturbed thought processes

Risk for Disturbed Personal Identity: Risk factor: delusions/fluctuating perceptions of stimuli

See Dementia

Orthopedic Traction

Ineffective Role Performance r/t limited physical mobility

Impaired Social Interaction r/t limited physical mobility

Impaired Transfer Ability r/t limited physical mobility

Risk for Impaired Religiosity: Risk factor: immobility

See Traction and Casts

Orthopnea

Ineffective Breathing Pattern r/t inability to breathe with head of bed flat

Decreased Cardiac Output r/t inability of heart to meet demands of body

Orthostatic Hypotension

See Dizziness

Osteoarthritis

Acute Pain r/t movement

Impaired Walking r/t inflammation and damage to joints

See Arthritis

Osteomyelitis

Decreased Diversional Activity Engagement r/t prolonged immobilization, hospitalization

Fear: Parental r/t concern regarding possible growth plate damage caused by infection, concern that infection may become chronic

Ineffective Health Maintenance Behaviors r/t continued immobility at home, possible extensive casts, continued antibiotics

Impaired Physical Mobility r/t imposed immobility as a result of infected area

Acute Pain r/t inflammation in affected extremity

Ineffective Thermoregulation r/t infectious process

Risk for Constipation: Risk factor: immobility

Risk for Infection: Risk factor: inadequate primary and secondary defenses

Risk for Impaired Skin Integrity: Risk factor: irritation from splint or cast

See Hospitalized Child

Osteoporosis

Deficient Knowledge r/t diet, exercise, need to abstain from alcohol and nicotine

Impaired Physical Mobility r/t pain, skeletal changes

Imbalanced Nutrition: Less than Body Requirements r/t inadequate intake of calcium and vitamin D

Acute Pain r/t fracture, muscle spasms

Risk for Injury: Fracture: Risk factors: lack of activity, risk of falling resulting from environmental hazards, neuromuscular disorders, diminished senses, cardiovascular responses to drugs

Risk for Adult Falls r/t decreased lower extremity strength

Risk for Powerlessness: Risk factor: debilitating disease

Readiness for Enhanced Health Self-Management: expresses desire to manage the treatment of illness and prevent complications

Ostomy

See Child with Chronic Condition; Colostomy; Ileal Conduit; Ileostomy

Otitis Media

Acute Pain r/t inflammation, infectious process

Risk for Delayed Child Development: Speech and Language: Risk factor: frequent otitis media

Anxiety r/t pain

Risk for Infection: Risk factors: eustachian tube obstruction, traumatic eardrum perforation, infectious process

Readiness for Enhanced Knowledge: information on treatment and prevention of disease

Ovarian Carcinoma

Death Anxiety r/t unknown outcome, possible poor prognosis

Fear r/t unknown outcome, possible poor prognosis

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding self-care, treatment of condition

Readiness for Enhanced Family Processes: family functioning meets needs of client

Readiness for Enhanced Resilience: participates in support groups

See Chemotherapy; Hysterectomy; Radiation Therapy

P

Pacemaker

Anxiety r/t change in health status, presence of pacemaker

Death Anxiety r/t worry over possible malfunction of pacemaker

Deficient Knowledge r/t self-care program, when to seek medical attention

Acute Pain r/t surgical procedure

Risk for Bleeding: Risk factor: surgery

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: pacemaker malfunction

Risk for Impaired Cardiovascular Function: Risk factor: cardiac dysrhythmias

Risk for Infection: Risk factors: invasive procedure, presence of foreign body (catheter and generator)

Risk for Powerlessness: Risk factor: presence of electronic device to stimulate heart

Readiness for Enhanced Health Management: appropriate health care management of pacemaker

Paget's Disease

Disturbed Body Image r/t possible enlarged head, bowed tibias, kyphosis

Deficient Knowledge r/t appropriate diet high in protein and calcium, mild exercise

Chronic Sorrow r/t chronic condition with altered body image

Risk for Physical Trauma: Fracture: Risk factor: excessive bone destruction

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Pain Management, Acute

Acute Pain r/t injury or surgical procedure

Imbalanced Energy Field r/t unpleasant sensory and emotional feelings

Pain Management, Chronic

Chronic Pain (See **Pain, Chronic,** Section III)

Chronic Pain Syndrome r/t persistent pain affecting daily living

Risk for Constipation: Risk factor: effects of medications on peristalsis

Readiness for Enhanced Knowledge: expresses a desire to learn alternative methods of nonpharmaceutical pain control

See Substance Misuse

Painful Breasts, Engorgement

Acute Pain r/t distention of breast tissue

Ineffective Role Performance r/t change in physical capacity to assume role of breastfeeding mother

Impaired Tissue Integrity r/t excessive fluid in breast tissues

Risk for Ineffective Breastfeeding: Risk factors: pain, infant's inability to latch on to engorged breast

Risk for Infection: Risk factor: milk stasis

Risk for Nipple-Areolar Complex Injury r/t breast engorgement

Painful Breasts, Sore Nipples

Insufficient Breast Milk Production r/t long breastfeeding time/pain response

Ineffective Breastfeeding r/t pain

Acute Pain r/t cracked nipples

Ineffective Role Performance r/t change in physical capacity to assume role of breastfeeding mother

Impaired Skin Integrity r/t mechanical factors involved in suckling, breastfeeding management

Nipple-Areolar Complex Injury r/t Maternal impatience with the breastfeeding process

Risk for Infection: Risk factor: break in skin

Pallor of Extremities

Ineffective Peripheral Tissue Perfusion r/t interruption of vascular flow

See Shock; Peripheral Vascular disease (PVD)

Palpitations (Heart Palpitations)

See Dysrhythmia

Pancreatic Cancer

Death Anxiety r/t possible poor prognosis of disease process

Ineffective Family Coping r/t poor prognosis

Fear r/t poor prognosis of the disease

Maladaptive Grieving r/t shortened lifespan

Deficient Knowledge r/t disease-induced diabetes, home management

Spiritual Distress r/t poor prognosis

Risk for impaired Liver Function: Risk factor: complications from underlying disease

See Cancer; Chemotherapy; Radiation Therapy; Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Pancreatitis

Ineffective Breathing Pattern r/t splinting from severe pain, disease process, and inflammation

Ineffective Denial r/t ineffective coping, alcohol use

Diarrhea r/t decrease in pancreatic secretions resulting in steatorrhea

Deficient Fluid Volume r/t vomiting, decreased fluid intake, fever, diaphoresis, fluid shifts

Ineffective Health Maintenance Behaviors r/t deficient knowledge concerning diet, alcohol use, medication

Nausea r/t irritation of gastrointestinal system

Imbalanced Nutrition: Less than Body Requirements r/t inadequate dietary intake, increased nutritional needs as a result of acute illness, increased metabolic needs caused by increased body temperature, disease process

Acute Pain r/t irritation and edema of the inflamed pancreas

Chronic Sorrow r/t chronic illness

Readiness for Enhanced Comfort: expresses desire to enhance comfort

Panic Disorder (Panic Attacks)

Ineffective Activity Planning r/t unrealistic perception of events

Anxiety r/t situational crisis

Ineffective Coping r/t personal vulnerability

Risk-Prone Health Behavior r/t low self-efficacy

Disturbed Personal Identity r/t situational crisis

Post-Trauma Syndrome r/t previous catastrophic event

Social Isolation r/t fear of lack of control

Risk for Loneliness: Risk factor: inability to socially interact because of fear of losing control

Risk for Post-Trauma Syndrome: Risk factors: perception of the event, diminished ego strength

Risk for Powerlessness: Risk factor: ineffective coping skills

Readiness for Enhanced Coping: seeks problem-oriented and emotion-oriented strategies to manage condition

See Anxiety; Anxiety Disorder

Paralysis

Disturbed Body Image r/t biophysical changes, loss of movement, immobility

Impaired Comfort r/t prolonged immobility

Constipation r/t effects of spinal cord disruption, inadequate fiber in diet

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding self-care with paralysis

Ineffective Home Maintenance Behaviors r/t physical disability

Mixed Urinary Incontinence r/t neurological impairment

Impaired Physical Mobility r/t neuromuscular impairment

Impaired Wheelchair Mobility r/t neuromuscular impairment

Self-Neglect r/t functional impairment

Powerlessness r/t illness-related regimen

Self-Care Deficit: Specify r/t neuromuscular impairment

Sexual Dysfunction r/t loss of sensation, biopsychosocial alteration

Chronic Sorrow r/t loss of physical mobility

Impaired Transfer Ability r/t paralysis

Risk for Autonomic Dysreflexia: Risk factor: cause of paralysis

Risk for Disuse Syndrome: Risk factor: paralysis

Risk for Adult Falls: Risk factor: paralysis

Risk for Injury: Risk factors: altered mobility, sensory dysfunction

Risk for Post-Trauma Syndrome: Risk factor: event causing paralysis

Risk for Impaired Religiosity: Risk factors: immobility, possible lack of transportation

Risk for Impaired Resilience: Risk factor: chronic disability

Risk for Situational Low Self-Esteem: Risk factor: change in body image and function

Risk for Impaired Skin integrity: Risk factors: altered circulation, altered sensation, immobility

Risk for Thrombosis: Risk factor: prolonged immobility

Readiness for Enhanced Self-Care: expresses desire to enhance knowledge and responsibility for strategies for self-care

See Child with Chronic Condition; Hemiplegia; Hospitalized Child; Neural Tube Defects (Meningocele, Myelomeningocele, Spina Bifida, Anencephaly); Spinal Cord Injury

P

Paralytic Ileus

Constipation r/t decreased gastrointestinal motility

Deficient Fluid Volume r/t loss of fluids from vomiting, retention of fluid in bowel

Dysfunctional Gastrointestinal Motility r/t recent abdominal surgery, electrolyte imbalance

Nausea r/t gastrointestinal irritation

Acute Pain r/t pressure, abdominal distention, presence of nasogastric tube

See Bowel Obstruction

Paranoid Personality Disorder

Ineffective Activity Planning r/t unrealistic perception of events

Anxiety r/t uncontrollable intrusive, suspicious thoughts

Risk-Prone Health Behavior r/t intense emotional state

Disturbed Personal Identity r/t difficulty with reality testing

Impaired Individual Resilience r/t psychological disorder

Chronic Low Self-Esteem r/t inability to trust others

Social Isolation r/t inappropriate social skills

Risk for Loneliness: Risk factor: social isolation

Risk for Other-Directed Violence: Risk factor: being suspicious of others and their actions

Paraplegia

See Spinal Cord Injury

Parathyroidectomy

Anxiety r/t surgery

Risk for Ineffective Airway Clearance: Risk factors: edema or hematoma formation, airway obstruction

Risk for Bleeding: Risk factor: surgery

Risk for Impaired Verbal Communication: Risk factors: possible laryngeal damage, edema

Risk for Infection: Risk factor: surgical procedure

See Hypocalcemia

Parent Attachment

Risk for Impaired Attachment (See **Attachment, Impaired, Risk for,** Section III)

Readiness for Enhanced Childbearing Process: demonstrates appropriate care of newborn

See Parental Role Conflict

Parental Role Conflict

Parental Role Conflict (See **Role Conflict, Parental,** Section III)

Ineffective Relationship r/t unrealistic expectations

Chronic Sorrow r/t difficult parent–child relationship

Risk for Spiritual Distress: Risk factor: altered relationships

Readiness for Enhanced Parenting: willingness to enhance parenting

Parenting

Readiness for Enhanced Parenting (See **Parenting, Readiness for Enhanced,** Section III)

Parenting, Impaired

Impaired Parenting (See **Parenting, Impaired,** Section III)

Chronic Sorrow r/t difficult parent–child relationship

Risk for Spiritual Distress: Risk factor: altered relationships

Parenting, Risk for Impaired

Risk for Impaired Parenting (See **Parenting, Impaired, Risk for,** Section III)

See Parenting, Impaired

Paresthesia

Risk for Injury: Risk factors: inability to feel temperature changes, pain

Risk for Impaired Skin Integrity: Risk factor: impaired sensation

Risk for Thermal Injury: Risk factor: neuromuscular impairment

Parkinson's Disease

Impaired Verbal Communication r/t decreased speech volume, slowness of speech, impaired facial muscles

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Constipation r/t weakness of muscles, lack of exercise, inadequate fluid intake, decreased autonomic nervous system activity

Frail Elderly Syndrome r/t chronic illness

Imbalanced Nutrition: Less than Body Requirements r/t tremor, slowness in eating, difficulty in chewing and swallowing

Chronic Sorrow r/t loss of physical capacity

Risk for Injury: Risk factors: tremors, slow reactions, altered gait

See Neurologic Disorders

Paroxysmal Nocturnal Dyspnea (PND)

See PND (Paroxysmal Nocturnal Dyspnea)

Patent Ductus Arteriosus (PDA)

See Congenital Heart Disease/Cardiac Anomalies

Patient-Controlled Analgesia (PCA)

See PCA (Patient-Controlled Analgesia)

Patient Education

Deficient Knowledge r/t lack of exposure to information misinterpretation, unfamiliarity with information resources to manage illness

Readiness for Enhanced Emancipated Decision-Making: expresses desire to enhance understanding of choices for decision-making

Readiness for Enhanced Knowledge (Specify): interest in learning

Readiness for Enhanced Health Management: expresses desire for information to manage the illness

PCA (Patient-Controlled Analgesia)

Deficient Knowledge r/t self-care of pain control

Nausea r/t side effects of medication

Risk for Injury: Risk factors: possible complications associated with PCA

Risk for Vascular Trauma: Risk factors: insertion site and length of insertion time

Readiness for Enhanced Knowledge: appropriate management of PCA

Acute Pain: guarding behaviors

Pectus Excavatum

See Marfan Syndrome

Pediculosis

See Lice

PEG (Percutaneous Endoscopic Gastrostomy)

See Tube Feeding

Pelvic Inflammatory Disease (PID)

See PID (Pelvic Inflammatory Disease)

Penile Prosthesis

Ineffective Sexuality Pattern r/t use of penile prosthesis

Risk for Surgical Site Infection: Risk factor: invasive surgical procedure

Risk for Situational Low Self-Esteem: Risk factor: ineffective sexuality pattern

Readiness for Enhanced Health Management: seeks information regarding care and use of prosthesis

See Erectile Dysfunction (ED); Impotence

Peptic Ulcer

See Ulcer, Peptic (Duodenal or Gastric)

Percutaneous Transluminal Coronary Angioplasty (PTCA)

See Angioplasty, Coronary

Pericardial Friction Rub

Decreased Cardiac Output r/t inflammation

Acute Pain r/t inflammation, effusion

Risk for Decreased Cardiac Tissue Perfusion: Risk factors: inflammation in pericardial sac, fluid accumulation compressing heart

Pericarditis

Decreased Activity Tolerance r/t reduced cardiac reserve, prescribed bed rest

Decreased Cardiac Output r/t impaired cardiac function from inflammation of pericardial sac

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: inflammation in pericardial sac

Deficient Knowledge r/t unfamiliarity with information sources

Risk for Imbalanced Nutrition: Less than Body Requirements: Risk factors: fever, hypermetabolic state associated with fever

Acute Pain r/t biological injury, inflammation

Periodontal Disease

Risk for Impaired Oral Mucous Membrane Integrity (See **Oral Mucous Membrane Integrity, Impaired, Risk for,** Section III)

Perioperative Hypothermia

Risk for Perioperative Hypothermia (See **Perioperative Hypothermia, Risk for,** Section III)

Perioperative Positioning

Risk for Perioperative Positioning Injury (See **Perioperative Positioning injury, Risk for,** Section III)

Peripheral Neuropathy

See Neuropathy, Peripheral

Peripheral Neurovascular Dysfunction

Risk for Peripheral Neurovascular Dysfunction (See **Peripheral Neurovascular Dysfunction, Risk for,** Section III)

See Neuropathy, Peripheral; Peripheral Vascular Disease (PVD)

Peripheral Vascular Disease (PVD)

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding self-care and treatment of disease

Chronic Pain: Intermittent Claudication r/t ischemia

Ineffective Peripheral Tissue Perfusion r/t disease process

Risk for Adult Falls: Risk factor: altered mobility

Risk for Injury: Risk factors: tissue hypoxia, altered mobility, altered sensation

Risk for Peripheral Neurovascular Dysfunction: Risk factor: possible vascular obstruction

Risk for Impaired Tissue Integrity: Risk factor: altered circulation or sensation

Readiness for Enhanced Health Management: self-care and treatment of disease

See Neuropathy, Peripheral; Peripheral Neurovascular Dysfunction

Peritoneal Dialysis

Ineffective Breathing Pattern r/t pressure from dialysate

Impaired Comfort r/t instillation of dialysate, temperature of dialysate

Ineffective Home Maintenance Behaviors r/t complex home treatment of client

Deficient Knowledge r/t treatment procedure, self-care with peritoneal dialysis

Chronic Sorrow r/t chronic disability

Risk for Ineffective Coping: Risk factor: disability requiring change in lifestyle

Risk for Unstable Blood Glucose Level: Risk factors: increased concentrations of glucose in dialysate, ineffective medication management

Risk for Imbalanced Fluid Volume: Risk factor: medical procedure

Risk for Infection: Peritoneal: Risk factors: invasive procedure, presence of catheter, dialysate

Risk for Powerlessness: Risk factors: chronic condition and care involved

See Child with Chronic Condition; Hemodialysis; Hospitalized Child; Renal Failure; Renal Failure, Acute/Chronic, Child

Peritonitis

Ineffective Breathing Pattern r/t pain, increased abdominal pressure

Constipation r/t decreased oral intake, decrease of peristalsis

Deficient Fluid Volume r/t retention of fluid in bowel with loss of circulating blood volume

Nausea r/t gastrointestinal irritation

Imbalanced Nutrition: Less than Body Requirements r/t nausea, vomiting

Acute Pain r/t inflammation and infection of gastrointestinal system

Risk for Dysfunctional Gastrointestinal Motility: Risk factor: gastrointestinal disease

Risk for Infection r/t inadequate knowledge to avoid exposure to pathogens

Pernicious Anemia

Diarrhea r/t malabsorption of nutrients

Fatigue r/t imbalanced nutrition: less than body requirements

Impaired Memory r/t lack of adequate red blood cells

Nausea r/t altered oral mucous membrane; sore tongue, bleeding gums

Imbalanced Nutrition: Less than Body Requirements r/t lack of appetite associated with nausea and altered oral mucous membrane

Impaired Oral Mucous Membrane Integrity r/t vitamin deficiency; inability to absorb vitamin B_{12} associated with lack of intrinsic factor

Risk for Adult Falls: Risk factors: dizziness, lightheadedness

Risk for Peripheral Neurovascular Dysfunction: Risk factor: anemia

Persistent Fetal Circulation

See Congenital Heart Disease/Cardiac Anomalies

Personal Identity Problems

Disturbed Personal Identity (See **Identity, Personal, Disturbed,** Section III)

Risk for Disturbed Personal Identity (See **Disturbed Personal Identity, Risk for,** Section III)

Personality Disorder

Ineffective Activity Planning r/t unrealistic perception of events

Impaired Individual Resilience r/t psychological disorder

See specific disorder: Antisocial Personality Disorder; Borderline Personality Disorder; OCD (Obsessive-Compulsive Disorder); Paranoid Personality Disorder

Pertussis (Whooping Cough)

Risk for Impaired Emancipated Decision-Making: Risk factor: indecision regarding administration of usual childhood vaccinations

See Respiratory Infections, Acute Childhood

Pesticide Contamination

Contamination r/t use of environmental contaminants; pesticides

Risk for Allergic Reaction: Risk factor: repeated exposure to pesticides

Petechiae

See Anticoagulant Therapy; Clotting Disorder; DIC (Disseminated Intravascular Coagulation); Hemophilia

Petit Mal Seizure

Readiness for Enhanced Health Management: wears medical alert bracelet; limits hazardous activities such as driving, swimming, working at heights, operating equipment

See Epilepsy

Pharyngitis

See Sore Throat

Phenylketonuria (PKU)

See PKU (Phenylketonuria)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Pheochromocytoma

Anxiety r/t symptoms from increased catecholamines—headache, palpitations, sweating, nervousness, nausea, vomiting, syncope

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding treatment and self-care

Insomnia r/t high levels of catecholamines

Nausea r/t increased catecholamines

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: hypertension

See Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Phlebitis

See Thrombophlebitis

Phobia (Specific)

Fear r/t presence or anticipation of specific object or situation

Powerlessness r/t anxiety about encountering unknown or known entity

Impaired Individual Resilience r/t psychological disorder

Readiness for Enhanced Power: expresses readiness to enhance identification of choices that can be made for change

See Anxiety; Anxiety Disorder; Panic Disorder (Panic Attacks)

Photosensitivity

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding medications inducing photosensitivity

Risk for Dry Eye: Risk factors: pharmaceutical agents, sunlight exposure

Risk for Impaired Skin Integrity: Risk factor: exposure to sun

Physical Abuse

See Abuse, Child; Abuse, Spouse, Parent, or Significant Other

Pica

Anxiety r/t stress

Imbalanced Nutrition: Less than Body Requirements r/t eating nonnutritive substances

Impaired Parenting r/t lack of supervision, food deprivation

Risk for Constipation: Risk factor: presence of undigestible materials in gastrointestinal tract

Risk for Dysfunctional Gastrointestinal Motility: Risk factor: abnormal eating behavior

Risk for Infection: Risk factor: ingestion of infectious agents via contaminated substances

Risk for Poisoning: Risk factor: ingestion of substances containing lead

See Anemia

PID (Pelvic Inflammatory Disease)

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding self-care, treatment of disease

Acute Pain r/t biological injury; inflammation, edema, congestion of pelvic tissues

Ineffective Sexuality Pattern r/t medically imposed abstinence from sexual activities until acute infection subsides, change in reproductive potential

Risk for Infection: Risk factors: insufficient knowledge to avoid exposure to pathogens; proper hygiene, nutrition, other health habits

See Maturational Issues, Adolescent; STD (Sexually Transmitted Disease)

PIH (Pregnancy-Induced Hypertension/ Preeclampsia)

Anxiety r/t fear of the unknown, threat to self and infant, change in role functioning

Death Anxiety r/t threat of preeclampsia

Decreased Diversional Activity Engagement r/t bed rest

Interrupted Family Processes r/t situational crisis

Ineffective Home Maintenance Behaviors r/t bed rest

Deficient Knowledge r/t lack of experience with situation

Impaired Physical Mobility r/t medically prescribed limitations

Impaired Parenting r/t prescribed bed rest

Powerlessness r/t complication threatening pregnancy, medically prescribed limitations

Ineffective Role Performance r/t change in physical capacity to assume role of pregnant woman or resume other roles

Situational Low Self-Esteem r/t loss of idealized pregnancy

Impaired Social Interaction r/t imposed bed rest

Risk for Imbalanced Fluid Volume: Risk factors: hypertension, altered kidney function

Risk for Injury: Fetal: Risk factors: decreased uteroplacental perfusion, seizures

Risk for Injury: Maternal: Risk factors: vasospasm, high blood pressure

Risk for Unstable Blood Pressure: Risk factor: hypertension, imbalanced fluid volume

Readiness for Enhanced Knowledge: exhibits desire for information on managing condition

Piloerection

Hypothermia r/t exposure to cold environment

Pink Eye

See Conjunctivitis

Pinworms

Impaired Comfort r/t itching

Ineffective Home Maintenance Behaviors r/t inadequate cleaning of bed linen and toilet seats

Insomnia r/t discomfort

Readiness for Enhanced Health Management: proper handwashing; short, clean fingernails; avoiding hand, mouth, nose contact with unwashed hands; appropriate cleaning of bed linen and toilet seats

Pituitary Tumor, Benign

See Cushing's Disease

PKU (Phenylketonuria)

Risk for Delayed Child Development: Risk factors: not following strict dietary program; eating foods extremely low in phenylalanine; avoiding eggs, milk, any foods containing aspartame (e.g., NutraSweet)

Readiness for Enhanced Health Management: testing for PKU and following prescribed dietary regimen

Placenta Abruptio

Death Anxiety r/t threat of mortality associated with bleeding

Fear r/t threat to self and fetus

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding treatment and control of hypertension associated with placenta abruptio

Acute Pain: Abdominal/Back r/t premature separation of placenta before delivery

Risk for Bleeding: Risk factor: placenta abruptio

Risk for Deficient Fluid Volume: Risk factor: maternal blood loss

Risk for Powerlessness: Risk factors: complications of pregnancy and unknown outcome

Risk for Shock: Risk factor: hypovolemia

Risk for Spiritual Distress: Risk factor: fear from unknown outcome of pregnancy

Placenta Previa

Death Anxiety r/t threat of mortality associated with bleeding

Disturbed Body Image r/t negative feelings about body and reproductive ability, feelings of helplessness

Ineffective Coping r/t threat to self and fetus

Decreased Diversional Activity Engagement r/t long-term hospitalization

Interrupted Family Processes r/t maternal bed rest, hospitalization

Fear r/t threat to self and fetus, unknown future

Ineffective Home Maintenance Behaviors r/t maternal bed rest, hospitalization

Impaired Physical Mobility r/t medical protocol, maternal bed rest

Ineffective Role Performance r/t maternal bed rest, hospitalization

Situational Low Self-Esteem r/t situational crisis

Spiritual Distress r/t inability to participate in usual religious rituals, situational crisis

Risk for Bleeding: Risk factor: placenta previa

Risk for Constipation: Risk factors: bed rest, pregnancy

Risk for Deficient Fluid Volume: Risk factor: maternal blood loss

Risk for Imbalanced Fluid Volume: Risk factor: maternal blood loss

Risk for Injury: Fetal and Maternal: Risk factors: threat to uteroplacental perfusion, hemorrhage

Risk for Disturbed Maternal–Fetal Dyad: Risk factor: complication of pregnancy

Risk for Impaired Parenting: Risk factors: maternal bed rest, hospitalization

Risk for Ineffective Peripheral Tissue Perfusion: Placental: Risk factors: dilation of cervix, loss of placental implantation site

Risk for Powerlessness: Risk factors: complications of pregnancy, unknown outcome

Risk for Shock: Risk factor: hypovolemia

Plantar Fasciitis

Impaired Comfort r/t inflamed structures of feet

Impaired Physical Mobility r/t discomfort

Acute Pain r/t inflammation

Chronic Pain r/t inflammation

Pleural Effusion

Ineffective Breathing Pattern r/t pain

Excess Fluid Volume r/t compromised regulatory mechanisms; heart, liver, or kidney failure

Acute Pain r/t inflammation, fluid accumulation

Pleural Friction Rub

Ineffective Breathing Pattern r/t pain

Acute Pain r/t inflammation, fluid accumulation

Pleural Tap

See Pleural Effusion

Pleurisy

Ineffective Breathing Pattern r/t pain

Impaired Gas Exchange r/t ventilation perfusion imbalance

Acute Pain r/t pressure on pleural nerve endings associated with fluid accumulation or inflammation

Impaired Walking r/t activity intolerance, inability to "catch breath"

Risk for Ineffective Airway Clearance: Risk factors: increased secretions, ineffective cough because of pain

Risk for Infection: Risk factor: exposure to pathogens

PMS (Premenstrual Syndrome)

Fatigue r/t hormonal changes

Excess Fluid Volume r/t alterations of hormonal levels inducing fluid retention

Deficient Knowledge r/t methods to deal with and prevent syndrome

Acute Pain r/t hormonal stimulation of gastrointestinal structures

Risk for Powerlessness: Risk factors: lack of knowledge and ability to deal with symptoms

Risk for Impaired Resilience: Risk factor: PMS symptoms

Readiness for Enhanced Communication: willingness to express thoughts and feelings about PMS

Readiness for Enhanced Health Management: desire for information to manage and prevent symptoms

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

PND (Paroxysmal Nocturnal Dyspnea)

Anxiety r/t inability to breathe during sleep

Ineffective Breathing Pattern r/t increase in carbon dioxide levels, decrease in oxygen levels

Insomnia r/t suffocating feeling from fluid in lungs on awakening from sleep

Sleep Deprivation r/t inability to breathe during sleep

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: hypoxia

Risk for Powerlessness: Risk factor: inability to control nocturnal dyspnea

Readiness for Enhanced Sleep: expresses willingness to learn measures to enhance sleep

Pneumonectomy

See Thoracotomy

Pneumonia

Decreased Activity Tolerance r/t imbalance between oxygen supply and demand

Ineffective Airway Clearance r/t inflammation and presence of secretions

Impaired Gas Exchange r/t decreased functional lung tissue

Dysfunctional Adult Ventilatory Weaning Response r/t fatigue

Ineffective Health Management r/t deficient knowledge regarding self-care and treatment of disease

Imbalanced Nutrition: Less than Body Requirements r/t loss of appetite

Impaired Oral Mucous Membrane Integrity r/t dry mouth from mouth breathing, decreased fluid intake

Ineffective Thermoregulation r/t infectious process

Risk for Acute Confusion: Risk factors: underlying illness, hypoxia

Risk for Deficient Fluid Volume: Risk factor: inadequate intake of fluids

Risk for Vascular Trauma: Risk factor: irritation from intravenous antibiotics

See Respiratory Infections, Acute Childhood

Pneumothorax

Fear r/t threat to own well-being, difficulty breathing

Impaired Gas Exchange r/t ventilation-perfusion imbalance, decreased functional lung tissue

Impaired Spontaneous Ventilation r/t respiratory muscle fatigue with difficulty breathing

Acute Pain r/t recent injury, coughing, deep breathing

Risk for Injury: Risk factor: possible complications associated with closed chest drainage system

See Chest Tubes

Poisoning, Risk for

Risk for Poisoning (See **Poisoning, Risk for,** Section III)

Poliomyelitis

See Paralysis

Polydipsia

See Diabetes Mellitus

Polyphagia

Readiness for Enhanced Nutrition: knowledge of appropriate diet for diabetes

See Diabetes Mellitus

Polyuria

See Diabetes Mellitus

Postoperative Care

See Surgery, Postoperative Care

Postpartum Depression

Anxiety r/t new responsibilities of parenting

Disturbed Body Image r/t normal postpartum recovery

Ineffective Childbearing Process r/t depression/lack of support system

Ineffective Coping r/t hormonal changes

Fatigue r/t childbirth, postpartum state, crying child

Risk-Prone Health Behavior r/t lack of support systems

Ineffective Home Maintenance Behaviors r/t fatigue, care of newborn

Hopelessness r/t stress, exhaustion

Deficient Knowledge r/t lifestyle changes

Impaired Parenting r/t hormone-induced depression

Ineffective Role Performance r/t new responsibilities of parenting

Sexual Dysfunction r/t fear of another pregnancy, postpartum pain, lochia flow

Sleep Deprivation r/t environmental stimulation of newborn

Impaired Social Interaction r/t change in role functioning

Risk for Disturbed Personal Identity: Risk factor: role change/depression/inability to cope

Risk for Situational Low Self-Esteem: Risk factor: decreased power over feelings of sadness

Risk for Spiritual Distress: Risk factors: altered relationships, social isolation

Readiness for Enhanced Hope: expresses desire to enhance hope and interconnectedness with others

See Depression (Major Depressive Disorder)

Postpartum Hemorrhage

Decreased Activity Tolerance r/t anemia from loss of blood

Death Anxiety r/t threat of mortality associated with bleeding

Disturbed Body Image r/t loss of ideal childbirth

Insufficient Breast Milk Production r/t fluid volume depletion

Interrupted Breastfeeding r/t separation from infant for medical treatment

Decreased Cardiac Output r/t hypovolemia

Fear r/t threat to self, unknown future

Deficient Fluid Volume r/t uterine atony, loss of blood

Ineffective Home Maintenance Behaviors r/t lack of stamina

Deficient Knowledge r/t lack of exposure to situation

Acute Pain r/t nursing and medical interventions to control bleeding

Ineffective Peripheral Tissue Perfusion r/t hypovolemia

Risk for Bleeding: Risk factor: postpartum complications

Risk for Impaired Childbearing: Risk factor: postpartum complication

Risk for Imbalanced Fluid Volume: Risk factor: maternal blood loss

Risk for Infection: Risk factors: loss of blood, depressed immunity

Risk for Impaired Parenting: Risk factor: weakened maternal condition

Risk for Powerlessness: Risk factor: acute illness

Risk for Shock: Risk factor: hypovolemia

Postpartum, Normal Care

Anxiety r/t change in role functioning, parenting

Effective Breastfeeding r/t basic breastfeeding knowledge, support of partner and health care provider

Fatigue r/t childbirth, new responsibilities of parenting, body changes

Acute Pain r/t episiotomy, lacerations, bruising, breast engorgement, headache, sore nipples, epidural or intravenous site, hemorrhoids

Sexual Dysfunction r/t recent childbirth

Impaired Tissue Integrity r/t episiotomy, lacerations

Sleep Deprivation r/t care of infant

Impaired Urinary Elimination r/t effects of anesthesia, tissue trauma

Risk for Constipation: Risk factors: hormonal effects on smooth muscles, fear of straining with defecation, effects of anesthesia

Risk for Infection: Risk factors: tissue trauma, blood loss

Readiness for Enhanced family Coping: adaptation to new family member

Readiness for Enhanced Hope: desire to increase hope

Readiness for Enhanced Parenting: expresses willingness to enhance parenting skills

Post-Trauma Syndrome

Post-Trauma Syndrome (See **Post-Trauma Syndrome,** Section III)

Post-Trauma Syndrome, Risk for

Risk for Post-Trauma Syndrome (See **Post-Trauma Syndrome, Risk for,** Section III)

Posttraumatic Stress Disorder (PTSD)

See PTSD (Post-Traumatic Stress Disorder)

Potassium, Increase/Decrease

See Hyperkalemia; Hypokalemia

Power/Powerlessness

Powerlessness (See **Powerlessness,** Section III)

Risk for Powerlessness (See **Powerlessness, Risk for,** Section III)

Readiness for Enhanced Power (See **Power, Readiness for Enhanced,** Section III)

Preeclampsia

See PIH (Pregnancy-Induced Hypertension/Preeclampsia)

Pregnancy, Cardiac Disorders

See Cardiac Disorders in Pregnancy

Pregnancy-Induced Hypertension/ Preeclampsia (PIH)

See PIH (Pregnancy-Induced Hypertension/Preeclampsia)

Pregnancy Loss

Anxiety r/t threat to role functioning, health status, situational crisis

Compromised Family Coping r/t lack of support by significant other because of personal suffering

Ineffective Coping r/t situational crisis

Maladaptive Grieving r/t loss of pregnancy, fetus, or child

Acute Pain r/t surgical intervention

Ineffective Role Performance r/t inability to assume parenting role

Ineffective Sexuality Pattern r/t self-esteem disturbance resulting from pregnancy loss and anxiety about future pregnancies

Chronic Sorrow r/t loss of a fetus or child

Spiritual Distress r/t intense suffering from loss of child

Risk for Deficient Fluid Volume: Risk factor: blood loss

Risk for Maladaptive Grieving: Risk factor: loss of pregnancy

Risk for Infection: Risk factor: retained products of conception

Risk for Powerlessness: Risk factor: situational crisis

Risk for Ineffective Relationship: Risk factor: poor communication skills in dealing with the loss

Risk for Spiritual Distress: Risk factor: intense suffering

Readiness for Enhanced Communication: willingness to express feelings and thoughts about loss

Readiness for Enhanced Hope: expresses desire to enhance hope

Readiness for Enhanced Spiritual Well-Being: desire for acceptance of loss

Pregnancy, Normal

Anxiety r/t unknown future, threat to self secondary to pain of labor

Disturbed Body Image r/t altered body function and appearance

Interrupted Family Processes r/t developmental transition of pregnancy

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Fatigue r/t increased energy demands

Fear r/t labor and delivery

Deficient Knowledge r/t primiparity

Nausea r/t hormonal changes of pregnancy

Imbalanced Nutrition: Less than Body Requirements r/t growing fetus, nausea

Imbalanced Nutrition: More than Body Requirements r/t deficient knowledge regarding nutritional needs of pregnancy

Sleep Deprivation r/t uncomfortable pregnancy state

Impaired Urinary Elimination r/t frequency caused by increased pelvic pressure and hormonal stimulation

Risk for Constipation: Risk factor: pregnancy

Risk for Sexual Dysfunction: Risk factors: altered body function, self-concept, body image with pregnancy

Readiness for Enhanced Childbearing Process: appropriate prenatal care

Readiness for Enhanced Family Coping: satisfying partner relationship, attention to gratification of needs, effective adaptation to developmental tasks of pregnancy

Readiness for Enhanced Family Processes: family adapts to change

Readiness for Enhanced Health Management: seeks information for prenatal self-care

Readiness for Enhanced Nutrition: desire for knowledge of appropriate nutrition during pregnancy

Readiness for Enhanced Parenting: expresses willingness to enhance parenting skills

Readiness for Enhanced Relationship: meeting developmental goals associated with pregnancy

Readiness for Enhanced Spiritual Well-Being: new role as parent

See Discomforts of Pregnancy

Premature Dilation of the Cervix (Incompetent Cervix)

Ineffective Activity Planning r/t unrealistic perception of events

Ineffective Coping r/t bed rest, threat to fetus

Decreased Diversional Activity Engagement r/t bed rest

Fear r/t potential loss of infant

Maladaptive Grieving r/t potential loss of infant

Deficient Knowledge r/t treatment regimen, prognosis for pregnancy

Impaired Physical Mobility r/t imposed bed rest to prevent preterm birth

Powerlessness r/t inability to control outcome of pregnancy

Ineffective Role Performance r/t inability to continue usual patterns of responsibility

Situational Low Self-Esteem r/t inability to complete normal pregnancy

Sexual Dysfunction r/t fear of harm to fetus

Impaired Social Interaction r/t bed rest

Risk for Infection: Risk factor: invasive procedures to prevent preterm birth

Risk for Injury: Fetal: Risk factors: preterm birth, use of anesthetics

Risk for Injury: Maternal: Risk factor: surgical procedures to prevent preterm birth (e.g., cerclage)

Risk for Impaired Resilience: Risk factor: complication of pregnancy

Risk for Spiritual Distress: Risk factors: physical/psychological stress

Premature Infant (Child)

Insufficient Breast Milk Production r/t ineffective sucking, latching on of the infant

Impaired Gas Exchange r/t effects of cardiopulmonary insufficiency

Disorganized Infant Behavior r/t prematurity

Insomnia r/t noisy and noxious intensive care environment

Neonatal Hyperbilirubinemia r/t infant experiences difficulty making transition to extrauterine life

Imbalanced Nutrition: Less than Body Requirements r/t delayed or understimulated rooting reflex, easy fatigue during feeding, diminished endurance

Impaired Swallowing r/t decreased or absent gag reflex, fatigue

Ineffective Thermoregulation r/t large body surface/weight ratio, immaturity of thermal regulation, state of prematurity

Risk for Delayed Child Development: Risk factor: prematurity

Risk for Infection: Risk factors: inadequate, immature, or undeveloped acquired immune response

Risk for Injury: Risk factor: prolonged mechanical ventilation, retinopathy of prematurity (ROP) secondary to 100% oxygen environment

Risk for Neonatal Hyperbilirubinemia: Risk factor: late preterm birth

Readiness for Enhanced Organized Infant Behavior: use of some self-regulatory measures

Premature Infant (Parent)

Ineffective Breastfeeding r/t disrupted establishment of effective pattern secondary to prematurity or insufficient opportunities

Decisional Conflict r/t support system deficit, multiple sources of information

Compromised Family Coping r/t disrupted family roles and disorganization, prolonged condition exhausting supportive capacity of significant persons

Ineffective Infant Feeding Dynamics r/t insufficient knowledge of nutritional needs

Maladaptive Grieving r/t loss of perfect child possibly leading to complicated grieving

Risk for Maladaptive Grieving (Prolonged) r/t unresolved conflicts

Parental Role Conflict r/t expressed concerns, expressed inability to care for child's physical, emotional, or developmental needs

Chronic Sorrow r/t threat of loss of a child, prolonged hospitalization

Spiritual Distress r/t challenged belief or value systems regarding moral or ethical implications of treatment plans

Risk for Impaired Attachment: Risk factors: separation, physical barriers, lack of privacy

Risk for Disturbed Maternal–Fetal Dyad: Risk factor: complication of pregnancy

Risk for Powerlessness: Risk factor: inability to control situation

Risk for Impaired Resilience: Risk factor: premature infant

Risk for Spiritual Distress: Risk factor: challenged belief or value systems regarding moral or ethical implications of treatment plans

Readiness for Enhanced Family Process: adaptation to change associated with premature infant

See Child with Chronic Condition; Hospitalized Child

Premature Rupture of Membranes

Anxiety r/t threat to infant's health status

Disturbed Body Image r/t inability to carry pregnancy to term

Ineffective Coping r/t situational crisis

Maladaptive Grieving r/t potential loss of infant

Situational Low Self-Esteem r/t inability to carry pregnancy to term

Risk for Ineffective Childbearing Process: Risk factor: complication of pregnancy

Risk for Infection: Risk factor: rupture of membranes

Risk for Injury: Fetal: Risk factor: risk of premature birth

Premenstrual Tension Syndrome (PMS)

See PMS (Premenstrual Tension Syndrome)

Prenatal Care, Normal

Readiness for Enhanced Childbearing Process: appropriate prenatal lifestyle

Readiness for Enhanced Knowledge: appropriate prenatal care

Readiness for Enhanced Spiritual Well-Being: new role as parent

See Pregnancy, Normal

Prenatal Testing

Anxiety r/t unknown outcome, delayed test results

Acute Pain r/t invasive procedures

Risk for Infection: Risk factor: invasive procedures during amniocentesis or chorionic villus sampling

Risk for Injury: Risk factor: invasive procedures

Preoperative Teaching

See Surgery, Preoperative Care

Pressure Injury

Impaired Bed Mobility r/t intolerance to activity, pain, cognitive impairment, depression, severe anxiety, severity of illness

Imbalanced Nutrition: Less than Body Requirements r/t limited access to food, inability to absorb nutrients because of biological factors, anorexia

Acute Pain r/t tissue destruction, exposure of nerves

Impaired Skin Integrity: Stage I or II Pressure Injury r/t physical immobility, mechanical factors, altered circulation, skin irritants, excessive moisture

Impaired Tissue Integrity: Stage III or IV Pressure Injury r/t altered circulation, impaired physical mobility, excessive moisture

Risk for Infection: Risk factors: physical immobility, mechanical factors (shearing forces, pressure, restraint, altered circulation, skin irritants, excessive moisture, open wound)

Risk for Adult Pressure Injury (See **Adult Pressure Injury,** Section III)

Risk for Child Pressure Injury (See **Child Pressure Injury,** Section III)

Risk for Neonate Pressure Injury (See **Neonate Pressure Injury,** Section III)

Preterm Labor

Anxiety r/t threat to fetus, change in role functioning, change in environment and interaction patterns, use of tocolytic drugs

Ineffective Coping r/t situational crisis, preterm labor

Decreased Diversional Activity Engagement r/t long-term hospitalization

Risk for Maladaptive Grieving r/t loss of idealized pregnancy, potential loss of fetus

Ineffective Home Maintenance Behaviors r/t medical restrictions

Impaired Physical Mobility r/t medically imposed restrictions

Ineffective Role Performance r/t inability to carry out normal roles secondary to bed rest or hospitalization, change in expected course of pregnancy

Situational Low Self-Esteem r/t threatened ability to carry pregnancy to term

Sexual Dysfunction r/t actual or perceived limitation imposed by preterm labor and/or prescribed treatment, separation from partner because of hospitalization

Sleep Deprivation r/t change in usual pattern secondary to contractions, hospitalization, treatment regimen

Impaired Social Interaction r/t prolonged bed rest or hospitalization

Risk for Injury: Fetal: Risk factors: premature birth, immature body systems

Risk for Injury: Maternal: Risk factor: use of tocolytic drugs

Risk for Powerlessness: Risk factor: lack of control over preterm labor

Risk for Vascular Trauma: Risk factor: intravenous medication

Readiness for Enhanced Childbearing Process: appropriate prenatal lifestyle

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Readiness for Enhanced Comfort: expresses desire to enhance relaxation

Readiness for Enhanced Communication: willingness to discuss thoughts and feelings about situation

Problem-Solving Dysfunction

Defensive Coping r/t situational crisis

Impaired Emancipated Decision-Making r/t problem-solving dysfunction

Risk for Chronic Low Self-Esteem: Risk factor: repeated failures

Readiness for Enhanced Communication: willing to share ideas with others

Readiness for Enhanced Relationship: shares information and ideas between partners

Readiness for Enhanced Resilience: identifies available resources

Readiness for Enhanced Spiritual Well-Being: desires to draw on inner strength and find meaning and purpose to life

Projection

Anxiety r/t threat to self-concept

Defensive Coping r/t inability to acknowledge that own behavior may be a problem, blaming others

Chronic Low Self-Esteem r/t failure

Impaired Social Interaction r/t self-concept disturbance, confrontational communication style

Risk for Loneliness: Risk factor: blaming others for problems

See Paranoid Personality Disorder

Prolapsed Umbilical Cord

Fear r/t threat to fetus, impending surgery

Ineffective Peripheral Tissue Perfusion: Fetal r/t interruption in umbilical blood flow

Risk for Ineffective Cerebral Tissue Perfusion: Fetal: Risk factor: cord compression

Risk for Injury: Risk factor (maternal): emergency surgery

See TURP (Transurethral Resection of the Prostate)

Prostatic Hypertrophy

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding self-care and prevention of complications

Sleep Deprivation r/t nocturia

Urinary Retention r/t obstruction

Risk for Infection: Risk factors: urinary residual after voiding, bacterial invasion of bladder

See BPH (Benign Prostatic Hypertrophy)

Prostatitis

Impaired Comfort r/t inflammation

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding treatment

Urge Urinary Incontinence r/t irritation of bladder

Ineffective Protection r/t depressed immune system

Pruritus

Impaired Comfort r/t inflammation of skin causing itching

Deficient Knowledge r/t methods to treat and prevent itching

Risk for Impaired Skin Integrity: Risk factors: scratching, dry skin

Psoriasis

Disturbed Body Image r/t lesions on body

Impaired Comfort r/t irritated skin

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding treatment modalities

Powerlessness r/t lack of control over condition with frequent exacerbations and remissions

Impaired Skin Integrity r/t lesions on body

Psychosis

Ineffective Activity Planning r/t compromised ability to process information

Ineffective Health Maintenance Behaviors r/t cognitive impairment, ineffective individual and family coping

Self-Neglect r/t mental disorder

Impaired Individual Resilience r/t psychological disorder

Situational Low Self-Esteem r/t excessive use of defense mechanisms (e.g., projection, denial, rationalization)

Risk for Disturbed Personal Identity: Risk factor: psychosis

Impaired Mood Regulation r/t psychosis

Risk for Post-Trauma Syndrome: Risk factor: diminished ego strength

See Schizophrenia

PTCA (Percutaneous Transluminal Coronary Angioplasty)

See Angioplasty, Coronary

PTSD (Posttraumatic Stress Disorder)

Anxiety r/t exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event

Chronic Sorrow r/t chronic disability (e.g., physical, mental)

Death Anxiety r/t psychological stress associated with traumatic event

Ineffective Breathing Pattern r/t hyperventilation associated with anxiety

Ineffective Coping r/t extreme anxiety

Ineffective Impulse Control r/t thinking of initial trauma experience

Ineffective Relationship r/t stressors

Insomnia r/t recurring nightmares

Post-Trauma Syndrome r/t exposure to a traumatic event

Sleep Deprivation r/t nightmares interrupting sleep associated with traumatic event

Spiritual Distress r/t feelings of detachment or estrangement from others

Risk for Impaired Resilience: Risk factor: chronicity of existing crisis

Risk for Powerlessness: Risk factors: flashbacks, reliving event

Risk for Ineffective Relationship: Risk factor: stressful life events

Risk for Self- or Other-Directed Violence: Risk factors: fear of self or others

Readiness for Enhanced Comfort: expresses desire to enhance relaxation

Readiness for Enhanced Communication: willingness to express feelings and thoughts

Readiness for Enhanced Spiritual Well-Being: desire for harmony after stressful event

Pulmonary Edema

Anxiety r/t fear of suffocation

Ineffective Airway Clearance r/t presence of tracheobronchial secretions

Decreased Cardiac Output r/t increased preload, infective forward perfusion

Impaired Gas Exchange r/t extravasation of extravascular fluid in lung tissues and alveoli

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding treatment regimen

Sleep Deprivation r/t inability to breathe

Risk for Acute Confusion: Risk factor: hypoxia

See Heart Failure

Pulmonary Embolism (PE)

Anxiety r/t fear of suffocation

Decreased Cardiac Output r/t right ventricular failure secondary to obstructed pulmonary artery

Fear r/t severe pain, possible death

Impaired Gas Exchange r/t altered blood flow to alveoli secondary to embolus

Deficient Knowledge r/t activities to prevent embolism, self-care after diagnosis of embolism

Acute Pain r/t biological injury, lack of oxygen to cells

Ineffective Peripheral Tissue Perfusion r/t deep vein thrombus formation

Risk for Thrombosis r/t sedentary lifestyle

See Anticoagulant Therapy

Pulmonary Stenosis

See Congenital Heart Disease/Cardiac Anomalies

Pulse Deficit

Risk for Decreased Cardiac Output r/t dysrhythmia

See Dysrhythmia

Pulse Oximetry

Readiness for Enhanced Knowledge: information about treatment regimen

See Hypoxia

Pulse Pressure, Increased

See Intracranial Pressure, Increased

Pulse Pressure, Narrowed

See Shock, Hypovolemic

Pulses, Absent or Diminished Peripheral

Ineffective Peripheral Tissue Perfusion r/t interruption of arterial flow

Risk for Peripheral Neurovascular Dysfunction: Risk factors: fractures, mechanical compression, orthopedic surgery trauma, immobilization, burns, vascular obstruction

Purpura

See Clotting Disorder

Pyelonephritis

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding self-care, treatment of disease, prevention of further urinary tract infections

Acute Pain r/t inflammation and irritation of urinary tract

Disturbed Sleep Pattern r/t urinary frequency

Impaired Urinary Elimination r/t irritation of urinary tract

Pyloric Stenosis

Imbalanced Nutrition: Less than Body Requirements r/t vomiting secondary to pyloric sphincter obstruction

Acute Pain r/t abdominal fullness

Risk for Decreased Fluid Volume: Risk factors: vomiting, dehydration

See Hospitalized Child

Pyloromyotomy (Pyloric Stenosis Repair)

See Surgery Preoperative Care, Perioperative Care, Postoperative Care

R

RA (Rheumatoid Arthritis)

See Rheumatoid Arthritis (RA)

Rabies

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding care of wound, isolation, and observation of infected animal

Acute Pain r/t multiple immunization injections

Risk for Ineffective Cerebral Tissue Perfusion: Risk factor: rabies virus

Radial Nerve Dysfunction

Acute Pain r/t trauma to hand or arm

Chronic Pain r/t trauma hand or arm

See Neuropathy, Peripheral

Radiation Therapy (Radiotherapy)

Decreased Activity Tolerance r/t fatigue from possible anemia

Disturbed Body Image r/t change in appearance, hair loss

Diarrhea r/t irradiation effects

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Fatigue r/t malnutrition from lack of appetite, nausea, and vomiting; side effect of radiation

Deficient Knowledge r/t what to expect with radiation therapy, how to do self-care

Nausea r/t side effects of radiation

Imbalanced Nutrition: Less than Body Requirements r/t anorexia, nausea, vomiting, irradiation of areas of pharynx and esophagus

Impaired Oral Mucous Membrane Integrity r/t irradiation effects

Ineffective Protection r/t suppression of bone marrow

Risk for Dry Mouth: Risk factor: possible side effect of radiation treatments

Risk for Impaired Oral Mucous Membrane Integrity: Risk factor: radiation treatments

Risk for Powerlessness: Risk factors: medical treatment and possible side effects

Risk for Impaired Resilience: Risk factor: radiation treatment

Risk for Impaired Skin Integrity: Risk factor: irradiation effects

Risk for Spiritual Distress: Risk factors: radiation treatment, prognosis

Ineffective Dry Eye Self-Management inattentive to dry eye symptoms from radiotherapy treatment regimen

Radical Neck Dissection

See Laryngectomy

Rage

Risk-Prone Health Behavior r/t multiple stressors

Labile Emotional Control r/t psychiatric disorders and mood disorders

Impaired Individual Resilience r/t poor impulse control

Stress Overload r/t multiple coexisting stressors

Risk for Self-Mutilation: Risk factor: command hallucinations

Risk for Suicidal Behavior: Risk factor: desire to kill self

Risk for Other-Directed Violence: Risk factors: panic state, manic excitement, organic brain syndrome

Rape-Trauma Syndrome

Rape-Trauma Syndrome (See **Rape-Trauma Syndrome,** Section III)

Chronic Sorrow r/t forced loss of virginity

Risk for Ineffective Childbearing Process r/t to trauma and violence

Risk for Post-Trauma Syndrome: Risk factor: trauma or violence associated with rape

Risk for Powerlessness: Risk factor: inability to control thoughts about incident

Risk for Ineffective Relationship: Risk factor: trauma and violence

Risk for Chronic Low Self-Esteem: Risk factors: perceived lack of respect from others, feeling violated

Risk for Spiritual Distress: Risk factor: forced loss of virginity

Rash

Impaired Comfort r/t pruritus

Impaired Skin Integrity r/t mechanical trauma

Risk for Infection: Risk factors: traumatized tissue, broken skin

Rationalization

Defensive Coping r/t situational crisis, inability to accept blame for consequences of own behavior

Ineffective Denial r/t fear of consequences, actual or perceived loss

Impaired Individual Resilience r/t psychological disturbance

Risk for Post-Trauma Syndrome: Risk factor: survivor's role in event

Readiness for Enhanced Communication: expresses desire to share thoughts and feelings

Readiness for Enhanced Spiritual Well-Being: possibility of seeking harmony with self, others, higher power, God

Rats, Rodents in Home

Ineffective Home Maintenance Behaviors r/t lack of knowledge, insufficient finances

Risk for Allergic Reaction: Risk factor: repeated exposure to environmental contamination

See Filthy Home Environment

Raynaud's Disease

Deficient Knowledge r/t lack of information about disease process, possible complications, self-care needs regarding disease process and medication

Ineffective Peripheral Tissue Perfusion r/t transient reduction of blood flow

Acute Pain r/t transient reduction in blood flow

RDS (Respiratory Distress Syndrome)

See Respiratory Conditions of the Neonate

Rectal Fullness

Chronic Functional Constipation r/t decreased activity level, decreased fluid intake, inadequate fiber in diet, decreased peristalsis, side effects of antidepressant or antipsychotic therapy

Risk for Chronic Functional Constipation: Risk factor: habitual denial of or ignoring urge to defecate

Rectal Lump

See Hemorrhoids

Rectal Pain/Bleeding

Chronic Functional Constipation r/t pain on defecation

Deficient Knowledge r/t possible causes of rectal bleeding, pain, treatment modalities

Acute Pain r/t pressure of defecation

Risk for Bleeding: Risk factor: rectal disease

Rectal Surgery

See Hemorrhoidectomy

Rectocele Repair

Chronic Functional Constipation r/t painful defecation

Ineffective Health Maintenance Behaviors r/t deficient knowledge of postoperative care of surgical site, dietary measures, exercise to prevent constipation

Acute Pain r/t surgical procedure

Urinary Retention r/t edema from surgery

Risk for Bleeding: Risk factor: surgery

Risk for Surgical Site Infection: Risk factors: surgical procedure, possible contamination of area with feces

Reflex Incontinence

Mixed Urinary Incontinence (See **Incontinence, Urinary, Reflex**, Section III)

Regression

Anxiety r/t threat to or change in health status

Defensive Coping r/t denial of obvious problems, weaknesses

Self-Neglect r/t functional impairment

Powerlessness r/t health care environment

Impaired Individual Resilience r/t psychological disturbance

Ineffective Role Performance r/t powerlessness over health status

See Hospitalized Child; Separation Anxiety

Regretful

Anxiety r/t situational or maturational crises

Death Anxiety r/t feelings of not having accomplished goals in life

Risk for Spiritual Distress: Risk factor: inability to forgive

Rehabilitation

Ineffective Coping r/t loss of normal function

Impaired Physical Mobility r/t injury, surgery, psychosocial condition warranting rehabilitation

Self-Care Deficit: Specify r/t impaired physical mobility

Risk for Adult Falls: Risk factor: physical deconditioning

Risk for Child Falls: Risk factor: Decreased lower extremity strength

Readiness for Enhanced Comfort: expresses desire to enhance feeling of comfort

Readiness for Enhanced Self-Concept: accepts strengths and limitations

Readiness for Enhanced Health Self-Management: expresses desire to manage rehabilitation

Relationship

Ineffective Relationship (See **Ineffective Relationship,** Section III)

Readiness for Enhanced Relationship (See **Risk for Enhanced Relationship,** Section III)

Relaxation Techniques

Anxiety r/t situational crisis

Readiness for Enhanced Comfort: expresses desire to enhance relaxation

Readiness for Enhanced Health Self-Management: desire to manage illness

Readiness for Enhanced Religiosity: requests religious materials or experiences

Readiness for Enhanced Resilience: desire to enhance resilience

Readiness for Enhanced Self-Concept: willingness to enhance self-concept

Readiness for Enhanced Spiritual Well-Being: seeking comfort from higher power

Religiosity

Impaired Religiosity (See **Religiosity, Impaired,** Section III)

Risk for Impaired Religiosity (See **Religiosity, Impaired, Risk for,** Section III)

Readiness for Enhanced Religiosity (See **Religiosity, Readiness for Enhanced,** Section III)

Religious Concerns

Spiritual Distress r/t separation from religious or cultural ties

Risk for Impaired Religiosity: Risk factors: ineffective support, coping, caregiving

Risk for Spiritual Distress: Risk factors: physical or psychological stress

Readiness for Enhanced Spiritual Well-Being: desire for increased spirituality

Relocation Stress Syndrome

Relocation Stress Syndrome (See **Relocation Stress Syndrome,** Section III)

Risk for Relocation Stress Syndrome (See **Relocation Stress Syndrome, Risk for,** Section III)

Renal Failure

Decreased Activity Tolerance r/t effects of anemia, heart failure

Death Anxiety r/t unknown outcome of disease

Decreased Cardiac Output r/t effects of heart failure, elevated potassium levels interfering with conduction system

Impaired Comfort r/t pruritus

Ineffective Coping r/t depression resulting from chronic disease

Fatigue r/t effects of chronic uremia and anemia

Excessive Fluid Volume r/t decreased urine output, sodium retention, inappropriate fluid intake

Ineffective Health Self-Management r/t complexity of health care regimen, inadequate number of cues to action, perceived barriers, powerlessness

Imbalanced Nutrition: Less than Body Requirements r/t anorexia, nausea, vomiting, altered taste sensation, dietary restrictions

Impaired Oral Mucous Membrane Integrity r/t irritation from nitrogenous waste products

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Chronic Sorrow r/t chronic illness

Spiritual Distress r/t dealing with chronic illness

Impaired Urinary Elimination r/t effects of disease, need for dialysis

Risk for Electrolyte Imbalance: Risk factor: renal dysfunction

Risk for Infection: Risk factor: altered immune functioning

Risk for Injury: Risk factors: bone changes, neuropathy, muscle weakness

Risk for Impaired Oral Mucous Membrane Integrity: Risk factors: dehydration, effects of uremia

Risk for Powerlessness: Risk factor: chronic illness

Risk for Sepsis: Risk factor: infection

Renal Failure Acute/Chronic, Child

Disturbed Body Image r/t growth retardation, bone changes, visibility of dialysis access devices (shunt, fistula), edema

Decreased Diversional Activity Engagement r/t immobility during dialysis

See Child with Chronic Condition; Hospitalized Child

Renal Failure, Nonoliguric

Anxiety r/t change in health status

Risk for Deficient Fluid Volume: Risk factor: loss of large volumes of urine

See Renal Failure

Respiratory Acidosis

See Acidosis, Respiratory

Respiratory Conditions of the Neonate (Respiratory Distress Syndrome [RDS], Meconium Aspiration, Diaphragmatic Hernia)

Ineffective Airway Clearance r/t sequelae of attempts to breathe in utero resulting in meconium aspiration

Fatigue r/t increased energy requirements and metabolic demands

Impaired Gas Exchange r/t decreased surfactant, immature lung tissue

Dysfunctional Ventilator Weaning Response r/t immature respiratory system

Risk for Infection: Risk factors: tissue destruction or irritation as a result of aspiration of meconium fluid

See Bronchopulmonary Dysplasia; Hospitalized Child; Premature Infant, Child

Respiratory Distress

See Dyspnea

Respiratory Distress Syndrome (RDS)

See Respiratory Conditions of the Neonate

Respiratory Infections, Acute Childhood (Croup, Epiglottitis, Pertussis, Pneumonia, Respiratory Syncytial Virus)

Decreased Activity Tolerance r/t generalized weakness, dyspnea, fatigue, poor oxygenation

Ineffective Airway Clearance r/t excess tracheobronchial secretions

Ineffective Breathing Pattern r/t inflamed bronchial passages, coughing

Fear r/t oxygen deprivation, difficulty breathing

Deficient Fluid Volume r/t insensible losses (fever, diaphoresis), inadequate oral fluid intake

Impaired Gas Exchange r/t insufficient oxygenation as a result of inflammation or edema of epiglottis, larynx, bronchial passages

Imbalanced Nutrition: Less than Body Requirements r/t anorexia, fatigue, generalized weakness, poor sucking and breathing coordination, dyspnea

Ineffective Thermoregulation r/t infectious process

Risk for Aspiration: Risk factors: inability to coordinate breathing, coughing, sucking

Risk for Infection: Transmission to Others: Risk factor: virulent infectious organisms

Risk for Injury (to Pregnant Others): Risk factors: exposure to aerosolized medications (e.g., ribavirin, pentamidine), resultant potential fetal toxicity

Risk for Suffocation: Risk factors: inflammation of larynx, epiglottis

See Hospitalized Child

Respiratory Syncytial Virus

See Respiratory Infections, Acute Childhood

Restless Leg Syndrome

Disturbed Sleep Pattern r/t leg discomfort during sleep relieved by frequent leg movement

Chronic Pain r/t leg discomfort

See Stress

Retinal Detachment

Anxiety r/t change in vision, threat of loss of vision

Deficient Knowledge r/t symptoms, need for early intervention to prevent permanent damage

Vision Loss r/t impaired visual acuity

Risk for Ineffective Home Maintenance Behaviors: Risk factors: postoperative care, activity limitations, care of affected eye

Risk for Impaired Resilience: Risk factor: possible loss of vision

See Vision Impairment

Retinopathy, Diabetic

See Diabetic Retinopathy

Retinopathy of Prematurity (ROP)

Risk for Injury: Risk factors: prolonged mechanical ventilation, ROP secondary to 100% oxygen environment

See Retinal Detachment

Rh Factor Incompatibility

Anxiety r/t unknown outcome of pregnancy

Neonatal Hyperbilirubinemia r/t Rh factor incompatibility

Deficient Knowledge r/t treatment regimen from lack of experience with situation

Powerlessness r/t perceived lack of control over outcome of pregnancy

Risk for Injury: Fetal: Risk factors: intrauterine destruction of red blood cells, transfusions

Risk for Neonatal Hyperbilirubinemia: Risk factor: Rh factor incompatibility

Readiness for Enhanced Health Management: prenatal care, compliance with diagnostic and treatment regimen

Rhabdomyolysis

Ineffective Coping r/t seriousness of condition

Impaired Physical Mobility r/t myalgia and muscle weakness

Risk for Deficient Fluid Volume: Risk factor: reduced blood flow to kidneys

Risk for Shock: Risk factor: hypovolemia

Readiness for Enhanced Health Management: seeks information to avoid condition

See Kidney Failure

Rheumatic Fever

See Endocarditis

Rheumatoid Arthritis (RA)

Imbalanced Nutrition: Less than Body Requirements r/t loss of appetite

Chronic Pain r/t joint inflammation

Disturbed Body Image r/t joint deformity and muscle atrophy

Impaired Physical Mobility r/t pain, impaired joints

Risk for Impaired Resilience: Risk factor: chronic, painful, progressive disease

See Arthritis; JRA (Juvenile Rheumatoid Arthritis)

Rib Fracture

Ineffective Breathing Pattern r/t fractured ribs

Acute Pain r/t movement, deep breathing

Impaired Gas Exchange r/t ventilation-perfusion imbalance, decreased depth of ventilation

Ridicule of Others

Defensive Coping r/t situational crisis, psychological impairment, substance abuse

Risk for Post-Trauma Syndrome: Risk factor: perception of event

Ringworm of Body

Impaired Comfort r/t pruritus

Impaired Skin Integrity r/t presence of macules associated with fungus

See Itching; Pruritus

Ringworm of Nails

Disturbed Body Image r/t appearance of nails, removed nails

Ringworm of Scalp

Disturbed Body Image r/t possible hair loss (alopecia)

See Itching; Pruritus

Roaches, Invasion of Home with

Ineffective Home maintenance Behaviors r/t lack of knowledge, insufficient finances

See Filthy Home Environment

Role Performance, Altered

Ineffective Role Performance (See **Role Performance, Ineffective,** Section III)

ROP (Retinopathy of Prematurity)

See Retinopathy of Prematurity (ROP)

RSV (Respiratory Syncytial Virus)

See Respiratory Infection, Acute Childhood

Rubella

See Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice, Impetigo)

Rubor of Extremities

Ineffective Peripheral Tissue Perfusion r/t interruption of arterial flow

See Peripheral Vascular Disease (PVD)

Ruptured Disk

See Low Back Pain

S

SAD (Seasonal Affective Disorder)

Readiness for Enhanced Resilience: uses SAD lights during winter months

See Depression (Major Depressive Disorder)

Sadness

Risk for Maladaptive Grieving r/t actual or perceived loss

Impaired Mood Regulation r/t chronic illness (See **Mood Regulation, Impaired,** Section III)

Spiritual Distress r/t intense suffering

Risk for Powerlessness: Risk factor: actual or perceived loss

Risk for Spiritual Distress: Risk factor: loss of loved one

Readiness for Enhanced Communication: willingness to share feelings and thoughts

Readiness for Enhanced Spiritual Well-Being: desire for harmony after actual or perceived loss

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

See Depression (Major Depressive Disorder); Major Depressive Disorder

Safe Sex

Readiness for Enhanced Health Self-Management: takes appropriate precautions during sexual activity to keep from contracting sexually transmitted disease

See Sexuality, Adolescent; STD (Sexually Transmitted Disease)

Safety, Childhood

Deficient Knowledge: Potential for Enhanced Health Self-Maintenance r/t parental knowledge and skill acquisition regarding appropriate safety measures

Risk for Aspiration (See **Aspiration, Risk for,** Section III)

Risk for Injury: Risk factors: developmental age, altered home maintenance

Risk for Impaired Parenting: Risk factors: lack of available and effective role model, lack of knowledge, misinformation from other family members (old wives' tales)

Risk for Poisoning: Risk factors: use of lead-based paint; presence of asbestos or radon gas; drugs not locked in cabinet; household products left in accessible area (bleach, detergent, drain cleaners, household cleaners); alcohol and perfume within reach of child; presence of poisonous plants; atmospheric pollutants

Risk for Thermal injury: Risk factor: inadequate supervision

Readiness for Enhanced Childbearing Process: expresses appropriate knowledge for care of child

Salmonella

Impaired Home Maintenance r/t improper preparation or storage of food, lack of safety measures when caring for pet reptile

Risk for Shock: Risk factors: hypovolemia, diarrhea, sepsis

Readiness for Enhanced Health Self-Management: avoiding improperly prepared or stored food, wearing gloves when handling pet reptiles or their feces

See Gastroenteritis; Gastroenteritis, Child

Salpingectomy

Decisional Conflict r/t sterilization procedure

Maladaptive Grieving r/t possible loss from tubal pregnancy

Risk for Impaired Urinary Elimination: Risk factor: trauma to ureter during surgery

See Hysterectomy; Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Sarcoidosis

Anxiety r/t change in health status

Impaired Gas Exchange r/t ventilation-perfusion imbalance

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding home care and medication regimen

Acute Pain r/t possible disease affecting joints

Ineffective Protection r/t immune disorder

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: dysrhythmias

Risk for Impaired Skin integrity: Risk factor: immunological disorder

SBE (Self–Breast Examination)

Readiness for Enhanced Health Self-Management: desires to have information about SBE

Readiness for Enhanced Knowledge: SBE

Scabies

See Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice, Impetigo)

Scared

Anxiety r/t threat of death, threat to or change in health status

Death Anxiety r/t unresolved issues surrounding end-of-life decisions

Fear r/t hospitalization, real or imagined threat to own well-being

Impaired Individual Resilience r/t violence

Readiness for Enhanced Communication: willingness to share thoughts and feelings

Schizophrenia

Ineffective Activity Planning r/t compromised ability to process information

Anxiety r/t unconscious conflict with reality

Impaired Verbal Communication r/t psychosis, disorientation, inaccurate perception, hallucinations, delusions

Ineffective Coping r/t inadequate support systems, unrealistic perceptions, inadequate coping skills, disturbed thought processes, impaired communication

Decreased Diversional Activity Engagement r/t social isolation, possible regression

Interrupted Family Processes r/t inability to express feelings, impaired communication

Fear r/t altered contact with reality

Ineffective Health Maintenance Behaviors r/t cognitive impairment, ineffective individual and family coping, lack of material resources

Ineffective Family Health Self-Management r/t chronicity and unpredictability of condition

Ineffective Home Maintenance Behaviors r/t impaired cognitive or emotional functioning, insufficient finances, inadequate support systems

Hopelessness r/t long-term stress from chronic mental illness

Disturbed Personal Identity r/t psychiatric disorder

Impaired Memory r/t psychosocial condition

Imbalanced Nutrition: Less than Body Requirements r/t fear of eating, lack of awareness of hunger, disinterest toward food

Impaired Individual Resilience r/t psychological disorder

Self-Care Deficit: Specify r/t loss of contact with reality, impairment of perception

Self-Neglect r/t psychosis

Sleep Deprivation r/t intrusive thoughts, nightmares

Impaired Social Interaction r/t impaired communication patterns, self-concept disturbance, disturbed thought processes

Social Isolation r/t lack of trust, regression, delusional thinking, repressed fears

Chronic Sorrow r/t chronic mental illness

Spiritual Distress r/t loneliness, social alienation

Risk for Caregiver Role Strain: Risk factors: bizarre behavior of client, chronicity of condition

Risk for Compromised Human Dignity: Risk factor: stigmatizing label

Risk for Loneliness: Risk factor: inability to interact socially

Risk for Post-Trauma Syndrome: Risk factor: diminished ego strength

Risk for Powerlessness: Risk factor: intrusive, distorted thinking

Risk for Impaired Religiosity: Risk factors: ineffective coping, lack of security

Risk for Suicidal Behavior: Risk factor: psychiatric illness

Risk for Self-Directed Violence: Risk factors: lack of trust, panic, hallucinations, delusional thinking

Risk for Other-Directed Violence: Risk factor: psychotic disorder

Readiness for Enhanced Hope: expresses desire to enhance interconnectedness with others and problem-solve to meet goals

Readiness for Enhanced Power: expresses willingness to enhance participation in choices for daily living and health and enhance knowledge for participation in change

Sciatica

See Neuropathy, Peripheral

Scoliosis

Risk-Prone Health Behavior r/t lack of developmental maturity to comprehend long-term consequences of noncompliance with treatment procedures

Disturbed Body Image r/t use of therapeutic braces, postsurgery scars, restricted physical activity

Impaired Comfort r/t altered health status and body image

Impaired Gas Exchange r/t restricted lung expansion as a result of severe presurgery curvature of spine, immobilization

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding treatment modalities, restrictions, home care, postoperative activities

Impaired Physical Mobility r/t restricted movement, dyspnea caused by severe curvature of spine

Acute Pain r/t musculoskeletal restrictions, surgery, reambulation with cast or spinal rod

Impaired Skin Integrity r/t braces, casts, surgical correction

Chronic Sorrow r/t chronic disability

Risk for Perioperative Positioning Injury: Risk factor: prone position

Risk for Impaired Resilience: Risk factor: chronic condition

Readiness for Enhanced Health Self-Management: desires knowledge regarding treatment for condition

See Hospitalized Child; Maturational Issues, Adolescent

Sedentary Lifestyle

Decreased Activity Tolerance r/t sedentary lifestyle

Sedentary Lifestyle (See **Sedentary Lifestyle,** Section III)

Obesity (See **Obesity,** Section III)

Overweight (See **Overweight,** Section III)

Risk for Overweight (See **Overweight,** Section III)

Risk for Ineffective Peripheral Tissue Perfusion: Risk factor: insufficient knowledge of aggravating factors (e.g., immobility, obesity)

Readiness for Enhanced Coping: seeking knowledge of new strategies to adjust to sedentary lifestyle

Seizure Disorders, Adult

Acute Confusion r/t postseizure state

Social Isolation r/t unpredictability of seizures, community-imposed stigma

Risk for Ineffective Airway Clearance: Risk factor: accumulation of secretions during seizure

Risk for Child Falls: Risk factor: uncontrolled seizure activity

Risk for Powerlessness: Risk factor: possible seizure

Risk for Impaired Resilience: Risk factor: chronic illness

Readiness for Enhanced Knowledge: anticonvulsive therapy

Readiness for Enhanced Self-Care: expresses desire to enhance knowledge and responsibility for self-care

See Epilepsy

Seizure Disorders, Childhood (Epilepsy, Febrile Seizures, Infantile Spasms)

Ineffective Health Maintenance Behaviors r/t lack of knowledge regarding anticonvulsive therapy, fever reduction (febrile seizures)

Social Isolation r/t unpredictability of seizures, community-imposed stigma

Risk for Ineffective Airway Clearance: Risk factor: accumulation of secretions during seizure

Risk for Delayed Child Development: Risk factors: effects of seizure disorder, parental overprotection

Risk for Child Falls: Risk factor: possible seizure

Risk for Injury: Risk factors: uncontrolled movements during seizure, falls, drowsiness caused by anticonvulsants

See Epilepsy

Self–Breast Examination (SBE)

See SBE (Self–Breast Examination)

Self-Care

Readiness for Enhanced Self-Care (See **Self-Care, Readiness for Enhanced,** Section III)

Self-Care Deficit, Bathing

Bathing Self-Care Deficit (See **Self-Care Deficit, Bathing,** Section III)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Self-Care Deficit, Dressing

Dressing Self-Care Deficit (See **Self-Care Deficit, Dressing,** Section III)

Self-Care Deficit, Feeding

Feeding Self-Care Deficit (See **Self-Care Deficit, Feeding,** Section III)

Self-Care Deficit, Toileting

Toileting Self-Care Deficit (See **Self-Care Deficit, Toileting,** Section III)

Self-Concept

Readiness for Enhanced Self-Concept (See **Self-Concept, Readiness for Enhanced,** Section III)

Self-Destructive Behavior

Post-Trauma Syndrome r/t unresolved feelings from traumatic event

Risk for Self-Mutilation: Risk factors: feelings of depression, rejection, self-hatred, depersonalization; command hallucinations

Risk for Suicidal Behavior: Risk factor: history of self-destructive behavior

Risk for Self-Directed Violence: Risk factors: panic state, history of child abuse, toxic reaction to medication

Self-Esteem, Chronic Low

Chronic Low Self-Esteem (See **Self-Esteem, Low, Chronic,** Section III)

Risk for Disturbed Personal Identity: Risk factor: chronic low self-esteem

Self-Esteem, Situational Low

Situational Low Self-Esteem (See **Self-Esteem, Low, Situational,** Section III)

Risk for Situational Low Self-Esteem (See **Self-Esteem, Low, Situational, Risk For,** Section III)

Self-Mutilation

Ineffective Impulse Control r/t ineffective management of anxiety

Self-Mutilation (See **Self-Mutilation,** Section III)

Risk for Self-Mutilation (See **Self-Mutilation, Risk for,** Section III)

Senile Dementia

Ineffective Relationship r/t cognitive changes in one partner

Sedentary Lifestyle r/t lack of interest in movement

See Dementia

Separation Anxiety

Ineffective Coping r/t maturational and situational crises, vulnerability related to developmental age, hospitalization, separation from family and familiar surroundings, multiple caregivers

Insomnia r/t separation for significant others

Risk for Impaired Attachment: Risk factor: separation

See Hospitalized Child

Sepsis, Child

Impaired Gas Exchange r/t pulmonary inflammation associated with disease process

Imbalanced Nutrition: Less than Body Requirements r/t anorexia, generalized weakness, poor sucking reflex

Delayed Surgical Recovery r/t presence of infection

Ineffective Thermoregulation r/t infectious process, septic shock

Ineffective Peripheral Tissue Perfusion r/t arterial or venous blood flow exchange problems, septic shock

Risk for Deficient Fluid Volume: Risk factor: inflammation leading to decreased systemic vascular resistance

Risk for Impaired Skin Integrity: Risk factor: desquamation caused by disseminated intravascular coagulation

See Hospitalized Child; Premature Infant, Child

Septicemia

Imbalanced Nutrition: Less than Body Requirements r/t anorexia, generalized weakness

Ineffective Peripheral Tissue Perfusion r/t decreased systemic vascular resistance

Risk for Deficient Fluid Volume: Risk factors: vasodilation of peripheral vessels, leaking of capillaries

Risk for Shock: Risk factors: hypotension, hypovolemia

Risk for Unstable Blood Pressure: Risk factor: hypovolemia

See Sepsis, Child; Shock, Septic

Service Animal

Readiness for Enhanced Power: expresses desire to enhance independence with actions for change

Readiness for Enhanced Resilience: expresses desire to enhance involvement in activities, desire to enhance environmental safety

Severe Acute Respiratory Syndrome (SARS)

See Pneumonia

Sexual Dysfunction

Sexual Dysfunction r/t insufficient knowledge about sexual function

Ineffective Relationship r/t reported sexual dissatisfaction between partners

Chronic Sorrow r/t loss of ideal sexual experience, altered relationships

Risk for Situational Low Self-Esteem: Risk factor: alteration in body function

See Erectile Dysfunction (ED)

Sexual Harassment Victim

Anxiety r/t situational crisis

Risk for Compromised Human Dignity: Risk factors: humiliation, dehumanizing treatment

Risk for Post-Trauma Syndrome: Risk factors: perceived traumatic event, insufficient social support

Risk for Spiritual Distress: Risk factors: physical, psychological stress

See Assault Victim

Sexuality, Adolescent

Disturbed Body Image r/t anxiety caused by unachieved developmental milestone (puberty) or deficient knowledge regarding reproductive maturation with expressed concerns regarding lack of growth of secondary sex characteristics

Impaired Emancipated Decision-Making: Sexual Activity r/t undefined personal values or beliefs, multiple or divergent sources of information, lack of relevant information

Ineffective Impulse control r/t denial of consequences of actions

Deficient Knowledge: Potential for Enhanced Health Self-Maintenance r/t multiple or divergent sources of information or lack of relevant information regarding sexual transmission of disease, contraception, prevention of toxic shock syndrome

See Maturational Issues, Adolescent

Sexuality Pattern, Ineffective

Ineffective Sexuality Pattern (See **Sexuality Pattern, Ineffective,** Section III)

Sexually Transmitted Disease (STD)

See STD (Sexually Transmitted Disease)

Shaken Baby Syndrome

Impaired Parenting r/t stress, history of being abusive

Impaired Individual Resilience r/t poor impulse control

Stress Overload r/t intense repeated family stressors, family violence

Risk for Other-Directed Violence: Risk factors: history of violence against others, perinatal complications

See Child Abuse; Suspected Child Abuse and Neglect (SCAN), Child; Suspected Child Abuse and Neglect (SCAN), Parent

Shakiness

Anxiety r/t situational or maturational crisis, threat of death

Shame

Situational Low Self-Esteem r/t inability to deal with past traumatic events, blaming of self for events not in one's control

Shingles

Acute Pain r/t vesicular eruption along the nerves

Ineffective Protection r/t abnormal blood profiles

Social Isolation r/t altered state of wellness, contagiousness of disease

Risk for Infection: Risk factor: tissue destruction

See Itching

Shivering

Impaired Comfort r/t altered health status

Fear r/t serious threat to health status

Hypothermia r/t exposure to cool environment

Ineffective Thermoregulation r/t serious infectious process resulting in immune response of fever

See Shock, Septic

Shock, Cardiogenic

Decreased Cardiac Output r/t decreased myocardial contractility, dysrhythmia

Shock, Hypovolemic

Deficient Fluid Volume r/t abnormal loss of fluid, trauma, third spacing

Shock, Septic

Deficient Fluid Volume r/t abnormal loss of intravascular fluid, pooling of blood in peripheral circulation, overwhelming inflammatory response

Ineffective Protection r/t inadequately functioning immune system

See Sepsis, Child; Septicemia

Shoulder Repair

Self-Care Deficit: Bathing, Dressing, Feeding r/t immobilization of affected shoulder

Risk for Perioperative Positioning Injury: Risk factor: immobility

See Surgery, Preoperative Care; *Surgery, Perioperative Care*; *Surgery, Postoperative Care*; *Total Joint Replacement (Total Hip/Total Knee/Shoulder)*

Sickle Cell Anemia/Crisis

Decreased Activity Tolerance r/t fatigue, effects of chronic anemia

Deficient Fluid Volume r/t decreased intake, increased fluid requirements during sickle cell crisis, decreased ability of kidneys to concentrate urine

Impaired Physical Mobility r/t pain, fatigue

Acute Pain r/t viscous blood, tissue hypoxia

Ineffective Peripheral Tissue Perfusion r/t effects of red cell sickling, infarction of tissues

Risk for Decreased Cardiac Tissue Perfusion: Risk factors: effects of red cell sickling, infarction of tissues

Risk for Infection: Risk factor: alterations in splenic function

Risk for Impaired Resilience: Risk factor: chronic illness

Risk for Ineffective Cerebral Tissue Perfusion: Risk factors: effects of red cell sickling, infarction of tissues

See Child with Chronic Condition; Hospitalized Child

SIDS (Sudden Infant Death Syndrome)

Anxiety: Parental Worry r/t life-threatening event

Interrupted Family Processes r/t stress as a result of special care needs of infant with apnea

Maladaptive Grieving r/t potential loss of infant

Insomnia: Parental/Infant r/t home apnea monitoring

Deficient Knowledge: Potential For Enhanced Health Self-Maintenance r/t knowledge or skill acquisition of cardiopulmonary resuscitation and home apnea monitoring

Impaired Resilience r/t sudden loss

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Risk for Sudden Infant Death (See **Sudden Infant Death, Risk for,** Section III)

Risk for Powerlessness: Risk factor: unanticipated life-threatening event

See Terminally Ill Child/Death of Child, Parent

Sitting Problems

Impaired Sitting (See **Sitting, Impaired,** Section III)

Situational Crisis

Imbalanced Energy Field r/t hyperactivity of the energy flow

Ineffective Coping r/t situational crisis

Interrupted Family Processes r/t situational crisis

Risk for Ineffective Activity Planning: Risk factor: inability to process information

Risk for Disturbed Personal Identity: Risk factor: situational crisis

Readiness for Enhanced Communication: willingness to share feelings and thoughts

Readiness for Enhanced Religiosity: requests religious material and/or experiences

Readiness for Enhanced Resilience: desire to enhance resilience

Readiness for Enhanced Spiritual Well-Being: desire for harmony following crisis

SJS (Stevens-Johnson Syndrome)

See Stevens-Johnson Syndrome (SJS)

Skin Cancer

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding self-care with skin cancer

Ineffective Protection r/t weakened immune system

Impaired Tissue Integrity r/t abnormal cell growth in skin, treatment of skin cancer

Readiness for Enhanced Health Self-Management: follows preventive measures

Readiness for Enhanced Knowledge: self-care to prevent and treat skin cancer

Skin Disorders

Impaired Skin Integrity (See **Skin Integrity, Impaired,** Section III)

Skin Turgor, Change in Elasticity

Deficient Fluid Volume r/t active fluid loss

Sleep

Readiness for Enhanced Sleep (See **Sleep, Readiness for Enhanced,** Section III)

Sleep Apnea

Ineffective Breathing Pattern r/t obesity, substance misuse, enlarged tonsils, smoking, or neurological pathology such as a brain tumor

Impaired Comfort r/t use of bilevel positive airway pressure (BiPAP)/continuous positive airway pressure (CPAP) machine

Sleep Deprivation

Fatigue r/t lack of sleep

Sleep Deprivation (See **Sleep Deprivation,** Section III)

Insomnia (See **Insomnia,** Section III)

Sleep Problems

Insomnia (See **Insomnia,** Section III)

Sleep Pattern, Disturbed, Parent/Child

Insomnia: Child r/t anxiety or fear

Insomnia: Parent r/t parental responsibilities, stress

See Suspected Child Abuse and Neglect (SCAN), Child; Suspected Child Abuse and Neglect (SCAN), Parent

Slurring of Speech

Impaired Verbal Communication r/t decrease in circulation to brain, brain tumor, anatomical defect, cleft palate

Situational Low Self-Esteem r/t speech impairment

See Communication Problems

Small Bowel Resection

See Abdominal Surgery

Smell, Loss of Ability to

Risk for Injury: Risk factors: inability to detect gas fumes, smoke smells

See Anosmia (Smell, Loss of Ability to)

Smoke Inhalation

Ineffective Airway Clearance r/t smoke inhalation

Impaired Gas Exchange r/t ventilation-perfusion imbalance

Risk for Acute Confusion: Risk factor: decreased oxygen supply

Risk for Infection: Risk factors: inflammation, ineffective airway clearance, pneumonia

Risk for Poisoning: Risk factor: exposure to carbon monoxide

Readiness for Enhanced Health Self-Management: functioning smoke detectors and carbon monoxide detectors in home and work, escape route planned and reviewed

See Atelectasis; Burns; Pneumonia

Smoking Behavior

Insufficient Breast Milk Production r/t smoking

Risk-Prone Health Behavior Risk factor: smoking

Ineffective Health Maintenance Behaviors r/t denial of effects of smoking, lack of effective support for smoking withdrawal

Readiness for Enhanced Knowledge: expresses interest in smoking cessation

Risk for Dry Eye: Risk factor: smoking

Risk for Ineffective Peripheral Tissue Perfusion: Risk factor: effect of nicotine

Risk for Thermal Injury: Risk factor: unsafe smoking behavior

Readiness for Enhanced Health Literacy: verbalizes desire to enhance understanding of health information to make health care choices

Social Interaction, Impaired

Impaired Social Interaction (See **Social Interaction, Impaired,** Section III)

Social Isolation

Social Isolation (See **Social Isolation,** Section III)

Sociopathic Personality

See Antisocial Personality Disorder

Sodium, Decrease/Increase

See Hyponatremia; Hypernatremia

Somatization Disorder

Anxiety r/t unresolved conflicts channeled into physical complaints or conditions

Ineffective Coping r/t lack of insight into underlying conflicts

Ineffective Denial r/t displaced psychological stress to physical symptoms

Nausea r/t anxiety

Chronic Pain r/t unexpressed anger, multiple physical disorders, depression

Impaired Individual Resilience r/t possible psychological disorders

Sore Nipples, Breastfeeding

Ineffective Breastfeeding r/t deficient knowledge regarding correct feeding procedure

Nipple-Areolar Complex Injury r/t breast engorgement

See Painful Breasts, Sore Nipples

Sore Throat

Impaired Comfort r/t sore throat

Deficient Knowledge r/t treatment, relief of discomfort

Impaired Oral Mucous Membrane Integrity r/t inflammation or infection of oral cavity

Impaired Swallowing r/t irritation of oropharyngeal cavity

Risk for Dry Mouth: Risk factor: painful swallowing

Sorrow

Maladaptive Grieving r/t loss of significant person, object, or role

Chronic Sorrow (See **Sorrow, Chronic,** Section III)

Readiness for Enhanced Communication: expresses thoughts and feelings

Readiness for Enhanced Spiritual Well-Being: desire to find purpose and meaning of loss

Spastic Colon

See IBS (Irritable Bowel Syndrome)

Speech Disorders

Anxiety r/t difficulty with communication

Impaired Verbal Communication r/t anatomical defect, cleft palate, psychological barriers, decrease in circulation to brain

Spina Bifida

See Neural Tube Defects (Meningocele, Myelomeningocele, Spina Bifida, Anencephaly)

Spinal Cord Injury

Decreased Diversional Activity Engagement r/t long-term hospitalization, frequent lengthy treatments

Fear r/t powerlessness over loss of body function

Disturbed Body Image r/t alteration in body function

Chronic Functional Constipation r/t inhibition of reflex arc

Maladaptive Grieving r/t loss of usual body function

Ineffective Coping r/t inability to meet basic needs and insufficient sense of control

Sedentary Lifestyle r/t lack of resources or interest

Impaired Physical Mobility r/t neuromuscular impairment

Impaired Wheelchair Mobility r/t neuromuscular impairment

Impaired Standing r/t spinal cord injury

Urinary Retention r/t inhibition of reflex arc

Risk for Autonomic Dysreflexia: Risk factors: bladder or bowel distention, skin irritation, deficient knowledge of client and caregiver

Risk for Ineffective Breathing Pattern: Risk factor: neuromuscular impairment

Risk for Infection: Risk factors: chronic disease, stasis of body fluids

Risk for Loneliness: Risk factor: physical immobility

Risk for Powerlessness: Risk factor: loss of function

Risk for Adult Pressure Injury: Risk factor: immobility and decreased sensation

Risk for Child Pressure Injury: Risk factor: immobility and decreased sensation

Risk for Thermal Injury: Risk factor: physical immobility

Risk for Thrombosis: Risk factor: physical immobility

See Child with Chronic Condition; Hospitalized Child; Neural Tube Defects (Meningocele, Myelomeningocele, Spina Bifida, Anencephaly); Paralysis

Spinal Fusion

Impaired Bed Mobility r/t impaired ability to turn side to side while keeping spine in proper alignment

Impaired Physical Mobility r/t musculoskeletal impairment associated with surgery, possible back brace

Readiness for Enhanced Knowledge: expresses interest in information associated with surgery

Risk for Adult Pressure Injury: Risk factor: immobility

Risk for Child Pressure Injury: Risk factor: immobility

See Acute Back Pain; Scoliosis; Surgery, Preoperative Care; Surgery, Perioperative Care; Surgery, Postoperative Care

Spiritual Distress

Spiritual Distress (See **Spiritual Distress,** Section III)

Risk for Chronic Low Self-Esteem: Risk factor: unresolved spiritual issues

Risk for Spiritual Distress (See **Spiritual Distress, Risk for,** Section III)

S

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Spiritual Well-Being

Readiness for Enhanced Spiritual Well-Being (See **Spiritual Well-Being, Readiness for Enhanced,** Section III)

Splenectomy

See Abdominal Surgery

Sprains

Acute Pain r/t physical injury

Impaired Physical Mobility r/t injury

Impaired Walking r/t injury

Stable Blood Pressure, Risk for Unstable

Deficient Knowledge r/t inconsistency with medication regimen (See **Unstable Blood Pressure, Risk for,** Section III)

Standing Problems

Impaired Standing (See **Impaired Standing,** Section III)

Stapedectomy

Hearing Loss r/t edema from surgery

Acute Pain r/t headache

Risk for Adult Falls: Risk factor: dizziness

Risk for Infection: Risk factor: invasive procedure

Stasis Ulcer

Impaired Tissue Integrity r/t chronic venous congestion

Risk for Infection: Risk factor: open wound

See CHF (Congestive Heart Failure); Varicose Veins

STD (Sexually Transmitted Disease)

Impaired Comfort r/t infection

Fear r/t altered body function, risk for social isolation, fear of incurable illness

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding transmission, symptoms, treatment of STD

Ineffective Sexuality Pattern r/t illness, altered body function, need for abstinence to heal

Social Isolation r/t fear of contracting or spreading disease

Risk for Infection: Spread of Infection: Risk factor: lack of knowledge concerning transmission of disease

Readiness for Enhanced Knowledge: seeks information regarding prevention and treatment of STDs

See Maturational Issues, Adolescent; PID (Pelvic Inflammatory Disease)

STEMI (ST-Elevation Myocardial Infarction)

See MI (Myocardial Infarction)

Stent (Coronary Artery Stent)

Risk for Injury: Risk factor: complications associated with stent placement

Risk for Decreased Cardiac Tissue Perfusion: Risk factor: possible restenosis

Risk for Vascular Trauma: Risk factors: insertion site, catheter width

Readiness for Enhanced Decision-Making: expresses desire to enhance risk-benefit analysis, understanding and meaning of choices, and decisions regarding treatment

See Angioplasty, Coronary; Cardiac Catheterization

Sterilization Surgery

Decisional Conflict r/t multiple or divergent sources of information, unclear personal values or beliefs

See Surgery, Preoperative Care; Surgery, Perioperative Care; Surgery, Postoperative Care; Tubal Ligation; Vasectomy

Stertorous Respirations

Ineffective Airway Clearance r/t pharyngeal obstruction

Stevens-Johnson Syndrome (SJS)

Impaired Oral Mucous Membrane Integrity r/t immunocompromised condition associated with allergic medication reaction

Acute Pain r/t painful skin lesions and painful mucosa lesions

Impaired Skin Integrity r/t allergic medication reaction

Risk for Deficient Fluid Volume: Risk factors: factors affecting fluid needs (hypermetabolic state, fever), excessive losses through normal routes (vomiting and diarrhea)

Risk for Infection: Risk factor: sloughing skin

Risk for Impaired Liver Function: Risk factor: impaired immune response

Stillbirth

See Pregnancy Loss

Stoma

See Colostomy; Ileostomy

Stomatitis

Impaired Oral Mucous Membrane Integrity r/t pathological conditions of oral cavity; side effects of chemotherapy

Risk for Impaired Oral Mucous Membrane Integrity (See **Impaired Oral Mucous Membrane Integrity, Risk for,** Section III)

Stool, Hard/Dry

Chronic Functional Constipation r/t inadequate fluid intake, inadequate fiber intake, decreased activity level, decreased gastric motility

Straining with Defecation

Chronic Functional Constipation r/t less than adequate fluid intake, less than adequate dietary intake

Risk for Decreased Cardiac Output: Risk factor: vagal stimulation with dysrhythmia resulting from Valsalva maneuver

Strep Throat

Risk for Infection: Risk factor: exposure to pathogen

See Sore Throat

Stress

Anxiety r/t feelings of helplessness, feelings of being threatened

Ineffective Coping r/t ineffective use of problem-solving process, feelings of apprehension or helplessness

Fear r/t powerlessness over feelings

Stress Overload r/t intense or multiple stressors

Readiness for Enhanced Communication: shows willingness to share thoughts and feelings

Readiness for Enhanced Spiritual Well-Being: expresses desire for harmony and peace in stressful situation

See Anxiety

Stress Urinary Incontinence

Stress Urinary Incontinence r/t degenerative change in pelvic muscles

Stridor

Ineffective Airway Clearance r/t obstruction, tracheobronchial infection, trauma

Stroke

See CVA (Cerebrovascular Accident)

Stuttering

Anxiety r/t impaired verbal communication

Impaired Verbal Communication r/t anxiety, psychological problems

Subarachnoid Hemorrhage

Acute Pain: Headache r/t irritation of meninges from blood, increased intracranial pressure

Risk for Ineffective Cerebral Tissue Perfusion: Risk factor: bleeding from cerebral vessel

See Intracranial Pressure, Increased

Substance Misuse

Acute Substance Withdrawal Syndrome: Risk factor: developed dependence to alcohol or other addictive substances

Anxiety r/t threat to self-concept, lack of control of drug use

Compromised Family Coping r/t codependency issues

Defensive Coping r/t substance misuse

Disabled Family Coping r/t differing coping styles between support persons

Ineffective Coping r/t use of substances to cope with life events

Ineffective Denial r/t refusal to acknowledge substance misuse problem

Dysfunctional Family Processes r/t substance misuse

Risk-Prone Health behavior r/t addiction

Deficient Community Health r/t prevention and control of illegal substances in community

Ineffective Impulse Control r/t addictive process

Insomnia r/t irritability, nightmares, tremors

Imbalanced Nutrition: Less than Body Requirements r/t poor eating habits

Powerlessness r/t feeling unable to change patterns of drug abuse

Ineffective Relationship r/t inability for well-balanced collaboration between partners

Sexual Dysfunction r/t actions and side effects of drugs

Sleep Deprivation r/t prolonged psychological discomfort

Impaired Social Interaction r/t disturbed thought processes from drug abuse

Risk for Acute Substance Withdrawal Syndrome: Risk factor: developed dependence to alcohol or other addictive substances

Risk for Impaired Attachment: Risk factor: substance misuse

Risk for Injury: Risk factors: hallucinations, drug effects

Risk for Disturbed Personal Identity: Risk factor: ingestion/inhalation of toxic chemicals

Risk for Chronic Low Self-Esteem: Risk factors: perceived lack of respect from others, repeated failures, repeated negative reinforcement

Risk for Thermal Injury: Risk factor: intoxication with drugs or alcohol

Risk for Unstable Blood Pressure: Risk factor: vasoconstriction of cardiac arteries

Risk for Vascular Trauma: Risk factor: chemical irritant self injected into veins

Risk for Self-Directed Violence: Risk factors: reactions to substances used, impulsive behavior, disorientation, impaired judgment

Risk for Other-Directed Violence: Risk factor: poor impulse control

Readiness for Enhanced Coping: seeking social support and knowledge of new strategies

Readiness for Enhanced Self-Concept: accepting strengths and limitations

See Alcoholism

Substance Misuse, Adolescent

See Alcoholism; Maturational Issues, Adolescent; Substance Misuse

Substance Misuse in Pregnancy

Ineffective Childbearing Process r/t substance misuse

Defensive Coping r/t denial of situation, differing value system

Ineffective Health Self-Management r/t addiction

Deficient Knowledge r/t lack of exposure to information regarding effects of substance misuse in pregnancy

Neonatal Abstinence Syndrome r/t in utero substance exposure secondary to maternal substance use

Risk for Impaired Attachment: Risk factors: substance misuse, inability of parent to meet infant's or own personal needs

Risk for Infection: Risk factors: intravenous drug use, lifestyle

Risk for Injury: Fetal: Risk factor: effects of drugs on fetal growth and development

Risk for Injury: Maternal: Risk factor: drug or alcohol misuse

Risk for Impaired Parenting: Risk factor: lack of ability to meet infant's needs due to addiction with use of alcohol or drugs

See Alcoholism; Substance Misuse

Substance Withdrawal

See Acute Substance Withdrawal Syndrome

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Sucking Reflex

Effective Breastfeeding r/t regular and sustained sucking and swallowing at breast

Sudden Infant Death Syndrome (SIDS)

See SIDS (Sudden Infant Death Syndrome)

Suffocation, Risk for

Risk for Suffocation (See **Suffocation, Risk for,** Section III)

Suicide Attempt

Risk-Prone Health Behavior r/t low self-efficacy

Ineffective Coping r/t anger, complicated grieving

Hopelessness r/t perceived or actual loss, substance misuse, low self-concept, inadequate support systems

Ineffective Impulse Control r/t inability to modulate stress, anxiety

Post-Trauma Syndrome r/t history of traumatic events, abuse, rape, incest, war, torture

Impaired Individual Resilience r/t poor impulse control

Situational Low Self-Esteem r/t guilt, inability to trust, feelings of worthlessness or rejection

Social Isolation r/t inability to engage in satisfying personal relationships

Spiritual Distress r/t hopelessness, despair

Risk for Post-Trauma Syndrome: Risk factor: survivor's role in suicide attempt

Risk for Suicidal Behavior (See **Suicide, Risk for,** Section III)

Readiness for Enhanced Communication: willingness to share thoughts and feelings

Readiness for Enhanced Spiritual Well-Being: desire for harmony and inner strength to help redefine purpose for life

See Violent Behavior

Support System, Inadequate

Readiness for Enhanced Family Coping: ability to adapt to tasks associated with care, support of significant other during health crisis

Readiness for Enhanced Family Processes: activities support the growth of family members

Readiness for Enhanced Parenting: children or other dependent person(s) expressing satisfaction with home environment

Suppression of Labor

See Preterm Labor

Surgery, Perioperative Care

Risk for Imbalanced Fluid Volume: Risk factor: surgery

Risk for Perioperative Hypothermia: Risk factors: inadequate covering of client, cold surgical room

Risk for Perioperative Positioning Injury: Risk factors: predisposing condition, prolonged surgery

Surgery, Postoperative Care

Decreased Activity Tolerance r/t pain, surgical procedure

Anxiety r/t change in health status, hospital environment

Deficient Knowledge r/t postoperative expectations, lifestyle changes

Nausea r/t manipulation of gastrointestinal tract, postsurgical anesthesia

Imbalanced Nutrition: Less than Body Requirements r/t anorexia, nausea, vomiting, decreased peristalsis

Ineffective Peripheral Tissue Perfusion r/t hypovolemia, circulatory stasis, obesity, prolonged immobility, decreased coughing, decreased deep breathing

Acute Pain r/t inflammation or injury in surgical area

Delayed Surgical Recovery r/t extensive surgical procedure, postoperative surgical infection

Urinary Retention r/t anesthesia, pain, fear, unfamiliar surroundings, client's position

Risk for Bleeding: Risk factor: surgical procedure

Risk for Ineffective Breathing Pattern: Risk factors: pain, location of incision, effects of anesthesia or opioids

Risk for Constipation: Risk factors: decreased activity, decreased food or fluid intake, anesthesia, pain medication

Risk for Imbalanced Fluid Volume: Risk factors: hypermetabolic state, fluid loss during surgery, presence of indwelling tubes, fluids used to distend organ structures being absorbed into body

Risk for Surgical Site Infection: Risk factors: invasive procedure, pain, anesthesia, location of incision, weakened cough as a result of aging

Surgery, Preoperative Care

Anxiety r/t threat to or change in health status, situational crisis, fear of the unknown

Insomnia r/t anxiety about upcoming surgery

Deficient Knowledge r/t preoperative procedures, postoperative expectations

Readiness for Enhanced Knowledge: shows understanding of preoperative and postoperative expectations for self-care

Surgical Recovery, Delayed

Delayed Surgical Recovery (See **Surgical Recovery, Delayed,** Section III)

Risk for Delayed Surgical Recovery (See **Surgical Recovery, Delayed, Risk for,** Section III)

Surgical Site Infection

Anxiety r/t unforeseen result of surgery

Impaired Comfort r/t surgical site pain

Risk for Ineffective Thermoregulation: Risk factor: infectious process

Risk for Delayed Surgical Recovery: Risk factor: interrupted healing of surgical site

Readiness for Enhanced Knowledge: expresses desire for knowledge of prevention and symptoms of infection

Suspected Child Abuse and Neglect (SCAN), Child

Ineffective Activity Planning r/t lack of family support

Anxiety: Child r/t threat of punishment for perceived wrongdoing

Deficient Community Health r/t inadequate reporting and follow-up of SCAN

Disturbed Personal Identity r/t dysfunctional family processes

Rape-Trauma Syndrome r/t altered lifestyle because of abuse, changes in residence

Risk for Impaired Resilience: Risk factor: adverse situation

Readiness for Enhanced Community Coping: obtaining resources to prevent child abuse, neglect

See Child Abuse; Hospitalized Child; Maturational Issues, Adolescent

Suspected Child Abuse and Neglect (SCAN), Parent

Disabled Family Coping r/t dysfunctional family, underdeveloped nurturing parental role, lack of parental support systems or role models

Dysfunctional Family Processes r/t inadequate coping skills

Ineffective Health Maintenance Behaviors r/t deficient knowledge of parenting skills as result of unachieved developmental tasks

Impaired Home Maintenance r/t disorganization, parental dysfunction, neglect of safe and nurturing environment

Ineffective Impulse Control r/t projection of anger, frustration onto child

Impaired Parenting r/t unrealistic expectations of child; lack of effective role model; unmet social, emotional, or maturational needs of parents; interruption in bonding process

Impaired Individual Resilience r/t poor impulse control

Chronic Low Self-Esteem r/t lack of successful parenting experiences

Risk for Other-Directed Violence: Parent to Child: Risk factors: inadequate coping mechanisms, unresolved stressors, unachieved maturational level by parent

Suspicion

Disturbed Personal Identity r/t psychiatric disorder

Powerlessness r/t repetitive paranoid thinking

Impaired Social Interaction r/t disturbed thought processes, paranoid delusions, hallucinations

Disturbed Thought Process r/t psychiatric disorder

Risk for Self-Directed Violence: Risk factor: inability to trust

Risk for Other-Directed Violence: Risk factor: impulsiveness

Swallowing Difficulties

Impaired Swallowing (See **Swallowing, Impaired,** Section III)

Risk for Aspiration r/t difficulty swallowing

Syncope

Anxiety r/t fear of falling

Impaired Physical Mobility r/t fear of falling

Ineffective Health Management Behaviors r/t lack of knowledge in how to prevent syncope

Social Isolation r/t fear of falling

Risk for Decreased Cardiac Output: Risk factor: dysrhythmia

Risk for Adult Falls: Risk factor: syncope

Risk for Injury: Risk factors: altered sensory perception, transient loss of consciousness, risk for falls

Risk for Ineffective Cerebral Tissue Perfusion: Risk factor: interruption of blood flow

Syphilis

See STD (Sexually Transmitted Disease)

Systemic Lupus Erythematosus

See Lupus Erythematosus

T

T & A (Tonsillectomy and Adenoidectomy)

Ineffective Airway Clearance r/t hesitation or reluctance to cough because of pain

Deficient Knowledge: Potential for Enhanced Health Maintenance Behaviors r/t insufficient knowledge regarding postoperative nutritional and rest requirements, signs and symptoms of complications, positioning

Nausea r/t gastric irritation, pharmaceuticals, anesthesia

Acute Pain r/t surgical incision

Risk for Aspiration: Risk factors: postoperative drainage and impaired swallowing

Risk for Deficient Fluid Volume: Risk factors: decreased intake because of painful swallowing, effects of anesthesia (nausea, vomiting), hemorrhage

Risk for Imbalanced Nutrition: Less than Body Requirements: Risk factors: hesitation or reluctance to swallow

Tachycardia

See Dysrhythmia

Tachypnea

Ineffective Breathing Pattern r/t pain, anxiety, hypoxia

See cause of Tachypnea

Tardive Dyskinesia

Ineffective Health Self-Management r/t complexity of therapeutic regimen or medication

Deficient Knowledge r/t cognitive limitation in assimilating information relating to side effects associated with neuroleptic medications

Risk for Injury: Risk factor: drug-induced abnormal body movements

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Taste Abnormality

Frail Elderly Syndrome r/t chronic illness

TB (Pulmonary Tuberculosis)

Ineffective Airway Clearance r/t increased secretions, excessive mucus

Ineffective Breathing Pattern r/t decreased energy, fatigue

Fatigue r/t disease state

Impaired Gas Exchange r/t disease process

Ineffective Health Self-Management r/t deficient knowledge of prevention and treatment regimen

Ineffective Home Maintenance Behaviors r/t client or family member with disease

Ineffective Thermoregulation r/t presence of infection

Risk for Infection: Risk factor: insufficient knowledge regarding avoidance of exposure to pathogens

Readiness for Enhanced Health Self-Management: takes medications according to prescribed protocol for prevention and treatment

TBI (Traumatic Brain Injury)

Interrupted Family Processes r/t traumatic injury to family member

Chronic Sorrow r/t change in health status and functional ability

Risk for Post-Trauma Syndrome: Risk factor: perception of event causing TBI

Risk for Impaired Religiosity: Risk factor: impaired physical mobility

Risk for Impaired Resilience: Risk factor: crisis of injury

See Head Injury; Neurologic Disorders

TD (Traveler's Diarrhea)

See Traveler's Diarrhea (TD)

Technology Addiction

Decreased Diversional Activity Engagement r/t insufficient motivation to separate from electronic devices

Impaired Social Interaction r/t lack of desire to engage in personal face-to-face contact with others

Risk for Impaired Attachment: Risk factor: preoccupation with electronic devices

Risk for Impaired Parenting: Risk factor: insufficient uninterrupted meaningful interaction between parent and child as the result of preoccupation with electronic devices

Risk for Ineffective Relationship: Risk factor: ineffective face-to-face communication skills

Temperature, Decreased

Hypothermia r/t exposure to cold environment

Temperature, High

Hyperthermia r/t neurological damage, disease condition with high temperature, excessive heat, inflammatory response

Temperature Regulation, Impaired

Ineffective Thermoregulation r/t trauma, illness, cerebral injury

TEN (Toxic Epidermal Necrolysis)

See Toxic Epidermal Necrolysis (TEN)

TENS Unit (Transcutaneous Electrical Nerve Stimulation)

Risk for Unstable Blood Pressure: Risk factor: improper use of TENS unit (front of neck)

Readiness for Enhanced Comfort: expresses desire to enhance resolution of complaints

Tension

Anxiety r/t threat to or change in health status, situational crisis

Readiness for Enhanced Communication: expresses willingness to share feelings and thoughts

See Stress

Terminally Ill Adult

Death Anxiety r/t unresolved issues relating to death and dying

Imbalanced Energy Field r/t weak energy field patterns

Risk for Spiritual Distress: Risk factor: impending death

Readiness for Enhanced Religiosity: requests religious material and/or experiences

Readiness for Enhanced Spiritual Well-Being: desire to achieve harmony of mind, body, spirit

See Terminally Ill Child/Death of Child, Parent

Terminally Ill Child, Adolescent

Disturbed Body Image r/t effects of terminal disease, already critical feelings of group identity and self-image

Ineffective Coping r/t inability to establish personal and peer identity because of the threat of being different or not being healthy, inability to achieve maturational tasks

Impaired Social Interaction r/t forced separation from peers

See Child with Chronic Condition; Hospitalized Child, Terminally Ill Child/Death of Child, Parent

Terminally Ill Child, Infant/Toddler

Ineffective Coping r/t separation from parents and familiar environment from inability to understand dying process

See Child with Chronic Condition, Terminally Ill Child/Death of Child, Parent

Terminally Ill Child, Preschool Child

Fear r/t perceived punishment, bodily harm, feelings of guilt caused by magical thinking (i.e., believing that thoughts cause events)

See Child with Chronic Condition, Terminally Ill Child/Death of Child, Parent

Terminally Ill Child, School-Age Child/Preadolescent

Fear r/t perceived punishment, body mutilation, feelings of guilt

Maladaptive Grieving r/t difficulty dealing with concurrent crises

See Child with Chronic Condition, Terminally Ill Child/Death of Child, Parent

Terminally Ill Child/Death of Child, Parent

Compromised Family Coping r/t inability or unwillingness to discuss impending death and feelings with child or support child through terminal stages of illness

Decisional Conflict r/t continuation or discontinuation of treatment, do-not-resuscitate decision, ethical issues regarding organ donation

Ineffective Denial r/t complicated grieving

Interrupted Family Processes r/t situational crisis

Maladaptive Grieving r/t death of child

Hopelessness r/t overwhelming stresses caused by terminal illness

Insomnia r/t grieving process

Impaired Parenting r/t risk for overprotection of surviving siblings

Powerlessness r/t inability to alter course of events

Impaired Social Interaction r/t complicated grieving

Social Isolation: Imposed by Others r/t feelings of inadequacy in providing support to grieving parents

Social Isolation: Self-Imposed r/t unresolved grief, perceived inadequate parenting skills

Spiritual Distress r/t sudden and unexpected death, prolonged suffering before death, questioning the death of youth, questioning the meaning of one's own existence

Risk for Maladaptive Grieving: Risk factors: prolonged, unresolved, obstructed progression through stages of grief and mourning

Risk for Impaired Resilience: Risk factor: impending death

Readiness for Enhanced Family Coping: impact of crisis on family values, priorities, goals, or relationships; expressed interest or desire to attach meaning to child's life and death

Tetralogy of Fallot

See Congenital Heart Disease/Cardiac Anomalies

Tetraplegia

Autonomic Dysreflexia r/t bladder or bowel distention, skin irritation, infection, deficient knowledge of client and caregiver

Maladaptive Grieving r/t loss of previous functioning

Powerlessness r/t inability to perform previous activities

Impaired Sitting r/t paralysis of extremities

Impaired Spontaneous Ventilation r/t loss of innervation of respiratory muscles, respiratory muscle fatigue

Risk for Aspiration: Risk factor: inadequate ability to protect airway from neurological damage

Risk for Infection: Risk factor: urinary stasis

Risk for Impaired Skin Integrity: Risk factor: physical immobilization and decreased sensation

Risk for Adult Pressure Injury: Risk factor: immobility and sensory loss

Risk for Child Pressure Injury: Risk factor: immobility and sensory loss

Risk for Ineffective Thermoregulation: Risk factors: inability to move to increase temperature, possible presence of infection to increase temperature

Thermoregulation, Ineffective

Ineffective Thermoregulation (See **Thermoregulation, Ineffective,** Section III)

Risk for Ineffective Thermoregulation (See **Ineffective Thermoregulation, Risk for,** Section III)

Thoracentesis

See Pleural Effusion

Thoracotomy

Decreased Activity Tolerance r/t pain, imbalance between oxygen supply and demand, presence of chest tubes

Ineffective Airway Clearance r/t drowsiness, pain with breathing and coughing

Ineffective Breathing Pattern r/t decreased energy, fatigue, pain

Deficient Knowledge r/t self-care, effective breathing exercises, pain relief

Acute Pain r/t surgical procedure, coughing, deep breathing

Risk for Bleeding: Risk factor: surgery

Risk for Surgical Site Infection: Risk factor: invasive procedure

Risk for Injury: Risk factor: disruption of closed-chest drainage system

Risk for Perioperative Positioning Injury: Risk factors: lateral positioning, immobility

Risk for Vascular Trauma: Risk factors: chemical irritant; antibiotics

Thought Disorders

See Schizophrenia

Thrombocytopenic Purpura

See ITP (Idiopathic Thrombocytopenic Purpura)

Thrombophlebitis

See Deep Vein Thrombosis (DVT)

Thyroidectomy

Risk for Ineffective Airway Clearance: Risk factor: edema or hematoma formation, airway obstruction

Risk for Impaired Verbal Communication: Risk factors: edema, pain, vocal cord or laryngeal nerve damage

Risk for Injury: Risk factor: possible parathyroid damage or removal

See Surgery, Preoperative Care; Surgery, Perioperative Care; Surgery, Postoperative Care

TIA (Transient Ischemic Attack)

Acute Confusion r/t hypoxia

Readiness for Enhanced Health Self-Management: obtains knowledge regarding treatment prevention of inadequate oxygenation

See Syncope

Tic Disorder

See Tourette's Syndrome (TS)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Tinea Capitis

Impaired Comfort r/t inflammation from skin irritation

See Ringworm of Scalp

Tinea Corporis

See Ringworm of Body

Tinea Cruris

See Jock Itch; Itching; Pruritus

Tinea Pedis

See Athlete's Foot; Itching; Pruritus

Tinea Unguium (Onychomycosis)

See Ringworm of Nails

Tinnitus

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding self-care with tinnitus

Hearing Loss r/t ringing in ears obscuring hearing

Tissue Damage, Integumentary

Impaired Tissue Integrity (See **Tissue Integrity, Impaired,** Section III)

Risk for Impaired Tissue Integrity (See **Tissue Integrity, Impaired, Risk for,** Section III)

Tissue Perfusion, Peripheral

Ineffective Peripheral Tissue Perfusion (See **Tissue Perfusion, Peripheral, Ineffective,** Section III)

Risk for Ineffective Peripheral Tissue Perfusion (See **Tissue Perfusion, Peripheral, Ineffective, Risk for,** Section III)

Toileting Problems

Toileting Self-Care Deficit r/t impaired transfer ability, impaired mobility status, intolerance of activity, neuromuscular impairment, cognitive impairment

Impaired Transfer Ability r/t neuromuscular deficits

Toilet Training

Deficient Knowledge: Parent r/t signs of child's readiness for training

Risk for Constipation: Risk factor: withholding stool

Risk for Infection: Risk factor: withholding urination

Tonsillectomy and Adenoidectomy (T & A)

See T & A (Tonsillectomy and Adenoidectomy)

Toothache

Impaired Dentition r/t ineffective oral hygiene, barriers to self-care, economic barriers to professional care, nutritional deficits, lack of knowledge regarding dental health

Acute Pain r/t inflammation, infection

Total Anomalous Pulmonary Venous Return

See Congenital Heart Disease/Cardiac Anomalies

Total Joint Replacement (Total Hip/Total Knee/Shoulder)

Disturbed Body Image r/t large scar, presence of prosthesis

Impaired Physical Mobility r/t musculoskeletal impairment, surgery, prosthesis

Risk for Injury: Neurovascular: Risk factors: altered peripheral tissue perfusion, impaired mobility, prosthesis

Risk for Peripheral Neurovascular Dysfunction: Risk factors: immobilization, surgical procedure

Ineffective Peripheral Tissue Perfusion r/t surgery

See Surgery, Preoperative Care; Surgery, Perioperative Care; Surgery, Postoperative Care

Total Parenteral Nutrition (TPN)

See TPN (Total Parenteral Nutrition)

Tourette's Syndrome (TS)

Hopelessness r/t inability to control behavior

Impaired Individual Resilience r/t uncontrollable behavior

Risk for Situational Low Self-Esteem: Risk factors: uncontrollable behavior, motor and phonic tics

See Attention Deficit Disorder

Toxemia

See PIH (Pregnancy-Induced Hypertension/Preeclampsia)

Toxic Epidermal Necrolysis (TEN) (Erythema Multiforme)

Death Anxiety r/t uncertainty of prognosis

Risk for Shock r/t deficient fluid volume

TPN (Total Parenteral Nutrition)

Imbalanced Nutrition: Less than Body Requirements r/t inability to digest food or absorb nutrients as a result of biological or psychological factors

Risk for Electrolyte Imbalance: Risk factor: need for regulation of electrolytes in TPN fluids

Risk for Excess Fluid Volume: Risk factor: rapid administration of TPN

Risk for Unstable Blood Glucose Level: Risk factor: high glucose levels in TPN to be regulated according to blood glucose levels

Risk for Infection: Risk factors: concentrated glucose solution, invasive administration of fluids

Risk for Vascular Trauma: Risk factors: insertion site, length of treatment time

Tracheoesophageal Fistula

Ineffective Airway Clearance r/t aspiration of feeding because of inability to swallow

Imbalanced Nutrition: Less than Body Requirements r/t difficulties swallowing

Risk for Aspiration: Risk factor: common passage of air and food

Risk for Vascular Trauma: Risk factors: venous medications and site

See Respiratory Conditions of the Neonate; Hospitalized Child

Tracheostomy

Ineffective Airway Clearance r/t increased secretions, mucous plugs

Anxiety r/t impaired verbal communication, ineffective airway clearance

Disturbed Body Image r/t abnormal opening in neck

Impaired Verbal Communication r/t presence of mechanical airway

Deficient Knowledge r/t self-care, home maintenance management

Acute Pain r/t edema, surgical procedure

Risk for Aspiration: Risk factor: presence of tracheostomy

Risk for Bleeding: Risk factor: surgical incision

Risk for Surgical Site Infection: Risk factors: invasive procedure, pooling of secretions

Traction and Casts

Constipation r/t immobility

Decreased Diversional Activity Engagement r/t immobility

Impaired Physical Mobility r/t imposed restrictions on activity because of bone or joint disease injury

Acute Pain r/t immobility, injury, or disease

Self-Care Deficit: Feeding, Dressing, Bathing, Toileting r/t degree of impaired physical mobility, body area affected by traction or cast

Impaired Transfer Ability r/t presence of traction, casts

Risk for Disuse Syndrome: Risk factor: mechanical immobilization

Risk for Child Pressure Injury: Risk factor: immobility and pressure over bony prominence

See Casts

Transfer Ability

Impaired Transfer Ability (See **Transfer Ability, Impaired,** Section III)

Transient Ischemic Attack (TIA)

See TIA (Transient Ischemic Attack)

Transposition of Great Vessels

See Congenital Heart Disease/Cardiac Anomalies

Transurethral Resection of the Prostate (TURP)

See TURP (Transurethral Resection of the Prostate)

Trauma in Pregnancy

Anxiety r/t threat to self or fetus, unknown outcome

Deficient Knowledge r/t lack of exposure to situation

Acute Pain r/t trauma

Impaired Skin Integrity r/t trauma

Risk for Bleeding: Risk factor: trauma

Risk for Deficient Fluid Volume: Risk factor: fluid loss

Risk for Infection: Risk factor: traumatized tissue

Risk for Injury: Fetal: Risk factor: premature separation of placenta

Risk for Disturbed Maternal–Fetal Dyad: Risk factor: complication of pregnancy

Trauma, Physical, Risk for

Risk for Physical Trauma (See **Physical Trauma, Risk for,** Section III)

Traumatic Brain Injury (TBI)

See TBI (Traumatic Brain Injury); Intracranial Pressure, Increased

Traumatic Event

Post-Trauma Syndrome r/t previously experienced trauma

Traveler's Diarrhea (TD)

Diarrhea r/t travel with exposure to different bacteria, viruses

Risk for Deficient Fluid Volume: Risk factor: excessive loss of fluids

Risk for Infection: Risk factors: insufficient knowledge regarding avoidance of exposure to pathogens (water supply, iced drinks, local cheese, ice cream, undercooked meat, fish and shellfish, uncooked vegetables, unclean eating utensils, improper handwashing)

Trembling of Hands

Fear r/t threat to or change in health status, threat of death, situational crisis

Tricuspid Atresia

See Congenital Heart Disease/Cardiac Anomalies

Trigeminal Neuralgia

Ineffective Health Self-Management r/t deficient knowledge regarding prevention of stimuli that trigger pain

Imbalanced Nutrition: Less than Body Requirements r/t pain when chewing

Acute Pain r/t irritation of trigeminal nerve

Risk for Corneal Injury: Risk factor: possible decreased corneal sensation

Truncus Arteriosus

See Congenital Heart Disease/Cardiac Anomalies

TS (Tourette's Syndrome)

See Tourette's Syndrome (TS)

TSE (Testicular Self-Examination)

Readiness for Enhanced Health Self-Management: seeks information regarding self-examination

Tubal Ligation

Decisional Conflict r/t tubal sterilization

See Laparoscopy

Tube Feeding

Risk for Aspiration: Risk factors: improper placement of feeding tube, improper positioning of client during and after feeding, excessive residual feeding or lack of digestion, altered gag reflex

Risk for Deficient Fluid Volume: Risk factor: inadequate water administration with concentrated feeding

Risk for Imbalanced Nutrition: Less than Body Requirements: Risk factors: intolerance to tube feeding, inadequate calorie replacement to meet metabolic needs

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Impaired Bowel Continence: Risk factor: tube feeding osmolality too high for proper nutrient absorption

Tuberculosis (TB)

See TB (Pulmonary Tuberculosis)

TURP (Transurethral Resection of the Prostate)

Deficient Knowledge r/t postoperative self-care, home maintenance management

Acute Pain r/t incision, irritation from catheter, bladder spasms, kidney infection

Urinary Retention r/t obstruction of urethra or catheter with clots

Risk for Bleeding: Risk factor: surgery

Risk for Deficient Fluid Volume: Risk factors: fluid loss, possible bleeding

Risk for Urge Urinary Incontinence: Risk factor: edema from surgical procedure

Risk for Infection: Risk factors: invasive procedure, route for bacteria entry

Risk for Urinary Tract Injury: Risk factor: invasive procedure

U

Ulcer, Peptic (Duodenal or Gastric)

Fatigue r/t loss of blood, chronic illness

Ineffective Health Maintenance Behaviors r/t lack of knowledge regarding health practices to prevent ulcer formation

Nausea r/t gastrointestinal irritation

Acute Pain r/t irritated mucosa from acid secretion

See GI Bleed (Gastrointestinal Bleeding)

Ulcerative Colitis

See Inflammatory Bowel Disease (Child and Adult)

Ulcers, Stasis

See Stasis Ulcer

Unilateral Neglect of One Side of Body

Unilateral Neglect (See **Unilateral Neglect,** Section III)

Unsanitary Living Conditions

Impaired Home Maintenance r/t impaired cognitive or emotional functioning, lack of knowledge, insufficient finances, addiction

Risk for Allergic Reaction: Risk factor: exposure to environmental contaminants

Upper Respiratory Infection

See Cold, Viral

Urgency to Urinate

Urge Urinary Incontinence (See **Incontinence, Urinary, Urge,** Section III)

Risk for Urge Urinary Incontinence (See **Incontinence, Urinary, Urge, Risk for,** Section III)

Urinary Catheter

Risk for Urinary Tract Injury: Risk factors: confused client, long-term use of catheter, large retention balloon or catheter, perirectal burn injured client

Risk for Infection: Risk factors: difficulty managing long-term invasive urinary catheter devices

Urinary Diversion

See Ileal Conduit

Urinary Elimination, Impaired

Impaired Urinary Elimination (See **Urinary Elimination, Impaired,** Section III)

Urinary Incontinence

See Incontinence of Urine

Urinary Retention

Urinary Retention (See **Urinary Retention,** Section III)

Urinary Tract Infection (UTI)

See UTI (Urinary Tract Infection)

Urolithiasis

See Kidney Stone

Uterine Atony in Labor

See Dystocia

Uterine Atony in Postpartum

See Postpartum Hemorrhage

Uterine Bleeding

See Hemorrhage; Postpartum Hemorrhage; Shock, Hypovolemic

UTI (Urinary Tract Infection)

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding methods to treat and prevent UTIs, prolonged use of indwelling urinary catheter

Acute Pain: Dysuria r/t inflammatory process in bladder

Impaired Urinary Elimination: Frequency r/t urinary tract infection

Risk for Acute Confusion: Risk factor: infectious process

Risk for Urge Urinary Incontinence: Risk factor: hyperreflexia from cystitis

Risk for Urinary Tract Injury: Risk factors: confused client, long-term use of catheter, large retention balloon or catheter

V

VAD (Ventricular Assist Device)

See Ventricular Assist Device (VAD)

Vaginal Hysterectomy

Urinary Retention r/t edema at surgical site

Risk for Urge Urinary Incontinence: Risk factors: edema, congestion of pelvic tissues

Risk for Infection: Risk factor: surgical site

Risk for Perioperative Positioning Injury: Risk factor: lithotomy position

Vaginitis

Impaired Comfort r/t pruritus, itching

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding self-care with vaginitis

Ineffective Sexuality Pattern r/t abstinence during acute stage, pain

Vagotomy

See Abdominal Surgery

Value System Conflict

Decisional Conflict r/t unclear personal values or beliefs

Spiritual Distress r/t challenged value system

Readiness for Enhanced Spiritual Well-Being: desire for harmony with self, others, higher power, God

Varicose Veins

Ineffective Health Maintenance Behaviors r/t deficient knowledge regarding health care practices, prevention, treatment regimen

Chronic Pain r/t impaired circulation

Ineffective Peripheral Tissue Perfusion r/t venous stasis

Risk for Impaired Tissue Integrity: Risk factor: altered peripheral tissue perfusion

Vascular Dementia (Formerly Called Multi-Infarct Dementia)

See Dementia

Vasectomy

Decisional Conflict r/t surgery as method of permanent sterilization

Venereal Disease

See STD (Sexually Transmitted Disease)

Venous Thromboembolism (VTE)

Anxiety r/t lack of circulation to body part

Acute Pain r/t vascular obstruction

Ineffective Peripheral Tissue Perfusion r/t interruption of circulatory flow

Risk for Peripheral Neurovascular Dysfunction: Risk factor: vascular obstruction

Ventilated Client, Mechanically

Ineffective Airway Clearance r/t increased secretions, decreased cough and gag reflex

Ineffective Breathing Pattern r/t decreased energy and fatigue as a result of possible altered nutrition: less than body requirements, neurological disease or damage

Impaired Verbal Communication r/t presence of endotracheal tube, inability to phonate

Fear r/t inability to breathe on own, difficulty communicating

Impaired Gas Exchange r/t ventilation-perfusion imbalance

Powerlessness r/t health treatment regimen

Social Isolation r/t impaired mobility, ventilator dependence

Impaired Spontaneous Ventilation r/t metabolic factors, respiratory muscle fatigue

Dysfunctional Ventilatory Weaning Response r/t psychological, situational, physiological factors

Risk for Adult Falls: Risk factors: impaired mobility, decreased muscle strength

Risk for Child Falls: Risk factors: impaired mobility, decreased lower extremity strength

Risk for Infection: Risk factors: presence of endotracheal tube, pooled secretions

Risk for Pressure Ulcer: Risk factor: decreased mobility

Risk for Impaired Resilience: Risk factor: illness

See Child With Chronic Condition; Hospitalized Child; Respiratory Conditions of the Neonate

Ventricular Assist Device (VAD)

Anxiety r/t possible failure of device

Risk for Infection: Risk factor: device insertion site

Risk for Vascular Trauma: Risk factor: insertion site

Readiness for Enhanced Decision-Making: expresses desire to enhance the understanding of the meaning of choices regarding implanting a VAD

See Open Heart Surgery

Ventricular Fibrillation

See Dysrhythmia

Veterans

Anxiety r/t possible unmet needs, both physical and psychological

Risk for Post-Trauma Syndrome: Risk factors: witnessing death, survivor role, guilt, environment not conducive to needs

Risk for Suicide: Risk factors: substance abuse, insufficient social support, physical injury, psychiatric disorder

Vertigo

See Syncope

Violent Behavior

Risk for Other-Directed Violence (See **Violence, Other-Directed, Risk for,** Section III)

Risk for Self-Directed Violence (See **Violence, Self-Directed, Risk for,** Section III)

Viral Gastroenteritis

Diarrhea r/t infectious process, Norovirus

Deficient Fluid Volume r/t vomiting, diarrhea

Ineffective Health Self-Management r/t inadequate handwashing

See Gastroenteritis, Child

Vision Impairment

Fear r/t loss of sight

Social Isolation r/t altered state of wellness, inability to see

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Risk for Impaired Resilience: Risk factor: presence of new crisis

See Blindness; Cataracts; Glaucoma

Vomiting

Nausea r/t infectious processes, chemotherapy, postsurgical anesthesia, irritation to the gastrointestinal system, stimulation of neuropharmacological mechanisms

Imbalanced Nutrition: Less than Body Requirements r/t inability to ingest food

Risk for Electrolyte Imbalance: Risk factor: vomiting

VTE (Venous Thromboembolism)

Risk for Thrombosis r/t ineffective management of preventive measures, immobility, dehydration

(See **Venous Thromboembolism, Risk for,** Section III)

W

Walking Impairment

Impaired Walking (See **Walking, Impaired,** Section III)

Wandering

Wandering (See **Wandering,** Section III)

Weakness

Fatigue r/t decreased or increased metabolic energy production

Risk for Adult Falls: Risk factor: weakness

Weight Gain

Overweight (See **Overweight,** Section III)

Risk for Metabolic Syndrome r/t absence of interest in improving health behaviors

Weight Loss

Imbalanced Nutrition: Less than Body Requirements r/t inability to ingest food because of biological, psychological, economic factors

Wellness-Seeking Behavior

Readiness for Enhanced Health Self-Management: Expresses desire for increased control of health practice

Wernicke-Korsakoff Syndrome

See Korsakoff's Syndrome

West Nile Virus

See Meningitis/Encephalitis

Wheelchair Use Problems

Impaired Wheelchair Mobility (See **Mobility, Wheelchair, Impaired,** Section III)

Wheezing

Ineffective Airway Clearance r/t tracheobronchial obstructions, secretions

Ineffective Breathing Pattern r/t tracheobronchial obstructions and fatigue

Wilms' Tumor

Chronic Functional Constipation r/t obstruction associated with presence of tumor

Acute Pain r/t pressure from tumor

See Chemotherapy; Hospitalized Child; Radiation Therapy; Surgery, Preoperative Care; Surgery, Perioperative Care; Surgery, Postoperative Care

Withdrawal from Alcohol

See Alcohol Withdrawal

Withdrawal from Drugs

See Acute Substance Withdrawal Syndrome; Substance Misuse

Wound Debridement

Acute Pain r/t debridement of wound

Impaired Tissue Integrity r/t debridement, open wound

Risk for Infection: Risk factors: open wound, presence of bacteria

Wound Dehiscence, Evisceration

Fear r/t client fear of body parts "falling out," surgical procedure not going as planned

Disturbed Body Image r/t change in body structure and wound appearance

Imbalanced Nutrition: Less than Body Requirements r/t inability to digest nutrients, need for increased protein for healing

Risk for Deficient Fluid Volume: Risk factors: inability to ingest nutrients, obstruction, fluid loss

Risk for Injury: Risk factor: exposed abdominal contents

Risk for Delayed Surgical Recovery: Risk factors: separation of wound, exposure of abdominal contents

Risk for Surgical Site Infection: Risk factor: open wound after surgical procedure

Wound Infection

Disturbed Body Image r/t open wound

Imbalanced Nutrition: Less than Body Requirements r/t biological factors, infection, fever

Ineffective Thermoregulation r/t infection in wound resulting in fever

Impaired Tissue Integrity r/t wound, presence of infection

Risk for Imbalanced Fluid Volume: Risk factor: increased metabolic rate

Risk for Infection: Spread of: Risk factor: imbalanced nutrition: less than body requirements

Risk for Delayed Surgical Recovery: Risk factor: presence of infection

Wounds, Open

See Lacerations

SECTION

III Guide to Planning Care

Section III is a collection of NANDA-I nursing diagnosis care plans. The care plans are arranged alphabetically by diagnostic concept. Each care plan includes the diagnosis label, domain and class, definition, defining characteristics and if appropriate risk factors, related factors, at-risk populations, and associated conditions. Risk diagnoses, however, only contain definition and risk factors. Care plans include suggested outcomes and interventions for all nursing diagnoses.

MAKING AN ACCURATE NURSING DIAGNOSIS

Verify the accuracy of the previously suggested nursing diagnoses (from Section II) or from the alphabetized list (front of the book) for the client.

STEPS

- Read the definition for the suggested nursing diagnosis and determine if it is appropriate.
- Compare the Defining Characteristics with the symptoms that were identified from the client data collected.

or

- Compare the Risk Factors with the factors that were identified from the client data collected.

WRITING OUTCOMES STATEMENTS AND NURSING INTERVENTIONS

After selecting the appropriate nursing diagnosis, use this section to identify appropriate client outcomes and interventions.

STEPS

- Use the Client Outcomes/Nursing Interventions as written by the authors and contributors (select ones that are appropriate for your client).

or

- Use the NOC/NIC outcomes and interventions (as appropriate for your client).
- Read the rationales; the majority of rationales are based on evidence supported by nursing research (EBN), clinical research, or clinical practice guidelines (EB) that validate the efficacy of the interventions. Every attempt has been made to use current references. Important research studies that are older than 5 years are included because they are either seminal research or the current best evidence available. They are designated as CEB (Classic Evidence-Based).

Following these steps, you will be able to write an evidence-based nursing care plan.

- Follow this care plan to administer evidence-based nursing care to the client.
- Document all steps and evaluate and update the care plan as needed.

A

Decreased Activity Tolerance

Domain 4 Activity/rest Class 2 Activity/exercise

Kelly Henrichs, DNP, RN, GNP-BC

NANDA-I

Definition

Insufficient endurance to complete required or desired daily activities.

Defining Characteristics

Abnormal blood pressure response to activity; abnormal heart rate response to activity; anxious when activity is required; electrocardiogram change; exertional discomfort; exertional dyspnea; expresses fatigue; generalized weakness

Related Factors

Decreased muscle strength; depressive symptoms; fear of pain; imbalance between oxygen supply/demand; impaired physical mobility; inexperience with an activity; insufficient muscle mass; malnutrition; pain; physical deconditioning; sedentary lifestyle

At-Risk Population

Individuals with history of decreased activity tolerance; older adults

Associated Conditions

Neoplasms; neurodegenerative diseases; respiration disorders; traumatic brain injuries; vitamin D deficiency

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Activity Tolerance; Endurance; Energy Conservation; Self-Care: Instrumental Activities of Daily Living (IADLs)

Example NOC Outcome with Indicators

Activity Tolerance as evidenced by the following indicators: Oxygen saturation with activity/Pulse rate with activity/Respiratory rate with activity/Blood pressure with activity/Electrocardiogram findings/Skin color/Walking distance. (Rate the outcome and indicators of **Activity Tolerance:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Participate in prescribed physical activity with appropriate changes in heart rate, blood pressure, and breathing rate; maintain monitor patterns (rhythm and ST segment) within normal limits
- State symptoms of adverse effects of exercise and report onset of symptoms immediately
- Maintain normal skin color; skin is warm and dry with activity
- Verbalize an understanding of the need to gradually increase activity based on testing, tolerance, and symptoms
- Demonstrate increased tolerance to activity

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Activity Therapy; Energy Management; Exercise Therapy: Ambulation

Example NIC Activities—Energy Management

Monitor cardiorespiratory response to activity; Monitor location and nature of discomfort or pain during movement/activity

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Nursing Interventions and *Rationales*

✱ Determine cause of Decreased Activity Tolerance (see Related Factors) and decide whether cause is physical, psychological, or motivational. **EB:** *As nurses, we are called on to ensure higher levels of safety and quality for our clients by our governments, professional organizations, and hospital administrations. It is essential that we implement evidence-based nursing care strategies to reduce avoidable errors in care so that clinical outcomes improve (Chu, 2017).*

● If mainly on bed rest, minimize cardiovascular, neuromuscular, and skeletal deconditioning by positioning the client in an upright position several times daily as tolerated and perform simple range-of-motion (ROM) techniques (passive or active). **EB:** *Physical inactivity leads to a deconditioning of the skeletal, neuromuscular, and cardiovascular systems. It can lead to impaired quality of life, loss of autonomy, falls, and fractures (Kramer et al, 2017).*

● Assess the client daily for appropriateness of activity and bed rest orders. Mobilize the client as soon as possible. **EB:** Mobilization is a simple method of maintaining stable cardiovascular parameters (i.e., blood pressure, heart rate), countering orthostatic intolerance, and reducing the risk of secondary problems in clients during long-term immobilization (Constantin & Dahlke, 2018).

● If the client is mostly immobile, consider use of a transfer chair or a chair that becomes a stretcher. **EB:** The use of simple shifting aids can optimize the client transfer by avoiding heavy lifting situations and possible back injury to the caregivers. It reduces the effort of the caregivers and makes sure that the client is not hurt during the process of conversion (Ahmed et al, 2015).

● When appropriate, gradually increase activity, allowing the client to assist with positioning, transferring, and self-care as able. Progress the client from sitting in bed to dangling, to standing, to ambulation. Always have the client dangle at the bedside before standing to evaluate for postural hypotension. **EB:** *A reduction in plasma volume associated with bed rest impacts the physiological responses of autonomic control of circulation (Goswami et al, 2017)*

▲ When getting a client up, observe for symptoms of intolerance such as nausea, pallor, dizziness, visual dimming, and impaired consciousness, as well as changes in vital signs; manual blood pressure monitoring is more accurate than use of an automated blood pressure device. When an adult rises to the standing position, blood pools in the lower extremities; symptoms of central nervous system hypoperfusion may occur, including feelings of weakness, nausea, headache, lightheadedness, dizziness, blurred vision, fatigue, tremulousness, palpitations, and impaired cognition. **EB:** *Impaired orthostatic blood pressure recovery, delayed recovery, and/or sustained orthostatic hypotension are independent risk factors for falls, unexplained falls, and falls with injury (Ciaren et al, 2017).*

● If the client has symptoms of postural hypotension, such as dizziness, lightheadedness, or pallor, take precautions, such as dangling the client and applying leg compression stockings, before the client stands. **EB:** *Put graduated compression stockings on the client or use lower limb compression bandaging, if ordered, to return blood to the heart and brain. Have the client dangle at the side of the bed with legs hanging over the edge of the bed, flexing and extending the feet several times after sitting up, then standing slowly with someone holding the client. If the client becomes lightheaded or dizzy, return him or her to bed immediately (Crawford & Harris, 2016).*

● Perform ROM exercises if the client is unable to tolerate activity or is mostly immobile. See care plan for Risk for **Disuse Syndrome**.

● Monitor and record the client's ability to tolerate activity: changes in mentation, pulse rate, blood pressure, respiratory pattern, dyspnea, use of accessory muscles, and skin color before, during, and after the activity. If the following signs and symptoms of cardiac decompensation develop, activity should be stopped immediately:
  ❍ Lightheadedness, confusion, ataxia, pallor, cyanosis, nausea, or any peripheral circulatory insufficiency
  ❍ Onset of chest discomfort or pain
  ❍ Changes in heart rate: increased, decreased, palpitations, dysrhythmia
  ❍ Drop in blood pressure or hypotension
  ❍ Rise in blood pressure or hypertension
  ❍ Dyspnea
  ❍ Decreased oxygen saturation
  ❍ Excessive fatigue

▲ Instruct the client to stop the activity immediately and report to the health care provider if the client is experiencing the following symptoms: new or worsened intensity or increased frequency of discomfort; tightness or pressure in chest, back, neck, jaw, shoulders, and/or arms; palpitations; dizziness; weakness; unusual and extreme fatigue; or excessive air hunger. **EB:** *Cardiovascular deconditioning has long been*

A

recognized as a characteristic of the physiological adaptation to long-term bed rest in clients. The process is thought to contribute to orthostatic intolerance and enhance secondary complications in a significant way (Kehler et al, 2019).

- Observe and document skin integrity several times a day. Decreased **Activity Tolerance** if resulting in immobility, may lead to pressure ulcers. Mechanical pressure, moisture, friction, and shearing forces all predispose to their development. Refer to the care plan Risk for Impaired **Skin** Integrity.
- Assess for constipation. If present, refer to care plan for **Constipation.** Decreased **Activity** Tolerance is associated with increased risk of **Constipation.**

▲ Refer the client to physical therapy to help increase activity levels and strength.

▲ Consider a dietitian referral to assess nutritional needs related to Decreased **Activity** Tolerance and provide nutrition as indicated. If the client is unable to eat food, use enteral or parenteral feedings as needed.

- Recognize that malnutrition causes significant morbidity because of the loss of lean body mass.
- Provide emotional support and encouragement to the client to gradually increase activity. Work with the client to set mutual goals that increase activity levels. *Fear of breathlessness, pain, or falling may decrease willingness to increase activity.*

▲ Observe for pain before activity. If possible, treat pain before activity and ensure that the client is not heavily sedated. *Pain restricts the client from achieving a maximal activity level and is often exacerbated by movement.*

▲ Obtain any necessary assistive devices or equipment needed before ambulating the client (e.g., walkers, canes, crutches, portable oxygen).

▲ Use a gait-walking belt when ambulating the client. **EBN:** *Use of gait belts is a nurse-driven intervention and encouraged to be used to assist in ambulation and transfer (King et al, 2018).*

▲ *Use evidence-based practices for safe client handling to reduce the risk of injury for both clients and health care workers (King et al, 2018).*

Decreased Activity Tolerance Due to Respiratory Disease

- If the client is able to walk and has chronic obstructive pulmonary disease (COPD), use the traditional 6-minute walk distance to evaluate activity tolerance with ambulation.

▲ Ensure that the client with pulmonary diseases has oxygen saturation testing with exercise. Use supplemental oxygen to keep oxygen saturation 90% or above or as prescribed with activity. **EB:** *Oxygen therapy can prolong life (Apps et al, 2016).*

- Monitor a respiratory client's response to activity by observing for symptoms of respiratory intolerance, such as increased dyspnea, loss of ability to control breathing rhythmically, use of accessory muscles, nasal flaring, appearance of facial distress, and skin tone changes such as pallor and cyanosis, changes in mentation, or inability to talk during activity.
- Instruct and assist the client in using conscious, controlled breathing techniques during exercise, including pursed-lip breathing, and inspiratory muscle use.

▲ Evaluate the client's nutritional status. Use nutritional supplements to increase nutritional level if needed. Refer to a dietitian if indicated.

▲ For the client in the intensive care unit, consider mobilizing the client with passive exercise. **EBN:** *Nurses should consider incorporating at least 20 minutes of passive exercise early in the plan of care for critically ill clients treated with mechanical ventilation so that opportunities to improve client outcomes are not missed (Sommers et al, 2015).*

▲ Refer the COPD client to a pulmonary rehabilitation program. **EB:** *Pulmonary rehabilitation improves client's functionality and decreases hospital admissions (Apps et al, 2016).*

Decreased Activity Tolerance Due to Cardiovascular Disease

- If the client is able to walk and has heart failure, consider use of the 6-minute walk test to determine physical ability.
- Allow for periods of rest before and after planned exertion periods such as meals, baths, treatments, and physical activity.

▲ Refer to a heart failure program or cardiac rehabilitation program for education, evaluation, and guided support to increase activity and rebuild life. **EB:** *Exercise training improves functional capacity, the ability to perform activities of daily living (ADLs), and quality of life, and it reduces the risk for subsequent cardiovascular events (Simon et al, 2018).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ Refer to a community support program that includes support of significant others. **EB:** *Contemporary studies now suggest that behavior change and multifactorial risk factor modification—especially smoking cessation and more intensive measures to control hyperlipidemia with diet, drugs, and exercise—may slow, halt, or even reverse (albeit modestly) the otherwise inexorable progression of atherosclerotic coronary artery disease (CAD) (Feigin et al, 2016).*

● See care plan for **Decreased Cardiac Output** for further interventions.

Pediatric

● Focus interview questions toward exercise tolerance, specifically including any history of asthma exacerbations. **EB:** *Cardiopulmonary deconditioning should be considered as an important differential diagnosis for breathlessness among obese adolescents. Some of these children may need pulmonary rehabilitation if difficulty breathing is the perceived reason for not exercising* (*Carpaji & van den Berge, 2018*).

Geriatric

✱ Slow the pace of care. Allow the client extra time to perform physical activities. Slow gait in older adults may be related to fear of falling, decreased strength in muscles, reduced balance or visual acuity, knee flexion contractures, and foot pain. **EB:** *Older clients with chronic cardiac conditions are more vulnerable to falls and injuries. Cardiovascular conditions, prevalent in older people, are also the frequent cause of potentially harmful fall injuries in this group. The need to identify the fall risk–related factors that cluster with arrhythmia and syncope is relevant, in that it will potentially reduce clients' risk for falls and fall injuries (Goswami et al, 2017).*

● Encourage families to help/allow an older client to be independent in whatever activities possible. **EB:** *Older adults can engage in a variety of physical activities to advance health ranging from walking and gardening to household chores and/or planned group exercise (World Health Organization, 2020).*

▲ Assess for swaying, poor balance, weakness, and fear of falling while older clients stand/walk. Refer to physical therapy if appropriate. **EB:** *A home exercise program was beneficial to improve the balance of community-dwelling frail older adults (Light et al, 2016).*

● Refer to the care plan for Risk for Adult **Falls** and Impaired **Walking**.

▲ Initiate ambulation by simply ambulating a client a few steps from bed to chair, once a health care provider's out-of-bed order is obtained. **EBN:** *Lack of ambulation and deconditioning effects of bed rest are some of the most predictable causes of loss of independent ambulation in hospitalized older persons. Nurses have been identified as the professionals most capable of promoting walking independence in the hospital setting (King et al, 2016).*

▲ Evaluate medications the client is taking to see if they could be causing Decreased **Activity** Tolerance. **EB:** *Polypharmacy and potentially inappropriate medications are associated with an increased risk of falls. The potential harms versus benefits of medications should be weighed in deciding to continue treatment in older adults with multiple chronic conditions (Masumoto et al, 2018).*

▲ Refer the disabled older client to physical therapy for functional training including gait training, stepping, and sit-to-stand exercises, or for strength training. **EBN:** *Older adults often experience functional losses during hospitalization. Clinical care activities have been increasingly promoted as a way to help older hospitalized clients offset these losses and recover from acute illness (Casey et al, 2016).*

Home Care

▲ Begin discharge planning as soon as possible with the case manager or social worker to assess the need for home support systems and the need for community or home health services. **EB:** *Discharging clients from acute care hospitals is complex and requires effective collaboration between multiprofessional teams and clients. Miscommunication around discharge instructions and/or follow-up care can lead to posthospital adverse events, client dissatisfaction, and increased 30-day readmissions (Patel et al, 2019).*

▲ Assess the home environment for factors that contribute to decreased activity tolerance such as stairs or distance to the bathroom. Refer the client for occupational therapy, if needed, and to assist the client in restructuring the home and ADL patterns. *During hospitalization, clients and families often estimate energy requirements at home inaccurately because the hospital's availability of staff support distorts the level of care that will be needed.*

▲ Refer the client for physical therapy for strength training and possible weight training to regain strength, increase endurance, and improve balance. If the client is homebound, the physical therapist can also initiate cardiac rehabilitation. **EB:** *The older and frailer the individual, the greater the rationale for the addition*

A

of progressive resistance and balance training to aerobic exercise programs, given the prevalence of sarcopenia, mobility impairment, and functional dependency in this group. Frailty is not a contraindication to exercise, but conversely, one of the most important reasons to prescribe it (Bauman et al, 2016).

- Encourage progress with positive feedback. The client's experience should be validated within expected norms. Recognition of progress enhances motivation.
- Teach the client/family the importance of and methods for setting priorities for activities, especially those having a high energy demand (e.g., home/family events). Instruct on realistic expectations.
- Encourage routine low-level exercise periods such as a daily short walk or chair exercises.
- Provide the client/family with resources such as senior centers, exercise classes, educational and recreational programs, and volunteer opportunities that can aid in promoting socialization and appropriate activity. Social isolation can be an outcome of and contribute to Decreased **Activity** Tolerance.
- Instruct the client and family on the importance of maintaining proper nutrition and use of dietary supplements as indicated. Illness may suppress appetite, leading to inadequate nutrition.
- ▲ Refer to medical social services as necessary to assist the family in adjusting to major changes in patterns of living because of Decreased **Activity** Tolerance.
- ▲ Assess the need for long-term supports for optimal activity tolerance of priority activities (e.g., assistive devices, oxygen, medication, catheters, massage), especially for a hospice client. Evaluate intermittently.
- ▲ Refer to home health aide services to support the client and family through changing levels of activity tolerance. Introduce aide support early. Instruct the aide to promote independence in activity as tolerated.
- Allow terminally ill clients and their families to guide care. Control by the client or family respects their autonomy and promotes effective coping.
- Provide increased attention to comfort and dignity of the terminally ill client in care planning. *Interventions should be provided as much for psychological effect as for physiological support. For example, oxygen may be more valuable as a support to the client's psychological comfort than as a booster of oxygen saturation.*
- ▲ Institute case management of frail elderly to support continued independent living.

Client/Family Teaching and Discharge Planning

- Instruct the client on techniques for avoiding Decreased **Activity** Tolerance, such as controlled breathing techniques.
- Teach the client techniques to decrease dizziness from postural hypotension when changing positions, especially when standing up.
- Help client with energy conservation and work simplification techniques in ADLs.
- Describe to the client the symptoms of Decreased **Activity** Tolerance, including which symptoms to report to the health care provider.
- Explain to the client how to use assistive devices, oxygen, or medications before or during activity.
- Help the client set up an activity log to record exercise and exercise tolerance.

Risk for Decreased Activity Tolerance

Domain 4 Activity/rest Class 2 activity/exercise

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to experiencing insufficient endurance to complete required or desired daily activities.

Risk Factors

Decreased muscle strength; depressive symptoms; fear of pain; imbalance between oxygen supply/demand; impaired physical mobility; inexperience with an activity; insufficient muscle mass; malnutrition; pain; physical deconditioning; sedentary lifestyle

At-Risk Population

Individuals with history of decreased activity tolerance; older adults

Associated Conditions

Neoplasms; neurodegenerative diseases; respiration disorders; traumatic brain injuries; vitamin D deficiency

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* and References

Refer to care plan for Decreased **Activity** Tolerance

Ineffective Activity Planning

Domain 9 Coping/stress tolerance Class 2 Coping responses

Jacquelyn Svoboda, DNP, RN, WHNP-C

NANDA-I

Definition

Inability to prepare for a set of actions fixed in time and under certain conditions.

Defining Characteristics

Absence of plan; excessive anxiety about a task; inadequate health resources; inadequate organizational skills; pattern of failure; reports fear of performing a task; unmet goals for chosen activity

A

Related Factors

Flight behavior when faced with proposed solution; hedonism; inadequate information processing ability; inadequate social support; unrealistic perception of event; unrealistic perception of personal abilities

At-Risk Population

Individuals with history of procrastination

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Cognition; Cognition; Orientation; Concentration; Decision-Making; Information Processing; Memory

Example NOC Outcome with Indicators

Cognition as evidenced by the following indicators: Communication clear and appropriate for age/Comprehension of the meaning of situations/Information processing/Alternatives weighed when making decisions. (Rate the outcome and indicators of **Cognition:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize need for self-directed activity
- Choose the health care option that fits his or her lifestyle within an appropriate amount of time that allows enactment of the choice
- Describe how the chosen option fits into current lifestyle before or after the decision has been made
- Verbalize the need for a behavioral change to improve physical activity
- Offer alternative options to those with barriers to participating in physical activity

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Activity Therapy; Anxiety Reduction; Behavior Management; Behavior Modification; Calming Technique; Coping Enhancement; Cognitive Restructuring; Decision-Making Support; Life Skills Enhancement

Example NIC Activities—Coping Enhancement

Assist client in developing an objective appraisal of the event; Explore with client previous methods of dealing with life problems

Nursing Interventions and *Rationales*

- Identify the client's perception of the problem and how they envision their participation to improve goal setting. **EB:** *Clients prioritize planning based on experiences with their specific illness, while caregivers prioritize future consequences of the illness* (*Sathanapally et al, 2020*).
- Identify the informational needs of the client such as client's understanding of health condition, treatment options, health system processes, diet, exercise, and access to important telephone numbers. **EB:** *This study of clients with breast cancer and lymphedema validated the need for an individual assessment to determine the unique informational needs, preference in delivery method, and timing of receipt of information for each client (Dorri et al, 2020).*
- Address the client's fears and anxieties and encourage him or her to modify their cognitive approach to planning. **EB:** *A systematic review and meta-analysis supports the concept that improvements can be made for addictive behaviors through the assessment of desired thinking and modifying those responses (Mansueto et al, 2019).*
- Client verbalizes need for behavioral change for improved physical activity. **EB:** *This study reports that clear direction and encouragement from health care providers on the benefits that exercise can have on the symptom progression and on exercise opportunities can promote client participation and engagement* (*Hurley et al, 2018*).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Encourage clients to verbalize the need for physical activity to help reduce role overload. **EB:** *This study demonstrated that the importance of integrating physical activity and exercise into life planning benefited the individuals affected by role overload, as well as benefited the family of the individuals* (*Shelton, 2018*).

▲ Determine factors that will increase opportunities to successfully plan activities and increase the success of the project: financial resources; family situation; prior medical, psychiatric, and psychosocial conditions; material resources; and the ability to manage stress. **EB:** *Discussions related to client lived experiences, cultural concepts, family dynamics, the etiology of health condition, and the barriers to physical activity are important in modifying and supporting healthy planning for diet and exercise (Lappan et al, 2020).*

▲ Encourage physical actively. Collaborate with occupational and/or physical therapy to establish activity opportunities and limitations. **EB:** *Cognitive impairment is correlated with higher mortality rates in the elderly clients who are inactive (Esteban-Cornejo et al, 2019).*

Pediatric

- Begin activity planning in preschool-age children of working parents. **EB:** *This study focused on preschool-age children and noted that sports participation resulted in better rule comprehension, improved memory, goal setting, and improved cognitive flexibility* (*Bryant et al, 2020*).
- Establish a contract. **EB:** *This study of adolescents with type 1 diabetes indicated that positive psychology intervention and behavioral contracts may be an important intervention to improve coping and glycemic control* (*Jaser et al, 2020*).
- Provide support to the schools for physical activities in all school venues. **EB:** *Urban schools are more successful in implementing physical activities when educators are allowed to formulate engaging and community-specific physical education curriculum that meets the needs of the students within the community and also when schools identify collaborating partnerships in the community to assist in funding needs* (*Sliwa et al, 2017*).
- Support safe neighborhood activity programs. **EB:** *Children of low-income households have a lower level of physical activity than average and the contributing factors that affect this activity were identified as working parents, dangerous activities in the neighborhood, lack of physical activity planning information, and lack of community input* (*Finkelstein et al, 2017*).

Geriatric

- Plan activities for older clients. **EB:** *In a study of elderly clients, it was found that physical activity may preserve cognitive function and the quality of memory* (*Kurdi & Flora, 2019*).
- Plan activities for older clients with impaired mental function. **EB:** *In this study, it was found that clients with impaired mental function have greater success in participating in a physical activity program that is formulated to address individual needs when there is ongoing supervision from the team to ensure adherence* (*Eckert et al, 2020*).
- Community-based activities for older adults. **EB:** *A study of certified nursing homes (CNH) identified that women clients who resided at higher star rated CNH had higher attendance in physical and social activity programs compared to lower star rated CNH and their male counterparts* (*Neils-Strunjas et al, 2020*).

Multicultural

✱ Provide literature and information in the appropriate language for the client who speaks little to no English. **EB:** *This study reinforces the importance of addressing cultural and language needs of underserved populations to increased participation in physical activity (Bantham et al, 2020).*

- Preplanning educational programs for the culturally diverse population needs to be developed. **EB:** *By providing activities close in proximity and utilizing native linguistics instructions, along with culturally applicable activities, there is improved participation in the activity programming* (*Montayre et al, 2020*).

▲ Support and education by the physician and family on how exercise can help reduce and/or prevent falls of older adults improves adherence to physical activity. **EB:** *A study done on factors that affect the older client's belief on fall risk and prevention noted that providers can influence how clients perceive fall prevention and how they adopt fall risk prevention activities such as exercise through engagement and encouragement (Stevens et al, 2018).*

Home Care

- Have a preplanned activity exercise for the home client with a debilitating musculoskeletal disease to help improve functional status. **EB:** *This study showed that for Parkinson's disease clients, an individualized home exercise and walking program prevented the anticipated physical decline over 12 months (Ellis et al, 2019).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

A

- Assess the home environment for barriers that can impact the client's motivation to be a participant in the activity planned. **EB:** *This study on homebound heart failure clients showed that facilitators to client participation in physical activity programming include an individualized intervention created by the health care team, which considers individual barriers as well as the participation of the family in planning sessions (Okwose et al, 2020).*
- Home care for the cardiac rehabilitation client. **EB:** *Providing a home exercise plan with telemonitoring guidance for the home care cardiac rehabilitation client resulted in improvement of the health status for the client and resulted in being as efficacious as rehabbing in a care center (Avila et al, 2018).*
- For additional interventions, refer to care plans for **Anxiety,** Readiness for Enhanced Family **Coping,** Readiness for Enhanced **Decision-Making, Fear,** Readiness for Enhanced **Hope,** Readiness for Enhanced **Power,** Readiness for Enhanced **Spiritual** Well-Being, and Readiness for Enhanced **Health** Self-Management

Risk for Ineffective Activity Planning

Domain 9 Coping/stress tolerance Class 2 Coping responses

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to an inability to prepare for a set of actions fixed in time and under certain conditions, which may compromise health.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Risk Factors

Flight behavior when faced with proposed solution; hedonism; inadequate information processing ability; inadequate social support; unrealistic perception of event; unrealistic perception of personal abilities

At-Risk Population

Individuals with history of procrastination

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Ineffective **Activity** Planning.

Ineffective Airway Clearance Domain 11 Safety/protection Class 2 Physical injury

Debra Siela, PhD, RN, ACNS-BC, CCRN-K, CNE, RRT

Definition

Reduced ability to clear secretions or obstructions from the respiratory tract to maintain a clear airway.

Defining Characteristics

Absence of cough; adventitious breath sounds; altered respiratory rhythm; altered thoracic percussion; altered thoraco-vocal fremitus; bradypnea; cyanosis; difficulty verbalizing; diminished breath sounds; excessive sputum; hypoxemia; ineffective cough; ineffective sputum elimination; nasal flaring; orthopnea; psychomotor agitation; subcostal retraction; tachypnea; use of accessory muscles of respiration

Related Factors

Dehydration; excessive mucus; exposure to harmful substance; fear of pain; foreign body in airway; inattentive to second-hand smoke; mucus plug; retained secretions; smoking

At-Risk Population

Children; infants

Associated Conditions

Airway spasm; allergic airway; asthma; chronic obstructive pulmonary disease; congenital heart disease; critical illness; exudate in the alveoli; general anesthesia; hyperplasia of the bronchial walls; neuromuscular diseases; respiratory tract infection

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Aspiration Prevention; Respiratory Status: Airway Patency, Gas Exchange, Ventilation

Example NOC Outcome with Indicators

Respiratory Status: Ventilation as evidenced by the following indicators: Respiratory rate/Respiratory rhythm/Depth of inspiration/Chest expansion symmetrical/Ease of breathing/Tidal volume/Vital capacity. (Rate each indicator of **Respiratory Status: Ventilation:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate effective coughing and clear breath sounds
- Maintain a patent airway at all times
- Explain methods useful to enhance secretion removal

A

- Explain the significance of changes in sputum to include color, character, amount, and odor
- Identify and avoid specific factors that inhibit effective airway clearance

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Airway Management; Airway Suctioning; Cough Enhancement

Example NIC Activities—Airway Management

Instruct how to cough effectively; Auscultate breath sounds, noting areas of decreased or absent ventilation and presence of adventitious sounds

Nursing Interventions and *Rationales*

- Auscultate breath sounds every 1 to 4 hours. The presence of crackles and wheezes may alert the nurse to airway obstruction, which may lead to or exacerbate existing hypoxia. **EB:** *In severe exacerbations of chronic obstructive pulmonary disease (COPD), lung sounds may be diminished or distant with air trapping (Bickley et al, 2020).*
- Monitor respiratory patterns, including rate, depth, and effort. **EB:** *A normal respiratory rate for an adult without dyspnea is 12 to 16 breaths per minute (Bickley et al, 2020). With secretions in the airway, the respiratory rate will increase.*
- Monitor blood gas values and pulse oxygen saturation levels as available. An oxygen saturation of less than 90% (normal: 95%–100%) or a partial pressure of oxygen of less than 80 mm Hg (normal: 80–100 mm Hg) indicates significant oxygenation problems (Bickley et al, 2020).
- ▲ Administer oxygen as ordered. Oxygen administration has been shown to correct hypoxemia (Sauls, 2021). **EB:** *Administer humidified oxygen through an appropriate device (e.g., nasal cannula or Venturi mask per the health care provider's order); aim for an oxygen (O_2) saturation level of 90% or above. Oxygen should be titrated to target an SpO_2 of 94% to 98%, except with carbon monoxide poisoning (100% oxygen), acute respiratory distress syndrome (ARDS) (88%–95%), those at risk for hypercapnia (88%–92%), and premature infants (88%–94%) (Siela & Kidd, 2017; Sauls, 2021).*
- Position the client in a semirecumbent position with the head of the bed at a 30- to 45-degree angle to decrease the aspiration of gastric, oral, and nasal secretions (Siela, 2010; Vollman et al, 2017; Sauls, 2021). **CEB/EB:** *In a mechanically ventilated client, there is a decreased incidence of ventilator-associated pneumonia (VAP) if the client is positioned at a 30- to 45-degree semirecumbent position rather than a supine position (Siela, 2010; American Association of Critical Care Nurses, 2017)*
- Help the client deep breathe and perform controlled coughing. Have the client inhale deeply, hold breath for several seconds, and cough two or three times with mouth open while tightening the upper abdominal muscles. **CEB/EB:** *Controlled coughing uses the diaphragmatic muscles, making the cough more forceful and effective (Gosselink et al, 2008; Sommers et al, 2015; Bickley et al, 2020).*
- If the client has obstructive lung disease, such as chronic obstructive pulmonary disease (COPD), cystic fibrosis, or bronchiectasis, consider helping the client use the forced expiratory technique, the "huff cough." The client does a series of coughs while saying the word "huff." **EB:** *This technique prevents the glottis from closing during the cough and is effective in clearing secretions (Chalmers et al, 2015; Sommers et al, 2015).*
- ▲ Encourage the client to use an incentive spirometer. Recognize that controlled coughing and deep breathing may be just as effective as incentive spirometry (Chalmers et al, 2015).
- Encourage activity and ambulation as tolerated. If the client cannot be ambulated, turn the client from side to side at least every 2 hours. *Body movement helps mobilize secretions.*
- Encourage fluid intake of up to 2500 mL/day within cardiac or renal reserve. *Fluids help minimize mucosal drying and maximize ciliary action to move secretions.*
- ▲ Administer medications such as bronchodilators or inhaled steroids as ordered. Watch for side effects such as tachycardia or anxiety with bronchodilators or inflamed pharynx with inhaled steroids. **EB:** *Bronchodilators decrease airway resistance, improve the efficiency of respiratory movements, improve exercise tolerance, and can reduce symptoms of dyspnea on exertion (Anzueto & Miravitlles, 2017). Pharmacologic therapy in COPD is used to reduce symptoms, reduce the frequency and severity of exacerbation, and improve health strategies and exercise tolerance (GOLD, 2020).*
- ▲ Provide percussion, vibration, and oscillation as appropriate for individual client needs. **EB:** *Airway clearance techniques for clients with acute exacerbations of COPD may have a small but important positive effect*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

on the need for and duration of ventilatory assistance and may reduce hospital length of stay (Chalmers, Aliberti, & Blasi, 2015; Sommers et al, 2015). Mucoregulators such as N-acetylcysteine and carbocysteine are recommended to reduce the frequency of COPD acute exacerbations (GOLD, 2020). High-frequency chest wall oscillation (HFCWO) significantly improves aeration of the dorsal lung region in hypersecretive clients with acute respiratory failure (Longhini et al, 2020).

- Use of positive expiratory pressure (PEP) with a mask for airway clearance shows a significant reduction in pulmonary exacerbations in people with cystic fibrosis (McIlwaine, Button, & Nevitt, 2019).
- Observe sputum, noting color, odor, and volume. **EB:** *Normal sputum is clear or gray and minimal; abnormal sputum is green, yellow, or bloody; malodorous; and often copious. The presence of purulent sputum during a COPD exacerbation can be sufficient indication for starting empirical antibiotic treatment. Notify health care provider of purulent sputum (GOLD, 2020).*

Critical Care

▲ In intubated clients, body positioning and mobilization may optimize airway secretion clearance. Lateral rotational movement provides continuous postural drainage and mobilization of secretions (St. Clair & MacDermott, 2017).

- Reposition the client as needed. Use rotational or kinetic bed therapy in clients for whom side-to-side turning is contraindicated or difficult. **EBN:** *Changing position frequently decreases the incidence of atelectasis, pooling of secretions, and resultant pneumonia. Continuous, lateral rotational therapy has been shown to improve oxygenation and decrease the incidence of VAP (St. Clair & MacDermott, 2017).*
- If the client is intubated, consider use of kinetic therapy, using a kinetic bed that slowly moves the client with 40-degree turns. **EB:** *Rotational therapy may decrease the incidence of pulmonary complications in high-risk clients with increasing ventilator support requirements, who are at risk for VAP, and with clinical indications for acute lung injury or ARDS with worsening PaO_2:FiO_2 ratio, presence of fluffy infiltrates via chest radiograph concomitant with pulmonary edema, and refractory hypoxemia (Case, 2021).*
- Assess for the presence or absence of a gag reflex. **EB:** *In individuals with prolonged ventilation, the presence of one or both gag reflexes could predict a reduction in extubation failure related to aspiration or excessive upper airway secretions (Howes et al, 2020).*

▲ Early mobility and physical rehabilitation can reduce muscle weakness, mechanical ventilation duration, intensive care unit stay, delirium, and hospitalization. **CEB/EB:** *The Awakening and Breathing Coordination, Delirium Monitoring and Management, and Early Mobility (ABCDEF) bundle has criteria to determine when clients are candidates for early mobility. An early mobility and walking program can promote weaning from ventilator support as a client's overall strength and endurance (Balas et al, 2012; Devlin et al, 2018).*

- If the client is intubated and is stable, consider getting the client up to sit at the edge of the bed, transfer to a chair, or walk as appropriate, if an effective interdisciplinary team is developed to keep the client safe (*Dirkes & Kozlowski, 2019*). **CEB:** *A study found that for every week of bed rest, muscle strength can decrease 20%; early ambulation also helped clients develop a positive outlook (Perme & Chandrashekar, 2009).* **EB:** *A systematic review and meta-analysis found that while early mobility programs did not influence overall morbidity, clients did demonstrate improvement in mobility status, muscle strength, and days alive out of hospital up to 180 days (Tipping et al, 2017).*
- When suctioning an endotracheal tube or tracheostomy tube for a client on a ventilator, do the following:
  - ❍ Explain the process of suctioning beforehand and ensure the client is not in pain or overly anxious. Suctioning can be a frightening experience; an explanation along with adequate pain relief or needed sedation can reduce stress, anxiety, and pain (Seckel, 2017).
  - ❍ Hyperoxygenate before and between endotracheal suction sessions. Studies have demonstrated that hyperoxygenation may help prevent oxygen desaturation in a suctioned client (Pedersen et al, 2009; Siela, 2010; Seckel, 2017; Vollman, Sole, & Quinn, 2017).
  - ❍ Suction for less than 15 seconds. Studies demonstrated that because of a drop in the partial pressure of oxygen with suctioning, preferably no more than 10 seconds should be used actually suctioning, with the entire procedure taking 15 seconds (Pedersen et al, 2009; Seckel, 2017).
  - ❍ Use a closed, in-line suction system. Closed in-line suctioning has minimal effects on heart rate, respiratory rate, tidal volume, and oxygen saturation and may reduce contamination (Seckel, 2017).
  - ❍ Avoid saline instillation during suctioning. **CEB/EBN:** Repeated studies have demonstrated that saline instillation before suctioning has an adverse effect on oxygen saturation in both adults and children (Pederson et al, 2009; Siela, 2010; Caparros, 2014; Seckel, 2017).

A

- ❍ Use of a subglottic suctioning endotracheal tube reduces the incidence of VAP or ventilator-associated complications (Vollman, Sole, & Quinn, 2017; Pozuelo-Carrascosa et al, 2020). A decrease in mortality occurs with use of subglottic secretion drainage (Pozuelo-Carrascosa et al, 2020).
- ❍ Document results of coughing and suctioning, particularly client tolerance and secretion characteristics such as color, odor, and volume (Seckel, 2017).

Pediatric

- Educate parents about the risk factors for ineffective airway clearance such as foreign body ingestion and passive smoke exposure.
- Educate children and parents on the importance of adherence to peak expiratory flow monitoring for asthma self-management.
- Educate parents and other caregivers that cough and cold medications bought over the counter are not safe for a child younger than 2 unless specifically ordered by a health care provider.
- See the care plan for Risk for **Suffocation**

Geriatric

- Encourage ambulation as tolerated without causing exhaustion. *Immobility is often harmful to older adults because it decreases ventilation and increases stasis of secretions, leading to atelectasis or pneumonia.*
- Actively encourage older adults to deep breathe and cough. *Cough reflexes are blunted, and coughing is decreased in older adults.*
- Ensure adequate hydration within cardiac and renal reserves. *Older adults are prone to dehydration and therefore more viscous secretions, because they frequently use diuretics or laxatives and forget to drink adequate amounts of water.*

Home Care

- Some of the above interventions may be adapted for home care use.
- ▲ Begin discharge planning as soon as possible with case manager or social worker to assess need for home support systems, assistive devices, and community or home health services.
- Assess home environment for factors that exacerbate airway clearance problems (e.g., presence of allergens, lack of adequate humidity in air, poor air flow, stressful family relationships).
- Assess affective climate within family and family support system. **EB:** *Problems with respiratory function and resulting anxiety can provoke anger and frustration in the client. Feelings may be displaced onto caregiver and require intervention to ensure continued caregiver support.* Refer to care plan for **Caregiver Role Strain.**
- Refer to GOLD guidelines for management of home care and indications of hospital admission criteria. http://www.goldcopd.org/.
- When respiratory procedures are being implemented, explain equipment and procedures to family members and caregivers, and provide needed emotional support. *Family members assuming responsibility for respiratory monitoring often find this stressful. They may not have been able to assimilate fully any instructions provided by hospital staff.*
- When electrically based equipment for respiratory support is being implemented, evaluate home environment for electrical safety, proper grounding, and so on. Ensure that notification is sent to the local utility company, the emergency medical team, and police and fire departments.
- Provide family with support for care of a client with chronic or terminal illness. *Breathing difficulty can provoke extreme anxiety, which can interfere with the client's ability or willingness to adhere to the treatment plan.*
- Witnessing breathing difficulties and facing concerns of dealing with chronic or terminal illness can create fear in caregiver. Fear inhibits effective coping. Refer to care plans for **Anxiety** and **Powerlessness.**
- Instruct the client to avoid exposure to persons with upper respiratory infections, avoid crowds of people, and wash hands after each exposure to groups of people or public places.
- ▲ Determine client adherence to medical regimen. Instruct the client and family on importance of reporting effectiveness of current medications to health care provider. *Inappropriate use of medications (too much or too little) can influence amount of respiratory secretions.*
- Teach the client when and how to use inhalant or nebulizer treatments at home.
- Teach the client/family importance of maintaining regimen and having "as-needed" drugs easily accessible at all times. *Success in avoiding emergency or institutional care may rest solely on medication compliance or availability.*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Instruct the client and family on the importance of maintaining proper nutrition, adequate fluids, rest, and behavioral pacing for energy conservation and rehabilitation.
- Instruct in use of dietary supplements as indicated. *Illness may suppress appetite, leading to inadequate nutrition. Supplements will allow clients to eat with minimal energy consumption.*
- Identify an emergency plan, including criteria for use. *Ineffective airway clearance can be life-threatening.*

▲ Refer for home health aide services for assistance with activities of daily living (ADLs). Clients with decreased oxygenation and copious respiratory secretions are often unable to maintain energy for ADLs.

▲ Assess family for role changes and coping skills. Refer to medical social services as necessary. *Clients with decreased oxygenation are unable to maintain role activities and therefore experience frustration and anger, which may pose a threat to family integrity. Family counseling to adapt to role changes may be needed.*

▲ For the client dying at home with a terminal illness, if the "death rattle" is present with gurgling, rattling, or crackling sounds in the airway with each breath, recognize that anticholinergic medications can often help control symptoms, if given early in the process. *Anticholinergic medications can help decrease the accumulation of secretions but do not decrease existing secretions. This medication must be administered early in the process to be effective.*

▲ For the client with a death rattle, nursing care includes turning to mobilize secretions, keeping the head of the bed elevated for postural drainage of secretions, and avoiding suctioning. **EB:** *Suctioning is a distressing and painful event for clients and families and is rarely effective in decreasing the death rattle (Kolb, Snowden, & Stevens, 2018).*

Client/Family Teaching and Discharge Planning

▲ Teach the importance of not smoking. Refer to a smoking cessation program, and encourage clients who relapse to keep trying to quit. Ensure that the client receives appropriate medications to support smoking cessation from the primary health care provider. **EB:** *A Cochrane review found that use of the antidepressant medications increased the rate of smoking withdrawal two to three times more than smoking withdrawal without use of medications (Howes et al, 2020).*

▲ Teach the client how to use a flutter clearance device if ordered, which vibrates to loosen mucus and gives positive pressure to keep airways open. **CEB:** *Studies have demonstrated that use of the mucus clearance device had improved exercise performance compared with COPD clients who use a sham device (Osadnik, McDonald, & Holland, 2013).*

▲ Teach the client how to use peak expiratory flow rate (PEFR) meter if ordered and when to seek medical attention if PEFR reading drops. Also teach how to use metered dose inhalers and self-administer inhaled corticosteroids as ordered following precautions to decrease side effects.

- Teach the client how to deep breathe and cough effectively. Controlled coughing uses the diaphragmatic muscles, making the cough more forceful and effective (Sommers et al, 2015).
- Teach the client/family to identify and avoid specific factors that exacerbate ineffective airway clearance, including known allergens and especially smoking (if relevant) or exposure to secondhand smoke (SHS).
- Educate the client and family about the significance of changes in sputum characteristics, including color, character, amount, and odor. With this knowledge, the client and family can identify early the signs of infection and seek treatment before acute illness occurs.
- Teach the client/family the importance of taking antibiotics as prescribed, consuming all tablets until the prescription has run out. Taking the entire course of antibiotics helps eradicate bacterial infection, which decreases lingering, chronic infection.
- Teach the family of the dying client in hospice with a death rattle that rarely are clients aware of the fluid that has accumulated, and help them find evidence of comfort in the client's nonverbal behavior (Kolb et al, 2018).

Risk for Allergy Reaction

Domain 11 Safety/protection Class 5 Defensive processes

Julianne E. Doubet, BSN, RN, EMT-B

NANDA-I

Definition

Susceptible to an exaggerated immune response or reaction to substances, which may compromise health.

Risk Factors

Exposure to allergen; exposure to environmental allergen; exposure to toxic chemicals; inadequate knowledge about avoidance of relevant allergens; inattentive to potential allergen exposure

At-Risk Population

Individuals with history of food allergy; individuals with history of insect sting allergy; individuals with repeated exposure to allergen-producing environmental substance

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Allergic Response: Systemic; Immune Hypersensitivity Response; Knowledge: Health Behavior, Risk Control, Risk Detection; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Immune Hypersensitivity Response as evidenced by the following indicators: Respiratory, cardiac, gastrointestinal, renal and neurological function status IER/Free of allergic reactions. (Rate each indicator of **Immune Hypersensitivity Response:** 1 = not controlled, 2 = slightly controlled, 3 = moderately controlled, 4 = well controlled, 5 = very well controlled [see Section I].)

IER, In expected range.

Client Outcomes

Client Will (Specify Time Frame)

- State risk factors for allergies
- Demonstrate knowledge of plan to treat allergic reaction

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Allergy Management; Environmental Risk Protection

Example NIC Activity

Place an allergy band on client

Nursing Interventions and *Rationales*

- A careful history is important in detecting allergens and avoidance of these allergens. **EB:** *In a review of the National Institute for Health and Care Excellence (NICE) recommendations, Walsh (2017) agreed that food allergies may be identified by using an "allergy-focused clinical history."*
- Obtain a precise history of allergies, as well as medications taken and foods ingested before surgery. **EB:** *In their study of perioperative anaphylaxis, Meng et al (2017) confirmed that antibiotics and neuromuscular blocking agents are common producers of anaphylaxis.*

▲ Teach the client about the correct use of the injectable epinephrine and have the client do a return demonstration. **EB:** *Research on the correct use of the injectable epinephrine showed that 84% of the clients were unable to do it correctly (Bonds, Asawa, & Ghazi, 2015).*

▲ Carefully assess the client for allergies. *Below is information that is important for clients with allergies. Refer for immediate treatment if anaphylaxis is suspected.*

Causes

Common allergens include animal dander; bee stings or stings from other insects; foods, especially nuts, fish, and shellfish; insect bites; medications; plants; pollens

Symptoms

Common symptoms of a mild allergic reaction include hives (especially over the neck and face); itching; nasal congestion; rashes; watery, red eyes

Symptoms of a moderate or severe reaction include cramps or pain in the abdomen; chest discomfort or tightness; diarrhea; difficulty breathing; difficulty swallowing; dizziness or lightheadedness; fear or feeling of apprehension or anxiety; flushing or redness of the face; nausea and vomiting; palpitations; swelling of the face, eyes, or tongue; weakness; wheezing; unconsciousness

First Aid

For a mild to moderate reaction: calm and reassure the person having the reaction because anxiety can worsen symptoms.

A

1. Try to identify the allergen and have the person avoid further contact with it. If the allergic reaction is from a bee sting, scrape the stinger off the skin with something firm (e.g., fingernail or plastic credit card). Do not use tweezers; squeezing the stinger will release more venom.
2. Apply cool compresses and over-the-counter hydrocortisone cream for itchy rash.
3. Watch for signs of increasing distress.
4. Get medical help. For a mild reaction, a health care provider may recommend over-the-counter medications (e.g., antihistamines).

For a Severe Allergic Reaction (Anaphylaxis)

1. Check the person's airway, breathing, and circulation (the ABCs of Basic Life Support). A warning sign of dangerous throat swelling is a very hoarse or whispered voice or coarse sounds when the person is breathing in air. If necessary, begin rescue breathing and cardiopulmonary resuscitation.
2. Call 911.
3. Calm and reassure the person.
4. If the allergic reaction is from a bee sting, scrape the stinger off the skin with something firm (e.g., fingernail or plastic credit card). Do not use tweezers; squeezing the stinger will release more venom.
5. If the person has emergency allergy medication on hand, help the person take or inject the medication as soon as possible. Avoid oral medication if the person is having difficulty breathing. **EB:** *Delaying the administration of epinephrine for anaphylaxis may be associated with higher morbidity and mortality (Shaker et al, 2020).*
6. Take steps to prevent shock. Have the person lie flat, raise the person's feet about 12 inches, and cover him or her with a coat or blanket. Do NOT place the person in this position if a head, neck, back, or leg injury is suspected or if it causes discomfort.

Do NOT

- Do NOT assume that any allergy shots the person has already received will provide complete protection.
- Do NOT place a pillow under the person's head if he or she is having trouble breathing. This can block the airways.
- Do NOT give the person anything by mouth if the person is having trouble breathing.

When to Contact a Medical Professional

Call for immediate medical emergency assistance if:

- The person is having a severe allergic reaction—always call 911. Do not wait to see if the reaction is getting worse.
- The person has a history of severe allergic reactions (check for a medical ID tag).

Prevention

- Avoid triggers such as foods and medications that have caused an allergic reaction (even a mild one) in the past. Ask detailed questions about ingredients when you are eating away from home. Carefully examine ingredient labels. **EB:** *Education concerning allergen vulnerability will help clients to prevent most accidental exposures to known allergic triggers (Mahr & Hernandez-Trujillo, 2017).*
- If you have a child who is allergic to certain foods, introduce one new food at a time in limited amounts so you can recognize an allergic reaction. **EB:** *There is a decrease in the threat for the evolution of food allergies in clients who are at risk with the early introduction of known allergy-producing foods: abstaining from these types of foods, without a clear history of allergic reactions, may increase the chances of developing an allergy (Schroer, Bjelac, & Leonard, 2017).*
- People who know that they have had serious allergic reactions should wear a medical ID tag. **EBN:** *Anaphylaxis is a dangerous, unpredictable, and usually rapid hypersensitivity response to an allergen and is generally caused by a known irritant; it is advised, then, that those who have had a severe allergic reaction wear medical alert jewelry (Hunt, 2016).*
- Preoperative clients should be closely assessed for allergies. **EB:** *According to Kuric et al (2017), general anesthesia may mask the classic, initial signs of allergy, which would be seen in the conscious client.*
- For clients with a history of serious allergic reactions, counsel to carry emergency medications (e.g., a chewable form of diphenhydramine and injectable epinephrine or a bee sting kit) according to their health care provider's instructions. **EB:** *The initial intervention for anaphylaxis should be epinephrine; medical providers across the board agree that its quick administration is vital to prevent progression of the reaction and improve client outcomes and that epinephrine use will contribute to a decrease in hospitalizations and fatalities (Fromer, 2016).*
- Instruct clients to not give their injectable epinephrine (or any other personal medication) to anyone else as they may have a condition (e.g., a heart problem) that could be negatively affected by this drug. **EB:**

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Those who "borrow" medications may defer primary treatment and delay professional assistance for their illness, plus the borrowed medication could mask serious symptoms of severe disease (Markotic et al, 2017).

▲ Refer the client for skin testing to confirm IgE-mediated allergic response. **EB:** *Stylianou et al (2016) stated that allergen-specific immunotherapy (SIT) is thought to be the most effective remedy for immunoglobulin E (IgE)–mediated allergies.*

● Provide all clients with a history of anaphylaxis with education about anaphylaxis, risk of recurrence, trigger avoidance, self-injectable epinephrine, and thresholds for further care. **EB:** *Evidence related to client education for anaphylaxis is associated with optimal outcomes (Shaker et al, 2020).*

▲ Refer all clients with a history of anaphylaxis to an allergist for follow-up evaluation. **EB:** *Evidence related to allergist referral for anaphylaxis is associated with optimal outcomes (Shaker et al, 2020).*

● See care plan for Risk for **Latex Allergy** Reaction.

Pediatric

● Teach parents and children with allergies to peanuts and tree nuts to avoid them and to identify them. **EBN:** *Nut allergies can have an undesirable impact on both the individual and their family; the key responsibilities of the nurse is ongoing support of those affected and aiding in creating a management plan to control allergen response (Proudfoot & Saul, 2016).*

● Teach parents and children with asthma about modifiable risk factors, which include allergy triggers. **EBN:** *Proudfoot & Saul (2016) recommended that those who care for asthmatic children have a "Risk Assessment Management Plan" that includes avoidance of the allergen (e.g., nuts), rescue medication, diabetic referral as needed, and continued support for both child and family.*

● Counsel parents to limit infant exposure to traffic and cigarette carbon monoxide pollution. **EBN:** *Children exposed to secondhand smoke (SHS) have an elevated rate of respiratory infections, ear infections, SHS-triggered asthma attacks, and sudden infant death syndrome (Kleier, Mites-Campbell, & Henson-Evertz, 2017).*

▲ Refer clients for food protein–induced enterocolitis syndrome (FPIES) in formula-fed infants with repetitive emesis, diarrhea, dehydration, and lethargy 1 to 5 hours after ingesting the offending food (the most common are cow's milk, soy, and rice). Remove the offending food. **EB:** *If FPIES becomes chronic, it may lead to an infant's failure to thrive (Nowak-Wegrzyn et al, 2015).*

▲ Children should be screened for seafood allergies and if an allergy is detected, avoid seafood and any foods containing seafood. **EB:** *According to a study by Presler (2016), fish and shellfish are powerful allergens that cause grave IgE antibody–mediated untoward reactions in those who are sensitive.*

A

Anxiety

Domain 9 Coping/stress tolerance Class 2 Coping responses

Lorraine Chiappetta, MSN, RN, CNE

NANDA-I

Definition

An emotional response to a diffuse threat in which the individual anticipates nonspecific impending danger, catastrophe, or misfortune.

Defining Characteristics

Behavioral/Emotional

Crying; decrease in productivity; expresses anguish; expresses anxiety about life event changes; expresses distress; expresses insecurity; expresses intense dread; helplessness; hypervigilance; increased wariness; insomnia; irritable mood; nervousness; psychomotor agitation; reduced eye contact; scanning behavior; self-focused

Physiological Factors

Altered respiratory pattern; anorexia; brisk reflexes; chest tightness; cold extremities; diarrhea; dry mouth; expresses abdominal pain; expresses feeling faint; expresses muscle weakness; expresses tension; facial flushing; increased blood pressure; increased heart rate; increased sweating; nausea; pupil dilation; quivering voice; reports altered sleep-wake cycle; reports heart palpitations; reports tingling in extremities; superficial vasoconstriction; tremors; urinary frequency; urinary hesitancy

Cognitive Factors

Altered attention; confusion; decreased perceptual field; expresses forgetfulness; expresses preoccupation; reports blocking of thoughts; rumination

Related Factors

Conflict about life goals; interpersonal transmission; pain; stressors; substance misuse; unfamiliar situation; unmet needs; value conflict

At-Risk Population

Individuals experiencing developmental crisis; individuals experiencing situational crisis; individuals exposed to toxins; individuals in the perioperative period; individuals with family history of anxiety; individuals with hereditary predisposition

Associated Conditions

Mental disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Anxiety Level; Anxiety Self-Control; Coping; Impulse Self-Control Fear Level; Fear Self-Control; Mood Equilibrium

Example NOC Outcome with Indicators

Anxiety Self-Control as evidenced by the following indicators: Eliminates precursors of anxiety/Monitors physical manifestations of anxiety/Controls anxiety response. (Rate the outcome and indicators of **Anxiety Self-Control:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Client Outcomes

Client Will (Specify Time Frame)

- Identify and verbalize symptoms of anxiety
- Identify, verbalize, and demonstrate techniques to manage anxiety
- Verbalize absence of or decrease in subjective distress
- Have vital signs that reflect baseline or decreased sympathetic stimulation
- Have posture, facial expressions, gestures, and activity levels that reflect decreased distress or a more tolerable level of anxiety
- Demonstrate improved concentration and accuracy of thoughts
- Demonstrate return of basic problem-solving skills
- Demonstrate increased external focus
- Demonstrate some ability to reassure self

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Anxiety Reduction; Calming Technique; Coping Enhancement; Impulse Control Training; Relaxation Therapy

Example NIC Activities—Anxiety Reduction

Use calm, reassuring approach; Explain all procedures, including sensations likely to be experienced during the procedure

Nursing Interventions and *Rationales*

- Assess the client's level of anxiety by noticing the physiologic, emotional, cognitive, and behavioral symptoms associated with the feeling state of anxiety. **EBN:** *Understanding the different levels of anxiety determines the most effective interventions. Assessing anxiety level on admission may help nurses develop plans of care that improve the client experience (Baldwin & Spears, 2019).*
- Introduce yourself and your role, explain what you will be doing and why, and explain usual hospital procedures. **EBN:** *Nurses can attempt to reduce any anxiety that clients experience by explaining the planned medical intervention and providing accurate information at the optimum time (Price, 2017).*
- Intervene when possible to remove sources of anxiety. **EBN:** *Aiding in the reduction of anxiety is an essential nursing intervention in client care state (Elham et al, 2015).*
- Explain all activities, procedures, and issues that involve the client; use nonmedical terms and calm, slow speech; and then validate the client's understanding. **EBN:** *In a study of the needs of anxious and/or depressed clients, Kim (2016) found that nursing care must include person-centered undertakings to form a bond between client and nurse, therefore reassuring and empowering these clients.*
- ▲ Use massage therapy to reduce anxiety. **EBN:** The use of massage therapy has been shown to markedly reduce psychological stress and anxiety (Kim et al, 2016).
- ▲ Consider massage therapy for preoperative clients. **EBN:** Complementary therapies, including massage, have been shown to aid client relaxation before surgery (Hansen, 2015).
- Use guided imagery to decrease anxiety. **EBN:** *Guided imagery can be used to aid clients in handling undesirable emotions connected with the symptoms of their illness* (Nooner et al, 2016).
- Suggest yoga to the client. **EBN:** *In a study by Centrella-Negro (2017), it was noted that the practice of yoga was beneficial to the welfare and comfort of cardiac clients.*
- Provide clients with a means to listen to music of their choice or audiotapes. **EBN:** *According to Quach (2017), nurses and other providers should recognize the value of music therapies and use them in client care when appropriate.*
- ▲ Refer to cognitive behavioral therapy (CBT). **EB:** *A systematic review found that Internet-delivered CBT was a cost-effective treatment for anxiety when compared with control treatments (Ophuis et al, 2017).*

Pediatric

- The previously mentioned interventions may be adapted for the pediatric client.

A

Geriatric

▲ Monitor the client for depression. Use appropriate interventions and referrals. **EBN/EB:** *Gould et al (2016) stated that "Anxiety disorders are common and debilitating in older individuals" and further noted that simple tests used to recognize anxiety symptoms in the older client are beneficial because they can begin discussions about current treatments.*

● Limit the use of benzodiazepines and nonbenzodiazepine agents for anxiety in the older adult. If these drugs must be used, give the lowest dose possible for short-term use only. **EB:** *Use of these medications increases the risk of development of delirium and increases fall risk in the elderly population (Subramanyam et al, 2018).*

Multicultural

● Identify how anxiety is manifested in the culturally diverse client. **EB:** *People of non-Western ethnocultural origins many times have diverse ideas and contrasting perceptions of mental health and illness as opposed to those from Western societies (Neftçi & Barnow, 2016).*

▲ Refer to culturally adapted CBT. **EB:** *A systematic review found that CBT was an effective anxiety treatment for Latinos and that cultural adaptations addressed some treatment barriers (Casas, Benuto, & González, 2020).*

Home Care

● The previously mentioned interventions may be adapted for home care use.

● Encourage effective communication between family members. **EB:** *Family can be a key site of support for individuals who are diagnosed with a health issue, as long as the health condition is known within the family unit (Hays, Maliski, & Warner, 2017).*

● Assist family in being supportive of the client in the face of anxiety symptoms. **EBN:** *Vieira et al (2015) surmised in a study that both client and caregiver/family must realize and accept that medical conditions will bring a change of lifestyle for each and they should adapt as best they can.*

▲ Consider referral for the prescription of antianxiety or antidepressant medications for clients who have panic disorder or other anxiety-related psychiatric disorders. **EBN:** *Pharmacotherapy is an effective intervention for anxiety disorders because it decreases symptoms and enhances a sense of well-being for the client (da Cruz et al, 2016).*

▲ Assist the client/family to institute the medication regimen appropriately. Instruct in side effects and the importance of taking medications as ordered. **EBN:** *Instruct the client and/or caregivers concerning possible drug side effects and interactions that could have detrimental results (e.g., sleepiness, nausea) on the client and be certain the client/caregiver understands how the medication is to be given (Creed, 2017).*

Client/Family Teaching and Discharge Planning

● Provide basic teaching information about anxiety and anxiety disorders that includes signs and symptoms, risk factors, treatments, and therapies. **EB:** *The results of this study indicate that higher stress perception scores are significantly correlated with the need for more client and caregiver education on health-related issues (Abuatiq et al, 2020).*

● Provide client education about medications that includes side effects, ways to manage side effects, special administration issues (e.g., take with food, take at night), including which medications to avoid using concurrently. Education should also include a list of adverse effects that should be reported to the health care practitioner. **EBN:** *For safe and effective therapy, clients need to understand their medications, especially at discharge (Talbot, 2018).*

▲ Teach use of appropriate community resources in emergency situations (e.g., suicidal thoughts), such as hotlines, emergency departments, law enforcement, and judicial systems. **EB:** *Boudreaux et al (2016) suggested that community mental health services, delivered in conjunction with community emergency departments, may improve client commitment to aftercare and, as a result, reduce future behavioral health crises as well as decrease return visits to the emergency department.*

● Teach the client to visualize or fantasize about the absence of anxiety or pain, successful experience of the situation, resolution of conflict, or outcome of procedure. **EB:** *Guided imagery has been shown to augment comfort and can be used as a psychosupportive intervention (Satija & Bhatnagar, 2017).*

● Teach the relationship between a healthy physical and emotional lifestyle and a realistic mental attitude. **EBN:** *Jiwani (2016) stated that "anxiety leads to physiological and psychological changes in the human body" and can be controlled with various learned self-help techniques.*

A

Death Anxiety

Domain 9 Coping/stress tolerance Class 2 Coping responses

Lorraine Chiappetta, MSN, RN, CNE

NANDA-I

Definition

Emotional distress and insecurity, generated by anticipation of death and the process of dying of oneself or significant others, which negatively effects one's quality of life.

Defining Characteristics

Dysphoria; expresses concern about caregiver strain; expresses concern about the impact of one's death on significant other; expresses deep sadness; expresses fear of developing terminal illness; expresses fear of loneliness; expresses fear of loss of mental abilities when dying; expresses fear of pain related to dying; expresses fear of premature death; expresses fear of prolonged dying process; expresses fear of separation from loved ones; expresses fear of suffering related to dying; expresses fear of the dying process; expresses fear of the unknown; expresses powerlessness; reports negative thoughts related to death and dying

A

Related Factors

Anticipation of adverse consequences of anesthesia; anticipation of impact of death on others; anticipation of pain; anticipation of suffering; awareness of imminent death; depressive symptoms; discussions on the topic of death; impaired religiosity; loneliness; low self-esteem; nonacceptance of own mortality; spiritual distress; uncertainty about encountering a higher power; uncertainty about life after death; uncertainty about the existence of a higher power; uncertainty of prognosis; unpleasant physical symptoms

At-Risk Population

Individuals experiencing terminal care of significant others; individuals receiving terminal care; individuals with history of adverse experiences with death of significant others; individuals with history of near-death experience; older adults; women; young adults

Associated Conditions

Depression; stigmatized illnesses with high fear of death; terminal illness

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Acceptance: Health Status; Anxiety Self-Control; Comfort Status: Psychospiritual; Comfortable Death; Coping; Dignified Life Closure; Family Coping; Fear Self-Control; Grief Resolution; Health Beliefs: Perceived Threat: Hope; Personal Resiliency; Psychosocial Adjustment; Life Change; Quality of Life

Example NOC Outcome with Indicators

Dignified Life Closure as evidenced by the following indicators: Expresses readiness for death/Resolves important issues/Shares feelings about dying/Discusses spiritual concerns. (Rate the outcome and indicators of **Dignified Life Closure:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Express feelings associated with death and the process of dying
- State concerns about impact of death on others
- Seek help in dealing with feelings
- Discuss realistic goals
- State concerns about the impact of death on significant others
- Use strategies to lessen anxiety surrounding death and dying including spiritual intelligence and finding meaning in one's life
- Use spiritual support for comfort

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening; Animal Assisted Therapy; Anticipatory Guidance; Anxiety Reduction; Aromatherapy; Coping Enhancement; Dying Care; Emotional Support; Grief Work Facilitation; Journaling; Respite Care; Spiritual Support; Support System Enhancement

Example NIC Activities—Dying Care

Communicate willingness to discuss death; Support client and family through stages of grief

Nursing Interventions and *Rationales*

- Complete a comprehensive nursing assessment on individuals with life-limiting illnesses. **EB:** The National Consensus Project Clinical Practice Guidelines for Quality Palliative Care includes the following content

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

domains of palliative care assessment and interventions: Structures and processes of care; physical aspects of care; psychological and psychiatric aspects of care; social aspects of care; spiritual, religious, and existential aspects of care; cultural aspects of care; care of the imminently dying client; ethical and legal aspects of care (*Ahluwalia et al, 2018*). **EB:** A thorough assessment paves the way to the most effective treatments of death anxiety, tailored to the individual's unique needs (*Menzies & Menzies, 2020*).

- Assess family and caregivers' responses to death and dying, looking for symptoms of death anxiety. **EB:** *Despite a high prevalence of death anxiety among family caregivers, it is frequently undiagnosed and can lead to denial of the client's death, a worse quality of life, greater risk of depression, and caregiver overwork (Abreu-Figueiredo et al, 2019).*
- Assess for the development of new maladaptive coping in response to the powerful sense of fear or meaninglessness that is associated with awareness of death. **EB:** *Awareness of death may also produce a powerful sense of fear or meaninglessness and may drive a number of maladaptive coping behaviors (Menzies & Menzies, 2020).*
- Develop a trusting therapeutic relationship with the client and family. **EB:** *A trusting relationship is important for the delivery of client-focused care and the development of trust is an essential component of that relationship (Polansky, 2019).*
- Continue to remain available and to use empathetic communication skills so that the client and family will continue to feel comfortable discussing ongoing concerns. **EB:** *In a study in which caregivers were interviewed, participation in the study was viewed as a positive experience because it gave participants the opportunity to express certain fears and concerns and because they felt that they were understood (Abreu-Figueiredo et al, 2019).*
- Assess clients for pain and provide pain relief measures. **EB:** *Pain can be a significant problem that has important ramifications on clients' quality of life and the management of pain can be obstructed by poor client–provider communication (Johnsen et al, 2016).*
- Assess client for fears related to death. **EB:** *In their study of chronic obstructive pulmonary disease (COPD) clients with end-of-life issues, Stenzel et al (2015) found that client care should not be limited to managing just the physical manifestation of the disease but also the need to address psychological anxiety and disease-specific concerns.*
- Use psychosocial techniques to decrease distress. **EB:** *Meta-analysis showed life review and meaning-based techniques/interventions such as dignity therapy (a therapy that gives clients the opportunity to speak about their life accomplishments and roles), mindfulness, and creative arts–based therapy to be effective in improving quality of life and in reducing emotional distress and existential suffering in clients receiving palliative care (Warth et al, 2019).*
- Assist clients with life planning: consider and redefine main life goals, focus on areas of strength and/or goals that will provide satisfaction, adopt realistic goals, and recognize those that are impossible to achieve. **EBN:** *Nurses have an obligation to communicate with those under their care, which should include the discussion of life preferences and relating pertinent, personal information (Coyle et al, 2015).*
- Assist clients with life review and reminiscence. **EBN:** *Chen et al (2017) found in their studies of life review, for those suffering life-threatening illnesses, that this practice aided in diminishing depression and augmenting self-esteem.*
- Provide music of the client's choosing**.** **EB:** *There is convincing evidence that music effectively assists those facing end-of-life concerns (Clement-Cortis, 2016).*
- Provide social support for families: understanding what is most important to families who are caring for clients at the end of life. **EBN:** *Nurses, who deal not only with technical and resuscitative aspects of critical client care, are now developing their expertise to include "advocating for, communicating with, teaching, and guiding clients and families through end-of-life issues" (Banjar, 2017).*
- Encourage clients to use spiritual supports. **EBN:** *The Society of Critical Care Medicine recommends that the spiritual needs of clients facing a critical end-of-life illness should be recognized and managed by the health care team (Fournier, 2017).*
- Explore ways to provide spiritual support by asking clients what is important to them and what you can do to help and refer as needed. **EB:** *Specific interventions, such as spiritual support and logotherapy (finding meaning in life), can reduce death anxiety (Abreu-Figueiredo et al, 2019).*
- As a nurse, be aware of your own increased risk of experiencing symptoms of death anxiety and the negative impact this may have on your well-being. Seek support as needed. **EB:** *Death anxiety is commonly experienced (by nurses) and is associated with more negative consequences for self and clients (Sharif Nia et al, 2016).*

Geriatric

- Carefully assess older adults for issues regarding death anxiety. **EB:** *This study by Bonnewyn et al (2016) proposed that the way older adults perceive dying, in part, affects whether they have a desire to die: it could be advantageous to explore the subject of death with your client.*
- Assess the individual's resolution of Erikson's developmental stage of integrity versus despair. In this stage those age 65 and older reflect on their life and either move into feeling satisfied and happy with one's life or feel a deep sense of regret. **EB:** *Successful resolution of integrity versus despair developmental crisis in old age is associated with decreased death anxiety (Taghiabadi et al, 2017).*
- Teach components of spiritual intelligence (the adaptive use of spiritual information to facilitate everyday problem solving and goal attainment). **EB:** *Learning the components of spiritual intelligence reduces the extent of death anxiety in the elderly (Majidi & Moradi, 2018).*
- Use strategies to strengthen the individual's spiritual health and support use of religion as a coping strategy when applicable. **EB:** *There is a positive relationship between spiritual health, religious coping, and reduced death anxiety in the elderly (Solaimanizadeh et al, 2020).*
- Refer to care plan for Maladaptive **Grieving.**

Multicultural

- Assist clients to identify with their culture and its values. **EBN:** *Cultures stand apart in their approach to how death is framed, viewed, and accepted (MacCloud et al, 2016).*
- Refer to care plans for **Anxiety** and Maladaptive **Grieving.**

Home Care

- The previously mentioned interventions may be adapted for home care.
- ▲ Support and facilitate a discussion of advance care plans/advanced directives as another strategy to lessen verbalized fears and concerns about death and the dying process. Document decisions. **EB:** *Residents with end-of-life care instructions in place were three times less likely to experience fear and anxiety in their last days than those who did not (Carr & Luth, 2017).*
- ▲ Make referrals to mental health professionals for CBT or logotherapy. **EB:** *Logotherapy is an existential psychotherapy that can help a person find meaning in life (Abreu-Figueiredo et al, 2019).* **EB:** *Meta-analysis revealed that psychosocial interventions produced significant reductions in death anxiety relative to control conditions (Menzies & Menzies, 2020).*
- ▲ Refer to appropriate medical services, social services, and/or mental health services, as needed. **EBN:** *The union between physical health and mental health needs requires added awareness and acknowledgment in the contemporary nursing care of palliative clients (Hayes, 2017).*
- ▲ Identify the client's preferences for end-of-life care; aid in honoring preferences as much as practicable. **EBN:** *To engage in person-centered care at end of life requires the entire health care team to enlist clients and families in communication and decision-making, especially about the clients' preferences and decisions concerning the use of life-extending technologies (Nouvet et al, 2016).*
- Refer to care plan for **Powerlessness.**

Client/Family Teaching and Discharge Planning

- Give information and reassurance to clients and families that distressing symptoms can often be anticipated and prevented and, when present, can be treated by health care professionals. **EB:** *A significant factor in the development of death anxiety was identified as fear of loneliness and abandonment (Abreu-Figueiredo et al, 2019).*
- Keep client and families informed about current health status and what to expect in the future. **EB:** *The findings of this study showed that the use of a health literacy might decrease levels of death anxiety in breast cancer clients (Bahrami & Behbahani, 2019).*
- Promote more effective communication to family members engaged in the caregiving role. **EB:** *Nurses can support family caregivers by fostering client–caregiver teamwork, family communication, and self-care; providing information; and referring to appropriate resources (Wittenberg et al, 2017).*

A

Risk for Aspiration

Domain 11 Safety/protection Class 2 Physical injury

Debra Siela, PhD, RN, ACNS-BC, CCRN-K, CNE, RRT

NANDA-I

Definition

Susceptible to entry of gastrointestinal secretions, oropharyngeal secretions, solids, or fluids to the tracheobronchial passages, which may compromise health.

Risk Factors

Barrier to elevating upper body; decreased gastrointestinal motility; difficulty swallowing; enteral nutrition tube displacement; inadequate knowledge of modifiable factors; increased gastric residue; ineffective airway clearance

A

At-Risk Population

Older adults; premature infants

Associated Conditions

Chronic obstructive pulmonary disease; critical illness; decreased level of consciousness; delayed gastric emptying; depressed gag reflex; enteral nutrition; facial surgery; facial trauma; head and neck neoplasms; incompetent lower esophageal sphincter; increased intragastric pressure; jaw fixation techniques; medical devices; neck surgery; neck trauma; neurological diseases; oral surgical procedures; oral trauma; pharmaceutical preparations; pneumonia; stroke; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Aspiration Prevention; Respiratory Status: Ventilation; Swallowing Status

Example NOC Outcome with Indicators

Aspiration Prevention as evidenced by the following indicators: Avoids risk factors/Maintains oral hygiene/Positions self upright for eating and drinking/Selects foods according to swallowing ability/Selects foods and fluid of proper consistency/Remains upright for 30 minutes after eating. (Rate the outcome and indicators of **Aspiration Prevention:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = continually demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain patent airway and clear lung sounds
- Swallow and digest oral, nasogastric, or gastric feeding without aspiration

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Aspiration Precautions

Example NIC Activities—Airway Management

Monitor level of consciousness, cough reflex, gag reflex, and swallowing ability; Check nasogastric or gastrostomy residual before feeding

Nursing Interventions and *Rationales*

- Monitor respiratory rate, depth, and effort. Note any signs of aspiration such as dyspnea, cough, cyanosis, wheezing, hoarseness, foul-smelling sputum, or fever. If there is a new onset of symptoms, perform oral suction and notify provider immediately. **EB:** *Signs of aspiration should be detected as soon as possible to prevent further aspiration and to initiate treatment that can be lifesaving (Gamache & Kamangar, 2018). Because of laryngeal pooling and residue in clients with dysphagia, silent aspiration may occur (Metheny, 2011b; Velayutham et al, 2018).*
- Auscultate lung sounds frequently and before and after feedings; note any new onset of crackles or wheezing. **EB:** *With decreased symptoms of pneumonia, an increased respiratory rate and/or crackles may be the first sign of pneumonia (Velayutham et al, 2018).*
- Take vital signs frequently, noting onset of a fever, increased respiratory rate, and increased heart rate. **EB:** *Implementation of an adapted aspiration risk assessment screening tool to document risk of hospital-acquired aspiration pneumonia and aspiration precautions protocol was associated with a decrease in aspiration pneumonia rates (Cipra, 2019).*
- Use of a bedside-aspiration risk screening process along with dysphagia therapists for acutely ill clients is a factor in decreasing client mortality from acquired aspiration. **EB:** *A systematic review and meta-analysis found that bedside aspiration risk screening with water offers sufficient information concerning aspiration risk, especially when other symptoms such as cough and choking with or without voice change occurs during the introduction of sips of water (Brodsky et al, 2016).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Before initiating oral feeding, check client's gag reflex and ability to swallow by feeling the laryngeal prominence as the client attempts to swallow (American Association of Critical Care Nurses, 2016a; Wangen, et al., 2019). If client is having problems swallowing, see nursing interventions for Impaired **Swallowing.**
- If client needs to be fed, feed slowly and allow adequate time for chewing and swallowing. **EB:** *Slowed feeding and fully chewing food allows time for more deliberate swallowing, reducing aspiration (Lee & Huang, 2019).* **EB:** *When feeding client, watch for signs of impaired swallowing or aspiration, including coughing, choking, change in voice, and spitting food (Brodsky et al, 2016).*
- Have suction machine available when feeding high-risk clients. If aspiration does occur, suction immediately. **EB:** *A client with aspiration needs immediate suctioning and may need further lifesaving interventions such as intubation and mechanical ventilation (Morata & Walsh, 2021).*
- Keep the head of the bed (HOB) elevated at 30 to 45 degrees, preferably with the client sitting up in a chair at 90 degrees when feeding. Keep head elevated for an hour after eating. **CEB/EB:** *Decreased gastric reflux occurs at both 30- and 45-degree HOB elevation. Thus, gastric-fed clients should be maintained at the highest HOB elevation that is comfortable to prevent aspiration (Metheny & Frantz, 2013; Morata & Walsh, 2021).*
- Note presence of nausea, vomiting, or diarrhea. Treat nausea promptly with antiemetics.
- If the client shows symptoms of nausea and vomiting, position on side. **EB:** *The side-lying position can help the client expel the vomitus and decrease the risk for aspiration (Morata & Walsh, 2021).*
- Assess the abdomen and listen to bowel sounds frequently, noting if they are decreased, absent, or hyperactive. **EB:** *Decreased or absent bowel sounds can indicate an ileus with possible vomiting and aspiration; increased high-pitched bowel sounds can indicate a mechanical bowel obstruction with possible vomiting and aspiration (Hasler & Owyang, 2018).*
- Note new onset of abdominal distention or increased rigidity of abdomen. **EB:** *Abdominal distention or rigidity can be associated with paralytic or mechanical obstruction and an increased likelihood of vomiting and aspiration (Hasler & Owyang, 2018).*
- If client has a tracheostomy, ask for referral to speech pathologist for swallowing studies before attempting to feed. **EB:** *There is an increased risk for aspiration when tracheostomy tubes are in place, and inflating the cuff does not prevent aspiration (Morata & Walsh, 2021).*
- Provide meticulous oral care including brushing of teeth at least two times per day. **EB:** *Good oral care can prevent bacterial or fungal contamination of the mouth, which can be aspirated (American Association of Critical Care Nurses, 2017a).* **CEB:** *Research has shown that excellent dental care/oral care can be effective in preventing hospital-acquired (or extended care–acquired) pneumonia (Munro, 2014).* **EB:** *Chlorhexidine mouthwash or gel reduces the incidence of developing ventilator-associated pneumonia in critically ill clients compared to placebo or usual care (Veitz-Keenan & Ferraiolo, 2017; Zhao et al, 2020).*
- Sedation agents can reduce cough and gag reflexes as well as interfere with the client's ability to manage oropharyngeal secretions. **EB:** *Using the smallest effective level of sedation may help reduce risk of aspiration (American Association of Critical Care Nurses, 2016a; Devlin et al, 2018).*

Enteral Feedings

- Insert nasogastric feeding tube using the internal nares to distal-lower esophageal-sphincter distance, an updated version of the Hanson method. The ear-to-nose-to-xiphoid process is often inaccurate. **CEB:** *A study demonstrated that the revised Hanson's method was more accurate in predicting the correct distance than the traditional method (Ellett et al, 2011).*
- Before instilling medication or enteral feeding, ensure proper gastric/duodenal tube placement. **CEB/EB:** *Verification of gastric tube placement should initially be obtained by radiography. Other methods of assessing proper gastric tube placement include capnography, aspirate assessment, tube markings, and pH tests. Auscultation should not be used to assess gastric tube placement (Metheny, Stewart, & McClave, 2011; Amirlak et al, 2012; Williams et al, 2014; American Association of Critical Care Nurses, 2016b).* **EB:** *If technology is present for confirmation by electromagnetic placement device, an x-ray confirmation of proper placement may not be* required *(Carter, Roberts, & Carson, 2018; Powers et al, 2018).*
- After radiographic verification of correct placement of the tube or the intestines, mark the tube's exit site clearly with tape or a permanent marker. **EB:** *Marking the tube's exit point can enable the nurse to identify possible migration or dislodgement of the tube (McGinnis, 2017).*
- Secure the nasogastric tube securely to the nose using a skin protectant under the tape or commercially available securement device. **CEBN:** *A research study found that insertion of the feeding tube into the small intestine and keeping the HOB position elevated to at least 30 degrees reduced the incidence of aspiration and aspiration-related pneumonia drastically in critically ill clients (Metheny, Davis-Jackson, & Stewart, 2010). Another study found that aspiration and pneumonia were reduced by feeding the clients in the mid-duodenum or farther in the*

A

small intestine (Metheny, Stewart, & McClave, 2011). **EBN:** *A study conducted in a critical care unit found that the nurse placement of a nasal bridal resulted in an 80% reduction in tube dislodgement (Taylor et al, 2018).*

- Measure and record the length of the tube that is outside of the body at defined intervals to help ensure correct placement. **EB:** *Note the length of the tube outside of the body; it is possible for a tube to slide out and be in the esophagus, without obvious disruption of the tape (American Association of Critical Care Nurses, 2016b).*
- Note the placement of the tube on any chest or abdominal radiographs that are obtained for the client. *Acutely ill clients receive frequent x-ray examinations. These are available for the nurse to determine continued correct placement of the nasogastric tube (American Association of Critical Care Nurses, 2016b; Boullata et al, 2017).*
- Check the pH of the aspirate. **EB:** *If the pH reading is 4 or less, the tube is probably in the stomach. Recognize that the pH may not indicate correct placement if the client is receiving continuous tube feedings, is receiving a hydrogen ion blocker or proton pump inhibitor, has blood in the aspirate, or is receiving antacids (American Association of Critical Care Nurses, 2016b). Enteral feeding tube pH can be recommended to evaluate gastric placement in neonates (Metheny et al, 2017; Kemper et al, 2019).*
- Do not rely on the air insufflation method to assess correct tube placement. **CEB/EBN:** *The auscultatory air insufflation method is not reliable for differentiating between gastric or respiratory placement; the "whooshing" sound can be heard even if the tube is incorrectly placed in the lung (Williams et al, 2014; American Association of Critical Care Nurses, 2016b; Boullata et al, 2017).*
- Follow unit policy regarding checking for gastric residual volume during continuous feedings or before feedings and holding feedings if increased residual is present. **CEB/EBN:** *There is little evidence to support the use of measurement of gastric residual volume, and the practice may or may not be effective in preventing aspiration (Boullata et al, 2017). It is still done at intervals if there is a question of tube feeding intolerance (Metheny et al, 2012; American Association of Critical Care Nurses, 2016b).*
- The practice of holding tube feedings if there is increased residual reduces the amount of calories given to the client. **EB:** *If the client has a small-bore feeding tube, it is difficult to check gastric residual volume and may be inaccurate. It is unclear if aspiration for residual volumes helps reduce the risk of aspiration (Metheny et al, 2012). Practice guidelines suggest continuing to feed the client until the residual is greater than 500 mL (Elke, Felbinger, & Heyland, 2015; Boullata et al, 2017; Yasuda et al, 2019).*
- Follow unit protocol regarding returning or discarding gastric residual volume. At this time there is not a definitive research base to guide practice. **EB:** *A recent systematic review and meta-analysis did not find compelling evidence that confirms that returning residual gastric aspirates provides more benefits than discarding them without increasing potential complications (Wen et al, 2019).*
- Do not use blue dye to tint enteral feedings. **CEB:** *The presence of blue and green skin and urine and serum discoloration from use of blue dye has been associated with the death of clients. The U.S. Food and Drug Administration (2003) has reported at least 12 deaths from the use of blue dye in enteral feedings.*
- During enteral feedings, position client with HOB elevated 30 to 45 degrees (*Schallom et al, 2015; American Association of Critical Care Nurses, 2016a).* **EB:** *HOB elevation greater than 30 degrees is feasible and preferred to 30 degrees for reducing oral secretion volume, reflux, and aspiration without pressure ulcer development in gastric-fed clients receiving mechanical ventilation (Schallom et al, 2015; American Association of Critical Care Nurses, 2017b).* **CEBN:** *A seminal study of mechanically ventilated clients receiving tube feedings demonstrated that there was an increase of the presence of pepsin (from gastric contents) in pulmonary secretions if the client was in a flat position versus being positioned with head elevated (Metheny & Frantz, 2013).* **EBN:** *Generally, do not turn off the tube feeding when repositioning clients. Stopping the tube feeding during repositioning is counterproductive because the client receives less nutrition and the rate of emptying of the stomach is slow. If it is imperative to keep the HOB elevated, consider use of reverse Trendelenburg (head higher than feet) when repositioning (Metheny, 2011a). Precautionary withholding of enteral feedings during repositioning does not reduce the incidence of aspiration in critically ill clients (DiLibero et al, 2015).*
- Nursing ventilated premature infants in right lateral position is associated with decreased aspiration of gastric secretions (Imam et al, 2019).
- Take actions to prevent inadvertent misconnections with enteral feeding tubes into intravenous (IV) lines or other harmful connections. Safety actions that should be taken to prevent misconnections include the following:
  - ❍ Trace tubing back to origin. Recheck connections at time of client transfer and at change of shift.
  - ❍ Label all tubing.
  - ❍ Use oral syringes for medications through the enteral feeding; do not use IV syringes.
  - ❍ Teach nonprofessional personnel "Do Not Reconnect" if a line becomes dislodged; rather, find the nurse instead of taking the chance of plugging the tube into the wrong place.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Critical Care

- Recognize that critically ill clients are at an increased risk for aspiration because of severe illness and interventions that compromise the gag reflex. **EB:** *Predisposing causes of aspiration include sedation, endotracheal intubation and mechanical ventilation, neurological disorders, altered level of consciousness, hemodynamic instability, sepsis, and client transport (American Association of Critical Care Nurses, 2016a; Talbert et al, 2020).*
- Recognize that intolerance to feeding as defined by increased gastric residual is more common early in the feeding process. **EB:** *For clients receiving gastric tube feedings, assess for gastrointestinal intolerance to the feedings at 4-hour intervals (American Association of Critical Care Nurses, 2016a).*
- Avoid bolus feedings in tube-fed clients who are at high risk for aspiration (American Association of Critical Care Nurses, 2016a).
- Maintain endotracheal cuff pressures at an appropriate level to prevent leakage of secretions around the cuff (American Association of Critical Care Nurses, 2016a).

Geriatric

- Carefully check older client's gag reflex and ability to swallow before feeding. *A slowed rate of swallowing is common in older adults (Morata & Walsh, 2021).*
- Watch for signs of aspiration pneumonia in older adults with cerebrovascular accidents, even if there are no apparent signs of difficulty swallowing or of aspiration. **EB:** *Bedside evaluation for swallow and aspiration can be inaccurate.* **CEB/EB:** *Silent aspiration can occur in the older population (Metheny, 2011b; Lee & Huang, 2019).*
- Recognize that older adults with aspiration pneumonia have fewer symptoms than younger people; repeat cases of pneumonia in older adults are generally associated with aspiration. **EB:** *Aspiration pneumonia can be undiagnosed in older adults because of decreased symptoms; sometimes the only obvious symptom may be new onset of delirium (Rodriguez & Restrepo, 2019).*
- Continually assess for the presence of gag reflex after critical illness that required mechanical ventilation. **EB:** *In individuals with prolonged ventilation the presence of one or both gag reflexes could predict a reduction in extubation failure related to aspiration or excessive upper airway secretions (Howes et al, 2020).*
- Use central nervous system depressants cautiously; older clients may have an increased incidence of aspiration with altered levels of consciousness. **EB:** *Older clients have altered metabolism, distribution, and excretion of drugs. Many medications can interfere with the swallowing reflex, including antipsychotic drugs, proton pump inhibitors, and angiotensin-converting enzyme inhibitors (Yoon et al, 2019).*
- Keep an older, mostly bedridden client sitting upright for 45 minutes to 1 hour after meals.
- Recommend to families that enteral feedings may or may not be indicated for clients with advanced dementia. Instead, if possible, use hand-feeding assistance, modified food consistency as needed, and feeding favorite foods for comfort. **EB:** *The American Geriatrics Society (2014) recommends that when feeding difficulties arise in individuals with advanced dementia, feeding tubes should not be used as they can increase agitation and result in aspiration leading to pneumonia and death. Careful hand feeding is advised in this population.*

Home Care

- The above interventions may be adapted for home care use.
- For clients at high risk for aspiration, obtain complete information from the discharging institution regarding institutional management.
- Assess the client and family for willingness and cognitive ability to learn and cope with swallowing, feeding, and related disorders.
- Assess caregiver understanding and reinforce teaching regarding positioning and assessment of the client for possible aspiration.
- Provide the client with emotional support in dealing with fears of aspiration. *Fear of choking can provoke extreme anxiety, which can interfere with the client's ability or willingness to adhere to the treatment plan.* Refer to care plan for **Anxiety.**
- Establish emergency and contingency plans for care of the client. *Clinical safety of the client between visits is a primary goal of home care nursing.*
- Have a speech and occupational therapist assess the client's swallowing ability and other physiological factors and recommend strategies for working with the client in the home (e.g., pureeing foods served to the client; providing adequate adaptive equipment for independence in eating). *Successful strategies allow the client to remain part of the family.*

A

- Obtain suction equipment for the home as necessary.
- Teach caregivers safe, effective use of suctioning devices. Inform the client and family that only individuals instructed in suctioning should perform the procedure.
- Institute case management of frail elderly to support continued independent living.

Client/Family Teaching and Discharge Planning

- Teach the client and family signs of aspiration and precautions to prevent aspiration.
- Teach the client and family how to safely administer tube feeding.
- Teach the family about proper client positioning to facilitate feeding and reduce risk of aspiration.
- Verify client family/caregiver knowledge about feeding, aspiration precautions, and signs of aspiration.

Risk for Impaired Attachment

Domain 7 Role relationship Class 2 Family relationships

Margaret Quinn, DNP, CPNP, CNE

NANDA-I

Definition

Susceptible to disruption of the interactive process between parent or significant other and child that fosters the development of a protective and nurturing reciprocal relationship.

Risk Factors

Anxiety; child's illness prevents effective initiation of parental contact; disorganized infant behavior; inability of parent to meet personal needs; insufficient privacy; parent's illness prevents effective initiation of infant contact; parent-child separation; parental conflict resulting from disorganized infant behavior; physical barrier; substance misuse

At-Risk Population

Premature infants

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Parent-Infant Attachment; Parenting Performance: Psychosocial Adjustment: Life Change

Example NOC Outcomes with Indicators

Holds infant close, touches, strokes, pats infant, responds to infant cues, holds infant for feeding, vocalizes to infant. (Rate the outcome and indicators of appropriate parent and infant behaviors that demonstrate an enduring affectionate bond: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

A

Client Outcomes

Parent(s)/Caregiver(s) Will (Specify Time Frame)

- Be willing to consider pumping breast milk (and storing appropriately) or breastfeeding, if feasible
- Demonstrate behaviors that indicate secure attachment to infant/child
- Provide a safe environment, free of physical hazards
- Provide nurturing environment sensitive to infant/child's need for nutrition/feeding, sleeping, comfort, and social play
- Read and respond contingently to infant/child's distress
- Support infant's self-regulation capabilities, intervening when needed
- Engage in mutually satisfying interactions that provide opportunities for attachment
- Give infant nurturing sensory experiences (e.g., holding, cuddling, stroking, rocking)
- Demonstrate an awareness of developmentally appropriate activities that are pleasurable, emotionally supportive, and growth fostering
- Avoid physical and emotional abuse and/or neglect as retribution for parent's perception of infant/child's misbehavior
- State appropriate community resources and support services

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Anticipatory Guidance; Attachment Promotion; Coping Enhancement; Counseling; Developmental Enhancement: Infant; Family Involvement Promotion; Parent Education: Infant; Parenting Promotion

Example NIC Activities—Anticipatory Guidance

Instruct about normal development and behavior, as appropriate; Provide a ready reference for the client (e.g., educational materials, pamphlets) as appropriate

Nursing Interventions and *Rationales*

Mother–Baby Dyad Interventions

- Establish a trusting relationship with parent/caregiver in the perinatal and postnatal period. **EBN:** *The early detection of deficiencies in the maternal-fetal relationship and the timely diagnosis of postpartum depression (PPD) can significantly improve the maternal-neonatal relationship in the future (Dubber et al, 2015).*
- Educate parents about the importance of the infant–caregiver relationship as a foundation for the development of the infant's self-regulation capacities. **EB:** *By showing the "calming and regulating effect" of moderate pressure massage, this study contributes to a greater understanding of the influence of self-regulation on the development of play and playfulness in preterm babies and on mothers' participation in such interventions with their infants (Hendel, 2017).*
- Educate parents in reading/responding sensitively to their infant's unique "body language" (behavior cues), which communicates approach ("I'm ready to play"), avoidance/stress ("I'm unhappy. I need a change."), and self-calming ("I'm helping myself"). **EB:** *Education about the principles of neurodevelopment and behavioral cues make individualized developmentally appropriate, neuroprotective care possible (Altimier & Phillips, 2016).*
- Encourage physical closeness using skin-to-skin experiences as appropriate. **EBN:** *Placing a newborn skin to skin on the mother is the essential first step to promote and establish successful breastfeeding (Jefferson & Bibb, 2019).*

Maternal/Parental Interventions

- Identify factors related to PPD/major depression and offer appropriate interventions/referrals. **EBN:** *A significant and inverse correlation was observed between PPD and all the domains of maternal-fetal attachment (Delvari et al, 2018).*
- Assess for additional comorbid factors related to depression and offer appropriate interventions/referrals. **EB:** *The combination of maternal depression and dual/disorganized attachment style may pose a special risk constellation for the developing mother–infant bond that should be addressed in prevention and early intervention programs (Nonnemacher et al, 2016).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Nurture parents so that they in turn can nurture their infant/child. **EB:** *Family-centered developmental care (FCDC) is designed to meet the needs of all babies, healthy newborns as well as hospitalized infants, and the needs of families coping with the crisis of the neonatal intensive care unit (NICU) experience (Craig et al, 2015).*
- Offer parents opportunities to verbalize their childhood fears associated with attachment. **EBN:** *Infants were more likely to form disorganized attachment relationships if their mothers had histories of attachment disorganization (Raby et al, 2015).*
- Identify mothers who may need assistance in enhancing maternal role attainment (MRA). **EBN:** *Peer support and role modeling may help mothers to develop maternal identity (Rossman et al, 2015).*
- Encourage positive involvement and relationship development between children and fathers. **EBN:** *Attachment between the father and child is significant (Frazier & Scharf, 2015).*

Premature Infants/Infants Requiring Specialty or Intensive Care

- Support mothers of preterm infants in providing pumped breast milk for their babies until they are ready for oral feedings and transitioning from gavage to breast. **CEBN:** *The Spatz Ten Steps model (Spatz, 2004) is associated with "significant improvements in parents' perception of nurses' support for mothers' efforts to breastfeed and [improvement] in the odds of the VLBW [very-low-birth-weight] infant receiving MOM [mother's own milk] at the time of hospital discharge" (Fugate et al, 2015).*
- Suggest journaling or scrapbooking as a way for parents of hospitalized infants to cope with stress and emotions. **EB:** *Narrative writing provides opportunities to remember and organize events in a meaningful and sensible manner. It helps create a feeling of problem-solving, stops unpleasant feelings, and gradually leads to the fading of negative experiences (Kadivar et al, 2015).*
- Offer parent-to-parent support to parents of infants in the NICU. **EBN:** *Quantitative studies showed parent-to-parent support increased perceptions of support, reduced maternal stress, and increased mothers' confidence in the ability to care for their baby (Hunt et al, 2019).*
- Plan ways for parents and their support system to interact/assist with infant/child caregiving. **EB:** *Full participation of parents is essential (Craig et al, 2015).*
- Educate and support parents' ability to relieve the infant/child's stress, distress, or pain. **EBN:** *Various studies demonstrate the efficacy of facilitated tucking as a nonpharmacological pain intervention in premature infants as young as 23 weeks' gestational age during such painful procedures as heel sticks, endotracheal suctioning, and venipuncture (Hartley et al, 2015).*
- Guide parents in adapting their behaviors/activities with infant/child cues and changing needs. **EB:** *Parents' emotional closeness to their preterm NICU infant "may be crucial to the well-being of the newborn, the development of mutual regulation, the establishment of a functioning parent–infant affective relationship and the parents' confidence in their ability to provide care for their baby" (Stefana & Lavelli, 2017).*
- Attend to both parents and infant/child to strengthen high-quality interactions. **EBN:** *NICU fathers of preterm infants have been found to exhibit coping strategies and needs different from NICU mothers. As a result, nursing support and intervention need to be tailored to parents individually to sustain caregiving engagement and the transition to post discharge parenting (Provenzi & Santoro, 2015).*
- Encourage opportunities for physical closeness. **EB:** *A study evaluating 11 NICUs in 6 European countries concluded that units providing facilities for parents to stay overnight had a higher level of parental presence, with younger mothers, in particular, staying close to their infants (Raisklia et al, 2017).*
- Recognize that fathers, compared with mothers, may have different starting points in the attachment process in the NICU because nurses encourage parents to have early skin-to-skin contact (SSC). **EB:** *Results of this Taiwanese study confirm the positive effects of father–infant SSC "in terms of exploring, talking, touching, and caring," as well as the enhancing of the relationship at 3 days postpartum (Chen et al, 2017).*

Pediatric

- Recognize and support infant/child's capacity for self-regulation and intervene when appropriate. *There is a significant yet weak association between attachment security and temperament, suggesting that attachment and temperament are relatively independent developmental constructs (Groh et al, 2017).*
- Provide lyrical, soothing music in the nursery and at home that is age appropriate (i.e., corrected, in the case of premature infants) and contingent with state or behavioral cues. **EBN:** *Implementing early intervention services, such as music therapy in the postpartum unit, can provide new mothers useful music applications that can enhance mother–infant interaction, especially mothers living in high-stress or negative environments (Robertson & Detmer, 2019).*
- Recognize and support infant/child's attention capabilities. **EBN:** *During social interactions, sensitive nonvocal behavior may serve to assist infants in coordinating their attention to objects differently than during*

A

social interactions where vocal behavior dominates, which draws infants' attention to the caregiver (Miller, Hurdish, & Gros-Louis, 2018).

- Encourage opportunities for mutually satisfying interactions between infant and parent. **EB:** *A secure attachment to a primary caregiver is necessary for the development of emotional security and the sense that one's needs are important (Berkowitz, 2020).*
- Encourage parents and caregivers to massage their infants and children. **EB:** *There is evidence that infant massage has beneficial effects on preterm infants in the NICU, including shorter length of stay; reduced pain; and improved weight gain, feeding tolerance, and neurodevelopment. Parents who performed massage with their infants in the NICU reported experiencing less stress, anxiety, and depression (Pados & McGlothen-Bell, 2019).*

Multicultural

- Provide culturally sensitive parent support to new immigrant families and other non–native-English-speaking mothers and families. **EB:** *Culturally competent care must be considered and implemented as a separate standalone aspect when caring for new immigrant and non–native-English-speaking families (Hendson et al, 2015).*
- Discuss cultural norms with families to provide care that is appropriate for enhancing attachment with the infant/child. **EB:** *It is important to consider factors such as who makes decisions on the child's behalf, how the family prefers to communicate and interact with the medical and nursing team, and roles of family members in the home country (Langer et al, 2015).*

Home Care

- The previously mentioned interventions may be adapted for home care use.
- Observe the attachment style and pattern during all clinical encounters with infants and parents. **EBN:** *Health care professionals can teach parents the importance of quality of their interaction with their infant and the effect of attachment on the development of the child's sense of self-worth, comfort, and trust (Hagan et al, 2017).*
- Assess for social and environmental risk factors. **EBN:** *Global maternal insensitivity was associated with higher attachment disorganization for infants of mothers with higher sociodemographic risk, but not for those of mothers with lower sociodemographic risk (Gedaly & Leerkes, 2016).*
- Assess quality of interaction between parent and infant/child. *Within the parent–child relationship, parents' sensitive responsiveness to infant attachment signals is believed to be the principal organizing force shaping the quality of the early attachment relationship (Groh et al, 2017).*

▲ Assess for PPD at the pediatric primary care visit at 1-, 2-, 4-, and 6-month visits. **EB:** *Pediatric primary care providers are in a good position to recognize the signs of PPD because they are in frequent contact with parents of infants (Earls et al, 2019).*

- Empower family members to draw on personal strengths in which multiple worldviews/values are recognized, incorporated, and negotiated. **EBN:** *Infants develop different patterns of attachment to different caregivers depending on the quality of care received from a specific caregiver (Groh et al, 2017).*

Special Considerations

- Promote attachment process/development of maternal sensitivity in incarcerated women. **EB:** *Separation from and attachment to children correlate with higher levels of depression, the influence of the inmate's mother on the context of what is a good mother, and the dichotomous tension (i.e., good mother/bad mother) between expectations and reality for the incarcerated mother (Baker, 2019).*
- Promote the attachment process in women who have abused substances by providing a culturally based, family-centered, supportive treatment environment. **EBN:** *With support, mothers embraced opportunities to bond with their infants, and they frequently acknowledged fears that they may be separated from their infants due to their history of substance use (Kramlich et al, 2018).*

▲ Encourage custodial grandparents to use support groups available for caregivers of children. **EBN:** *In addition to providing useful parenting advice and direct support to custodial grandparents, pediatricians should refer these families as needed to local grandparenting groups, social service agencies, experienced legal counsel, and relevant national organizations for support and guidance (Ge & Adesman, 2017).*

- Provide options for communication for infants and children whose parents have been separated for military or work deployment **EBN:** *Video-mediated communication may be ideally suited when families are separated geographically during the perinatal period and early infancy (e.g., military/work deployment, hospitalization, educational opportunity and migrant/refugee families who send one parent ahead), as it provides communication context by adding visual cues and contextualizing auditory cues (Furukawa, Driessnack, & Kobori, 2020).*

A

Autonomic Dysreflexia

Domain 9 Coping/stress tolerance Class 3 Neurobehavioral stress

Carla Aresco, MSL, CRNP

NANDA-I

Definition

Life-threatening, uninhibited sympathetic response of the nervous system to a noxious stimulus after a spinal cord injury at the 7th thoracic vertebra (T7) or above.

Defining Characteristics

Blurred vision; bradycardia; chest pain; chilling; conjunctival congestion; diaphoresis above the injury; diffuse pain in different areas of the head; Horner's syndrome; metallic taste in mouth; nasal congestion; pallor below injury; paresthesia; paroxysmal hypertension; pilomotor reflex; red blotches on skin above the injury; tachycardia

Related Factors

Gastrointestinal Stimuli

Bowel distention; constipation; difficult passage of feces; digital stimulation; enemas; fecal impaction; suppositories

Integumentary Stimuli

Cutaneous stimulation; skin irritation; sunburn; wound

Musculoskeletal-Neurological Stimuli

Irritating stimuli below level of injury; muscle spasm; painful stimuli below level of injury; pressure over bony prominence; pressure over genitalia; range of motion exercises

Regulatory-Situational Stimuli

Constrictive clothing; environmental temperature fluctuations; positioning

Reproductive-Urological Stimuli

Bladder distention; bladder spasm; instrumentation; sexual intercourse

Other Factors

Inadequate caregiver knowledge of disease process; inadequate knowledge of disease process

At-Risk Population

Individuals exposed to environmental temperature extremes; men with spinal cord injury or lesion who are experiencing ejaculation; women with spinal cord injury or lesion who are experiencing labor; women with spinal cord injury or lesion who are menstruating; women with spinal cord injury or lesion who are pregnant

Associated Conditions

Bowel fractures; detrusor sphincter dyssynergia; digestive system diseases; epididymitis; heterotopic bone; ovarian cyst; pharmaceutical preparations; renal calculi; substance withdrawal; surgical procedures; urinary catheterization; urinary tract infection; venous thromboembolism

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Neurological Status; Neurological Status: Autonomic; Vital Signs

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NOC Outcome with Indicators

Neurological Status: Autonomic as evidenced by the following indicators: Systolic blood pressure/Diastolic blood pressure/Apical heart rate/Perspiration response pattern/Goose bumps response pattern/Pupil reactivity/Peripheral tissue perfusion. (Rate each indicator of **Neurological Status: Autonomic:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain baseline blood pressure
- Remain free of dysreflexia symptoms
- Explain symptoms, treatment, and prevention of dysreflexia

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Dysreflexia Management

Example NIC Activities—Dysreflexia Management

Identify and minimize stimuli that may precipitate dysreflexia; Monitor for signs and symptoms of autonomic dysreflexia

Nursing Interventions and *Rationales*

- Teach clients with a spinal cord injury (SCI) about potential causes, symptoms, treatment, and prevention of autonomic dysreflexia (AD). **EB:** *The nurse should inform the individual and his or her family about the signs and symptoms of AD. The nurse should also inform the client that the first occurrence of AD is often 3 to 6 months after injury (Perkins, 2020). Written material about AD treatment should be given to the client as well. The nurse should emphasize the importance of keeping a dysreflexia diary and encourage clients to carry an AD card at all times (Vatansever, 2015).*
- Monitor the client for symptoms of dysreflexia, particularly those with high-level and more complete SCIs. See Defining Characteristics. **EB:** *This condition most commonly occurs in individuals with lesions at or above the level of sympathetic splanchnic outflow (T6), with incidence increasing with more clinically complete SCI (Solinsky et al, 2016). The most common signs and symptoms of AD are a sudden increase in systolic blood pressure (SBP) of at least 20 mm Hg from baseline, bradycardia, pounding headache, diaphoresis, flushing, and piloerection above the level of injury (Vatansever, 2015; Liepvre et al, 2017). Although bradycardia is more common, it is not uncommon for clients to develop tachycardia and cardiac arrhythmias (ACOG Committee on Obstetric Practice, 2020).*

▲ Collaborate with providers and caregivers to identify the cause of dysreflexia. AD is triggered by a stimulus from below the level of injury, leading to systemic vasoconstriction. The most common triggers are bladder distention, kidney stones, kink in urinary catheter, urinary tract infection, fecal impaction, pressure ulcer, ingrown toenail, menstruation, hemorrhoids, tight clothing, invasive testing, and sexual intercourse (*ACOG Committee on Obstetric Practice, 2020*; *Perkins, 2020*). **EB:** *It is important to understand that untreated AD increases the risk of stroke, myocardial infarction, retinal detachment, hypertensive encephalopathy, cardiac arrest, seizures, and death. Recurring AD can lead to chronic cardiovascular and immune problems (Perkins, 2020).*

- If dysreflexia symptoms are present, immediately place client in high Fowler's position, remove all support hoses or binders, loosen clothing, check the urinary catheter for kinks, and attempt to determine the noxious stimulus causing the response. Check the client's blood pressure every 3 to 5 minutes. If blood pressure cannot be decreased following these initial interventions, notify the provider emergently (i.e., STAT). **EB:** *Sitting allows some gravitational pooling of blood in the lower extremities. Survey the person for instigating causes beginning with the most common cause, the urinary system. To determine the stimulus for dysreflexia:*
  - ❍ First, assess bladder function. Check for distention, and if present, catheterize the client using an anesthetic jelly as a lubricant. Do not use the Valsalva maneuver or Crede's method to empty the bladder because this form of reflex voiding could worsen AD. Ensure existing catheter patency and irrigate if

A

necessary. Also assess for signs of urinary tract infection. **EB:** *Bladder distention or irritation is responsible for up to 90% of AD cases (Vatansever, 2015; O'Stephenson & Berliner, 2017).*

- ❍ Second, assess bowel function. Numb the bowel area with a topical anesthetic as ordered and gently check for impaction. **EB:** *Check the rectal vault. Instill lidocaine gel into the rectum, pause for 2 minutes, and gently remove any stool (Solinsky et al, 2016).*
- ❍ Third, assess the skin. Look for any pressure points, wounds, and ingrown toenails. **EB:** *Any noxious stimuli can cause AD. Although bladder and intestinal problems are most common, approximately 2% of AD cases are attributed to skin issues (Vatansever, 2015).*

▲ Initiate antihypertensive therapy as soon as ordered and monitor for cardiac dysrhythmias. **EB:** *Because of the large amount of sympathetic discharge following AD, clients in hypertensive crisis are at risk for arrhythmias, myocardial infarction, cerebral hemorrhage, seizures, and death (Perkins, 2020). Antihypertensives should be administered when SBP remains at 150 mm Hg. Nitrates and nifedipine are most commonly used for acute episodes of AD, whereas clonidine is most effective for recurrent AD (Caruso et al, 2015; O'Stephenson & Berliner, 2017; Biering-Sørensen et al, 2018).*

- ● Monitor vital signs every 3 to 5 minutes during an acute event; continue to monitor vital signs after event is resolved (e.g., symptoms resolve and vital signs return to baseline, usually up to 2 hours after the event). **EB:** *Monitor pulse and blood pressure every 2 to 5 minutes during an episode of AD, keeping in mind that impaired autonomic function can lead to labile blood pressure. Monitor for rebound hypotension following antihypertensive administration (O'Stephenson & Berliner, 2017).*
- ● Watch for complications of dysreflexia, including signs of cerebral hemorrhage, seizures, cardiac dysfunction, or intraocular hemorrhage. **EB:** *Extremely high blood pressure can cause stroke, myocardial injury and dysfunction, and death (Perkins, 2020).*
- ● Accurately and completely record any incidences of dysreflexia; especially note the precipitating stimuli. *It is imperative to determine the noxious stimuli that precipitated AD and whether the condition is recurrent, requiring the client to take medications routinely or to implement different interventions to prevent repeat incidences (Perkins, 2020).*
- ● Use the following interventions to prevent dysreflexia:
  - ❍ Ensure catheter patency and empty urinary catheter bags frequently. Assess the client for signs and symptoms of urinary tract infection during every shift. **EB:** *Approximately 90% of AD episodes are caused by genitourinary issues (Vatansever, 2015).*
  - ❍ Ensure a regular pattern of defecation to prevent fecal impaction. **EB:** *Approximately 8% of AD episodes can be attributed to the gastrointestinal system (Vatansever, 2015). A regular bowel program is essential in preventing constipation, impaction, or ileus. Topical lidocaine is useful in preventing dysreflexia from occurring during a bowel program (O'Stephenson & Berliner, 2017).*
  - ❍ Frequently change position of client to relieve pressure and prevent formation of pressure injuries. **EB:** *Routine weight shifts while sitting and frequent skin checks are imperative in preventing pressure injury. Any skin breakdown should be addressed by a physician or wound care personnel (O'Stephenson & Berliner, 2017).*

▲ Notify all health care team members of recurrent AD episodes. **EB:** *Recurrent dysreflexia may be caused by an occult or insidious pathophysiological process, which requires a more comprehensive workup (Biering-Sørensen et al, 2018).*

▲ For female clients with SCI, assess the client for AD during menstrual cycle. If the client becomes pregnant, collaborate with obstetrical health care practitioners to monitor for signs and symptoms of dysreflexia. **EB:** *In a recent cohort study, 60% of pregnant women with a spinal cord lesion above T6 experienced AD, with two cases resulting in cerebral hemorrhage during labor (Liepvre et al, 2017). Pregnancy in the female SCI population must be preceded by preconceptional consultation with a multiprofessional team including both prenatal and neurological specialists (Hollenbach, et al, 2020).*

Home Care

- ● The previously mentioned interventions may be adapted for home care use.
- ● Provide the client and caregiver with written information on common causes of AD and initial treatment. **EB:** *Despite the availability of consensus-based resources, first responders and emergency department (ED) health care professionals (HCPs) have limited knowledge regarding AD (Krassioukov et al, 2016). An AD card is available from the Craig Hospital Autonomic Dysreflexia Resources page (see* https://craighospital.org/uploads/Educational-PDFs/624.CRADEnglishWalletID.pdf*), as well as from the Christopher and*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Dana Reeve Foundation (see https://www.christopherreeve.org/living-with-paralysis/free-resources-and-downloads/wallet-cards*) (Christopher and Dana Reeve Foundation, 2015; Craig, 2017).*

- Provide resources to clients with any known proclivity toward dysreflexia. Advise them to wear a medical alert bracelet and carry a medical alert wallet card when not accompanied by knowledgeable caregivers. **EB:** *Always keep an AD emergency kit on hand. Include the following items: blood pressure cuff, lubricating jelly (for rectal check), spare urinary catheter and insertion kit, bladder irrigation kit, and prescribed antihypertensives (Craig, 2020).*

▲ Establish an emergency plan: maintain a current prescription of antihypertensive medication, and administer antihypertensives when dysreflexia is refractory to nonmedicinal interventions. If SBP remains over 150 mm Hg following the previously mentioned interventions, go to the nearest ED and present the AD wallet card on arrival. **EB:** *A paucity of knowledge regarding AD diagnosis and treatment still exists among ED HCPs; therefore it is important to present the wallet card on arrival to ensure safe and effective care (Krassioukov et al, 2016).*

- When an episode of dysreflexia has resolved, continue to monitor blood pressure every 30 to 60 minutes for the next 2 hours or admit to an institution for observation. **EB:** *AD may resolve following administration of antihypertensive medication; however, if the underlying cause is not corrected, recurrence should be expected (O'Stephenson & Berliner, 2017).*

Client/Family Teaching and Discharge Planning

- Teach recognition of early dysreflexia symptoms, appropriate interventions, and the need to obtain help immediately. Give client a written card describing signs and symptoms of AD and initial actions. **EB:** *If AD occurs, sit at 90 degrees and lower legs if possible, as this will help decrease blood pressure; loosen or remove anything tight (abdominal binder, compression hose or tight socks, clothes, belts, shoes or leg bag strap, external catheter tape); find and correct the cause (check bladder; is your catheter tube kinked; do you need to be catheterized; if AD occurs during bowel program, stop digital stimulation, check skin); check blood pressure; if your blood pressure is elevated and does not come down within 20 to 30 minutes, go to the ED and bring your AD wallet card (Craig, 2017).*
- Teach steps to prevent dysreflexia episodes: routine bladder and bowel care, pressure injury prevention, and preventing other forms of noxious stimuli (e.g., not wearing clothing that is too tight, nail care). Discuss the potential impact of sexual intercourse and pregnancy on AD. **EB:** *Sperm retrieval methods used in men with SCI lesions at T6 and above can stimulate an episode of AD (Ibrahim et al, 2016).*

A

Risk for Autonomic Dysreflexia

Domain 9 Coping/stress tolerance Class 3 Neurobehavioral stress

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to life-threatening, uninhibited response of the sympathetic nervous system post–spinal shock, in an individual with spinal cord injury or lesion at the 6th thoracic vertebra (T6) or above (has been demonstrated in patients with injuries at the 7th thoracic vertebra [T7] and the 8th thoracic vertebra [T8]), which may compromise health.

Risk Factors

Gastrointestinal Stimuli

Bowel distention; constipation; difficult passage of feces; digital stimulation; enemas; fecal impaction; suppositories

Integumentary Stimuli

Cutaneous stimulations; skin irritation; sunburn; wound

Musculoskeletal-Neurological Stimuli

Irritating stimuli below level of injury; muscle spasm; painful stimuli below level of injury; pressure over bony prominence; pressure over genitalia; range of motion exercises

Regulatory-Situational Stimuli

Constrictive clothing; environmental temperature fluctuations; positioning

Reproductive-Urological Stimuli

Bladder distention; bladder spasm; instrumentation; sexual intercourse

Other Factors

Inadequate caregiver knowledge of disease process; inadequate knowledge of disease process

At-Risk Population

Individuals with spinal cord injury or lesion exposed to extremes of environmental temperature; men with spinal cord injury or lesion who are experiencing ejaculation; women with spinal cord injury or lesion who are experiencing labor; women with spinal cord injury or lesion who are menstruating; women with spinal cord injury or lesion who are pregnant

Associated Conditions

Bone fractures; detrusor sphincter dyssynergia; digestive system diseases; epididymitis; heterotopic bone; ovarian cyst; pharmaceutical preparations; renal calculi; substance withdrawal; surgical procedures; urinary catheterization; urinary tract infection; venous thromboembolism

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for **Autonomic Dysreflexia.**

Risk for Bleeding

Domain 11 Safety/projection Class 2 Physical injury

Kimberly Anne Rumsey, RN, MSN, CNE

B

NANDA-I

Definition

Susceptible to a decrease in blood volume, which may compromise health.

Risk Factors

Inadequate knowledge of bleeding precautions

At-Risk Population

Individuals with a history of falls

Associated Conditions

Aneurysm; circumcision; disseminated intravascular coagulopathy; gastrointestinal condition; impaired liver function; inherent coagulopathy; postpartum complication; pregnancy complication; trauma; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Blood Coagulation; Blood Loss Severity; Circulation Status; Fall Prevention Behavior; Gastrointestinal Function; Knowledge: Personal Safety, Maternal Status, Physical Injury Severity, Risk Control, Safe Home Environment, Vital Signs

Example NOC Outcome with Indicators

Blood Coagulation as evidenced by the following indicators: Clot formation/International normalized ratio (INR)/Hemoglobin (Hgb)/Platelet Count/Bleeding/Bruising/Hematuria/Hematemesis. (Rate the outcome and indicators of **Blood Coagulation:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range.)

Client Outcomes

Client Will (Specify Time Frame)

- Identify clients at risk for bleeding and implement precautions to prevent bleeding and subsequent complications
- Identify and implement interventions to alleviate bleeding episodes
- Discuss precautions to prevent bleeding complications
- Explain actions that should be taken if bleeding happens
- Maintain adherence to mutually agreed upon anticoagulant medication and follow-up laboratory regimen
- Monitor for signs and symptoms of bleeding

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Admission Care; Bleeding Precautions; Bleeding Reduction; Blood Product Administration; Circumcision Care; Fluid Management; Health Screening; Hemorrhage Control; Neurologic Monitoring; Postpartum Care; Risk Identification; Teaching: Disease Process; Prescribed Medication; Oxygen Therapy; Shock Prevention; Surveillance; Vital Signs Monitoring

Example NIC Activities—Bleeding Precautions

Monitor the client closely for hemorrhage; Monitor coagulation studies; Monitor orthostatic vital signs, including blood pressure; Instruct the client and/or family on signs of bleeding and appropriate actions in case bleeding occurs

B

Nursing Interventions and *Rationales*

- Identify clients at risk for bleeding episodes. Consider client-related and procedure-related risk factors. **EBN:** *Early identification of client at risk for bleeding episode decreases morbidity related to bleeding episodes (Lopes et al, 2015).*
- Perform admission fall risk assessment. Safety precautions should be implemented for all at-risk clients. **EBN:** *On client admission to any health care facility, nurses should assess for fall risk factors that could increase the risk of bleeding (Health Research & Educational Trust, 2016).*
- Monitor the client at increased risk for bleeding for signs or symptoms of bleeding, including bleeding of the gums; nosebleed; blood in sputum, emesis, urine, or stool; bleeding from a wound or site of invasive procedure; petechiae; ecchymosis; and purpura. **EB:** *Clients at increased risk for bleeding may include older individuals (>60 years of age) and individuals with active gastroduodenal ulcer, anemia, intrapartum and postpartum women, previous bleeding episode, hypertension, labile INRs or INR greater than 3.0, low platelet count, malignancy, renal or liver failure, intensive care unit stay, drug or alcohol use, coadministration of antiplatelets and nonsteroidal antiinflammatory drugs (NSAIDs), and antithrombotic and anticoagulant therapies (Chapman et al, 2019; Sheth et al, 2020).*

▲ Clients with a history of cancer, current cancer, or leukemias are at a higher risk of bleeding associated with the disease and/or interplay of treatment-related factors. Risk of bleeding may be higher because of associated thrombocytopenia, platelet dysfunction, infection, and liver disease. **CEB/EB:** *Ensure the client is aware of signs and symptoms of bleeding and informs health care provider of changes. Prophylactic platelet transfusions or administration of medications such as mesna or tranexamic acid may be prescribed (Damron et al, 2009; Corbitt et al, 2019).*

- If bleeding develops, apply pressure over the site or appropriate artery as needed. Apply pressure dressing; if unable to stop the bleeding, then consider a tourniquet if indicated. **EB:** *Nonpharmacological means, such as application of pressure, may reduce bleeding (Cassell, 2017; Raval et al, 2017).*

▲ Collaborate on an appropriate bleeding management plan, including nonpharmacological and pharmacological measures to stop bleeding based on the antithrombotic used. **EB:** *Recommendations for bleeding risk prevention and management carefully weigh the risks and benefits of nonpharmacological and pharmacological interventions (Gimbel, Minderhoud, & ten Berg, 2018).*

▲ Monitor coagulation studies, including prothrombin time, INR, activated partial thromboplastin time (aPTT), fibrinogen, fibrin degradation/split products, and platelet counts as appropriate. **EB:** *New direct oral anticoagulants (DOACs) often have no requirement for routine coagulation studies; however, vigilance is still warranted because the risk for bleeding without benefit of reversal agents exists, except for dabigatran (Pradaxa), which can be reversed with intravenous (IV) idarucizumab (Praxbind) (Barras, Hughes, & Ullner, 2016; Raval et al, 2017). INR is the preferred method to evaluate warfarin therapy, typically at least 16 hours after the last dose is administered. Dose adjustments will not result in a steady-state INR value for up to 3 weeks (Witt et al, 2016).*

- Assess vital signs at frequent intervals to assess for physiological evidence of bleeding, such as tachycardia, tachypnea, and hypotension. Symptoms may include dizziness, shortness of breath, altered mental status, and fatigue. **EB:** *Carefully assess for compensatory changes associated with bleeding, including increased heart rate and respiratory rate. Initially, blood pressure may be stable, before beginning to decrease. Assess for orthostatic blood pressure changes (drop in systolic by >20 mm Hg and/or a drop in diastolic by >10 mm Hg in 3 minutes) by taking blood pressure with the client in lying, sitting, and standing positions (Emergency Nurses Association, 2018).*

▲ Monitor all medications for potential to increase bleeding, including antiplatelets, NSAIDs, selective serotonin reuptake inhibitors (SSRIs), and complementary and alternative therapies such as coenzyme Q10 and ginger. **EB:** *Antiplatelet medications can increase the risk of bleeding in high-risk clients. Instruct clients that ginger, when taken with medicines that slow clotting, may increase the chances for bruising and bleeding. There is a multitude of medications including over-the-counter medications and herbs/natural supplements that can interact with anticoagulants. When any of these medications are stopped or started, closer monitoring of INR may be warranted (Witt et al, 2016; Melkonian et al, 2017; Sheth et al, 2020).*

Safety Guidelines for Anticoagulant Administration: The Joint Commission National Patient Safety Goals

✱ Follow approved protocol for anticoagulant administration:

- Use prepackaged medications and prefilled or premixed parenteral therapy as ordered.
- Check laboratory tests (i.e., INR) before administration.

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Use programmable pumps when using parenteral administration.
- Ensure appropriate education for client/family and all staff concerning anticoagulants used.
- Notify dietary services when warfarin is prescribed (to provide consistent vitamin K in diet).
- Monitor for any symptoms of bleeding before administration. **EB:** *Standard defined protocols can decrease errors in administration (Barras, Hughes, & Ullner, 2016; Witt et al, 2016; The Joint Commission, 2020).*
- Anticoagulation therapy is complex and requires consistent implementation of medication reconciliation in all settings. **EBN:** *Nurses have an integral role in medication management through the education of clients.* **EB:** *Medication reconciliation at clinical transition points reduces client safety concerns (Kern et al, 2017). Risk of bleeding is reduced in clients who receive appropriate education in anticoagulant therapy use (The Joint Commission, 2020).*

▲ Before administering anticoagulants, assess the clotting profile of the client. If the client is on warfarin, assess the INR. If the INR is outside of the recommended parameters, notify the provider. **EB:** *Target INR for warfarin is between 2 and 3 for nonvalvular atrial fibrillation and between 2.5 and 3.5 for valvular atrial fibrillation. Risk for bleeding increases when INR is >4 and risk for thromboembolism increases when INR is <1.7. A single slightly out of range INR <0.3 units above or below therapeutic range may just be monitored. It is not recommended to skip or boost doses for a slightly out of range INR in the absence of bleeding (Barras, Hughes, & Ullner, 2016; Witt et al, 2016).*

▲ Recognize that vitamin K for vitamin K antagonists (e.g., warfarin, phenprocoumon, Sinthrome, and phenindione) may be given orally or intravenously as ordered for INR levels greater than 4.5 without signs of bleeding. In the case of major bleeding, prohemostatic therapies may be warranted for the rapid reversal of vitamin K antagonists (tranexamic acid, fresh frozen plasma, cryoprecipitate, platelet transfusion, fibrinogen concentrate, factor IV prothrombin complex concentrate [Kcentra], and activated prothrombin complex concentrate) (Witt et al, 2016; Corbitt et al, 2019). **EB:** *With INR levels above 4.5, it is recommended to give vitamin K rather than withholding the warfarin; administration of vitamin K is by oral or IV route, because subcutaneous and intramuscular routes result in erratic absorption (Christos & Naples, 2016).*

▲ Manage fluid resuscitation and volume expansion as ordered. **EB:** *A Cochrane systematic review included 69 studies and more than 30,000 critically ill client comparing colloids (starches, dextrans, gelatins, albumin, or fresh frozen plasma) to crystalloids for fluid resuscitation found minimal evidence that either solution is safer or more effective than any other (Lewis et al, 2018). CEB: Blood products (including human albumin), nonblood products, or combinations can be used to restore circulating blood volume in individuals at risk for blood losses from trauma, burns, or surgery. Administration of albumin over normal sterile saline does not alter survival rates (Damron et al, 2009).*

▲ Consider use of permissive hypotension and restrictive transfusion strategies when treating bleeding episodes. **EB:** *The effectiveness of permissive hypotension/hypotensive resuscitation and restricted/controlled resuscitation is still inconclusive. Additional research is needed (Kudo, Yoshida, & Kushimoto, 2017).*

▲ Consider discussing the coadministration of a proton-pump inhibitor alongside traditional NSAIDs or with the use of a cyclooxygenase 2 inhibitor with the prescriber. **EB:** *Risk of NSAID-related bleeding may be reduced with the use of a proton-pump inhibitor or cyclooxygenase 2 inhibitor (Witt et al, 2016).*

✱ Ensure adequate nurse staffing to provide a high level of surveillance capability. **EB:** *A key component in surveillance is monitoring; additional research is warranted in this area to identify new technologies and processes to optimize surveillance. The number and skill of nurses staffed in hospitals have been demonstrated to have a direct effect on client outcomes. Lower levels of nurse staffing have been associated with higher rates of poor client outcomes (Cho et al, 2016).*

Pediatric

▲ Recognize that prophylactic vitamin K administration should be used in neonates for vitamin K deficiency bleeding (VKDB). **EB:** *A dose of 0.5 to 1 mg vitamin K remains a standard administration for neonates to avoid VKDB and associated problems (Marchili et al, 2018).*

▲ Recognize warning signs of VKDB, including minimal bleeds, evidence of cholestasis (icteric sclera, dark urine, and irritability), and failure to thrive. **EB:** *Signs of classic VKDB may be mild and include delayed or difficulty feeding or bruising in 24 hours to 1 week, whereas late VKDB associated with breastfeeding may occur at 2 to 12 weeks (Marchilli et al, 2018).*

▲ Use caution in administering NSAIDs in children. *Ensure adequate hydration before administration of NSAIDs.*

▲ Monitor children and adolescents for potential bleeding after blunt trauma. **EB:** *Blunt trauma in children has been associated with early coagulopathy and subsequent bleeding requiring close monitoring to reduce*

B

rate of blood loss and minimize need for transfusions (Hagedorn et al, 2019). **EB:** *Children and adolescents who take SSRIs need to be closely monitored because the potential for bleeding exists across age groups (Laporte et al, 2017).*

Client/Family Teaching and Discharge Planning

- Teach client and family or significant others about any anticoagulant medications prescribed, including when to take, how often to have laboratory tests done, signs of bleeding to report, dietary consistency, and need to wear medic alert bracelet and precautions to be followed. Instruct the client to report any adverse side effects to his or her health care provider. *Medication teaching includes the drug name, purpose, administration instructions (e.g., with or without food), necessary laboratory tests, and any side effects. Provision of such information using clear communication principles and an understanding of the client's health literacy level may facilitate appropriate adherence to the therapeutic regimen by enhancing knowledge base (National Institutes of Health [NIH], 2016; The Joint Commission, 2020).*
- Instruct the client and family on the disease process and rationale for care. When clients and their family members have sufficient understanding of their disease process, they can participate more fully in care and healthy behaviors. Knowledge empowers clients and family members, allowing them to be active participants in their care. **EB:** *Use of written, verbal, and/or video education enhances client retention of information needed when managing potent medications. Clients actively engaged in their health care report better experiences, improved outcomes, and lower health care costs (The Joint Commission, 2020).*
- Provide client and family or significant others with both oral and written educational materials that meet the standards of client education and health literacy. **EB:** *The use of clear communication, materials written at a fifth-grade level, and the teach-back method enhances the client's ability to understand important health-related information and improves self-care safety (NIH, 2016; Hull, Garcia, & Vazquez, 2021).*

B

Risk for Unstable Blood Pressure

Domain 4 Activity/rest Class 4 Cardiovascular/pulmonary responses

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to fluctuating forces of blood flowing through arterial vessels, which may compromise health.

Risk Factors

Inconsistency with medication regimen; orthostasis

Associated Conditions

Adverse effects of pharmaceutical preparations; adverse effects of cocaine; cardiac dysrhythmia; Cushing's syndrome; fluid retention; fluid shifts; hormonal change; hyperparathyroidism; hyperthyroidism; hypothyroidism; increased intracranial pressure; pharmaceutical preparations; rapid absorption and distribution of pharmaceutical preparations; sympathetic responses

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Fatigue; Arrhythmia; Dizziness; Confusion; Blurred Vision; Circulation Status; Tissue Perfusion: Cardiac; Tissue Perfusion: Cellular; Vital Signs

Example NOC Outcome with Indicators

Tissue Perfusion: Cardiac as evidenced by the following indicators: Heart rate/Arrhythmia/Profuse diaphoresis/Nausea/Vomiting. (Rate the outcome and indicators of **Tissue Perfusion: Cardiac:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain vital signs within normal range
- Remain asymptomatic with cardiac rhythm (have absence of arrhythmias, tachycardia, or bradycardia)
- Be free from dizziness with changes in positions (lying to standing)
- Deny fatigue, nausea, vomiting
- Deny chest pain

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Cardiac Care; Cardiac Precautions; Hypertension Management; Hypotension Management; Dysrhythmia Management; Vital Signs Monitoring

B

Example NIC Activity—Vital Signs Monitoring

Note trends and wide fluctuations in blood pressure; Monitor blood pressure while client is lying, sitting, and standing before and after position change as appropriate; Monitor blood pressure after client has taken medications if possible; Monitor for central and peripheral cyanosis

Nursing Interventions and *Rationales*

▲ Hypertension (HTN) is a major risk factor for cardiovascular disease, placing the client at increased risk of myocardial infarction and stroke (Whelton et al, 2017). **EB:** *The 2017 clinical practice guidelines for the management of adults with HTN now defines HTN as a blood pressure above 130/80 mm Hg for anyone at risk of a myocardial infarction or stroke. Significant emphasis is placed on ensuring the client understands the importance of lifestyle modifications, including regular exercise and dietary changes (Whelton et al, 2017).*

● Provide client-specific education about the importance of a healthy lifestyle to reduce complications associated with HTN. **EB:** *A heart-healthy diet with low-sodium content, maintaining a normal weight, limiting alcohol consumption, and a regular exercise program can lower the client's blood pressure and associated risk of cardiovascular disease (Whelton et al, 2017).*

● Provide drug- and client-specific education if medications are prescribed to manage the client's HTN. *Blood pressure medications may cause hypotension or secondary complications such as electrolyte imbalances, dehydration, and orthostasis (Whelton et al, 2017).*

▲ Screen clients for secondary causes of HTN with abrupt onset or age <30 years. **EB:** *Secondary HTN should be explored so that the primary cause of the HTN is treated. The client should be evaluated for undetected renal disease, primary aldosteronism, obstructive sleep apnea (OSA), thyroid disease, and alcohol-induced HTN (Whelton et al, 2017; Wolf et al, 2018).*

▲ Review the client's medical history. **EB:** *Understanding the client's risk for secondary causes of HTN is important to establish a proper plan of care and follow-up treatments (Wolf et al, 2018).*

● Explore the client's subjective statements concerning poor sleep, report of snoring, and daytime fatigue. **EB:** *OSA compromises cardiovascular health. Assessment of OSA can be easily incorporated into practice using valid and reliable assessment tools such as STOP Bang (Nagappa et al, 2015; Miller & Berger, 2016). If OSA is assessed, the nurse should notify the provider for additional monitoring to address OSA and HTN management.*

● Review the client's history of arrhythmias, especially a history of atrial fibrillation. **EB:** *Atrial fibrillation alters cardiac output and can cause hypotension and HTN episodes that result in client falls and/or altered mentation, chest pain, and increased stroke risk (Gumprecht et al, 2019).*

● Review the client's current medications, both prescribed and over the counter. **EB:** *Many medications and over-the-counter agents can cause HTN and interfere with antihypertension treatments (Gumprecht et al, 2019).*

● Steroid agents, administered at higher doses (e.g., 80–200 mg/day), can trigger HTN. **EB:** *Teach the client to monitor blood pressure and report changes to the prescribing provider (Johns Hopkins Medicine, 2021).* **EB:** *Individuals who have abused anabolic steroids have been found to have HTN and aortic stiffness (Rasmussen et al, 2018).*

● Ask the client if they are prescribed antidepressant agents. **EB:** *Several antidepressant agents cause an elevation in blood pressure that may be progressively clinically significant if the diastolic blood pressure rises above 90 mm Hg (Whelton et al, 2017).*

● Nonsteroidal antiinflammatory drugs (NSAIDs) can induce HTN and/or interfere with antihypertensive therapy. **EB:** *Ask if the client uses NSAIDS, including dose and frequency of consuming these over-the-counter drugs (Whelton et al, 2017; MedlinePlus, 2021).*

● Overconsumption of caffeine stimulates sympathetic activity, which causes a rise in blood pressure that can be followed by a decrease in blood pressure once the effects of the caffeine have worn off. **EB:** *Ask the client to describe their caffeine consumption, including frequency, dose, and physical effects when consuming products containing caffeine (Turnbull et al, 2017).*

● Licorice consumption may trigger HTN in some clients. **EB:** *A systematic review and meta-analysis found that chronic licorice consumption can prolong cortisol metabolism associated with an 11β-hydroxysteroid dehydrogenase deficiency leading to HTN and a drop in plasma potassium levels. Ask the client about typical consumption of licorice and teach the client about risks associated with chronic licorice consumption (Penninkilampi et al, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Some herbal products may induce HTN and/or interfere with antihypertensive treatment. **CEB/EB:** *Over-the counter herbal agents are poorly regulated; however, some agents such as arnica, bitter orange, blue-cohosh, dong quai, ephedra, ginkgo, ginseng, guarana, licorice, pennyroyal oil, Scotch broom, senna, southern bayberry, St. John's wort, and yohimbine are known stimulants that may elevate blood pressure (Jalili et al, 2013; Jain et al, 2018). Ask the client about herbal agents, including dose, frequency, and reason for taking the herbal agent.*
- Alcohol is known to elevate blood pressure and increases the client's risk of HTN. **EB:** *Inquire about the client's typical alcohol consumption. Current recommendations suggest men should be limited to no more than two drinks per day and women to no more than one standard alcohol drink per day (Whelton et al, 2017).*
- Blood pressure may be unstable with substance abuse disorders (SUDs). Certain drugs have specific effects on the cardiovascular system. **EB:** *Clients may experience tachycardia along with severe hypotension or HTN with an overdose of opioid, cocaine, and synthetic cannabinoids (Akerele & Olupona, 2017).*
- Cocaine use causes increased alertness and feelings of euphoria, along with dilated pupils, increased body temperature, tachycardia, and increased blood pressure. **EB:** *Tachyarrhythmias and marked elevated blood pressure can be life-threatening. Cocaine overdose can present as a myocardial infarction or arterial dissection (Akerele & Olupona, 2017).*
- Cocaine overdose is a medical emergency because of the risk of cardiac toxicity. **EB:** *Treatment is focused on lowering body temperature with external cooling devices and antipyretic medications, administering sedation agents to treat hyperactivity, oxygen to address increased myocardial oxygen needs, and possible administration of antithrombotic agents if a myocardial infarction is suspected (Akerele & Olupona, 2017).*
- Opioid intoxication results in changes in heart rate, slowed breathing, and decrease in blood pressure leading to loss of alertness. **EB:** *Opioid intoxication and overdose lead to primarily respiratory arrest with subsequent cardiovascular arrest (Jones et al, 2015; Akerele & Olupona, 2017).*
- Synthetic cannabinoids are manmade, mind-altering chemicals that may be added to foods or inhaled. There is a growing availability of these designer drugs in which adverse effects are not well known. **EB:** *The primary effect of synthetic cannabinoid intoxication results in severe anxiety, paranoia, nausea, vomiting, and cardiovascular symptoms to include slurred speech, HTN, chest pain, skin pallor, muscle twitches, and hypokalemia that may lead to arrhythmias (Weaver, Hooper, & Gunderson, 2015; Akerele & Olupona, 2017).*
- Explore client use of wearable technology for self-monitoring heart rhythm irregularities. **EB:** *There is a growing body of evidence that smartwatch wearable devices are increasingly more accurate at detecting heart rate abnormalities, atrial fibrillation, and associated changes in blood pressure (Wasserlauf et al, 2019; Seshadri et al, 2020).*

Critical Care

- Monitor the client for symptoms associated with chest pain, myocardial infarction, acute HTN, and hypotension. **EB:** *Alterations in blood pressure, HTN, and hypotension adversely affect cardiac function and myocardial oxygen consumption that can result in myocardial muscle injury. Nursing interventions to monitor cardiac function and reduce oxygen needs should be implemented along with continuous cardiac function monitoring (Habib, 2018).*
- Clients with hypertensive crisis will require close monitoring for signs and symptoms consistent with acute renal failure, stroke, myocardial infarction, and acute heart failure. **EB:** *Many conditions may cause hypertensive crisis; however, uncontrolled HTN is the most common cause. Subjective symptoms include severe headache, shortness of breath, faintness, and severe anxiety (Habib, 2018).*
- Myxedema coma is an acute emergency associated with hypothyroidism that manifests with severe hypotension, bradycardia, hypothermia, seizures, and coma. **EB:** *Treatment focuses on supporting the client's blood pressure and restoring thyroid function by administering levothyroxine as prescribed and supporting other organ systems (Munir, 2018).*
- Thyroid storm (thyrotoxicosis) is an acute, life-threatening, hypermetabolic state induced by excessive release of thyroid-stimulating hormone (TSH). Symptoms are severe and include fever, tachycardia, HTN, congestive heart failure leading to hypotension and shock, profuse sweating, respiratory distress, nausea and vomiting, diarrhea, abdominal pain, jaundice, anxiety, seizures, and coma. **EB:** *Nursing care focuses on symptom management, including reducing fever and cardiovascular support (Munir, 2018).*

B

Pediatric

- HTN is an underrecognized disease in children. Current recommendations include annual blood pressure monitoring with more focused monitoring in high-risk children. **EB:** *Blood pressure monitoring should be initiated starting at age 3. Client risk factors that include obesity and inactivity should be addressed during well-child visits to reduce the cardiovascular risks associated with childhood HTN (Dionne, 2017).*

▲ Secondary causes of HTN should be explored in the absence of childhood obesity, known cardiovascular disease, and family history. **EB:** *Kidney disease should be explored as a possible etiology of unexplained HTN (Dionne, 2017).*

- Normal ranges for child and adolescent blood pressure measurements were recently updated to reflect age, gender, and weight considerations. *Revisions to the blood pressure table are intended to facilitate earlier detection of abnormal blood pressure allowing for earlier intervention to reduce the risk of end-organ injury (Flynn et al, 2017).*

Geriatric

- Risk of cardiac arrhythmias increases with advanced age, placing the client at increased risk of HTN and hypotension. **EB:** *Ask the client about a history of arrhythmias, feeling his or her heart "skip beats," history of falls, lightheadedness, and any associated pain or discomfort during these episodes (Gumprecht et al, 2019).*
- Comorbid cardiovascular disease risks increase with advanced age. **EB:** *Clients, regardless of age, should be encouraged to engage in daily physical activity, consume a heart-healthy diet, maintain ideal body weight, and monitor effects of prescribed cardiovascular medications (Whelton et al, 2017).*
- Polypharmacy is a risk for both hypotension and HTN in older clients. *Review the client's medications frequently, including prescribed and over-the-counter medications and herbal agents.*

Client/Family Teaching and Discharge Planning

- Nutritional education has been found to be an important variable in an individual maintaining cardiovascular health. **EB:** *Assumptions have been made that individuals understand what a healthy diet means. Current guidelines suggest that using props such as a plate and food types/portions along with practicing reading food labels are essential to client nutritional education/learning (Allison, 2017).*
- Teach the client to monitor blood pressure and to report changes in blood pressure to the provider and with each health care visit. **EB:** *A recent systematic review and meta-analysis found that teaching the client to properly self-monitor blood pressure, along with other cardiovascular treatments (i.e., diet, exercise, medications), has been found to clinically lower blood pressure for up to a year (Tucker et al, 2017).*

Disturbed Body Image

Domain 6 Self-perception Class 3 Body image

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Negative mental picture of one's physical self.

Defining Characteristics

Altered proprioception; altered social involvement; avoids looking at one's body; avoids touching one's body; consistently compares oneself with others; depressive symptoms; expresses concerns about sexuality; expresses fear of reaction by others; expresses preoccupation with change; expresses preoccupation with missing body part; focused on past appearance; focused on past function; focused on past strength; frequently weighs self; hides body part; monitors changes in one's body; names body part; names missing body part; neglects nonfunctioning body part; nonverbal response to body changes; nonverbal response to perceived body changes; overexposes body part; perceptions that reflect an altered view of appearance; refuses to acknowledge change; reports feeling one has failed in life; social anxiety; uses impersonal pronouns to describe body part; uses impersonal pronouns to describe missing body part

Related Factors

Body consciousness; conflict between spiritual beliefs and treatment regimen; conflict between values and cultural norms; distrust of body function; fear of disease recurrence; low self-efficacy; low self-esteem; obesity; residual limb pain; unrealistic perception of treatment outcome; unrealistic self-expectations

At-Risk Population

Cancer survivors; individuals experiencing altered body weight; individuals experiencing developmental transition; individuals experiencing puberty; individuals with altered body function; individuals with scars; individuals with stomas; women

Associated Conditions

Binge-eating disorder; chronic pain; fibromyalgia; human immunodeficiency virus infections; impaired psychosocial functioning; mental disorders; surgical procedures; treatment regimen; wounds and injuries

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Body Image; Self-Esteem; Acceptance Health Status: Coping, Personal Identity

B

Example NOC Outcome with Indicators

Body Image as evidenced by the following indicators: Congruence between body reality, body ideal, and body presentation/Satisfaction with body appearance/Adjustment to changes in physical appearance. (Rate the outcome and indicators of **Body Image:** 1 = never positive, 2 = rarely positive, 3 = sometimes positive, 4 = often positive, 5 = consistently positive [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate adaptation to changes in physical appearance or body function as evidenced by adjustment to lifestyle change
- Identify and change irrational beliefs and expectations regarding body size or function
- Recognize health-destructive behaviors and demonstrate willingness to adhere to treatments or methods that will promote health
- Verbalize congruence between body reality and body perception
- Describe, touch, or observe affected body part
- Demonstrate social involvement rather than avoidance and use adaptive coping and/or social skills
- Use cognitive strategies or other coping skills to improve perception of body image and enhance functioning
- Use strategies to enhance appearance (e.g., wig, clothing)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Body Image Enhancement; Counseling; Eating Disorders Management; Referral; Self-Awareness Enhancement; Self-Esteem Enhancement; Support Group; Therapy Group; Weight Gain Assistance

Example NIC Activities—Body Image Enhancement

Determine client's body image expectations based on developmental stage; Assist client to identify actions that will enhance appearance

Nursing Interventions and *Rationales*

- Incorporate psychosocial questions related to body image as part of nursing assessment to identify clients at risk for body image disturbance.
- Maintain awareness of conditions or changes that are likely to cause a disturbed body image: removal of a body part or change/loss of body function such as blindness or hearing loss, cancer survivors, clients with eating disorders, burns, skin disorders, or those with stomas or other disfiguring conditions, or a loss of perceived attractiveness such as hair loss.
- Incorporate an appropriate body image assessment tool or questions to identify clients at risk for body image disturbance. **EB:** *A systematic review of body image assessments supported the majority of measures in terms of reliability and validity, but suitability varied across populations and some measurement properties were insufficiently evaluated (Kling et al, 2019).*
- Assess the impact of body image on sexual function and sexuality. **EB:** *A study of clients with urticaria found that 57.8% of the clients reported that their sexual life was affected by chronic urticaria. These individuals had lower body image and sexual self-confidence scores (Simsek et al, 2020).*
- Be aware of the impact of treatments and surgeries that involve the face and neck and be prepared to address the client's psychosocial needs. **EB:** *A cross-sectional survey of 150 clients with head and neck cancer demonstrated that radical neck surgery has a significant impact on their body image (Hung et al, 2017).*
- Maintain understanding that age, gender, and other demographic identifiers may be associated with higher degrees of body image disturbance. **EB:** *A study of body image disturbance in clients with stomas was demonstrated to be higher in males, younger adults, and overweight clients (Jayarajah & Samarasekera, 2017).*
- Consideration should be given to providing counseling for women with breast cancer to assist with acceptance of the reality of the disease and to increase their resilience against breast surgery. **EB:** *Current*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

research supports previous findings regarding the change in body image satisfaction following breast surgery (Mushtaq & Naz, 2017).

- Offer breast cancer clients with appearance-related treatment side effects a beauty care intervention. Beauty care interventions can consist of make-up, hair care, or a photo shoot. **EB:** *A study found that clients with breast cancer who received beauty care interventions reported fewer symptoms of depression, higher quality of life, and higher self-esteem (Richard et al, 2019).*
- Encourage individuals to express self-compassion related to their body image through writing. **EB:** *A study found that a self-compassion writing intervention improved body dissatisfaction (Moffitt, Neumann, & Williamson, 2018).*
- Nurses and other health professionals should support clients with stomas in problem-focused coping strategies. **EBN:** *It is also important for nurses to encourage clients to have contact with their friends and family, as well as stoma support groups (Burch, 2017).*

Pediatric

- Many of the previously mentioned interventions are appropriate for the pediatric client.
- Educate parents on the role their own attitudes play in a child's body perception and acceptance. **EB:** *A recent study confirms previous research demonstrating that body dissatisfaction is related to internalization of a socially acceptable body size and the pressure to change body shape among parents. There is an elevated risk that parents can model negative body attitudes to their children* (*Kościcka et al, 2016*).
- Avoid or redirect fat talk or negative comments about one's body. **EB:** *A meta-analysis found that fat talk is related to a broader range of body image constructs and suggests that fat talk is a risk factor for body image issues* (*Mills & Fuller-Tyszkiewicz, 2017*).
- For adolescent clients, incorporate media literacy interventions to promote a healthy body image. Media literacy interventions are designed to influence media-related beliefs and attitudes to prevent risky behaviors. **EB:** *A study using media literacy-based healthy body image interventions found change in positive embodiment and health-related quality of life among participants* (*Sundgot-Borgen et al, 2019*).
- When caring for adolescents, be aware of the impact of acne vulgaris on body image and mental health. Assess for symptoms of social withdrawal, limited eye contact, and expressions of low self-esteem. Provide education on skin care and hygiene, and assist with referrals to a dermatologist as needed. **EB:** *A review of studies indicated that acne vulgaris has a substantial negative impact on clients' self-esteem and body image (Gallitano & Berson, 2017*).

Geriatric

- Assess older adults with chronic illness for body image issues. **EB:** *Research suggests that chronic illness may elevate risk for body dissatisfaction in older adults (Rakhkovskaya & Holland, 2017).*

Multicultural

- Acknowledge that body image disturbances can affect all individuals regardless of culture, race, or ethnicity. Assess for the influence of cultural beliefs, regional norms, and values on the client's body image. **EB:** *A study of Indian college students found that males were slightly more at risk for eating disorders than female students (Chaudhari et al, 2017), and another study found some discrepancies in body image perception correlated to ethnicity (Goldzak-Kunik & Leshem, 2017). A study of Brazilian women found that a significant number of those studied reported having a worse quality of life associated with being overweight or underweight (Medeiros de Morais et al, 2017).*

Home Care

- The previously mentioned interventions may be adapted for home care use.
- Assess client's level of social support. Social support is one of the determinants of the client's recovery and emotional health.
- Assess family/caregiver level of acceptance of the client's body changes.
- Encourage clients to discuss concerns related to sexuality and provide support or information as indicated. Many conditions that affect body image also affect sexuality.
- Teach all aspects of care. Involve clients and caregivers in self-care as soon as possible. Do this in stages if clients still have difficulty looking at or touching a changed body part.

B

Client/Family Teaching and Discharge Planning

- Advise clients with a stoma about the support available to them. **EBN:** *Proper discharge preparation for clients with a stoma involves the anticipation of psychological issues and depression and support to manage these issues (Burch, 2017).*

Insufficient Breast Milk Production

Domain 2 Nutrition Class 1 Ingestion

Barbara A. Reyna, PhD, RN, NNP-BC

NANDA-I

Definition

Inadequate supply of maternal breast milk to support nutritional state of an infant or child.

Defining Characteristics

Absence of milk production with nipple stimulation; breast milk expressed is less than prescribed volume for infant; delayed milk production; infant constipation; infant frequently crying; infant frequently seeks to suckle at breast; infant refuses to suckle at breast; infant voids small amounts of concentrated urine; infant weight gain <500 g in a month; prolonged breastfeeding time; unsustained suckling at breast

Related Factors

Ineffective latching on to breast; ineffective sucking reflex; infant's refusal to breastfeed; insufficient maternal fluid volume; insufficient opportunity for suckling at the breast; insufficient suckling time at breast; maternal alcohol consumption; maternal malnutrition; maternal smoking; maternal treatment regimen

At-Risk Population

Women who become pregnant while breastfeeding

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Breastfeeding Establishment: Infant, Maternal; Breastfeeding Maintenance; Anxiety Self-Control; Parent-Infant Attachment

Example NOC Outcome with Indicators

Breastfeeding Establishment: as evidenced by the following indicators: Proper alignment/Latch on/Areolar compression/Suck reflex/Nursing minimum of 15 minutes per breast/Urinations and stools appropriate for age/Weight gain appropriated for age. (Rate the outcome and indicators of **Breastfeeding Establishment:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State knowledge of indicators of adequate milk supply
- State and demonstrate measures to ensure adequate milk supply

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Lactation Counseling; Lactation Suppression; Kangaroo Care; Parent Education: Infant

Example NIC Activities—Lactation Counseling

Correct misconceptions, misinformation, and inaccuracies about breastfeeding; Provide educational material, as needed; Encourage attendance at breastfeeding classes and support groups

Nursing Interventions and *Rationales*

- Provide lactation support at all phases of lactation. **EB:** *Lactation support for early breastfeeding challenges can improve breastfeeding initiation, duration, and exclusivity rates (Patel & Patel, 2016; Anstey et al, 2018).*
- Assess maternal intention regarding breastfeeding and communicate routine advice to mothers without making them feel pressured or guilty. **CEB:** *Interactions with providers about milk supply concern evoked strong emotions among mothers (Flaherman et al, 2012).*
- Verify mothers' understanding and reinforce critical information. **EB:** *Ensuring mothers receive and understand the fundamental breastfeeding information is a modifiable factor to increase breastfeeding duration (Leurer & Misskey, 2015).*
- Initiate skin-to-skin holding at birth and undisturbed contact for the first hour following birth. **EBN:** *Immediate or early skin-to-skin holding should be common practice for healthy newborns, including those delivered by cesarean and those born at 35 weeks or more (Moore et al, 2016; Yilmaz et al, 2019).*
- Encourage postpartum women to start breastfeeding based on infant need as early as possible and reduce formula use to increase breastfeeding frequency. Use nonnarcotic analgesics as early as possible. **EBN:** *Mothers with intention to fully breastfeed whose infants receive formula supplementation may need additional support to attain exclusive breastfeeding by hospital discharge (Bentley et al, 2017; Huang & Chih, 2020).*
- Provide suggestions for mothers on how to increase milk production and how to determine the infant is receiving sufficient milk. **EBN:** *Increase in breastfeeding frequency is associated with elevated prolactin levels, increased milk production, and improved infant weight gain (Huang & Chih, 2020).*
- Instruct mothers that breastfeeding frequency, sucking times, and volume produced are variable and normal. **EBN:** *Implementing more effective informational, emotional, and practical support can reduce common problems experienced by multiparous mothers (Demirtas, 2015). Breastfeeding rates may be affected by a maternal perception of insufficient milk production and improved with interventions that develop maternal confidence in their breastfeeding capacity (Galipeau et al, 2018).*

B

▲ Consider the use of medication for mothers of preterm infants with insufficient expressed breast milk. **EB:** *There is inconclusive evidence supporting the efficacy and safety of natural and pharmacological galactogogues for mothers breastfeeding their healthy term infants and the effect on continued breastfeeding (Foong et al, 2020). Use of domperidone in mothers of preterm infants lacks evidence for optimal timing and dose, and safety has not been established (Asztalos et al, 2017).*

▲ *Not in the scope of practice for International Board of Lactation Consultants (IBLC) to recommend galactagogues (Brodribb & The Academy of Breastfeeding Medicine, 2018).*

Pediatric

● Provide individualized follow-up with extra home visits or outpatient visits for teen mothers within the first few days after hospital discharge and encourage schools to be more compatible with breastfeeding. **EBN:** *In a study of Hispanic and non-Hispanic White teen mothers, few breastfed to 6 months. Most common reasons for stopping included latch or suck difficulties, insufficient milk volume, painful, and competing demands of work (Cota-Robles et al, 2017).*

Multicultural

✱ Provide information and support to mothers on benefits of breastfeeding at antenatal visits. **EBN:** *Rates of breastfeeding initiation and duration vary based on ethnicity and race. In a study of Mexican American mothers, breastfeeding decisions were influenced by their cultural beliefs and practices, and continued breastfeeding was challenged by competing demands outside of the home, limited breastmilk supply, and personal concerns (Wambach et al, 2016).*

● Refer to care plans Interrupted **Breastfeeding** and Readiness for Enhanced **Breastfeeding** for additional interventions.

Ineffective Breastfeeding Domain 2 Nutrition Class 1 Ingestion

Barbara A. Reyna, PhD, RN, NNP-BC

B

NANDA-I

Definition

Difficulty providing milk from the breast, which may compromise nutritional status of the infant/child.

Defining Characteristics

Infant or Child

Arching at breast; crying at breast; crying within 1 hour after breastfeeding; fussing within 1 hour after breastfeeding; infant inability to latch on to maternal breast correctly; inadequate stooling; inadequate weight gain; resisting latching on to breast; sustained weight loss; unresponsive to other comfort measures; unsustained suckling at breast

Mother

Insufficient emptying of each breast during feeding; insufficient signs of oxytocin release; perceived inadequate milk supply; sore nipples persisting beyond first week

Related Factors

Delayed stage II lactogenesis; inadequate family support; inadequate parental knowledge regarding breastfeeding techniques; inadequate parental knowledge regarding importance of breastfeeding; ineffective infant suck-swallow response; insufficient breast milk production; insufficient opportunity for suckling at breast; interrupted breastfeeding; maternal ambivalence; maternal anxiety; maternal breast anomaly; maternal fatigue; maternal obesity; maternal pain; pacifier use; supplemental feedings with artificial nipple

At-Risk Population

Individuals with history of breast surgery; individuals with history of breastfeeding failure; premature infants; women with short maternity leave

Associated Conditions

Oropharyngeal defect

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes and Example

Breastfeeding Establishment: Infant/Maternal; Breastfeeding Maintenance; Knowledge: Breastfeeding; Refer to care plan for Readiness for Enhanced **Breastfeeding**

Client Outcomes

Client Will (Specify Time Frame)

- Achieve effective milk transfer (dyad)
- Verbalize/demonstrate techniques to manage breastfeeding problems (mother)
- Manifest signs of adequate intake at the breast (infant)
- Manifest positive self-esteem in relation to the infant feeding process (mother)
- Explain alternative method of infant feeding if unable to continue exclusive breastfeeding (mother)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Referral; Lactation Counseling; Teaching Infant Nutrition 0-3 Months

B

Nursing Interventions and *Rationales*

- Identify women with risk factors for lower breastfeeding initiation and continuation rates, as well as factors contributing to ineffective breastfeeding (see conditions listed in the section Related Factors) as early as possible in the perinatal experience. **EBN:** *Health care professionals are well positioned to identify mothers at risk for breastfeeding challenges and to provide accurate information and support the development of breastfeeding skills, which facilitates breastfeeding confidence and success (Balogun et al, 2016; Ogbo et al, 2017).* **CEB:** *The Breastfeeding Self-Efficacy Scale Short Form (BSES-SF) is a reliable measure of breastfeeding self-efficacy and can be used to identify mothers who are likely to be successful and mothers needing additional support to ensure success (Dennis, 2003).*
- Provide time for clients to express expectations and concerns, and provide emotional support as needed. **EBN:** *Lactation consultants, nurses, and peers play a key role in the establishment and continuation of breastfeeding (Balogun et al, 2016; McFadden et al, 2017).*
- Encourage skin-to-skin holding, beginning immediately after delivery. **EBN:** *Skin-to-skin holding is associated with improved milk supply, early initiation of breastfeeding, and improved breastfeeding duration (Moore et al, 2016; Yilmaz et al, 2020).*
- Use valid and reliable tools to assess breastfeeding performance and identify dyads at risk for breastfeeding failure. **CEB:** *A study to evaluate the validity and reliability of the Infant Breastfeeding Assessment Tool (IBFAT), the Mother Baby Assessment (MBA) Tool, and the LATCH scoring system found them to be reliable and compatible to assess the efficiency of breastfeeding (Altuntas et al, 2014).* **EBN:** *Casal et al (2017) examined 16 instruments measuring breastfeeding attitudes, knowledge, and social support and found that not all scales demonstrated content, construct, and predictive validity.*
- Promote comfort and relaxation to reduce pain and anxiety. **EB:** *Women experiencing postpartum anxiety and negative postpartum mood are less likely to breastfeed exclusively and more likely to terminate breastfeeding earlier (Fallon et al, 2016).*
- Avoid supplemental feedings. **EBN:** *A correlation exists between formula and/or water supplements and failure to succeed with exclusive breastfeeding (Tarrant et al, 2015).*
- Teach mother to observe for infant behavioral cues and responses to breastfeeding. **EBN:** *Providing support and education to mother will build her confidence and knowledge base, and it is associated with improved breastfeeding duration and exclusivity (McFadden et al, 2017).*
- ▲ Provide necessary equipment/instruction/assistance for milk expression as needed. **EB:** *Expressing breast milk by hand may be more effective in the removal of milk, particularly in the immediate postpartum period, than the use of electric pumps (Becker et al, 2016).*
- ▲ Provide referrals and resources: lactation consultants, nurse and peer support programs, community organizations, and written and electronic sources of information. **EBN:** *Systematic reviews support the use of professionals with special skills in breastfeeding, peer support programs, and written and electronic information to promote continued breastfeeding (McFadden et al, 2017). Novel approaches to education, such as text messages to mothers and interactive online education programs for fathers/partners, have demonstrated improved breastfeeding knowledge base and self-efficacy and improved breastfeeding exclusivity rates (Abbass-Dick et al, 2017; Harari et al, 2018).*
- See care plan for Readiness for Enhanced **Breastfeeding.**

Multicultural

- Assess whether the client's cultural beliefs about breastfeeding are contributing to ineffective breastfeeding. **EB:** *Women from different cultures may add formula as a result of concerns that the infant is not getting enough to eat and the perception that "big is healthy" (Kuswara et al, 2016; Wandel et al, 2016).* **EB:** *Some traditional cultures consider colostrum unsuitable for feeding the newborn, and liquids other than breast milk may be substituted. These feedings may significantly increase the risk of infection, particularly in developing countries in which sanitation may be poor. In addition, failure to empty the breasts regularly in the early hours and days after delivery may result in suboptimal milk supply (Agho et al, 2016).*
- Assess the influence of family support on the decision to continue or discontinue breastfeeding. **EBN:** *Family members' impressions and ideas about breastfeeding influence breastfeeding initiation, duration, and exclusivity in Chinese mothers (Lok et al, 2017).*
- See care plan for Readiness for Enhanced **Breastfeeding.**

Home Care

- The previously mentioned interventions may be adapted for home care use.

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Provide anticipatory guidance in relation to home management of breastfeeding. **EB:** *The two most common problems experienced by breastfeeding women are nipple and/or breast pain and low (or perceived low) milk supply; these problems may be preventable with anticipatory guidance (Cleugh & Langseth, 2017; Wood & Sanders, 2018).* **EBN:** *For mothers returning to the workforce, longer maternity leaves and regularly pumping milk during the workday are associated with enhanced work–life balance and longer breastfeeding duration (Jantzer et al, 2018).*

▲ Investigate availability of support services and refer to public health department, hospital home follow-up breastfeeding program, or other postdischarge support. **EBN:** *Postdischarge follow-up has been associated with improved breastfeeding duration (Wood & Sanders, 2018).*

- See care plan for Risk for Impaired **Attachment.**

Client/Family Teaching and Discharge Planning

- Instruct the client on maternal breastfeeding behaviors/techniques (preparation for, positioning, initiation of/promoting latch-on, burping, completion of session, and frequency of feeding) using a variety of strategies such as written materials, videos, and online resources. **EB:** *Assessing breastfeeding mothers to determine knowledge deficits and providing individualized teaching facilitates breastfeeding success (Cleugh & Langseth, 2017; Nilsson et al, 2017).*
- Teach the mother self-care measures (e.g., breast care, management of breast/nipple discomfort, nutrition/fluid, rest/activity). **EBN:** *Painful nipples, mastitis, inadequate hydration, and fatigue are some potentially modifiable problems a breastfeeding woman may experience (McFadden et al, 2017).*
- Provide information regarding infant feeding cues and behaviors and appropriate maternal responses, as well as measures of infant feeding adequacy. **EBN:** *Improved knowledge base and ongoing support to learn psychomotor skills facilitate effective breastfeeding (McFadden et al, 2017).*
- Provide education to partner/family/significant others as needed. **EBN:** *Family members' impressions and ideas about breastfeeding influence breastfeeding initiation and duration (Lok et al, 2017).*

Interrupted Breastfeeding

Domain 2 Nutrition Class 1 Ingestion

Barbara A. Reyna, PhD, RN, NNP-BC

NANDA-I

Definition

Break in the continuity of feeding milk from the breasts, which may compromise breastfeeding success and/or nutritional status of the infant/child.

Defining Characteristics

Nonexclusive breastfeeding

Related Factors

Abrupt weaning of infant; maternal-infant separation

At-Risk Population

Employed mothers; hospitalized children; hospitalized infants; premature infants

Associated Conditions

Contraindications to breastfeeding; infant illness; maternal illness

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Breastfeeding Maintenance; Knowledge: Breastfeeding; Parent-Infant Attachment

Example NOC Outcome with Indicators

Breastfeeding Maintenance as evidenced by the following indicators: Infant's growth and development in normal range/Ability to safely collect and store breast milk/Awareness that breastfeeding can continue beyond infancy/Knowledge of benefits from continued breastfeeding. (Rate the outcome and indicators of **Breastfeeding Maintenance: Infant:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

Infant

- Receive mother's breast milk if not contraindicated by maternal conditions (e.g., certain drugs, infections) or infant conditions (e.g., galactosemia)

Maternal

- Maintain lactation
- Achieve effective breastfeeding or satisfaction with the breastfeeding experience
- Demonstrate effective methods of breast milk collection and storage

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Bottle Feeding; Cup Feeding: Newborn; Emotional Support; Lactation Counseling

Example NIC Activities—Lactation Counseling

Instruct client to contact health care provider (lactation consultant, nurse, midwife, or physician) to assist in determining status of milk supply (i.e., whether insufficiency is perceived or actual); Encourage employers to provide opportunities and private facilities for lactating mothers to pump and store breast milk during the workday

Nursing Interventions and *Rationales*

- Provide information and support to mother and partner/family regarding mother's desire/intention to begin or resume breastfeeding. **EBN:** *Mothers who perceived that care providers, partners, and other family members favored exclusive breastfeeding achieved significantly higher rates of breastfeeding compared with those who perceived that care providers and family were neutral about the method of infant feeding (Radzyminski & Callister, 2015; Lok et al, 2017).*
- Clarify the indication for interrupting breastfeeding is warranted. **EB:** *Use of gadolinium or iodinated contrast with magnetic resonance imaging (MRI) is not an indication to interrupt breastfeeding (ACOG, 2017). LactMed is a resource to obtain the most current data on a prescribed medication during lactation. Rare exceptions exist in regard to maternal immunization and lactation (Sachs & AAP, 2013).*
- Provide anticipatory guidance to the mother/family regarding potential duration of the interruption when possible/feasible, ensuring that measures to sustain or restart lactation and promote parent–infant attachment can make it possible to resume breastfeeding when the condition/situation requiring interruption is resolved. **EB:** *Factors contributing to the establishment of relactation are motivation of the mother to reinitiate breastfeeding, nipple stimulation, and strong support and encouragement (Mehta et al, 2018).*
- Reassure the mother/family that the infant will benefit from any amount of breast milk provided. **EBN:** *One of the most common reasons mothers supplement or stop breastfeeding is their perception of the baby not getting milk and/or enough milk* (*Wood & Sanders, 2018*).
- Assess mother's concerns, and observe mother performing psychomotor skills (expression, storage, alternative feeding, skin-to-skin care, and/or breastfeeding) and assist as needed. **EBN:** *Individualized support and instruction improves likelihood of breastfeeding success (Becker et al, 2016; McFadden et al, 2017).*
- Collaborate with mother/family/health care providers (as needed) to develop a plan for skin-to-skin contact. **EBN:** *Skin-to-skin contact between mothers and newborns results in improved rates of exclusive breastfeeding (McFadden et al, 2017).*
- Collaborate with the mother/family/health care provider/employer (as needed) to develop a plan for expression/pumping of breast milk and/or infant feeding. **EB:** *Individualized education focused on evidence-based strategies to optimize milk production and extraction enhances milk quality and quantity (Becker et al, 2016).* **EBN:** *A supportive employee lactation program can ease the transition of returning to work (Froh & Spatz, 2016; Snyder et al, 2018).*
- Monitor for signs indicating infant's ability to breastfeed and interest in breastfeeding. **EBN:** *Teach the mother to recognize and respond to her baby's feeding cues and signs that her breasts are filling (McFadden et al, 2017).*
- ▲ Use formula supplementation only as medically indicated. **EB:** *Reducing the number of formula supplements given to infants in the hospital is associated with increased rates of exclusive breastfeeding and breastfeeding duration (Tarrant et al, 2015; Bentley et al, 2017).*
- Provide anticipatory guidance for common problems associated with interrupted breastfeeding (e.g., incomplete emptying of milk glands, diminishing milk supply, infant difficulty with resuming breastfeeding, or infant refusal of alternative feeding method). **EBN:** *Emotional support, as well as information regarding how to prevent and respond to breastfeeding problems, contributes to promotion of exclusive breastfeeding (Wood & Sanders, 2018; Gianni et al, 2019).*
- ▲ Initiate follow-up and make appropriate referrals.
- Provide emotional support for the mother if effective breastfeeding is not achieved and assist with learning an alternative method of infant feeding. **EB:** *The inability to breastfeed can be devastating for a mother and can be best supported with unconditional respect (McGuire, 2016).*
- See care plans for Readiness for Enhanced **Breastfeeding** and Ineffective **Breastfeeding.**

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

B

Multicultural

- Assess the client's cultural beliefs about breastfeeding and the ability to exclusively breastfeed. **EBN:** *A study examining breastfeeding exclusivity among immigrant and Canadian-born Chinese women found that immigrant women are at increased risk for discontinuation of exclusive breastfeeding (Dennis et al, 2019).* **EB:** *Some traditional cultures consider colostrum unsuitable to feed the newborn and substitute other liquids. Breast expression/pumping is needed to ensure breasts are regularly emptied and to facilitate an optimal milk supply (Agho et al, 2016).*
- See care plans for Readiness for Enhanced **Breastfeeding** and Ineffective **Breastfeeding.**

Home Care

- The previously mentioned interventions may be adapted for home care use.

Client/Family Teaching and Discharge Planning

- Teach mother effective methods to express breast milk. **EB:** *Expressing breast milk by hand may be more effective in the removal of milk, particularly in the immediate postpartum period, than the use of electric pumps* (*Becker et al, 2016*).
- Teach mother/parents about skin-to-skin care. **EBN:** *Skin-to-skin care promotes attachment, facilitates improved milk production, and contributes to improved rate and duration of breastfeeding* (*Moore et al, 2016*; *Crenshaw, 2019*).
- Instruct mother on safe breast milk handling and storage. **EB:** *Breastfeeding mothers can retain the high quality of breast milk and the health of their infant by using safe preparation guidelines and storage methods* (*Eglash et al, 2017*).
- See care plans for Readiness for Enhanced **Breastfeeding** and Ineffective **Breastfeeding.**

Readiness for Enhanced Breastfeeding

Domain 2 Nutrition Class 1 Ingestion

Barbara A. Reyna, PhD, RN, NNP-BC

B

NANDA-I

Definition

A pattern of providing milk from the breasts to an infant or child, which can be strengthened.

Defining Characteristics

Expresses desire to enhance ability to exclusively breastfeed; expresses desire to enhance ability to provide breast milk for child's nutritional needs

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Breastfeeding Establishment: Infant, Maternal; Breastfeeding Maintenance

Example NOC Outcome with Indicators

Breastfeeding Establishment: Infant as evidenced by the following indicators: Proper alignment and latch-on/Proper areolar grasp/Effective areolar compression/Correct suck and tongue placement/Audible swallow/Breastfeeding a minimum of 5 to 10 minutes per breast/Minimum eight feedings per day/Urinations per day appropriate for age/Weight gain appropriate for age. (Rate the outcome and indicators of **Breastfeeding Establishment: Infant:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain effective breastfeeding
- Maintain normal growth patterns (infant)
- Verbalize satisfaction with breastfeeding process (mother)

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Lactation Counseling

Example NIC Activities—Lactation Counseling

Provide information about psychological and physiological benefits of breastfeeding; Provide mother the opportunity to breastfeed after birth, when possible

Nursing Interventions and *Rationales*

- Encourage expectant mothers to learn about breastfeeding during pregnancy. **EBN:** *Individualized, needs-based health education by a health care professional, provided in the antenatal and perinatal period, is most likely to increase breastfeeding initiation rates* (*Jacobsen, 2018*; *Huang et al, 2019*).
- Encourage and facilitate early skin-to-skin contact. **EBN:** *Skin-to-skin holding is associated with improved milk supply, early initiation of breastfeeding, and improved breastfeeding duration* (*Moore et al, 2016*; *Yilmaz et al, 2020*).
- Encourage breastfeeding on demand and rooming-in. **EB:** *Breastfeeding on demand supports continued breastfeeding* (*Colombo et al, 2018*). **EB:** *Effects of rooming-in on breastfeeding duration is uncertain but there is some evidence that mothers who room-in with their infants are more likely to be exclusively breastfeeding in the short term* (*Jaafar et al, 2016*; *Ng et al, 2019*).

- Monitor the breastfeeding process, identify opportunities to enhance knowledge and experience, and provide direction as needed. **EBN:** *Individualized education focused on evidence-based strategies improves breastfeeding duration and exclusivity* (*McFadden et al, 2017*).
- Provide encouragement and positive feedback to mothers as they learn to breastfeed. **EBN:** *A mother's belief that she can breastfeed successfully will be more likely to lead her to exclusively breastfeed and for longer duration* (*Brockway et al, 2017*). **EBN:** *Lactation consultants, nurses, and peers play a key role in the establishment and continuation of breastfeeding* (*Balogun et al, 2016*; *McFadden et al, 2017*).
- Discuss prevention and treatment of common breastfeeding problems, such as nipple pain and/or trauma. **EBN:** *Emotional support, as well as information regarding how to prevent and respond to breastfeeding problems, contributes to promotion of exclusive breastfeeding* (*Wood & Sanders, 2018*; *Gianni et al, 2019*).
- Teach mother to observe for infant behavioral cues and responses to breastfeeding. **EBN:** *Providing support and education to mother will build her confidence and knowledge base, and it is associated with improved breastfeeding duration and exclusivity* (*McFadden et al, 2017*).
- Identify current support-person network and opportunities for continued breastfeeding support. **EB:** *Family members' impressions and ideas about breastfeeding influence breastfeeding initiation and duration* (*Lok et al, 2017*).
- Use formula supplementation only as medically indicated, and do not provide samples of formula on discharge from hospital. **EB:** *Reducing the number of formula supplements given to infants in hospital, and refraining from sending formula samples home, is associated with increased rates of exclusive breastfeeding and increased breastfeeding duration* (*Tarrant et al, 2015*; *Bentley et al, 2017*).

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on current breastfeeding practices. **EBN:** *Women from different cultures, such as Chinese, Somali, and Hispanic women, may add formula as a result of concerns that the infant is not getting enough to eat and the perception that "big is healthy" (Kuswara et al, 2016; Wandel et al, 2016).* **EB:** *Some traditional cultures consider colostrum unsuitable for feeding the newborn and liquids other than breast milk may be substituted; thus, formula may be required to prevent hypoglycemia and dehydration, and breast expression/pumping is needed to ensure breasts are regularly emptied to facilitate an optimal milk supply (Agho et al, 2016).*

Home Care

- The previously mentioned interventions may be adapted for home care use.

Client/Family Teaching and Discharge Planning

- Include the partner and other family members in education about breastfeeding. **EB:** *Family members' impressions and ideas about breastfeeding influence breastfeeding initiation and duration (Lok et al, 2017).*
- Teach the client the importance of maternal nutrition and self-care. **CEB:** *Breastfeeding mothers should consume about 500 calories more per day than nonpregnant, nonnursing women, with a focus on nutrient-dense foods, including 200 to 300 mg docosahexaenoic acid (DHA) (the amount ingested with consumption of one to two portions of fish per week) (AAP & Section on Breastfeeding, 2012).* **EB:** *Consuming a balanced diet with adequate nutrient intakes during the breastfeeding period can affect healthy body weight and some nutrients with breastmilk (Koletzko et al, 2019).*
- Teach mother to observe for the infant's hunger cues (e.g., rooting, sucking, mouthing, hand-to-mouth and hand-to-hand activity) and encourage her to breastfeed on demand. **EBN:** *Evidence-based practice guidelines support the teaching/reinforcement of these skills as important to effective breastfeeding (McFadden et al, 2017).*
- Review guidelines for frequency of feeds (at least every 2–3 hours, or 8–12 feedings per 24 hours) and feeding duration (until suckling and swallowing slow down and satiety is reached). **EBN:** *In the first few days, frequent and regular stimulation of the breasts is important to establish an adequate milk supply; after breastfeeding is established, feeding lasts until the breasts are drained (McFadden et al, 2017).*

▲ Provide referrals and resources: lactation consultants, nurse and peer support programs, community organizations, and written and electronic sources of information. **EBN:** *Systematic reviews support the use of professionals with special skills in breastfeeding and peer support programs to promote continued breastfeeding (McFadden et al, 2017; Wood & Sanders, 2018).*

B

Ineffective Breathing Pattern

Domain 4 Activity/rest Class 4 Cardiovascular/pulmonary responses

Debra Siela, PhD, RN, ACNS-BC, CCRN-K, CNE, RRT

NANDA-I

Definition

Inspiration and/or expiration that does not provide adequate ventilation.

Defining Characteristics

Abdominal paradoxical respiratory pattern; altered chest excursion; altered tidal volume; bradypnea; cyanosis; decreased expiratory pressure; decreased inspiratory pressure; decreased minute ventilation; decreased vital capacity; hypercapnia; hyperventilation; hypoventilation; hypoxemia; hypoxia; increased anterior-posterior chest diameter; nasal flaring; orthopnea; prolonged expiration phase; pursed-lip breathing; subcostal retraction; tachypnea; use of accessory muscles to breathe; use of three-point position

Related Factors

Anxiety; body position that inhibits lung expansion; fatigue; increased physical exertion; obesity; pain

B

At-Risk Population

Young women

Associated Conditions

Bony deformity; chest wall deformity; chronic obstructive pulmonary disease; critical illness; heart diseases; hyperventilation syndrome; hypoventilation syndrome; increased airway resistance; increased serum hydrogen concentration; musculoskeletal impairment; neurological immaturity; neurological impairment; neuromuscular diseases; reduced pulmonary complacency; sleep-apnea syndromes; spinal cord injuries

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Respiratory Status: Airway Patency, Ventilation; Vital Signs

Example NOC Outcome with Indicators

Respiratory Status: Ventilation as evidenced by the following indicators: Respiratory rate/Moves sputum out of airway/Adventitious breath sounds not present/Shortness of breath not present/Auscultated breath sounds/Auscultated vocalization/Chest x-ray findings (Rate each indicator of **Respiratory Status: Ventilation:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate a breathing pattern that supports blood gas results within the client's normal parameters
- Report ability to breathe comfortably
- Demonstrate ability to perform pursed-lip breathing and controlled breathing
- Identify and avoid specific factors that exacerbate episodes of ineffective breathing patterns

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Airway Management; Respiratory Monitoring

Example NIC Activities—Airway Management

Encourage slow, deep breathing, turning, and coughing; Monitor respiratory and oxygenation status as appropriate

Nursing Interventions and *Rationales*

- Monitor respiratory rate, depth, and ease of respiration. *Normal respiratory rate is 10 to 20 breaths per minute in the adult (Jarvis, 2019).*
- Note pattern of respiration. If client is dyspneic, note what seems to cause the dyspnea, the way in which the client deals with the condition, and how the dyspnea resolves or gets worse. **EB:** *Ask the client if they are short of breath (Mahler & O'Donnell, 2015).* **EBN:** *When possible, use a valid and reliable objective tool, such as the Respiratory Distress Observation Scale, a numerical scale, or a visual analog scale that allows assessment of intensity of dyspnea when the client cannot self-report (Campbell, 2017).*
- Note amount of anxiety associated with the dyspnea. **EB:** *A normal respiratory pattern is regular in a healthy adult. To assess dyspnea, it is important to consider all of its dimensions, including antecedents, mediators, reactions, and outcomes* (*Sauls, 2021*).
- Attempt to determine if client's dyspnea is physiological or psychological in cause. **EB:** *The evaluation of a client with dyspnea continues to be dependent on a thorough history and physical examination. In the client with acute worsening of chronic breathlessness, the health care provider must be attuned to the possibility of a new pathophysiological derangement superimposed on a known disorder. Instruments or sections of instruments pertaining to dyspnea should be classified as addressing domains of sensory-perceptual experience, affective distress, or symptom/disease impact or burden* (*Mahler & O'Donnell, 2015*; *Budhwar, & Syed, 2020*).

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- The rapidity of which the onset of dyspnea is noted is also an indicator of the severity of the pathological condition. **EB:** *Evaluate the rate and depth along with changes in mentation when assessing a client with dyspnea (Sauls, 2021).*

Psychological Dyspnea—Hyperventilation

- Monitor for symptoms of hyperventilation, including rapid respiratory rate, sighing breaths, lightheadedness, numbness and tingling of hands and feet, palpitations, and sometimes chest pain (Bickley et al, 2020).
- Assess cause of hyperventilation by asking client about current emotions and psychological state.
- Pulmonary rehabilitation programs that contain components of behavioral, cognitive, or psychosocial components have been shown to improve dyspnea and reduce anxiety and depression, particularly in clients with COPD (GOLD, 2020).
- Pharmacological treatment to reduce anxiety and panic disorders that likely increase dyspnea may not be recommended for clients with asthma and COPD (GOLD, 2020).
- Ask the client to breathe with you to slow down respiratory rate. **EB:** *Maintain eye contact and give reassurance. By making the client aware of respirations and giving support, the client may gain control of the breathing rate (Sauls, 2021).*
- ▲ Consider having the client breathe in and out of a paper bag as tolerated. *This simple treatment helps associated symptoms of hyperventilation, including helping to retain carbon dioxide, which will decrease associated symptoms of hyperventilation (Bickley et al, 2020).*
- ▲ If client has chronic problems with hyperventilation, numbness and tingling in extremities, dizziness, and other signs of panic attacks, refer for counseling or pulmonary rehabilitation. **EB:** *A systematic review and meta-analysis found that continued supervised pulmonary rehabilitation programs compared with usual care resulted in significant reduction in symptoms, improved self-report of dyspnea, and reduced risk of respiratory-cause hospital admission (Jenkins et al, 2018).*

Physiological Dyspnea

- ▲ Ensure that clients in acute dyspneic state have received any ordered medications, oxygen, and any other treatment needed. **EB:** *Providing oxygen and opioids is often immediately helpful in relieving acute dyspnea, and cooling the room or use of a fan has been reported by clients to ease symptoms (Baldwin & Cox, 2016).* **EB:** *It is important for the nurse to know different modes of oxygen delivery and percent of oxygen to avoid risks associated with oxygen toxicity (Siela & Kidd, 2017).*
- Use valid and reliable tools to evaluate perceived dyspnea. **CEB/EB:** *Determine intensity, unpleasantness, or distress of dyspnea using a rating scale such as an intensity-focused modified Borg scale or Respiratory Distress Observation Scale visual analog scale* (*Parshall et al, 2012*; *Campbell, 2017*).
- Ask the client to describe the quality of breathing effort. **EB:** *Dyspnea and breathlessness are subjective symptoms; thus asking questions as to triggers for dyspneic events, chest tightness, air hunger, inability to breathe deeply, urge to breathe, starved for air, or feeling of suffocation is important to understand and more fully address the client's dyspnea* (*Baldwin & Cox, 2016*; *Campbell, 2017*).
- Acute onset of dyspnea is often accompanied by signs of respiratory distress, which include tachypnea, cough, stridor, wheezing, cyanosis, impaired speech, tachycardia, hypotension, peripheral edema, frothy sputum, pursed-lip breathing, accessory respiratory muscle use, crackles, tripod positioning, and other signs.
- Observe color of tongue, oral mucosa, and skin for signs of cyanosis. *In central cyanosis, both the skin and mucous membranes are affected due to seriously impaired pulmonary function from unventilated or underventilated alveoli. Peripheral cyanosis (skin only) usually indicates vasoconstriction or obstruction to blood flow (Loscalzo, 2018).*
- Auscultate breath sounds, noting decreased or absent sounds, crackles, or wheezes. *These abnormal lung sounds can indicate a respiratory pathology associated with an altered breathing pattern (Bickley et al, 2020).*
- Assess for hemodynamic stability for the client with acute dyspnea. **EB:** *Rapid evaluation for impending respiratory failure is essential and includes fragmented speech, tripod positioning, diaphoresis, cyanosis, Pao_2 less than 50 mm Hg, $Paco_2$ greater than 70, and use of accessory muscles. Hypotension along with dyspnea indicates threat of cardiopulmonary collapse* (*Baldwin & Cox, 2016*).
- Monitor oxygen saturation continuously using pulse oximetry. Note blood gas results as available. *An oxygen saturation of less than 90% (normal: 95%–100%) or a partial pressure of oxygen of less than 80 mm Hg (normal: 80–100 mm Hg) indicates significant oxygenation problems (Loscalzo, 2018).*

B

- Using touch on the shoulder, coach the client to slow respiratory rate, demonstrating slower respirations, making eye contact with the client, and communicating in a calm, supportive fashion. The nurse's presence, reassurance, and help in controlling the client's breathing can be beneficial in decreasing anxiety. **EB:** *Anxiety is an important indicator of severity of client's disease with chronic obstructive pulmonary disease (COPD) (Baldwin & Cox, 2016; Campbell, 2017).*
- Support the client in using pursed-lip and controlled breathing techniques. **EB:** *Pursed-lip breathing may relieve dyspnea in advanced COPD. Pursed-lip breathing results in increased use of intercostal muscles, decreased respiratory rate, increased tidal volume, and improved oxygen saturation levels (Nguyen & Duong, 2020).*
- If the client is acutely dyspneic, consider having the client lean forward over a bedside table, resting elbows on the table if tolerated. **EB:** *Leaning forward can help decrease dyspnea, possibly because gastric pressure allows better contraction of the diaphragm. This is called the tripod position and is used during times of distress, including when walking (Baldwin & Cox, 2016; Nguyen & Duong, 2020).*
- Position the client in a semi-Fowler's position to address dyspnea symptoms. **EB:** *Most clients will have optimal vital capacity, when upright with arms elevated on pillows or a bedside table; however, semi-Fowler's position can facilitate better oxygen diffusion and reduce air hunger* (Baldwin & Cox, 2016; Campbell, 2017; Loscalzo, 2018).

▲ Administer oxygen as ordered. **EB:** *Supplemental oxygen may not relieve all dyspnea. Other interventions such as exercise, behavioral therapy, mindfulness exercises, treating anxiety, opioids, and a fan have been found to provide relief to clients with dyspnea who are not hypoxemic (Baldwin & Cox, 2016; Campbell, 2017).*

- Opioids may be used for both acute and terminal dyspnea, considering careful safe dosing for relief and side effect of constipation (Baldwin & Cox, 2016; Campbell, 2017).
- Use of music as a distraction may reduce the perception of dyspnea. **EB:** *A randomized control trial found that using music reduced the perceived severity of dyspnea and anxiety but did not positively affect vital signs. Using music was found to be an easy and effective intervention in addressing acute dyspnea* (Ergin et al, 2018).
- Increase client's activity to walking three times per day as tolerated. Assist the client in using oxygen during activity as needed. **EB:** *Walking 20 minutes per day is recommended for those unable to be in a structured program. Supervised exercise has been shown to decrease dyspnea and increase tolerance to activity* (GOLD, 2020).
- Schedule rest periods before and after activity. **EB:** *Respiratory clients with dyspnea are easily exhausted and need additional rest. Nurses coordinate all client care and are integral to ensuring spacing of activity to minimize or prevent dyspnea* (Campbell, 2017).

▲ Evaluate the client's nutritional status. Refer to a dietitian if needed. Use nutritional supplements to increase nutritional level if needed. **EB:** *The Academy of Nutrition and Dietetics strongly recommends that people with COPD have their body weight and medical nutrition therapy assessed and monitored by a registered dietitian nutritionist (Hanson et al, 2021).*

- Provide small, frequent feedings. **EB:** *Small feedings are given to avoid compromising ventilatory effort and to conserve energy. Clients with dyspnea often do not eat sufficient amounts of food because their priority is breathing* (Hanson et al, 2021).
- Encourage the client to take deep breaths at prescribed intervals and do controlled coughing. **EB:** *Pulmonary exercises, including practice with pursed-lip breathing, have been found to facilitate the client's self-care management of dyspnea symptoms* (Nguyen & Duong, 2020).
- Help the client with chronic respiratory disease to evaluate dyspnea experience to determine whether previous incidences of dyspnea were similar and to recognize that the client survived those incidences. Encourage the client to be self-reliant if possible, use problem-solving skills, and maximize use of social support. **EB:** *The focus of attention on sensations of breathlessness has an impact on judgment used to determine the intensity of the sensation* (Campbell, 2017).
- See care plan for Ineffective **Airway** Clearance if client has a problem with increased respiratory secretions.

▲ Refer the client with COPD for pulmonary rehabilitation. **EB:** *Clients receiving pulmonary rehabilitation have a significant and clinically meaningful improvement in dyspnea discomfort and also an improvement in the effect of dyspnea on activities of daily living and overall quality of life. Among the beneficial effects of pulmonary rehabilitation are a reduction in exertional dyspnea during exercise and improved exercise tolerance, as well as decreases in self-reported dyspnea with activity. Pulmonary rehabilitation benefits for COPD clients include reduction of the perceived intensity of breathlessness (GOLD, 2020).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Geriatric

- Assess respiratory systems in older adults with the understanding that inspiratory muscles weaken, resulting in a slight barrel chest. **EB:** *Expiratory muscles work harder with use of accessory muscles (Mahler, 2017).*
- Encourage ambulation as tolerated. **EB:** *Immobility is harmful to older adults because it decreases ventilation, increases stasis of secretions, and worsens dyspnea symptoms* (*Brummel et al, 2015*).
- Encourage older clients to sit upright or stand and to avoid lying down for prolonged periods during the day. **EB:** *Encouraging the older adult to engage in activities of daily living fosters independence and movement, which is important to increase pulmonary capacity and reduce breathlessness* (*Brummel et al, 2015*; *Mahler, 2017*).

Home Care

- Work with the client to determine what strategies are most helpful during times of dyspnea. Educate and empower the client to self-manage the disease associated with impaired gas exchange.
- Assist the client and family with identifying other factors that precipitate or exacerbate episodes of ineffective breathing patterns (e.g., stress, allergens, stairs, activities that have high energy requirements). **EB:** *Awareness of precipitating factors helps clients avoid them and decreases risk of ineffective breathing episodes (Baldwin & Cox, 2016; Campbell, 2017).*
- Assess client knowledge of and compliance with medication regimen. *Client/family may need repetition of instructions received at hospital discharge and may require reiteration as fear of a recent crisis decreases. Fear interferes with the ability to assimilate new information.*

▲ Refer the client for telemonitoring with a pulmonologist as appropriate, with use of an electronic spirometer or an electronic peak flowmeter.

- Teach the client and family the importance of maintaining the therapeutic regimen and having as-needed drugs easily accessible at all times. **EB:** *Appropriate and timely use of medications can decrease the risk of exacerbating ineffective breathing. The 2020 GOLD Report states that bronchodilator medications are central to management of dyspnea (GOLD, 2020).*
- Provide the client with emotional support in dealing with symptoms of respiratory difficulty. Provide family with support for care of a client with chronic or terminal illness. *Witnessing breathing difficulties and facing concerns of dealing with chronic or terminal illness can create fear in caregiver. Fear inhibits effective coping (Campbell, 2017).* Refer to care plan for **Anxiety.**
- When electrically based equipment for respiratory support is being implemented, evaluate home environment for electrical safety, such as proper grounding. Ensure that notification is sent to the local utility company, the emergency medical team, and police and fire departments. *Notification is important to provide priority service. Identify an emergency plan including when to call the health care provider or 911. Having a ready emergency plan reassures the client and promotes client safety.*
- Support clients' efforts at self-care. Ensure they have all the information they need to participate in care.

▲ Referral for in-home occupational therapy evaluation and teaching of energy conservation techniques and appropriate home safety (GOLD, 2020).

▲ Institute case management of frail elderly to support continued independent living (Mahler, 2017).

Client/Family Teaching and Discharge Planning

- Teach pursed-lip and controlled breathing techniques. **EB:** *Studies have demonstrated that pursed-lip breathing was effective in decreasing breathlessness and improving respiratory function* (*Nguyen & Duong, 2020*).
- Teach about dosage, actions, and side effects of medications. *Inhaled steroids and bronchodilators can have undesirable side effects, especially when taken in inappropriate doses.*
- Teach client progressive muscle relaxation techniques. **EB:** *Relaxation therapy may help reduce dyspnea and anxiety Benefits of pulmonary rehabilitation include reduction of anxiety and depression associated with COPD* (*GOLD, 2020*).
- Teach the client to identify and avoid specific factors that exacerbate ineffective breathing patterns, such as exposure to other sources of air pollution, especially smoking. If client smokes, refer to a smoking cessation program. **EB:** *A systematic review and meta-analysis found that multimodal smoking cessation plans (group work and medications) are often required to support a client change in smoking behavior and successful efforts to quit (Chen & Wu, 2015).*

Decreased Cardiac Output

Domain 4 Activity/rest Class 4 Cardiovascular/pulmonary responses

Ann Will Poteet, MS, RN, CNS, AGNP-C

NANDA-I

Definition

Inadequate volume of blood pumped by the heart to meet the metabolic demands of the body.

Defining Characteristics

Altered Heart Rate/Rhythm

Bradycardia, electrocardiogram change; heart palpitations; tachycardia

Altered Preload

Decrease in central venous pressure; decrease in pulmonary artery wedge pressure; edema; fatigue; heart murmur; increased central venous pressure; increased pulmonary artery wedge pressure; jugular vein distention; weight gain

Altered Afterload

Abnormal skin color; altered blood pressure; clammy skin; decreased peripheral pulses; decreased pulmonary vascular resistance; decreased systemic vascular resistance; dyspnea; increased pulmonary vascular resistance; increased systemic vascular resistance; oliguria; prolonged capillary refill

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Altered Contractility

Adventitious breath sounds; coughing; decreased cardiac index; decreased ejection fraction; decreased left ventricular stroke work index; decreased stroke volume index; orthopnea; paroxysmal nocturnal dyspnea; presence of S3 heart sound; presence of S4 heart sound

Behavioral/Emotional

Anxiety; psychomotor agitation

Related Factors

To be developed

Associated Conditions

Altered afterload, altered contractility; altered heart rate; altered heart rhythm; altered preload; altered stroke volume

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Cardiac Pump Effectiveness; Circulation Status; Tissue Perfusion: Abdominal Organs, Peripheral; Vital Signs

Example NOC Outcome with Indicators

Cardiac Pump Effectiveness as evidenced by the following indicators: Blood pressure/Heart rate/Cardiac index/Ejection fraction/Activity tolerance/Peripheral pulses/Neck vein distention not present/Heart rhythm/Heart sounds/Angina not present/Peripheral edema not present/Pulmonary edema not present. (Rate the outcome and indicators of **Cardiac Pump Effectiveness:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate adequate cardiac output as evidenced by blood pressure, pulse rate, and rhythm within normal parameters for client; strong peripheral pulses; maintained level of mentation; lack of chest discomfort, dyspnea, or edema; maintain adequate urinary output; maintain an ability to tolerate activity without symptoms of dyspnea, syncope, or chest pain
- Remain free of side effects from the medications used to achieve adequate cardiac output
- Explain actions and precautions to prevent primary or secondary cardiac disease

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Cardiac Care; Cardiac Care: Acute

Example NIC Activities—Cardiac Care

Evaluate chest pain (e.g., intensity, location, radiation, duration, precipitating and alleviating factors); Document cardiac dysrhythmias

Nursing Interventions and *Rationales*

- Recognize characteristics of decreased cardiac output including, but not limited to, fatigue, dyspnea, edema, orthopnea, paroxysmal nocturnal dyspnea, chest pain, decreased exercise capacity, weight gain, hepatomegaly, jugular venous distention, palpitations, lung rhonchi, cough, clammy skin, skin color changes, dysuria, altered mental status, anemia, and hemodynamic changes.
- Monitor and report presence and degree of symptoms including dyspnea at rest, reduced exercise capacity, difficulty with activities of daily living, orthopnea, paroxysmal nocturnal dyspnea, cough, palpitations, chest pain, distended abdomen, early satiety, fatigue, presyncope/syncope, or weakness. Monitor

and report signs including jugular vein distention, peripheral edema, firm or distended abdomen, prominent S2, S3 gallop, rales, positive hepatojugular reflux, ascites, laterally displaced or pronounced point of maximal impact, holosystolic murmur, narrow pulse pressure, cool extremities, tachycardia with pulsus alternans, pulsus paradoxus, and irregular heartbeat. CEB/EB: *These are symptoms and signs consistent with heart failure (HF) and decreased cardiac output (Yancy et al, 2013; Konstam et al, 2018).*

- Monitor orthostatic blood pressures, oxygenation, hemodynamic values, urine output, and daily weights. CEB/EB: *These interventions assess for fluid volume status. Peripheral edema or the lack of peripheral edema is not always indicative of hypervolemia or decreased cardiac output (Yancy et al, 2013; Konstam et al, 2018).*
- Recognize that decreased cardiac output can occur in a number of noncardiac disorders such as septic shock, electrolyte imbalances, and hypovolemia. Expect variation in orders for differential diagnoses related to decreased cardiac output, because orders will be distinct to address the primary cause of the altered cardiac output.
- Obtain a thorough client-specific and familial history. CEB/EB: *It is important to assess for cardiac and noncardiac disorders and/or behaviors that might accelerate the progression of HF symptoms, such as high-sodium diet, excess fluid intake, substance abuse, missed medication doses, hypertension, diabetes mellitus, metabolic syndrome, obesity, hyperlipidemia, hormonal abnormalities, genetic disorders, coronary artery disease, sleep disordered breathing, congenital heart disease, cancer, immune disorders, and pregnancy (Yancy et al, 2013, 2017; Bozkurt et al, 2016).*

▲ Monitor pulse oximetry and administer oxygen as needed per health care provider's order. Supplemental oxygen increases oxygen availability to the myocardium and can relieve symptoms of hypoxemia. Resting hypoxia or oxygen desaturation may indicate fluid overload or concurrent pulmonary disease.

- Place client in semi-Fowler's or high Fowler's position with legs down or in a position of comfort. Elevating the head of the bed and legs in the down position may decrease the work of breathing and may decrease venous return and preload.
- During acute events, ensure client remains on short-term bed rest or maintains activity level that does not compromise cardiac output.
- Provide a restful environment by minimizing controllable stressors and unnecessary disturbances. Reducing stressors decreases cardiac workload and oxygen demand.

▲ Apply graduated compression stockings or intermittent pneumatic compression (IPC) leg sleeves as ordered. Ensure proper fit by measuring accurately. Remove stockings at least twice a day, and then reapply. Assess the condition of the extremities frequently. Graduated compression stockings may be contraindicated in clients with peripheral arterial disease. CEB: *A Cochrane review that assessed use of knee-length graduated compression stockings versus thigh-length graduated compression stockings found no difference in effectiveness. Type of stocking should be determined by client preference, cost, and ease of use (Sajid et al, 2012).* EB: *Graduated compression stockings, alone or used in conjunction with other prevention modalities, help promote venous return and reduce the risk of deep vein thrombosis in hospitalized clients who have undergone general or orthopedic surgery. Further research is needed in regard to* graduated compression stockings *in medical clients not undergoing surgical procedures (Sachdeva et al, 2018).*

▲ Check blood pressure, pulse, and condition before administering cardiac medications (e.g., angiotensin-converting enzyme inhibitors, angiotensin receptor blockers, angiotensin receptor-neprilysin inhibitors, calcium channel blockers, diuretics, digoxin, and beta-blockers). Notify health care provider if heart rate or blood pressure is low before holding medications. It is important that the nurse evaluate how well the client is tolerating current medications before administering cardiac medications; do not hold medications without health care provider input. The health care provider may decide to have medications administered even though the blood pressure or pulse rate has lowered. EB: *Clients with preserved ejection heart failure (HFpEF) or reduced ejection fraction heart failure (HFrEF) and persistent hypertension, and those with HF and increased cardiovascular risk (age >75 years old, established vascular disease, chronic renal disease, or Framingham risk score >15%), should receive guideline-directed medical therapy (GDMT) to maintain a systolic blood pressure less than 130 mm Hg (Yancy et al, 2017).*

- Observe for and report chest pain or discomfort; note location, radiation, severity, quality, duration, and associated manifestations such as nausea, indigestion, or diaphoresis; also note precipitating and relieving factors. Chest pain/discomfort may indicate an inadequate blood supply to the heart, which can further compromise cardiac output. CEB: *Clients with decreased cardiac output may present with myocardial ischemia. Those with myocardial ischemia may present with decreased cardiac output and HF (Yancy et al, 2013; Amsterdam et al, 2014).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ If chest pain is present, refer to the interventions in Risk for Decreased **Cardiac** Tissue Perfusion care plan.

● Recognize the effect of sleep disordered breathing in HF and that sleep disorders are common in clients with HF (Yancy et al, 2013, 2017). EB: *Central sleep apnea is recognized as an independent risk factor for worsening HF and reduced survival in clients with HF. The pathological effects of sleep apnea that contribute to worsening cardiac function include sympathetic nervous system stimulation, systemic inflammation, oxidative stress, and endothelial dysfunction (Costanzo et al, 2015).* EB: *For obstructive sleep apnea, continuous positive airway pressure (CPAP) can reduce apneic events, improve nocturnal oxygenation, and improve sleep quality (Yancy et al, 2017).*

● Administer CPAP or supplemental oxygen at night as ordered for management of suspected or diagnosed sleep disordered breathing. EB: *Both CPAP and nocturnal oxygen supplementation have been shown to reduce episodes of sleep apnea, reduce sympathetic nervous system stimulation, reduce occurrence of atrial arrhythmias, and improve cardiac function (Costanzo et al, 2015; Yancy et al, 2017).*

▲ Closely monitor fluid intake, including intravenous lines. Maintain fluid restriction if ordered. Clients with decreased cardiac output, poorly functioning ventricles, and ventricular dysfunction may not tolerate increased fluid volumes. CEB: *Fluid restriction along with sodium restriction can enhance volume management with diuretics, and in some clients can improve outcomes (Yancy et al, 2013).*

● Monitor intake and output (I&O). If client is acutely ill, measure hourly urine output and note decreases in output. Decreased cardiac output results in decreased perfusion of the kidneys, with a resulting decrease in urine output. CEB: *Clinical practice guidelines cite that monitoring I&O is useful for monitoring effects of HF treatment, including diuretic therapy (Yancy et al, 2013).*

▲ Note results of initial diagnostic studies, including electrocardiography, echocardiography, and chest radiography. CEB: *Clinical practice guidelines suggest that chest radiography, echocardiography, and electrocardiogram are recommended in the initial assessment of HF (Yancy et al, 2013).*

▲ Note results of further diagnostic imaging studies such as radionuclide imaging, stress echocardiography, cardiac catheterization, computed tomography (CT), or magnetic resonance imaging (MRI). CEB: *Clinical practice guidelines state that radionuclide and MRI are useful studies when assessing left ventricular ejection fraction and volume if echocardiography is not sufficient (Yancy et al, 2013).*

▲ Review laboratory data as needed, including arterial blood gases, complete blood count, serum electrolytes (sodium, potassium, magnesium, and calcium), blood urea nitrogen, creatinine, iron studies, urinalysis, glucose, fasting lipid profile, liver function tests, thyroid-stimulating hormone, B-type natriuretic peptide assay (BNP), or N-terminal pro-B-type natriuretic peptide (NTpro-BNP). Routine blood work can provide insight into the etiology of HF and extent of decompensation. EB: *Clinical practice guidelines recommend that BNP or NTpro-BNP assay should be measured in clients to determine prognosis or disease severity in chronic or acute decompensated HF, guide treatment during hospitalization, and establish a baseline at time of hospital discharge. BNP can also be evaluated in at-risk clients for prevention in the outpatient setting (Chow et al, 2017; Yancy et al, 2017).* EB: *Iron-deficiency anemia is related to decreased exercise capacity, and anemia is a strong indication of HF severity (Yancy et al, 2017).*

● Gradually increase activity when the client's condition is stabilized by encouraging slower-paced activities, or shorter periods of activity, with frequent rest periods after exercise prescription; observe for symptoms of intolerance. Take blood pressure and pulse before and after activity and note changes. Activity of the cardiac client should be closely monitored. See care plan Decreased **Activity** Tolerance.

▲ Encourage a diet that promotes cardiovascular health and reduces risk of hypertension, atherosclerotic disease, renal impairment, insulin resistance, and hypervolemia, within the context of an individual's cultural preferences (Van Horn et al, 2016; Whelton et al, 2018; Arnett et al, 2019). EB: *Reduced sodium intake, weight loss, healthy diet (low sugar, legumes, whole grains, fruits and vegetables, low total fat, fish), and avoidance of excess caloric intake is recommended for individuals with elevated blood pressure and prevention of cardiovascular disease (Van Horn et al, 2016; Whelton et al, 2018).* EB: *Replacing saturated fats with polyunsaturated or monounsaturated fats, and reducing intake of processed meats, refined carbohydrates, and sweetened beverages, will help to decrease atherosclerotic cardiovascular disease (ASCVD) risk (Sacks et al, 2017; Arnett et al, 2019).*

▲ Monitor bowel function. Provide stool softeners as ordered. Caution client not to strain when defecating, as this may cause vasovagal syncope. Decreased activity, pain medication, and diuretics can cause constipation.

- ● Weigh the client at the same time daily (after voiding). Daily weight is a good indicator of fluid balance. Use the same scale if possible when weighing clients for consistency. Increased weight and severity of symptoms can signal decreased cardiac function with retention of fluids. CEB: *Clinical practice guidelines state that weighing at the same time daily is useful to assess effects of diuretic therapy (Yancy et al, 2013).*
- ▲ Provide influenza and pneumococcal vaccines as needed before client discharge for those who have yet to receive those inoculations (Centers for Disease Control and Prevention, 2020).
- ● Evaluate a client's social determinants of health (SDOH), including race, gender identity, socioeconomic position, insurance coverage, living condition, food security, access to transportation, social support, and health literacy, among other factors. EB: *The "downstream" effects of SDOH can negatively affect clients by reducing access to care and contributing to poor HF outcomes. By assessing a client's SDOH you can reduce health care disparities (White-Williams et al, 2020).*
- ● Assess for presence of depression and/or anxiety and refer for treatment if present. See Nursing Interventions and Rationales for Anxiety to facilitate reduction of anxiety in clients and family. CEB: *Depression is common in clients with HF, and it has been found that individuals with depressive symptoms have poorer quality of life, use health care services more frequently, have poorer self-care, and have worse clinical outcomes (Yancy et al, 2013).*
- ▲ Refer to a cardiac rehabilitation program for education and monitored exercise. EB/CEB: Exercise training or regular physical activity is recommended for HF clients. Cardiac rehabilitation can improve quality of life and functional capacity (*Yancy et al, 2013*; *Anderson et al, 2016*). EB: A systematic review of outcomes of exercise-based interventions in clients with HF found that cardiac rehabilitation likely reduces hospital admissions and can improve quality of life, but does not appear to have an effect on mortality (*Long et al, 2019*).
- ▲ Refer to an HF program for education, evaluation, and guided support to increase activity and rebuild quality of life. Support for the HF client should be client centered, culturally sensitive, and include family and social support. CEB: Multiprofessional systems of care that are designed to support clients with HF can improve outcomes (*Yancy et al, 2013*).

Critically Ill

- ▲ Observe for symptoms of cardiogenic shock, including impaired mentation, hypotension, decreased peripheral pulses, cold clammy skin, signs of pulmonary congestion, and decreased organ function. If present, notify the health care provider immediately. Cardiogenic shock is a state of circulatory failure from loss of cardiac function associated with inadequate organ perfusion and a high mortality rate. CEB: *Critical cardiogenic shock presents with severe hypotension, increasing inotropic and vasopressor support, organ hypoperfusion, and worsening acidosis and lactate levels (Yancy et al, 2013).*
- ▲ If shock is present, monitor hemodynamic parameters for an increase in pulmonary wedge pressure, an increase in systemic vascular resistance, or a decrease in stroke volume, cardiac output, and cardiac index. CEB: *Hemodynamic monitoring with a pulmonary artery catheter can be beneficial in clients with respiratory distress, impaired systemic perfusion, and dependence on intravenous inotropic support, and when clinical assessment is inadequate or severe symptoms persist despite recommended therapies (Yancy et al, 2013).*
- ▲ Titrate inotropic and vasoactive medications within defined parameters to maintain contractility, preload, and afterload per health care provider's order. By following parameters, the nurse ensures maintenance of a delicate balance of medications that stimulate the heart to increase contractility while maintaining adequate perfusion of the body. CEB: *Clinical practice guidelines recommend that intravenous inotropic drugs might be reasonable for HF clients presenting with low blood pressure and low cardiac output to maintain systemic perfusion and preserve end-organ performance (Yancy et al, 2013).*
- ▲ Identify significant fluid overload and initiate intravenous diuretics as ordered. Monitor I&O, daily weight, and vital signs, as well as signs and symptoms of congestion. Watch laboratory data, including cardiac biomarkers, serum electrolytes, creatinine, and urea nitrogen. CEB: *Intravenous loop diuretics should be initiated in the HF client who presents with significant fluid overload as either intermittent boluses or continuous infusion to reduce morbidity (Yancy et al, 2013).* EB: *Monitor for acute kidney injury and cardiorenal syndrome, as well as diuretic resistance (Rangaswami et al, 2019).*
- ▲ When using pulmonary arterial catheter technology, be sure to appropriately level and zero the equipment, use minimal tubing, maintain system patency, perform square wave testing, position the client appropriately, and consider correlation to respiratory and cardiac cycles when assessing waveforms and integrating data into client assessment. CEB: *Clinical practice guidelines recommend that invasive hemodynamic monitoring can be useful in acute HF with persistent symptoms when therapy is refractory, fluid status*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

is unclear, systolic pressures are low, renal function is worsening, vasoactive agents are required, or when considering advanced device therapy or transplantation (Yancy et al, 2013).

▲ Observe for worsening signs and symptoms of respiratory compromise. Recognize that invasive or noninvasive ventilation may be required for clients with acute cardiogenic pulmonary edema. EB/CEB: *Clinical practice guidelines for HF state that CPAP improves daily functional capacity and quality of life for those with HF and obstructive sleep apnea and is reasonable for clients with refractory HF not responding to other medical therapies (Yancy et al, 2013; Costanzo et al, 2015).* EB: *Noninvasive positive pressure ventilation (NPPV), including CPAP and bilevel NPPV, can reduce hospital mortality, intensive care unit (ICU) length of stay, and intubation rate, and result in faster client improvement (Berbenetz et al, 2019).*

▲ Monitor client for signs and symptoms of fluid and electrolyte imbalance when clients are receiving ultrafiltration or continuous renal replacement therapy (CRRT). Clients with refractory HF may have ultrafiltration or CRRT ordered as a mechanical method to remove excess fluid volume. CEB: *Clinical practice guidelines cite that ultrafiltration is reasonable for clients with obvious volume overload and congestion, and refractory congestion not responsive to medical therapy (Yancy et al, 2013).*

● Recognize that hypoperfusion from low cardiac output can lead to altered mental status and decreased cognition. CEB: *A study that assessed an association among cardiac index and neuropsychological ischemia found that decreased cardiac function, even with normal cardiac index, was associated with accelerated brain aging (Jefferson et al, 2010).*

● Recognize that clients with severe HF may undergo additional therapies, such as internal pacemaker or defibrillator placement, and/or placement of a ventricular assist device (VAD). CEB: *The use of VADs is a reasonable treatment as a bridge to recovery, transplant, or decision-making in selected HF clients with reduced ejection fraction and profound hemodynamic compromise (Yancy et al, 2013).*

Geriatric

● Recognize that older clients may demonstrate fatigue and depression as signs of HF and decreased cardiac output.

● Recognize that older adults in the critical care setting often have geriatric syndromes such as polypharmacy, multimorbidity, cognitive decline, and frailty that can be exacerbated in the critical care setting and contribute to prolonged hospitalization, increased mortality, increased HF, increased disability, and decreased quality of life (Damluji et al, 2019).

▲ If the client has heart disease–causing activity intolerance, refer for cardiac rehabilitation. EB: *Cardiac rehabilitation can positively affect an individual's quality of life and reduce hospitalizations regardless of age (Anderson et al, 2016; Long et al, 2019).*

▲ Recognize that edema can present differently in the older population. CEB: *In the older population, lower extremity edema is often related to peripheral causes, such as dependency, rather than cardiac causes (Yancy et al, 2013).*

▲ Recognize that blood pressure control is beneficial for older clients to reduce the risk of worsening HF. CEB: *Hypertension treatment is particularly beneficial in the older population, and control of both systolic and diastolic hypertension has been shown to reduce the risk of HF (Yancy et al, 2013).* CEB: *Clients with stage A HF and hypertension, with increased cardiovascular risk (age >75 years old, established vascular disease, chronic renal disease, or Framingham risk score >15%), should have a target systolic blood pressure less than 130 mm Hg (Yancy et al, 2017).* EB: *Older clients are at higher risk for resistant hypertension and may require multiple antihypertensive medications for blood pressure control (Carey et al, 2018).*

▲ Recognize that renal function is not always accurately represented by serum creatinine in the older population because of less muscle mass (Yancy et al, 2013).

▲ Observe for side effects from cardiac medications. Older adults can have difficulty with metabolism and excretion of medications because of decreased function of the liver and kidneys; therefore, toxic side effects are more common. EB: *Older adults are at increased risk for digoxin toxicity, especially at larger doses, because of lower body mass and impaired renal function (Yancy et al, 2013).*

▲ Older adults may require more frequent visits, closer monitoring of medication dose changes, and more gradual increases in medications *because of changes in the metabolism of medications and impaired renal function (Yancy et al, 2013).*

▲ Recognize that older adults still benefit from smoking cessation *to reduce risk of worsening cardiovascular disease (Arnett et al, 2019).*

▲ As older adults approach end of life, clinicians should help to facilitate a comprehensive plan of care that incorporates the client and family's values, goals, and preferences (Allen et al, 2012; National Consensus

Project for Quality Palliative Care, 2018). EB: *For older adults (>65 years old) with multiple comorbidities and limited life expectancy, it is reasonable to use a team-based approach to weigh the risks and benefits of tight blood pressure control and choice of antihypertensive medication (Whelton et al, 2018).*

Home Care

- Some of the previously mentioned interventions may be adapted for home care use. Home care agencies may use specialized staff and methods to care for chronic HF clients. CEB: *A study assessing HF outcomes over a 10-year period between a multiprofessional home care intervention and usual care found significantly improved survival and prolonged event-free survival and was both cost and time effective (Ingles et al, 2006).*
- Assess for fatigue and weakness frequently. Assess home environment for safety, as well as resources/obstacles to energy conservation.
- Help family adapt daily living patterns to establish life changes that will maintain improved cardiac functioning in the client. Take the client's perspective into consideration and use a holistic approach in assessing and responding to client planning for the future.
- Assist client to recognize and exercise power in using self-care management to adjust to health change. Refer to care plan for **Powerlessness.**

▲ Refer to medical social services, cardiac rehabilitation, telemonitoring, and case management as necessary for assistance with home care, access to resources, and counseling about the impact of severe or chronic cardiac diseases. EB/CEB: *Access to systems that promote care coordination is essential for successful care of the HF client. Good communication and documentation between services, health care providers, and transitions of care is essential to ensure improved outcomes in HF clients (Yancy et al, 2013; Albert et al, 2015).*

▲ As the client chooses, refer to palliative care, which can begin earlier in the care of the HF client. Palliative care can be used to increase comfort and quality of life in the HF client before end-of-life care. EB/CEB: *Palliative care should address quality of life, ongoing symptom control, preferences about end of life, psychosocial distress, and caregiver support (Yancy et al, 2013; National Consensus Project for Quality Palliative Care, 2018).*

▲ If the client's condition warrants, refer to hospice. CEB: *The palliative care and HF teams are best suited to determine when end-of-life care is appropriate for the client and family (Yancy et al, 2013).*

Client/Family Teaching and Discharge Planning

- Begin discharge planning as soon as possible on admission to the emergency department (ED) if appropriate with a case manager or social worker to assess home support systems and the need for community or home health services. EB: *Discharge planning should include adherence to the treatment plan, medication management, follow-up with health care providers and care coordination, dietary and physical activities, cardiac rehabilitation, and secondary prevention recommendations (Yancy et al, 2013; Albert et al, 2015).*
- Discharge education should be comprehensive, evidence based, culturally sensitive, and include both the client and family (Yancy et al, 2013).
- Teach the client about any medications prescribed. Medication teaching includes the drug name; its purpose; administration instructions, such as taking it with or without food; and any side effects. Instruct the client to report any adverse side effects to his or her health care provider.
- Teach the importance of performing and recording daily weights on arising for the day, and to report weight gain. Ask if client has a scale at home; if not, assist in getting one. EB: *Clinical practice guidelines suggest that daily weight monitoring leads to early recognition of excess fluid retention, which, when reported, can be offset with additional medication to avoid hospitalization from HF decompensation (Yancy et al, 2013).*
- Teach the types and progression patterns of worsening HF symptoms, when to call a health care provider for help, and when to go to the hospital for urgent care (Yancy et al, 2013).
- Stress the importance of ceasing tobacco use (Whelton et al, 2018). CEB/EB: *Effects of nicotine include increasing pulse and blood pressure and constricting blood vessels. Tobacco use is a primary factor in heart disease (Amsterdam et al, 2014; Whelton et al, 2018).* EB: *To facilitate cessation, a combination of behavioral and pharmacotherapy is recommended to improve cessation rates (Arnett et al, 2019).*

▲ Individuals should be screened for electronic cigarette use (e-cigarette). CEB: *Although more studies are needed regarding the health effects of e-cigarette use, the American Heart Association recommends that all health care providers educate their clients regarding the long-term use of e-cigarettes given the known toxicities present in e-cigarettes, as well as the presence of nicotine in most types of e-cigarettes (Bhatnagar et al, 2014).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- On hospital discharge, educate clients about low-sodium, low–saturated fat diet, with consideration of client education, literacy, and health literacy level.
- Educate clients that comorbidities, including obesity, hypertension, metabolic syndrome, diabetes mellitus, and hyperlipidemia, are common in individuals with HF and can affect clinical outcomes related to HF if not controlled (Bozkurt et al, 2016). EB: *One of the most important factors in preventing HF is to promote a healthy lifestyle (Arnett et al, 2019).*
- For clients with diabetes mellitus, educate about the importance of glycemic control. EB: *Individuals with diabetes mellitus are at increased risk for HF and should be managed according to recommended guidelines. Thiazolidinediones should be avoided in individuals with class III or IV HF because of increased fluid retention (Bozkurt et al, 2016).* EB: *To reduce the risk of worsening HF outcomes, educate clients with type 2 diabetes mellitus about the importance of improving dietary habits and regular exercise. Clients should also be initiated on metformin, a sodium-glucose cotransporter 2 inhibitor (SGLT2i), or a glucagon-like peptide-1 receptor agonist (GLP-1) to improve glycemic control and reduce risk for worsening cardiovascular disease or cardiorenal syndrome (Arnett et al, 2019; Rangaswami et al, 2019).*
- Instruct client and family on the importance of regular follow-up care with health care providers. EB: *Post-discharge support can significantly reduce hospital readmissions and improve health care outcomes, quality of life, and costs (Yancy et al, 2013).*

▲ Teach stress reduction (e.g., meditation, imagery, controlled breathing, muscle relaxation techniques). EB: *Meditation is a reasonable adjunct to GDMT for reduction of cardiovascular risk and lifestyle modification (Levine et al, 2017).*

- Discuss advance directives with the HF client, including resuscitation preferences. EB/CEB: *Evidence suggests that advance directives can help to reduce overall health care costs, reduce in-hospital deaths, and increase hospice use (Yancy et al, 2013; National Consensus Project for Quality Palliative Care, 2018).*
- Clients should be provided with education regarding the influenza vaccine and pneumococcal vaccine before discharge. EB: *The influenza vaccine is recommended for all adults, and the pneumococcal vaccine is recommended for individuals more than 65 years old and for individuals who are at high risk for cardiovascular disease (Centers for Disease Control and Prevention, 2020).*
- Teach the importance of physical activity as tolerated. EB: *Exercise helps control blood pressure and weight, which are the most important controlled risk factors for cardiovascular disease. Individuals should engage in aerobic physical activity of varying intensity as tolerated and incorporate variable anaerobic activities such as resistance training (Bozkurt et al, 2016; Arnett et al, 2019).* EB: *Exercise is beneficial in the prevention of cardiovascular disease and HF. Ideally, clients should engage in 150 minutes per week of moderate-intensity aerobic exercise if able. At minimum, any aerobic moderate-intensity exercise is ideal (Bozkurt et al, 2016; Arnett et al, 2019).* EB: *Clients with arrhythmias or advanced HF may require supervision or monitoring during exercise (Bozkurt et al, 2016).*

Risk for Decreased Cardiac Output

Domain 4 Activity/rest Class 4 Cardiovascular/pulmonary responses

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to inadequate blood pumped by the heart to meet metabolic demands of the body, which may compromise health.

Risk Factors

To be developed

Associated Conditions

Altered afterload; altered contractility; altered heart rate; altered heart rhythm; altered preload; altered stroke volume

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Decreased **Cardiac** Output.

● = Independent; ▲ = Collaborative; EBN = Evidence-Based Nursing; EB = Evidence-Based; ✱ = QSEN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Risk for Decreased Cardiac Tissue Perfusion

Domain 4 Activity/rest Class 4
Cardiovascular/pulmonary responses

Ann Will Poteet, MS, RN, CNS, AGNP-C

C

NANDA-I

Definition

Susceptible to a decrease in cardiac (coronary) circulation, which may compromise health.

Risk Factors

Inadequate knowledge of modifiable factors; substance misuse

At-Risk Population

Individuals with a family history of cardiovascular disease

Associated Conditions

Cardiac tamponade; cardiovascular surgery; coronary artery spasm; diabetes mellitus; elevated C-reactive protein; hyperlipidemia; hypertension; hypovolemia; hypoxemia; hypoxia; pharmaceutical preparations

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Cardiac Pump Effectiveness; Circulation Status; Tissue Perfusion: Cardiac; Tissue Perfusion: Cellular; Vital Signs

Example NOC Outcome with Indicators

Tissue Perfusion: Cardiac as evidenced by the following indicators: Angina/Arrhythmia/Tachycardia/Bradycardia/Nausea/Vomiting/Profuse diaphoresis. (Rate the outcome and indicators of **Tissue Perfusion: Cardiac:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain vital signs within normal range
- Retain an asymptomatic cardiac rhythm (have absence of arrhythmias, tachycardia, or bradycardia)
- Be free from chest and radiated discomfort as well as associated symptoms related to acute coronary syndromes (ACSs)
- Deny nausea and be free of vomiting or gastrointestinal distress
- Have skin that is dry and of normal temperature
- Maintain normal cognition
- Maintain healthy lifestyle behaviors that promote primary prevention of cardiovascular disease

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Cardiac Care; Cardiac Precautions; Embolus Precautions; Dysrhythmia Management; Vital Signs Monitoring; Shock Management: Cardiac

Example NIC Activity—Cardiac Precautions

Avoid causing intense emotional situations; Avoid overheating or chilling the client; Provide small frequent meals; Substitute artificial salt and limit sodium intake if appropriate; Promote effective techniques for reducing stress; Restrict smoking

C

Nursing Interventions and *Rationales*

- Be aware that the primary cause of ACS which include unstable angina (UA), non–ST-elevation myocardial infarction (NSTEMI), and ST-elevation myocardial infarction (STEMI), is an imbalance between myocardial oxygen consumption and demand that is associated with partially or fully occlusive thrombus development in coronary arteries (Amsterdam et al, 2014).
- Assess for symptoms of coronary hypoperfusion and possible ACS, including chest discomfort (pressure, tightness, crushing, squeezing, dullness, or achiness), with or without radiation (or originating) in the retrosternal area, back, neck, jaw, shoulder, or arm discomfort or numbness; shortness of breath (SOB); associated diaphoresis; abdominal pain; dizziness, lightheadedness, loss of consciousness, or unexplained fatigue; nausea or vomiting with chest discomfort, heartburn, or indigestion; and associated anxiety. EB/CEB: *These symptoms are signs of decreased cardiac perfusion and ACSs, such as UA, NSTEMI, or STEMI, as well as other cardiovascular disorders such as aortic aneurysm, valve disorders, myocarditis, spontaneous coronary artery dissection (SCAD), heart failure, and pericarditis. A physical assessment will aid in the assessment of the extent, location, and presence of, and complications resulting from, a myocardial infarction (MI). It will promote rapid triage and treatment. It is also important to assess whether the client had a prior stroke, heart failure, or other cardiovascular disorder. It is important to note that certain psychiatric disorders (somatoform disorders, panic attack, and anxiety disorders) can mimic ACS, but they are typically noncardiac causes of chest pain (Amsterdam et al, 2014; Mehta et al, 2016).*
- Evaluate client for noncardiac causes of chest pain, other than psychiatric disorders, including gastrointestinal disorders (reflux disease, esophagitis), pleuritic pain (secondary to pulmonary embolus, infection), costochondritis, and musculoskeletal disorders.
- Consider atypical presentations of ACS for women, older adults, and individuals with diabetes mellitus, impaired renal function, and dementia. EB/CEB: *Women, older adults, and individuals with diabetes mellitus, impaired renal function, and dementia may present with atypical findings (Amsterdam et al, 2014; Mieres et al, 2014; McSweeney et al, 2016; Mehta et al, 2016). Research continues to confirm that that women had significantly less chest discomfort and were more likely to present with fatigue, neck pain, syncope, nausea, right arm pain, abdominal and back pain, dizziness, and jaw pain (Lau et al, 2016). Delaying identification of atypical presentations can have negative effects on timely intervention and management of ACS, resulting in poorer outcomes and higher mortality (Mehta et al, 2016).*
- Evaluate the client for socioeconomic or race/ethnicity factors that put them at higher risk for atherosclerotic cardiovascular disease (ASCVD). EB: *Understanding a client's socioeconomic factors leads to shared decision-making between the client and clinician, thereby guiding treatment decisions that meet the client's needs. Socioeconomic factors are strong determinants of CVD risk, and failure to identify these factors may lead to poor treatment adherence or decrease the efficacy of known prevention recommendations (Arnett et al, 2019).*
- Review the client's medical, surgical, social, and familial history. CEB: *A medical history must be concise and detailed to determine the possibility of ACS and to help determine the possible cause of cardiac symptoms and pathology (Amsterdam et al, 2014).*
- Perform physical assessments for both coronary artery disease (CAD) and noncoronary findings related to decreased coronary perfusion, including vital signs, pulse oximetry, equal blood pressure in both arms, heart rate, respiratory rate, and pulse oximetry. Check bilateral pulses for quality and regularity. Report tachycardia, bradycardia, hypotension or hypertension, pulsus alternans or pulsus paradoxus, tachypnea, or abnormal pulse oximetry reading. Assess cardiac rhythm for arrhythmias; skin and mucous membrane color, temperature, and dryness; and capillary refill. Assess for peripheral vascular disease. Assess neck veins for elevated central venous pressure, cyanosis, and pericardial or pleural friction rub. Examine client for cardiac S4 gallop, new heart murmur, lung crackles, altered mentation, pain on abdominal palpation, abdominal distention, decreased bowel sounds, or decreased urinary output. CEB: *These indicators help assess for cardiac and noncardiac etiologies of symptoms and differential diagnoses (Amsterdam et al, 2014).*
- ▲ Administer supplemental oxygen as ordered and needed for clients presenting with ACS, respiratory distress, or other high-risk features of hypoxemia to maintain a Po_2 of at least 90%. EB: *American Heart Association guidelines for emergency cardiovascular care during ACS recommend administering oxygen for breathlessness, hypoxemia, signs of heart failure, or if signs of shock are present, and the need for oxygen should be guided by noninvasive monitoring of oxygen saturation. There is limited evidence to support or refute the use of high-flow or low-flow supplemental oxygen if a normal oxygen level (>90%) is present, but it is reasonable to withhold supplemental oxygen in normoxic individuals (O'Connor et al, 2015).* EB: *A Cochrane review found there was limited evidence to support or refute the use of routine supplemental oxygen with acute MI, and that harm from excess supplemental oxygen cannot be ruled out, recommending further studies (Cabello et al, 2016).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ Use continuous pulse oximetry as ordered. CEB: *Prevention and treatment of hypoxemia include maintaining arterial oxygen saturation over 90% (Amsterdam et al, 2014).*

▲ Insert one or more large-bore intravenous catheters to keep the vein open. Routinely assess saline locks for patency. Clients who come to the hospital with possible decrease in coronary perfusion or ACS may have intravenous fluids and medications ordered routinely or emergently to maintain or restore adequate cardiac function and rhythm.

▲ Observe the cardiac monitor for hemodynamically significant arrhythmias, ST depressions or elevations, T-wave inversions, and/or Q-waves as signs of ischemia or injury. Be aware that clients with prior cardiothoracic surgery may have abnormal electrocardiogram (ECG) changes at baseline. Report abnormal findings. CEB: *Arrhythmias and ECG changes indicate myocardial ischemia, injury, and/or infarction. Note that left ventricular hypertrophy, ventricular pacing, and bundle branch blocks can mask signs of ischemia or injury (Amsterdam et al, 2014).*

● Have emergency equipment and defibrillation capability nearby and be prepared to defibrillate immediately if ventricular tachycardia with clinical deterioration or ventricular fibrillation occurs.

▲ Perform a 12-lead ECG as ordered to be interpreted within 10 minutes of emergency department arrival and during episodes of chest discomfort or angina equivalent. CEB: *A 12-lead ECG should be performed within 10 minutes of emergency department arrival for all clients who are having chest discomfort. ECGs are used to identify the area of ischemia or injury, such as ST depressions or elevations, new left-bundle branch block, T-wave inversions, and/or Q-waves, and to guide treatment (O'Gara et al, 2013; Amsterdam et al, 2014).*

▲ Administer non–enteric-coated aspirin as ordered, as soon as possible after presentation and for maintenance. CEB: *Aspirin has been shown to prevent platelet clumping, aggregation, and activation that leads to thrombus formation, which in coronary arteries leads to ACSs. Contraindications include active peptic ulcer disease, bleeding disorders, and aspirin allergy (O'Gara et al, 2013; Amsterdam et al, 2014).*

▲ Administer nitroglycerin tablets sublingually as ordered, every 5 minutes until the chest pain is resolved while monitoring the blood pressure for hypotension, for a maximum of three doses as ordered. Administer nitroglycerin paste or intravenous preparations as ordered. CEB: *Nitroglycerin causes coronary arterial and venous dilation, and at higher doses peripheral arterial dilation, reducing preload and afterload and decreasing myocardial oxygen demand while increasing oxygen delivery (Amsterdam et al, 2014).*

● Do not administer nitroglycerin preparations to individuals with hypotension, or individuals who have received phosphodiesterase type 5 inhibitors, such as sildenafil, tadalafil, or vardenafil, in the last 24 hours (48 hours for long-acting preparations). CEB: *Synergistic effect causes marked exaggerated and prolonged vasodilation/hypotension (Amsterdam et al, 2014).*

▲ Administer morphine intravenously as ordered, every 5 to 30 minutes until pain is relieved while monitoring blood pressure when nitroglycerin alone does not relieve chest discomfort. EB: *Morphine has potent analgesic and antianxiolytic effects and causes mild reductions in blood pressure and heart rate that reduce myocardial oxygen consumption. Hypotension and respiratory depression are the most serious complications of morphine use, and naloxone may be administered as ordered for morphine overdose (Amsterdam et al, 2014).*

▲ Assess and report abnormal laboratory work results of cardiac enzymes, specifically troponin I or high-sensitivity troponin T, B-type natriuretic peptide, chemistries, hematology, coagulation studies, arterial blood gases, finger stick blood sugar, elevated C-reactive protein, or drug screen. CEB: *Abnormalities can identify the cause of the decreased perfusion and identify complications related to the decreased perfusion such as anemia, hypovolemia, coagulopathy, drug abuse, hyperglycemia, kidney (renal) failure, and heart failure. Markedly elevated cardiac enzymes are usually indicative of an MI, and the cardiac enzymes can help determine short- and long-term prognosis (Amsterdam et al, 2014).*

● Assess for individual risk factors for CAD, such as hypertension, dyslipidemia, cigarette smoking, diabetes mellitus, metabolic syndrome, obesity, or family history of heart disease. Other risk factors including socioeconomic factors, sedentary lifestyle, obesity, or cocaine or amphetamine use. Note age and gender as risk factors. EB/CEB: *Certain conditions place clients at higher risk for decreased cardiac tissue perfusion (Amsterdam et al, 2014; Mieres et al, 2014; Mehta et al, 2016; Arnett et al, 2019).* EB: *Screening with ASCVD risk estimator evidence-based tools can help to inform treatment decisions. Frequency of screening for ASCVD risk should be based on age categories (Arnett et al, 2019).*

▲ Administer additional heart medications as ordered, including beta-blockers, calcium channel blockers, angiotensin-converting enzyme inhibitors, angiotensin II receptor blockers, aldosterone antagonists, antiarrhythmics, diuretics, antiplatelet agents, and anticoagulants. Always check blood pressure and pulse rate before administering these medications. If the blood pressure or pulse rate is low, contact the health care provider to establish whether the medication should be withheld. Also check platelet counts, renal

function, and coagulation studies as ordered to assess proper effects of these agents. CEB: *These medications are useful to optimize cardiac and kidney function, including blood pressure, heart rate, myocardial oxygen demand, intravascular fluid volume, and cardiac rhythm (Amsterdam et al, 2014).*

▲ Administer lipid-lowering therapy as ordered. EB/CEB: *Use of statin drugs and/or combination therapy with other nonstatin lipid-lowering agents (ezetimibe, bile acid sequestrants, and PCSK9 inhibitors) has been shown to reduce an individual's risk of recurrent MI, stroke, and coronary heart disease mortality, especially with high-intensity statins that lower low-density lipoprotein cholesterol levels (Amsterdam et al, 2014; Grundy et al, 2019).* EB: *The decision to start drug therapy should be based on 10-year ASCVD risk and lifetime risk estimation as well as comorbidities, including diabetes mellitus, and other risk-enhancing factors (Arnett et al, 2019; Grundy et al, 2019).*

▲ Prepare client with education, withholding of meals and/or medications, and intravenous access for early invasive therapy with cardiac catheterization, reperfusion therapy, and possible percutaneous coronary intervention in individuals with refractory angina or hemodynamic or electrical instability, and first medical contact to device time of less than 90 minutes if STEMI is suspected. CEB: *First medical contact to device time of less than 90 minutes was associated with improved client outcomes (O'Gara et al, 2013; Amsterdam et al, 2014).*

▲ Prepare clients with education, withholding of meals and/or medications, and intravenous access for noninvasive cardiac diagnostic procedures such as echocardiogram, exercise, or pharmacological stress test, and cardiac computed tomography scan as ordered. CEB: *Clients suspected of decreased coronary perfusion should receive these diagnostic procedures as appropriate to evaluate for CAD (Fletcher et al, 2013; Amsterdam et al, 2014; Mieres et al, 2014).*

▲ Request a referral to a cardiac rehabilitation program. CEB: *Cardiac rehabilitation programs are designed to limit the physiological and psychological effects of cardiac disease, reduce the risk for sudden cardiac death and reinfarction, control symptoms and stabilize or reverse the process of plaque formation, and enhance psychosocial and vocational status of clients (Amsterdam et al, 2014).* EB: *Cardiac rehabilitation can improve quality of life and functional capacity, and decrease cardiovascular mortality, hospitalizations, and associated health care costs (Anderson et al, 2016).*

Geriatric

● Consider atypical presentations of possible ACS in older adults. EB/CEB: *Older adults may present with atypical signs and symptoms such as weakness, stroke, syncope, or change in mental status (Amsterdam et al, 2014; McSweeney et al, 2016; Mehta et al, 2016).*

▲ Ask the prescriber about possible reduced dosage of medications for older clients, considering weight, creatinine clearance, and glomerular filtration rate. EB/CEB: *Older clients can have reduced pharmacokinetics and pharmacodynamics, including reduced muscle mass, reduced renal and hepatic function, and reduced volume of distribution, which can alter drug dosing, efficacy, and safety, as well as some drug–drug interactions (Amsterdam et al, 2014; Grundy et al, 2019).*

● Consider issues such as quality of life, palliative care, end-of-life care, and differences in sociocultural aspects for clients and families when supporting them in decisions regarding aggressiveness of care. Ask about living wills, as well as medical and durable power of attorney. EB/CEB: *Management decisions, including decisions regarding invasive treatment, should be client-centered and take into account client preferences and goals, cultural considerations, comorbidities, cognitive and functional status, and life expectancy (Amsterdam et al, 2014; McSweeney et al, 2016; Mehta et al, 2016; National Consensus Project for Quality Palliative Care, 2018; Grundy et al, 2019).*

Client/Family Teaching and Discharge Planning

▲ Client and family education regarding a multiprofessional plan of care should start early. Special attention to client and family education should occur during transitions of care. CEB: *It is important to provide the client and family with a comprehensive plan of care and education materials that are evidence based to assist with client compliance and to potentially reduce hospital readmissions related to ACS. The plan of care should take into consideration the client's psychosocial and socioeconomic status, access to care, risk for depression and/or social isolation, and health care disparities (Amsterdam et al, 2014).*

● Teach the client and family to call 911 for symptoms of new angina, existing angina unresponsive to rest and sublingual nitroglycerin tablets, or heart attack, or if an individual becomes unresponsive.

● On discharge, instruct clients about symptoms of ischemia, when to cease activity, when to use sublingual nitroglycerin, and when to call 911.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Teach client about any medications prescribed. Medication teaching includes the drug name, its purpose, administration instructions such as taking it with or without food, and any side effects. Instruct the client to report any adverse side effects to the health care provider.
- On hospital discharge, educate clients and significant others about discharge medications, including nitroglycerin sublingual tablets or spray, with written, easy to understand, culturally sensitive information. CEB: *Clients and significant others need to be prepared to act quickly and decisively to relieve ischemic discomfort (Amsterdam et al, 2014).*
- Provide client education related to risk factors for decreased cardiac tissue perfusion, such as hypertension, hyperlipidemia, metabolic syndrome, diabetes mellitus, tobacco use, obesity, advanced age, and female gender. EB/CEB: *Those with two or more risk factors should have a 10-year risk screening for development of symptomatic coronary heart disease. Client education is a vital part of nursing care for the client. Start with the client's base level of understanding and use that as a foundation for further education. It is important to factor in cultural and/or religious beliefs in the education provided (Amsterdam et al, 2014; Barnason et al, 2017; Arnett et al, 2019).*
- Instruct the client on antiplatelet and anticoagulation therapy, and about signs of bleeding, need for ongoing medication compliance, and international normalized ratio monitoring. CEB: *Special attention and education should be provided to older individuals because they are at greater risk for bleeding (Amsterdam et al, 2014).*
- After discharge, continue education and support for client blood pressure and diabetes control, weight management, and resumption of physical activity. EB/CEB: *Reducing risk factors acts as secondary prevention of CAD (Amsterdam et al, 2014; Arnett et al, 2019).* EB: *Participation in cardiac rehabilitation therapy reduces cardiovascular mortality (Anderson et al, 2016).*
- ▲ Clients should be provided with education regarding the influenza vaccine and pneumococcal vaccine before hospital discharge. EB/CEB: *The influenza vaccine is recommended for all adults, and the pneumococcal vaccine is recommended for individuals older than 65 years and for individuals who are at high risk for cardiovascular disease (Amsterdam et al, 2014; Centers for Disease Control and Prevention, 2020).*
- ▲ Stress the importance of ceasing tobacco use. EB/CEB: *Tobacco use can cause or worsen decreased blood flow in the coronaries, as well as cause vasoconstriction, which can lead to atherosclerotic disease. Effects of nicotine include increasing pulse and blood pressure and constricting blood vessels. Tobacco use is a primary factor in heart disease (Amsterdam et al, 2014; Whelton et al, 2018).* EB: *To facilitate cessation, a combination of behavioral and pharmacotherapy is recommended to improve cessation rates (Arnett et al, 2019).*
- ▲ Individuals should be screened for electronic cigarette (e-cigarette) use. CEB: *Although more studies are needed regarding the health effects of e-cigarette use, the American Heart Association recommends that all health care providers educate their clients regarding the long-term use of e-cigarettes given the known toxicities present in e-cigarettes, as well as the presence of nicotine in most types of e-cigarettes (Bhatnagar et al, 2014).*
- ▲ On hospital discharge, educate clients about a low-sodium, low–saturated fat diet, with consideration to client education, literacy, and health literacy level. CEB: *Reducing risk factors acts as secondary prevention of CAD (Amsterdam et al, 2014).*
- Teach the importance of exercise and physical activity as tolerated. EB/CEB: *Aerobic and resistance exercise help to control blood pressure, reduce weight, improve physical functioning, and improve glycemic control, all of which lower ASCVD risk. Individuals should engage in moderate or vigorous aerobic and/or anaerobic physical activity as tolerated to reduce ASCVD risk (Amsterdam et al, 2014; Bozkurt et al, 2016; Arnett et al, 2019).* EB: Clients with arrhythmias or advanced heart failure may require supervision or monitoring during exercise (*Bozkurt et al, 2016*).

Risk for Impaired Cardiovascular Function

Domain 4 Activity/rest Class 4 Cardiovascular/pulmonary responses

Mary Beth Flynn Makic, PhD, RN, CNS, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to disturbance in substance transport, body homeostasis, tissue metabolic residue removal, and organ function, which may compromise health.

Risk Factors

Anxiety; average daily physical activity is less than recommended for age and gender; body mass index above normal range for age and gender; excessive accumulation of fat for age and gender; excessive alcohol intake; excessive stress; inadequate dietary habits; inadequate knowledge of modifiable factors; inattentive to second-hand smoke; ineffective blood glucose level management; ineffective blood pressure management; ineffective lipid balance management; smoking; substance misuse

At-Risk Population

Economically disadvantaged individuals; individuals with family history of diabetes mellitus; individuals with family history of dyslipidemia; individuals with family history of hypertension; individuals with family history of metabolic syndrome; individuals with family history of obesity; individuals with history of cardiovascular event; men; older adults; postmenopausal women

Associated Conditions

Depression; diabetes mellitus; dyslipidemia; hypertension; insulin resistance; pharmaceutical preparations

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning and References

See the care plans for Decreased **Cardiac** Output; Risk for Decreased **Cardiac** Tissue Perfusion; Risk for **Metabolic Syndrome;** and Risk for **Thrombosis**

Caregiver Role Strain Domain 7 Role relationship Class 1 Caregiving roles

Olga F. Jarrín, PhD, RN and Mary Velahos, BSN

NANDA-I

Definition

Difficulty in fulfilling care responsibilities, expectations and/or behaviors for family or significant others.

Defining Characteristics

Caregiving Activities

Apprehensive about future ability to provide care; apprehensive about future health of care receiver; apprehensive about potential institutionalization of care receiver; apprehensive about well-being of care receiver if unable to provide care; difficulty completing required tasks; difficulty performing required tasks; dysfunctional change in caregiving activities; preoccupation with care routine

Caregiver Health Status

Physiological: Fatigue; gastrointestinal distress; headache; hypertension; rash; reports altered sleep-wake cycle; weight change
Emotional: Depressive symptoms; emotional lability; expresses anger; expresses frustration; impatience; insufficient time to meet personal needs; nervousness; somatization
Socioeconomic: Altered leisure activities; isolation; low work productivity; refuses career advancement

Caregiver-Care Receiver Relationship

Difficulty watching care receiver with illness; sadness about altered interpersonal relations with care receiver; uncertainty about alteration in interpersonal relations with care receiver

Family Processes

Family conflict; reports concern about family member(s)

Related Factors

Caregiver

Competing role commitments; depressive symptoms; inadequate fulfillment of others' expectations; inadequate fulfillment of self-expectations; inadequate knowledge about community resources; inadequate psychological resilience; inadequate recreation; ineffective coping strategies; inexperience with caregiving; insufficient physical endurance; insufficient privacy; not developmentally ready for caregiver role; physical conditions; social isolation; stressors; substance misuse; unrealistic self-expectations

Care Receiver Factors

Discharged home with significant needs; increased care needs; loss of independence; problematic behavior; substance misuse; unpredictability of illness trajectory; unstable health status

Caregiver-Care Receiver Relationship

Abusive interpersonal relations; codependency; inadequate interpersonal relations; unaddressed abuse; unrealistic care receiver expectations; violent interpersonal relations

Caregiving Activities

Altered nature of care activities; around-the-clock care responsibilities; complexity of care activities; excessive caregiving activities; extended duration of caregiving required; inadequate assistance; inadequate equipment for providing care; inadequate physical environment for providing care; inadequate respite for caregiver; insufficient time; unpredictability of care situation

C

Family Processes

Family isolation; ineffective family adaptation; pattern of family dysfunction; pattern of family dysfunction prior to the caregiving situation; pattern of ineffective family coping

Socioeconomic

Difficulty accessing assistance; difficulty accessing community resources; difficulty accessing support; inadequate community resources; inadequate social support; inadequate transportation; social alienation

At-Risk Population

Care receiver with developmental disabilities; caregiver delivering care to partner; caregiver with developmental disabilities; female caregiver; individuals delivering care to infants born prematurely; individuals experiencing financial crisis

Associated Conditions

Care Receiver

Impaired health status; psychological disorder

Caregiver

Chronic disease; congenital disorders; illness severity; mental disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Caregiver Adaptation to Patient Institutionalization; Caregiver Emotional Health; Caregiver Home Care Readiness; Caregiver Lifestyle Disruption; Caregiver-Patient Relationship; Caregiver Performance: Direct Care; Caregiver Performance: Indirect Care; Caregiver Physical Health; Caregiver Role Endurance; Caregiver Stressors; Caregiver Well-Being; Family Resiliency; Family Coping

Example NOC Outcome with Indicators

Caregiver Emotional Health with plans for a positive future as evidenced by the following indicators: Satisfaction with life/Sense of control/Self-esteem/Certainty about future/Perceived social connectedness/Perceived spiritual well-being/Perceived adequacy of resources. (Rate the outcome and indicators of **Caregiver Emotional Health:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Throughout the Care Situation, the Caregiver Will

- Be able to express feelings of strain
- Feel supported by health care professionals, family, and friends; feel they have adequate information to provide care
- Report reduced or acceptable feelings of burden or distress
- Take part in self-care activities to maintain own physical and psychological/emotional health; identify resources (family and community) available to help in giving care
- Verbalize mastery of the care activities; feel confident and competent to provide care; have the skills to provide care
- Ask for help when needed
- Not refuse help when offered

Throughout the Care Situation, the Care Recipient Will

- Obtain quality and safe physical care and emotional care
- Be treated with respect and dignity

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Caregiver Support

Example NIC Activities—Caregiver Support

Determine caregiver's acceptance of role; Accept expressions of negative emotion

Nursing Interventions and *Rationales*

- Assess for caregiver role strain at the onset of the care situation, at regular intervals throughout the care situation, at care transitions, and with changes in care recipient status. EBN: *Changes in the care recipient's health status necessitate new skills and monitoring from the caregiver and affect the caregiver's ability to continue to provide care and may affect caregiver health (Trevino et al, 2018).* EB: *Valid and reliable instruments to assess caregiver health include the Caregiver Strain Risk Index, Positive Aspects of Caregiving Questionnaire (Abdollahpour et al, 2017), Caregiver Burden Inventory, Caregiver Reaction Assessment (Given et al, 1992), Screen for Caregiver Burden, Subjective and Objective Scale, Family Caregiver Self Expectations, Caregiver Preparedness Scale (Petruzzo et al, 2017), the Family Caregiver Activation in Transitions (FCAT) Tool, and DECAFTM Family Caregiver Tool (Coleman et al, 2015).*
- Monitor overall health of the caregiver at regular intervals for signs and symptoms of depression, anxiety, role strain, hopelessness, posttraumatic stress, and deteriorating physical health, particularly their control over chronic diseases and comorbid conditions. EB: *Caregivers of stroke survivors had difficulty dealing with depressive feelings, feelings of guilt, anxious/panic episodes, feelings of uncertainty and hopelessness, posttraumatic stress symptoms, and feelings of role strain from commitments (McCurley et al, 2019).* EB: *Caregivers with high levels of depressive symptoms have demonstrated poor health and increased health care utilization and cost (Shaffer et al, 2017).*
- Identify caregiver personal resources such as resilience, proficiency in caregiving skills, social support, optimism, positive aspects of care and resilience, and utilization or availability of social services (e.g., state-funded senior services, veterans' services, Area Agency on Aging resources). EB: *Identification and appreciation of resources may help buffer the negative effects of providing care on caregivers' emotional health and increase the effectiveness of interventions to reduce strain (Joling et al, 2017).*
- Encourage the caregiver to share feelings, concerns, uncertainties, and fears; support groups, including Internet-based ones, can be helpful to gain support. EB: *Internet social support groups can be an effective form of support (Parker Oliver et al, 2017).*
- Regularly assess for any evidence of caregiver or care recipient violence or abuse, especially emotional and verbal abuse; risk factors include substance abuse, poor premorbid relationship, and psychiatric illness. EB: *Caregivers are often unaware of the effect of their behavior on care recipient, and the definition of abuse (Liu et al, 2019).*
- ♦ Ensure appropriate referrals for physical, occupational, and speech-language therapy, as well as social work, including referrals for outpatient therapy or skilled home health care if needed (including therapy needed to maintain functional abilities and prevent decline). EB: *Improvement in client physical function resulted in better physical and psychological quality of life for both client and caregiver (Pucciarelli et al, 2017).*
- Talk with caregivers early and often about palliative care as a means of symptom management for the care recipient. EB: *Many care recipients and their families do not know what palliative care means, which may lead to underutilization of comfort measures (Scott et al, 2017).*
- Help the caregiver learn mindfulness stress management techniques, which can reduce psychological distress. EB: *Mindfulness stress reduction interventions can result in improvement in quality of life, self-compassion, caregiver burden, and relationship satisfaction (Schellekens et al, 2017).*
- Assist the client to identify spiritual beliefs and engage in spiritual practices. EB: *Spiritual beliefs and practices may help caregivers cope because it protects them from depression (Penman, 2018).*
- Encourage regular and open communication with the care recipient and with the health care team. EB: *Care transitions are a critical point to ensure that caregivers have adequate information for client safety and efficient and effective care (Scott et al, 2017).*

C

Geriatric

- The interventions described previously may be adapted for use with geriatric clients.
- Monitor the caregiver for psychological distress and signs of depression, especially if there was an unsatisfactory family relationship before caregiving. EB: *Family caregivers report higher levels of resiliency in providing care when their relationship with care recipient was harmonious before the caregiving role (Joling et al, 2017).*
- To improve the ability to provide safe care: assess caregiver's support and learning needs and provide skills training related to direct care, perform complex monitoring tasks, supervise, and interpret client symptoms, assist with decision-making, assist with medication adherence. EB: *Caregivers need individualized resources and support to master skills needed for care management, care coordination, and medical/nursing tasks (Polenick et al, 2017).*

Pediatric

- Assess parents for perceived self-blame or worsened relationship with their child, especially if their child's condition is psychiatric in nature, and assist them to seek social support, instill hope, and identify how they might grow. EB: *Parents of children with severe mental illness including self-mutilation, suicidal ideation, obsessive compulsive disorders, eating disorders, and so on, often placed a high amount of responsibility on themselves and reported feeling the psychiatric disorder pushed them and their child apart (Whitlock et al, 2018).*
- Assess for partner support of the caregiver in dual-earning households, and provide resources related to couples' or family therapy if needed. EB: *Perceived lack of support from a partner is associated with greater caregiver role strain and psychological distress, and strain between partners leads to further stress (DePasqale et al, 2017).*

Multicultural

- Assess for cultural and spiritual needs of client and caregiver. EB: *Culturally competent care can improve client care quality and outcomes; cultural competence refers to the ability of health providers and organizations to deliver services that meet the cultural, social, and religious needs of clients and their families (Mahdavi et al, 2017; Swihart et al, 2021).*

Home Care

- Assess the client and caregiver at every visit for the quality of their relationship and for the quality and safety of the care provided. EB: *Education, social support, and behavioral management are the most effective support for caregivers of dementia clients (Clarkson et al, 2017).*
- Encourage use of respite care, which may include regular care and assistance at home, or a brief period of total care (24/7) at home or in an inpatient facility to allow the caregiver to recover from an illness, attend a wedding, or go on a short vacation. EB: *Respite care provides time away from the care situation and may help alleviate some caregiver distress (Vandepitte et al, 2016; Sakurai & Kohno, 2020).*

Client/Family Teaching and Discharge Planning

- Identify client and caregiver factors that necessitate the use of skilled home health care services or need to be addressed before the client can be safely discharged. EBN: *Interventions to be considered needed at discharge may include medication management, medication reconciliation, symptom monitoring, identification of community-based resources, skills training for clients and caregivers, and specific client or caregiver concerns about home health care (Mollica et al, 2017).*
- Collaborate with the caregiver and discuss the care needs of the client, disease processes, medications, and what to expect as part of discharge planning and transition care. EBN: *Components of comprehensive and effective transitional care may require adaptation and include client and caregiver well-being, caregiver engagement, caregiver education, client engagement, client education, complexity/medication management, care continuity, and accountability (Naylor et al, 2017, 2018).*
- Involve the family caregiver in care transitions and discharge from institutions; use a multiprofessional team to provide medical and social services for detailed instruction and planning specific to the care need. EB: *Family members need education specific to their situation at discharge, and this educational approach should be based on the cltient's needs. The postdischarge visit serves as an important vehicle to prevent readmissions and improve quality of care for clients (Rodakowski et al, 2017; Soufer et al, 2017).*

Risk for Caregiver Role Strain

Domain 7 Role relationship Class 1 Caregiving roles

Marina Martinez-Kratz, MS, RN, CNE

C

NANDA-I

Definition

Susceptible to difficulty in fulfilling care responsibilities, expectations, and/or behaviors for family or significant others, which may compromise health.

Risk Factors

Caregiver Factors

Competing role commitments; depressive symptoms; inadequate fulfillment of others' expectations; inadequate fulfillment of self-expectations; inadequate knowledge about community resources; inadequate psychological resilience; inadequate recreation; ineffective coping strategies; inexperience with caregiving; insufficient physical endurance; insufficient privacy; not developmentally ready for caregiver role; physical conditions; stressors; substance misuse; unrealistic self-expectations; unstable health status

Care Receiver Factors

Discharged home with significant needs; increased care needs; loss of independence; problematic behavior; substance misuse; unpredictability of illness trajectory; unstable health condition

Caregiver-Care Receiver Relationship

Abusive interpersonal relations; codependency; inadequate interpersonal relations; unaddressed abuse; unrealistic care receiver expectations; violent interpersonal relations

Caregiving Activities

Altered nature of care activities; around-the-clock care responsibilities; complexity of care activities; excessive caregiving activities; extended duration of caregiving required; inadequate assistance; inadequate equipment for providing care; inadequate physical environment for providing care; inadequate respite for caregiver; insufficient time; unpredictability of care situation

Family Processes

Family isolation; ineffective family adaptation; pattern of family dysfunction; pattern of family dysfunction prior to the caregiving situation; pattern of ineffective family coping

Socioeconomic

Difficulty accessing assistance; difficulty accessing community resources; difficulty accessing support; inadequate community resources; inadequate social support; inadequate transportation; social alienation; social isolation

At-Risk Population

Care receiver with developmental disabilities; care receiver's condition inhibits conversation; caregiver delivering care to partner; caregiver with developmental disabilities; female caregiver; individuals delivering care to infants born prematurely; individuals experiencing financial crisis

Associated Conditions

Caregiver Factors

Impaired health status; psychological disorder

Care Receiver Factors

Chronic disease; congenital disorders; illness severity; mental disorders

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching, and References

Refer to care plan for **Caregiver Role Strain.**

Risk for Ineffective Cerebral Tissue Perfusion

Domain 4 Activity/rest Class 4
Cardiovascular/pulmonary responses

Kimberly S. Meyer, PhD, ACNP-BC, CNRN

C

NANDA-I

Definition

Susceptible to a decrease in cerebral tissue circulation, which may compromise health.

Risk Factors

Substance misuse

At-Risk Population

Individuals with history of recent myocardial infarction

Associated Conditions

Abnormal serum partial thromboplastin time; abnormal serum prothrombin time; akinetic left ventricular wall segment; atherosclerosis; atrial fibrillation; atrial myxoma; brain injuries; brain neoplasm; carotid stenosis; cerebral aneurysm; coagulopathy; dilated cardiomyopathy; disseminated intravascular coagulopathy; embolism; hypercholesterolemia; hypertension; infective endocarditis; mechanical prosthetic valve; mitral stenosis; pharmaceutical preparations; sick sinus syndrome; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Acute Confusion Level; Tissue Perfusion: Cerebral; Agitation Level; Neurological Status; Cognition; Seizure Control; Motor Strength

Example NOC Outcome with Indicators

Tissue Perfusion: Cerebral as evidenced by the following indicators: Headache/Restlessness/Listlessness/Agitation/Vomiting/Fever/Impaired cognition/Decreased level of consciousness/Motor weakness/Dysphagia/Slurred speech. (Rate the outcome and indicators of **Tissue Perfusion: Cerebral:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State stable or improved headache
- Demonstrate appropriate orientation to person, place, time, and situation
- Demonstrate ability to follow simple commands
- Demonstrate equal bilateral motor strength
- Demonstrate adequate swallowing ability
- Maintain (or improve) neurological examination

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Medication Management; Neurologic Monitoring; Positioning: Neurologic; Cerebral Perfusion Promotion; Fall Prevention; Cognitive Stimulation; Environmental Management: Safety

Example NIC Activities—Neurologic Monitoring

Monitor pupillary size, shape, symmetry, and reactivity; Monitor level of consciousness; Monitor level of orientation; Monitor trend of Glasgow Coma Scale; Monitor facial symmetry; Note complaint of headache; Monitor blood pressure (BP) and heart rate; Monitor respiratory function

C

Nursing Interventions and *Rationales*

- To decrease risk of reduced cerebral perfusion related to stroke or transient ischemic attack (TIA):
  - ❍ Obtain a family history of hypertension, diabetes, and stroke to identify persons who may be at increased risk of stroke. EB: *A positive family history of stroke increases risk of stroke significantly (Pourasgari & Mohamadkhani, 2020).*
  - ❍ Monitor BP regularly because hypertension is a major risk factor for both ischemic and hemorrhagic stroke. EB: *Systolic BP should be treated to a goal of less than 140 mm Hg and diastolic BP to less than 90 mm Hg, whereas clients with diabetes or renal disease have a BP goal of less than 130/80 mm Hg (Flack & Adekola, 2020).*
  - ❍ Teach hypertensive clients the importance of taking their health care provider–ordered antihypertensive agent to prevent stroke. EB: *Treatment of hypertension in adults with diabetes with a calcium channel blocker or angiotensin-converting enzyme (ACE) inhibitor may be useful (Flack & Adekola, 2020).*
  - ❍ Stress smoking cessation at every encounter with clients, using multimodal techniques to aid in quitting, such as counseling, nicotine replacement, and oral smoking cessation medications. Provide client and family education to reduce lifestyle-associated risk factors for stroke. EB: *Studies show that a consistent and overwhelming relationship between lifestyle risk factors such as smoking, physical inactivity, and poor diet associated with obesity increases the client risk of both ischemic and hemorrhagic stroke (Ding et al, 2019; Parikh et al, 2020).*
  - ❍ Teach clients who experience a transient TIA that they are at increased risk for a stroke. Instruct clients that adherence to medication therapy decreases recurrent TIA/stroke risk. EB: *The 90-day risk for stroke after a TIA is as high as 17%, with the greatest risk occurring in the first week (Heron, 2016).* EB: *Dual antiplatelet therapy decreases the incidence of subsequent ischemic events (Johnston et al, 2020).*
  - ❍ Screen clients 65 years of age and older for atrial fibrillation with pulse assessment. EB: *Atrial fibrillation is associated with a fivefold increase in stroke. Systematic pulse assessment in a primary care setting resulted in a 60% increase in the detection of atrial fibrillation (Jones et al, 2020).*
  - ❍ Instruct the client regarding the appropriate use and side effects of anticoagulation in the prevention of cardioembolic stroke. EB: *With therapeutic dosing, vitamin K agonists and non–vitamin K agonists reduce the stroke risk in client with atrial fibrillation (Wutzler et al, 2019).*
  - ❍ Call 911 or activate the rapid response team of a hospital immediately when clients display symptoms of stroke as determined by the Cincinnati Stroke Scale (F: facial drooping; A: arm drift on one side; S: speech slurred), being careful to note the time of symptom appearance. Additional symptoms of stroke include sudden numbness/weakness of face, arm, or leg, especially on one side; sudden confusion; trouble speaking or understanding; sudden difficulty seeing with one or both eyes; sudden trouble walking, dizziness, loss of balance, or coordination; or sudden severe headache (Jauch et al, 2013). EB: *The Cincinnati Stroke Scale (derived from the National Institutes of Health [NIH] Stroke Scale) is used to identify clients having a stroke who may be candidates for thrombolytic therapy or mechanical thrombectomy (De Luca et al, 2019; Crowe et al, 2021). Emergency medical services (EMS) activation results in faster health care provider assessment, computed tomography, and neurological evaluation, which facilitates administering thrombolytics to eligible individuals who had a stroke within the required 3- to 4.5-hour time period (Jauch et al, 2013).*
  - ❍ Use clinical practice guidelines for glycemic control and BP targets to guide the care of clients with diabetes who have had a stroke or TIA. EB: *The American Stroke Association recommends that evidence-based guidelines be used in the care of clients with diabetes. Good glycemic control has been associated with decreased incidence of strokes (Zhu et al, 2019).* EB: *Hypoglycemia (blood sugar <60 mg/dL) should be corrected immediately to improve stroke outcomes (Powers et al, 2019).* EB: *Persistent hyperglycemia (blood sugar >180 mg/dL) should be avoided because hyperglycemia is associated with worse stroke outcomes (Powers et al, 2019; Zheng & Zhou, 2020).*
  - ❍ Maintain head of bed less than 30 degrees in the acute phase (<72 hours of symptom onset) of ischemic stroke. EB: *Cerebral blood flow is decreased when head of bed is elevated from 0 to 30 degrees in clients with acute ischemic stroke but the effects on recovery outcomes are unclear (Anderson & Olivarría, 2018).*
  - ❍ Head of bed may be elevated to sitting position without detrimental effect to cerebral blood flow in clients with ischemic stroke or hemorrhagic stroke at 72 hours after symptom onset. EB: *Head of bed elevation of 45 and 70 degrees in the subacute phase of ischemic stroke resulted in minor changes in cerebral blood flow velocities (Aries et al, 2013).* EB: *Cerebral blood flow had no significant changes in head of bed elevations from 0 to 90 degrees in clients with subarachnoid hemorrhage at days 3, 7, and 10 (Kung et al, 2013).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- ❍ Administer enteric/oral nimodipine as prescribed by the health care provider after aneurysmal subarachnoid hemorrhage for 21 days. EB: *Nimodipine, a calcium channel blocker, has been shown by multiple randomized clinical trials to improve outcome by limiting delayed cerebral ischemia after subarachnoid hemorrhage strokes (Pal'a et al, 2019).* EB: *If hypotension occurs following nimodipine administration, vasopressor support and modification of the dosing schedule to include smaller, more frequent dosages should be implemented as missed doses result in adverse outcomes (Ehrlich et al, 2019; Pal'a et al, 2019).*
- ❍ Monitor neurological function frequently in the first 2 weeks after subarachnoid hemorrhage because subtle declines may be related to cerebral vasospasm. EB: *Cerebral vasospasm occurs in up to two-thirds of clients with subarachnoid hemorrhage and can lead to delayed cerebral ischemia (Reynolds et al, 2020; Thomas & Petrone, 2020).*
- ❍ Maintain cerebral perfusion pressure (CPP) 60 to 70 mm Hg in clients with traumatic brain injury. EB: *When injury-related impaired autoregulation is present, CPP less than 60 is associated with worse outcomes (Carney et al, 2017; Güiza et al, 2017).*

▲ To decrease risk of reduced CPP: CPP = Mean arterial pressure − intracranial pressure (CPP = MAP − ICP)

- ❍ Maintain euvolemia. EB: Infusing isotonic intravenous fluids to sustain normal circulating volume helps maintain normal cerebral blood flow and reduces the incidence of vasospasm (Hemphill et al, 2015; Rumalla et al, 2021).

▲ To treat decreased CPP:

- ❍ Clients with subarachnoid hemorrhagic stroke experiencing delayed cerebral ischemia, as evidenced by declining neurological examination, should undergo a stepwise trial of induced hypertension up to 220 mm Hg. EB: *Medically managed hypertension increased cerebral blood flow and produced neurological improvement in the majority of clients (Suwatcharangkoon et al, 2019).*
- ❍ Administer vasopressor infusions to raise MAP per collaborative protocol. EB: *Clients with delayed cerebral ischemia treated with norepinephrine or phenylephrine have better BP augmentation and better clinical outcomes than clients treated with other vasopressors (Roy et al, 2017; Rouanot & Silva, 2019).*
- ❍ Mobilize clients with subarachnoid hemorrhage as early as 1 day after aneurysm is secured. EB: *Clients undergoing early mobilization are less likely to develop severe cerebral vasospasm, have a shorter hospital length of stay, and are more likely to discharge to home or acute rehabilitation (Karic et al, 2017; Young et al, 2019).*

Ineffective Childbearing Process

Domain 8 Sexuality Class 3 Reproduction

Dianne F. Hayward, RN, MSN, WHNP

NANDA-I

Definition

Inability to prepare for and/or maintain a healthy pregnancy, childbirth process, and care of the newborn for ensuring well-being.

Defining Characteristics

During Pregnancy

Failure to utilize social support; inadequate attachment behavior; inadequate prenatal care; inadequate prenatal lifestyle; inadequate preparation of newborn care items; inadequate preparation of the home environment; inadequate respect for unborn baby; ineffective management of unpleasant symptoms in pregnancy; unrealistic expectations about labor and delivery

During Labor and Delivery

Decreased proactivity during labor and delivery; failure to utilize social support; inadequate attachment behavior; inadequate lifestyle for stage of labor; inappropriate response to onset of labor

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

After Birth

Failure to utilize social support; inadequate attachment behavior; inadequate baby care techniques; inadequate infant clothing; inappropriate baby feeding techniques; inappropriate breast care; inappropriate lifestyle; unsafe environment for an infant

Related Factors

Domestic violence; inadequate knowledge of childbearing process; inadequate mental preparation for parenting; inadequate parental role model; inadequate prenatal care; inadequate social support; inconsistent prenatal health visits; low maternal confidence; maternal malnutrition; maternal powerlessness; maternal psychological distress; substance misuse; unrealistic birth plan; unsafe environment

At-Risk Population

Individuals experiencing unplanned pregnancy; individuals experiencing unwanted pregnancy

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Fetal Status: Antepartum, Intrapartum; Maternal Status: Antepartum, Intrapartum; Depression Level; Family Resiliency; Knowledge: Substance Use Control; Social Support; Spiritual Support; Risk for Infection

Example NOC Outcome with Indicators

Maternal Status: Antepartum as evidenced by the following indicators: Emotional attachment to fetus/ Coping with discomforts of pregnancy/Mood lability/Has realistic birth plan/Has support system. (Rate each indicator of **Maternal Status: Antepartum:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

Antepartum

- Obtain early prenatal care in the first trimester and maintain regular visits
- Demonstrate appropriate care of oneself during pregnancy including good nutrition and psychological health
- Attend prenatal education either virtual or in person with significant other or involved family member
- Understand the risks of substance abuse and resources available
- Feel empowered to seek social and spiritual support for emotional well-being during pregnancy
- Prepare home for baby (e.g., crib, diapers, infant car seat, outfits, blankets) before due date
- Use support systems for emotional support
- Develop a realistic birth plan, taking into account any high-risk pregnancy issues before due date
- Understand the labor and delivery process and comfort measures to manage labor pain before due date

Intrapartum

- Use support system for emotional support during labor and delivery
- Demonstrate appropriate understanding of choices in labor and delivery
- Demonstrate effective coping strategies during labor and delivery

Postpartum

- Provide a safe environment for self and infant
- Demonstrate appropriate newborn care and postpartum care of self
- Demonstrate appropriate bonding and parenting skills

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

High-Risk Pregnancy Care; Intrapartal Care; Infant Care: Newborn

Example NIC Activities—High-Risk Pregnancy Care

Instruct client in self-care techniques to increase the chance of a healthy outcome (e.g., hydration, diet, activity modifications, importance of regular prenatal checkups, normalization of blood sugars, and sexual precautions, including abstinence).

Monitor physical and psychosocial status closely throughout pregnancy. Refer as appropriate for specific programs (e.g., smoking cessation, substance abuse treatment, diabetes education, preterm birth prevention education, abuse shelter as needed).

C

Nursing Interventions and *Rationales*

- Encourage early prenatal care (PNC) and regular prenatal visits. EB: *PNC is essential for a good pregnancy outcome for mothers and infants. Many women in the United States receive late or no PNC, resulting in avoidable adverse health outcomes (Oghogho & Beck-Sagué, 2020). The World Health Organization (WHO) guidelines for antenatal care include a minimum of eight contacts to reduce perinatal mortality and improve women's experience of care, counseling about healthy eating, and keeping physically active during pregnancy (World Health Organization, 2016).*
- Identify any high-risk factors that may require additional surveillance, such as preterm labor, hypertensive disorders of pregnancy, diabetes, depression, other chronic medical conditions, presence of fetal anomalies, virus exposure, homelessness (resources can be accessed through the HUD exchange [https://www.hudexchange.info/resources] and Homeless Prenatal Program [www.homelessprenatal.org]), or other high-risk factors. EB: *Preeclampsia is a major cause of maternal morbidity and is associated with adverse fetal outcomes, including intrauterine growth restriction, preterm birth, placental abruption, fetal distress, and fetal death in utero (Fox et al, 2019).* EBN: *It is exceedingly difficult for homeless pregnant women to access prenatal care, often leading to poorer maternal and neonatal outcomes. Nurses need to be prepared to make timely referrals to support services as an important first step (Azarmehr et al, 2018).*
- ▲ Assess and screen for signs and symptoms of depression during pregnancy and in the postpartum period and refer for behavioral-cognitive counseling and/or medication. EB: *Susser et al (2016) reported that nearly 20% of women in pregnancy and in the postpartum period are affected with depression.*
- ▲ Observe for signs of alcohol misuse and counsel women to stop drinking during pregnancy. Give appropriate referral for treatment if needed. EBN: *There is no safe time to drink alcohol during pregnancy and can fetal alcohol spectrum disorder (FASD). FASD is a range of physical, mental, behavioral, and/or learning disabilities with potential lifelong implications that occur after exposure to alcohol in utero (Association of Women's Health, Obstetric and Neonatal Nurses [AWHONN] Position Statement, 2019).*
- ▲ Obtain a smoking history and counsel women to stop smoking for the safety of the baby. Give appropriate referral to a smoking cessation program if needed. EBN: *Many women who do stop smoking during their pregnancies relapse in the postpartum period. Smoking is a major cause of adverse pregnancy and birth outcomes (Fallin-Bennett et al, 2019). A free and helpful website for quitting smoking is available at* https://women.smokefree.gov/tools-tips-women/text-programs/smokefreemom *(U.S. Department of Health and Human Services, n.d.).*
- ▲ Monitor for substance misuse with recreational drugs. Refer to a treatment program as needed. Refer opiate-dependent women to methadone clinics to improve maternal and fetal pregnancy outcomes. EB: *Pregnancy is an opportune time to identify substance misuse dependence, facilitate conversion to maintenance treatment, and coordinate comprehensive prenatal care with specialists in addiction medicine, behavioral health, and social services (Krans et al, 2015).*
- Monitor for psychosocial issues, including lack of social support system, loneliness, depression, lack of confidence, maternal powerlessness, and socioeconomic problems. EBN: *Expanded screening of at-risk women should include significant risk factors other than depression and anxiety symptoms (Ruyak et al, 2017).*
- ▲ Monitor for signs of domestic violence. Refer to a community program for abused women that provides safe shelter as needed. EBN: *Abuse during pregnancy can result in poor maternal, neonatal, and early childhood outcomes; routine screening and assessment may interrupt further abuse and promote positive outcomes (Bianchi et al, 2016).*
- Provide antenatal education to increase the woman's knowledge needed to make informed choices during pregnancy, labor, and delivery and to promote a healthy lifestyle. Encourage pregnant women to use digital resources such as Text4Baby (see https://www.text4baby.org or https://www.whattoexpect.com)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

to track pregnancy progress and provide education and motivation to make healthy lifestyle choices in nutrition (abstinence from poor nutrition, smoking, and alcohol, and illicit drugs). EBN: *Multiple digital sources of health-related information are available and women may need help to identify those that are most reputable and useful (Lowe & Hartley, 2018).*

- Encourage expectant parents to prepare a realistic birth plan or "birth preferences" to prepare for the physical and emotional aspects of the birth process and to plan ahead for how they want various situations handled. EBN: *The birth plan allows the woman to communicate her expectations and needs (Biescas et al, 2017). A flexible approach to the birth plan is necessary, including the consideration of using alternative approaches and allowing for unexpected circumstances (Divall et al, 2017).*
- Encourage good nutritional intake during pregnancy to facilitate proper growth and development of the fetus. Women should consume an additional 300 calories per day during pregnancy, take a multimicronutrient supplement containing at least 400 µg folic acid, and achieve a total weight gain of 25 to 30 pounds. EB: *Nutritional information during pregnancy can be found at* choosemyplate.gov, *which presents healthy choices from each food group (U.S. Department of Agriculture [USDA], 2020). The U.S. Preventive Services Task Force (USPSTF) has updated its recommendation that all women who are planning a pregnancy or capable of becoming pregnant take a daily supplement containing 0.4 to 0.8 mg (400–800 µg) of folic acid (USPSTF as cited in Bibbins-Domingo et al, 2017).*

Multicultural

- ▲ Provide for a translator as needed. EBN: *In most Middle Eastern cultures female translators would be necessary because they are reluctant or sometimes forbidden to discuss female concerns with men (Meyer et al, 2016).* EBN: *The appropriate use of translation services and good communication skills are necessary to make women feel heard and have the opportunity to make choices (Rowland-Neve, 2017).*
- ▲ Provide depression screening. EB: *A 2015 study found that Mexican American women exhibit higher prenatal maternal depressive symptoms. Depressive symptoms increased when the women tried to mesh American and Mexican cultural values, and incorporation of the Anglo value of self-reliance and independence was a risk factor for depression (D'Anna-Hernandez et al, 2015).*
- Perform a cultural assessment and provide care that is culturally appropriate. EBN: *Nonjudgmental care that promotes equality can be accomplished through the appropriate use of translation services and good communication skills to make certain that women feel heard and have the opportunity to make choices (Rowland-Neve, 2017).*

Postpartal

- Assess client's beliefs and concerns about the postpartum period to provide culturally appropriate health and nutrition information and guidance on contemporary postpartum practices. EB: *Encourage women to adopt a healthy diet with protein-rich foods (Chakona & Shackleton, 2019).*

C

Readiness for Enhanced Childbearing Process

Domain 8 Sexuality Class 3
Reproduction

Gail B. Ladwig, MSN, RN and Dianne F. Hayward, RN, MSN, WHNP

NANDA-I

Definition

A pattern of preparing for and maintaining a healthy pregnancy, childbirth process and care of the newborn for ensuring well-being which can be strengthened.

Defining Characteristics

During Pregnancy

Expresses desire to enhance knowledge of childbearing process; expresses desire to enhance management of unpleasant pregnancy symptoms; expresses desire to enhance prenatal lifestyle; expresses desire to enhance preparation for newborn

During Labor and Delivery

Expresses desire to enhance lifestyle appropriate for stage of labor; expresses desire to enhance proactivity during labor and delivery

After Birth

Expresses desire to enhance attachment behavior; expresses desire to enhance baby care techniques; expresses desire to enhance baby feeding techniques; expresses desire to enhance breast care; expresses desire to enhance environmental safety for the baby; expresses desire to enhance postpartum lifestyle; expresses desire to enhance use of support system

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Knowledge: Pregnancy; Knowledge: Infant Care; Knowledge: Postpartum Maternal Health; Knowledge: Breastfeeding, Parent-Infant Attachment

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NOC Outcome with Indicators

Knowledge: Pregnancy as evidenced by client conveying understanding of the following indicators: Importance of frequent prenatal care/Importance of prenatal education/Benefits of regular exercise/ Healthy nutritional practices/Anatomic and physiological changes of pregnancy/Psychological changes associated with pregnancy/Birthing options/Effective labor techniques/Signs and symptoms of labor. (Rate the outcome and indicators of **Knowledge: Pregnancy:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

Antepartum

- Attend all scheduled prenatal visits and attend prenatal education either with significant other or involved family member
- Use appropriate self-care for discomforts of pregnancy
- Prepare home for baby (e.g., crib, diapers, infant car seat, outfits, blankets) before due date
- Develop a realistic birth plan, taking into account any high-risk pregnancy issues before due date
- Feel empowered to seek social and spiritual support for emotional well-being during pregnancy
- Make healthy lifestyle choices prenatally: activity and exercise/healthy nutritional practices
- Use strategies to balance activity and rest

Intrapartum

- Demonstrate appropriate lifestyle choices during labor
- State knowledge of birthing options, signs and symptoms of labor before due date
- Demonstrate effective labor techniques
- Use support systems for labor and emotional support

Postpartum

- Demonstrate appropriate lifestyle choices postpartum
- Report normal physical sensations after delivery
- State understanding of recommended nutrient intake, strategies to balance activity and rest, appropriate exercise, time frame for resumption of sexual activity, strategies to manage stress
- Demonstrate bonding with infant
- Demonstrate proper handling and positioning of infant/infant safety
- Demonstrate feeding technique and bathing of infant

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Prenatal Care; Intrapartal Care; Postpartal Care; Attachment Promotion; Infant Care: Newborn; Lactation Counseling; Family Support

Example NIC Activities—Prenatal Care

Encourage prenatal class attendance either virtual or in person and encourage involvement of client's partner or involved family member; Discuss nutritional needs and concerns (e.g., balanced diet, folic acid, food safety, and supplements); Discuss activity level with client (e.g., appropriate exercise, activities to avoid, and importance of rest); Discuss importance of participating in prenatal care throughout entire pregnancy

Nursing Interventions and *Rationales*

▲ Refer to care plans Risk for Impaired **Attachment;** Readiness for Enhanced **Breastfeeding;** Readiness for Enhanced Family **Coping;** Readiness for Enhanced **Family** Processes; Readiness for Enhanced **Nutrition;** Readiness for Enhanced **Parenting;** and Ineffective **Role** Performance.

C

Prenatal Care

- Encourage early prenatal care (PNC) and regular prenatal visits. EB: *PNC is essential for a good pregnancy outcome for mothers and infants. In the United States, many women receive late or no PNC, resulting in avoidable adverse health outcomes (Oghogho & Beck-Sagué, 2020).* EB: *The World Health Organization (WHO) guidelines for antenatal care include a minimum of eight contacts to reduce perinatal mortality and improve women's experience of care, counseling about healthy eating, and keeping physically active during pregnancy (World Health Organization, 2016).*
- ▲ Ensure that pregnant clients have an adequate diet and take multimicronutrient supplements containing at least 400 µg of folic acid, especially during early pregnancy. EB: *Nutritional information can be found at* choosemyplate.gov. *which presents healthy choices from each food group needed for a healthy pregnancy (U.S. Department of Agriculture [USDA], 2020).* EB: *The U.S. Preventive Services Task Force (USPSTF) has updated its recommendation that all women who are planning or capable of pregnancy take a daily supplement containing 0.4 to 0.8 mg (400–800 µg) of folic acid to prevent neural tube deficits (Bibbins-Domingo et al, 2017).*
- Assess smoking status of pregnant clients and offer effective smoking-cessation interventions. EBN: *Many women who do stop smoking during their pregnancies relapse in the postpartum period. Smoking is a major cause of adverse pregnancy and birth outcomes (Fallin-Bennett et al, 2019). A free and helpful website for quitting smoking is available at* https://women.smokefree.gov/tools-tips-women/text-programs/smokefreemom *(U.S. Department of Health and Human Services, n.d.).*
- ▲ Assess all pregnant clients for signs of depression and make appropriate referral for inadequate weight gain, underutilization of PNC, substance misuse, and premature birth. EBN: *Maternal depression is associated with adverse perinatal outcomes, including an increased risk of poor adherence to treatment regimen, inadequate nutrition, loss of interpersonal and financial resources, smoking and substance misuse (Kendig et al, 2017).*
- Provide the pregnant client with breastfeeding education. EB: *Early initiation, exclusive, and continued breastfeeding are among the most effective interventions to reduce infant and child morbidity and mortality. Breastfeeding also improves early childhood development and reduces the risks of childhood obesity and noncommunicable disease (Rollins & Doherty, 2019).*

Intrapartal Care

Provide a calm, relaxing, and supportive birth environment. EBN: *The client's outcome and safety are affected by the birth environment and culture. The care providers, whether midwives, doulas, and/or the nursing staff, must be knowledgeable and committed to providing labor support (Stark et al, 2016).*

Offer the client in labor a clear liquid diet and water if allowed. EB: *The American College of Obstetricians and Gynecologists now endorses clear liquids during labor; however, current recommendations suggest that solid food intake should be avoided. According to Sperling et al, recent evidence from a systematic review involving 3130 women in active labor suggests that oral intake should not be restricted in women at low risk of complications (Sperling et al, 2016).*

Multicultural

Prenatal

- ▲ Provide for an appropriate translator if needed. EBN: *In the Arab and most Middle Eastern cultures female translators would be necessary because they are reluctant or sometimes forbidden to discuss female concerns with men (Meyer et al, 2016).* EBN: *The appropriate use of translation services and good communication skills are necessary to make women feel heard and have the opportunity to make choices (Rowland-Neve, 2017).*
- Assess the client's beliefs and concerns to inform culturally appropriate PNC. EBN: *When caring for a woman of a different culture recognize the danger of making assumptions about the health care needs of the group to which she belongs. Identify the specific needs of the individual (Rowland-Neve, 2017).*

Intrapartal

- Assess client's beliefs and concerns about labor. EBN: *Instead of reducing the choices available to women during the birth experience, providers should understand, respect, and integrate cultural interpretations of childbirth and the needs of women and their families (Withers et al, 2018).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Postpartal

- Assess client's beliefs and concerns about the postpartum period to provide culturally appropriate health and nutrition information and guidance on contemporary postpartum practices. EB: *Encourage women to adopt a healthy diet with protein-rich foods (Chakona & Shackleton, 2019).*

Home Care

Prenatal

▲ As needed refer pregnant clients to drug treatment programs that include coordinated interventions in several areas, such as drug misuse, infectious diseases, mental health, personal and social welfare, and gynecological/obstetric care. EB: *Pregnancy is an opportune time to identify substance misuse, facilitate conversion to maintenance treatment, and coordinate comprehensive PNC with specialists in addiction medicine, behavioral health, and social services (Krans et al, 2015).*

Postpartal

Provide information about parenting websites approved by the health care provider to support new parents with postpartum advice, newborn care, and breastfeeding. EB: *Online family support websites afford parents an alternative, cost-effective service that can be accessed from anywhere, increasing opportunities for parents to become active in their own support (Lamberton, Devaney, & Bunting, 2016).*

Client/Family Teaching and Discharge Planning

Prenatal

- Provide dietary and lifestyle counseling as part of PNC to pregnant women. EBN: *Pregnancy is an opportunity to address health behavior change. Recognizing both barriers and motivators during this time frame can allow for more focused interventions to be created and applied to the population (McCloud, 2018).*

Postpartal

- Encourage physical activity in postpartum women, after being cleared by the health care provider. EBN: *By becoming more physically active, a woman can see benefits of this self-care in her sense of well-being and perceived fitness (Shelton & Lee, 2018).*

▲ Provide breastfeeding mothers contact information for a lactation consultant, phone numbers, and website information for the La Leche League (http://www.lalecheleague.org), and local breastfeeding support groups. EBN: *In 2015 the Association of Women's Health, Obstetric and Neonatal Nurses (AWHONN) published its position statement on breastfeeding: it "supports, protects, and promotes breastfeeding as the ideal and most normal method for feeding infants" (Henry et al, 2017).*

- Teach mothers of young children principles to substitute foods high in saturated fat with foods moderate in PUFAs such as avocados, tuna, walnuts, and olive oil. Include lean protein, fruits and vegetables, and complex carbohydrates. EB: *Parental feeding behavior has a significant influence on the development of children's food preferences (Russell, Worsley, & Campbell, 2015).*

C

Risk for Ineffective Childbearing Process

Domain 8 Sexuality Class 3 Reproduction

Dianne F. Hayward, RN, MSN, WHNP

NANDA-I

Definition

Susceptible to an inability to prepare for and/or maintain a healthy pregnancy, childbirth process and care of the newborn for ensuring well-being.

Risk Factors

Inadequate knowledge of childbearing process; inadequate mental preparation for parenting; inadequate parental role model; inadequate prenatal care; inadequate social support; inconsistent prenatal health visits; low maternal confidence; maternal malnutrition; maternal powerlessness; maternal psychological distress; substance misuse; unaddressed domestic violence; unrealistic birth plan; unsafe environment

At-Risk Population

Individuals experiencing unplanned pregnancy; individuals experiencing unwanted pregnancy

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching, and References

Refer to care plan for Ineffective **Childbearing** Process.

Impaired Comfort

Domain 12 Comfort Class 1 Physical comfort

Gail B. Ladwig, MSN, RN and Julianne E. Doubet, BSN, RN, EMT-B

NANDA-I

Definition

Perceived lack of ease, relief, and transcendence in physical, psychospiritual, environmental, cultural, and/or social dimensions.

Defining Characteristics

Anxiety; crying; difficulty relaxing; expresses discomfort; expresses discontentment with situation; expresses fear; expresses feeling cold; expresses feeling warm; expresses itching; expresses psychological distress;

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

irritable mood; moaning; psychomotor agitation; reports altered sleep-wake cycle; reports hunger; sighing; uneasy in situation

Related Factors

Inadequate control over environment; inadequate health resources; inadequate situational control; insufficient privacy; unpleasant environmental stimuli

Associated Conditions

Illness-related symptoms; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Client Satisfaction; Symptom Control; Comfort Status; Coping; Hope; Pain Control; Anxiety Level Personal Well-Being; Spiritual Health

Example NOC Outcomes with Indicators

Comfort Status as evidenced by the following indicators: Physical and psychological well-being/ Symptom control/Enhanced comfort. (Rate the outcome and indicators of **Comfort Status:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Provide evidence for improved comfort compared to baseline
- Identify strategies, with or without significant others, to improve and/or maintain acceptable comfort level
- Perform appropriate interventions, with or without significant others, as needed to improve and/or maintain acceptable comfort level
- Evaluate the effectiveness of strategies to maintain/and or reach an acceptable comfort level
- Maintain an acceptable level of comfort when possible

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Calming Techniques; Massage; Healing Touch; Heat/Cold Application; Hope Inspiration; Humor; Meditation Facilitation; Music Therapy; Pain Management; Acute/Chronic; Presence; Progressive Muscle Relaxation; Spiritual Growth Facilitation; Distraction

Example NIC Activities—Hope Inspiration

Assist the client/significant others to identify areas of hope in life; Help expand spiritual self; Involve the client actively in own care

Nursing Interventions and *Rationales*

- Assess client's understanding of ranking his or her comfort level. EB: *Teachings that are easily understood (as well as client participation in discussions before discharge), which target client comprehension of instructions, have the potential to increase client knowledge and strengthen the ability to self-manage (Flink & Ekstedt, 2016).* EBN: *Routine pain assessments should be encouraged, and the significance of the results explained to the client (Dequeker et al, 2018).*
- Ask about client's current level of comfort. This is the first step in helping clients achieve improved comfort. EBN: *Vuille et al (2018) found in their study that the assessment of pain intensity using a validated pain scale/tool should be the initial step in evaluating a client's level of discomfort: client's self-reporting of pain quality is widely accepted as the key to effective pain management.*

- Comfort is a holistic state under which pain management is included. EBN: *Nurses have a responsibility to promote optimal comfort for clients and to intercede in certain situations to protect the client's level of comfort (Karabulut et al, 2015).*
- Manipulate the environment as necessary to improve comfort. EBN: *The theoretical foundation of holistic comfort, which consists of relief, ease, and transcendence, in the settings of physical, psychological, social, and environmental experiences, enables the nurse to meet the individual comfort needs of the client (Ng, 2017).*
- Encourage early mobilization and provide routine position changes. Range of motion and weight-bearing decrease physical discomforts and disability associated with bed rest. EBN: *It has been shown that immobility is linked to many unacceptable client outcomes in critical care units. Mobility takes many forms (e.g., passive and active range of motion exercises, sitting up, dangling legs on side of bed), along with walking, and these should be included in client care (Crowe et al, 2017).*
- Provide simple massage. Massage has many therapeutic effects, including improved relaxation, circulation, and well-being. EBN: *Lind (2017), in his theses on the use of massage as a complementary therapy in client relaxation techniques, found that massage has shown the most potential in helping to alleviate the client's pain and comfort issues.*
- Provide a healing touch, which is well suited for clients who cannot tolerate more stimulating interventions. EBN: *According to Anderson et al (2017), providing nurses with the knowledge of healing touch and demonstrating its use in acute client care gives the nurse another means of ensuring positive client outcomes.*
- Encourage clients to use relaxation techniques to reduce pain, anxiety, depression, and fatigue. EBN: *Ju et al (2019) state that administration of analgesics for client comfort is a fundamental part of nursing practice, but the use of nonpharmacological interventions such as massage, music, guided imagery, and relaxation as adjuncts to support pain control is becoming increasingly more common.*

Geriatric

- Use hand massage for older adults. Most older adults respond well to touch and the health care provider's presence. Lines of communication open naturally during hand massage. EBN: *Hand massage has been found to ease apprehension, generate a positive effect on vital signs, and enhance the client's comfort (Çavdar et al, 2020).*
- Discomfort from cold can be treated with warmed blankets. There are physiological dangers associated with hypothermia. EBN: *The nurse plays an effective role in advocating for clients' well-being by monitoring the individual client's environment and adjusting it, as necessary, to fit the client's specific comfort needs (Hussein & Karim, 2020).*
- Use complementary therapies such as doll therapy in clients with dementia to increase comfort and reduce stress. EBN: *Both staff and families of clients with advanced dementia confined to a nursing care facility found that complementary therapies were supportive in reducing loneliness and in offering interventions that afforded companionship for residents in distress (Mitchell et al, 2020).*
- Address any unmet physical, psychological, emotional, spiritual, and environmental needs when attempting to mediate the behavior of an older client with dementia. EBN: *As nursing and health care adjust to serve an aging population, there is a renewed interest in providing holistic nursing care appropriate to the client's mental and physical conditions (Pryor & Clarke, 2017).*

Multicultural

- Identify and clarify cultural language used to describe pain and other discomforts. Expressions of pain and discomfort vary across cultures. EBN: *Nurses today are challenged to find means to facilitate culturally harmonious care for all clients; according to Jeffreys and Zoucha (2017), this can be accomplished "through ongoing assessment, education, research, and practice initiatives."*
- Encourage and allow clients to practice their own cultural beliefs and recognize the impact that diverse cultures have on a client's belief about health care, comforting measures, and decision-making. EBN: *Cultural competence is a necessary element of complete nursing care and is achieved by establishing good communication, having skill in making the correct diagnosis, and recognition of clients' language and beliefs as they relate to health and illness (Debiasi & Selleck, 2017).*
- Assess for cultural and religious beliefs when providing care. EB: *According to Schweda et al (2017), in their study of cultural stereotyping, it was found that there is not just one perspective on culture and/or religion, but each individual's stance is formed by political, social, and situation beliefs.*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Client/Family Teaching and Discharge Planning

- Teach techniques to use when the client is uncomfortable, including relaxation techniques, guided imagery, hand massage, and music therapy. EBN: *Many complementary therapies can be conducted by the nurse and then taught to the client and family for use at home (Blackburn et al, 2019).*
- At end of life, the dying client is comforted by having a companion. EBN: *Most clients questioned by Thompson et al (2019), in their study regarding dying alone, acknowledged that they would welcome social connections as they neared the end of their life.*
- Teach the client to follow up with the health care provider if problems persist. EBN: *Dahlberg et al (2018), in their study of follow-up for postoperative clients discharged home, found that it is essential for clients to feel secure, assured, and responded to during their recovery.*
- Use nonpharmacological strategies to enhance comfort. EBN: *Supplementing pain management by nonpharmacological means can enhance pain control and reduce unpleasant side effects, thus leading to improved client and nurse satisfaction (Blackburn et al, 2019).*
- Encourage clients to use the Internet as a means of providing education to complement medical care for those who may be homebound or unable to attend face-to-face education. EB: *According to a study by Sánchez-Valle et al (2017), use of the Internet by older adults can offer a means of dynamic aging and could affect their lifestyle and could have a positive effect on the community as well.*
- Encourage clients to use guided imagery techniques. Guided imagery helps distract clients from stressful situations and facilitates relaxation. EBN: *The use of guided imagery by nurses is economical, uncomplicated, and easily accessible and has shown effectiveness in the delivery of comfort care (Coelho et al, 2018).*
- Provide psychospiritual support and a comforting environment to enhance comfort during emotional crises. EBN: *As health care professionals, nurses should intervene and provide care that recognizes and reduces strain for the client, caregiver, and family during a mental health crisis (Naseimento et al, 2016).*
- When nurses attend to the comfort of perioperative clients, the clients' sense of hope for a full recovery increases. EBN: *Fowler (2020) states that nurses can "assess, inspire, and evaluate hope" and that nurses, no matter what their area of expertise, use comparable approaches to foster hope in their clients.*
- Providing music and verbal relaxation therapy enhances holistic comfort by reducing anxiety. EBN: *Music is one of the complementary and alternative medicine therapies that has shown positive results in easing anxiety, pain, and the use of opioids (Poulsen & Coto, 2018).*
- Caregivers should not hesitate to use humor when caring for their clients. EBN: *Zhao et al (2019), in their analysis of laughter and humor use as a complementary medicine intervention, observed that humor is valuable in easing depression and anxiety, and has shown value in augmenting sleep quality in adults.*

Readiness for Enhanced Comfort

Domain 12 Comfort Class 2 Environmental comfort

Gail B. Ladwig, MSN, RN and Julianne E. Doubet, BSN, RN, EMT-B

NANDA-I

Definition

A pattern of ease, relief, and transcendence in physical, psychospiritual, environmental, and/or social dimensions, which can be strengthened.

Defining Characteristics

Expresses desire to enhance comfort; expresses desire to enhance feelings of contentment; expresses desire to enhance relaxation; expresses desire to enhance resolution of complaints

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Client Satisfaction: Caring; Symptom Control; Comfort Status; Coping; Hope; Motivation; Pain Control; Participation in Health Care Decisions; Spiritual Health

Example NOC Outcomes with Indicators

Comfort Status as evidenced by the following indicators: Physical well-being/Symptom control/ Psychological well-being. (Rate the outcome and indicators of **Comfort Level:** 1 = not at all satisfied, 2 = somewhat satisfied, 3 = moderately satisfied, 4 = very satisfied, 5 = completely satisfied [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Assess current level of comfort as acceptable
- Express the need to achieve an enhanced level of comfort

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Identify strategies to enhance comfort
- Perform appropriate interventions as needed for increased comfort
- Evaluate the effectiveness of interventions at regular intervals
- Maintain an enhanced level of comfort when possible

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Calming Technique; Cutaneous Stimulation; Environmental Management: Comfort; Heat/Cold Application; Hope Inspiration; Humor; Meditation Facilitation; Music Therapy; Pain Management: Acute and Chronic; Presence; Guided Imagery; Massage; Relaxation Therapy; Spiritual Growth Facilitation; Therapeutic Play; Therapeutic Touch; Touch; Distraction

Example NIC Activities—Spiritual Growth Facilitation

Assist the client with identifying barriers and attitudes that hinder growth or self-discovery; Assist the client to explore beliefs as related to healing of the body, mind, and spirit; Model healthy relating and reasoning skills

Nursing Interventions and *Rationales*

- Assess clients' comfort needs and current level of comfort in various contexts, as outlined in Kolcaba's comfort theory and practice: physical, psychospiritual, sociocultural, and environmental. EBN: *By using the comfort theory's framework, the nurse can recognize the client's physical, psychosocial, sociocultural, and environmental needs; bringing these aspects into play will aid in identifying nursing problems and the necessary interventions that can be implemented to enrich the client's environment (Ng, 2017).*
- Educate clients about the various contexts of comfort and help them understand that enhanced comfort is a desirable, positive, and achievable goal. EBN: *According to Silveira Mendes et al (2016), nursing care should incorporate all aspects of the client's comfort needs and not just the physical, which are both expressed and unexpressed.*
- Enhance feelings of trust between the client and the health care provider to maintain an effective and therapeutic relationship. EBN: *Kornhaber et al (2016) found that the ability to deliver person-centered care is essential for nurses; connecting with clients therapeutically will augment positive health-related results.*
- Maintain an open and effective communication with clients and keep them informed about their health, their plan of care, and their environment. EBN: *By asking relevant questions, the nurse can first build trust with the client, but Price (2017) also maintains that as care evolves, it will be necessary for the nurse to continue to support the client's sense of psychological well-being.*
- Implement comfort rounds that regularly assess for clients' comfort needs. EBN: *Regular nurse–client contact advances client–nurse interactions and augments the early recognition of client comfort and safety needs (Sims et al, 2018).*
- Collaborate with other health care professionals, such as health care providers, pharmacists, social workers, chaplains, occupational and physical therapists, and dietitians, among others, in planning interventions that address comfort needs in various contexts: physical, psychospiritual, sociocultural, and environmental. EBN: *Kolcaba's comfort theory can be used as a guide for client care in offering uncomplicated and holistic standards that assist the nurse in recognizing clients' needs, developing interventions to satisfy those needs, assessing the outcomes of these interventions, and meeting goals of quality client and family care. These goals may also encompass discharge planning and follow-up with various health and spiritual providers (Boudiab & Kolcaba, 2015).*
- Educate clients about and encourage the use of various integrative therapies and modalities to provide options that enhance comfort, beyond the traditional plan of care.
  - Massage. EBN: *Zhao et al (2020)* noted that the use of massage therapy, alone or in combination with other nonpharmaceutical interventions (e.g., aromatherapy, calming music), can noticeably reduce symptoms of anxiety and agitation for clients with dementia.
  - Guided imagery. EBN: *Guided imagery is effective in relieving postoperative pain in adults (Álvarez-García & Yaban, 2020).*

- ❍ Mindfulness and mindfulness-based interventions. EBN: *Mindfulness-based stress reduction (MBSR) is a beneficial approach offering clients a plan for self-management that can be employed when challenged by the potential for stress and disease (El Aoufy et al, 2018).*
- ❍ Energy therapy or biofield therapy such as healing touch, therapeutic touch, and Reiki. EBN: *According to Mangione et al (2017), biofield practices that include healing touch and Reiki encourage relaxation, ease anxiety and stress, and positively complement mood.*
- ❍ Acupuncture and auricular acupuncture. EBN: *Faircloth (2015) stated that acupuncture and acupressure have been found to decrease apprehension preoperatively, reduce intraoperative anesthetic requirements, diminish postoperative discomfort, lower the occurrence of postoperative nausea and vomiting, and fortify the treatment of chronic pain management.*
- ❍ Aromatherapy. EB: *In their study of individuals exposed to the lemon grass scent, Costa Goes et al (2015) found that there was a reduction in anxiety and subjective stress within minutes of the aroma's administration.*
- ❍ Music. EBN: *Music, as a nursing intervention, has been shown to be beneficial in relieving clients' discomfort, apprehension, and distress (Waterworth & Rickson, 2017).*
- ❍ Other mind–body therapies such as meditation or yoga. EB: *Meditation is a strategy of self-care that offers potential usefulness in mental health situations, behavioral self-regulation, and integrative medical care (Burke et al, 2017).*

- ● Foster and instill hope in clients whenever possible. See the care plan for **Hopelessness**. EBN: *Fowler (2020) found, in her study of critical-care nurses and hope, that nurses can "assess, inspire, and evaluate hope."*
- ● Provide opportunities for and enhance spiritual care activities. EBN: *As spirituality has been acknowledged by numerous health care professionals as a vital component in health and healing, Hawthorne and Gordon (2020) state that holistic nursing care should then incorporate the assessment and response of clients' essential spiritual needs.*
- ▲ Enhance social support and family involvement. EBN: In their survey (based on Kolcaba's enhanced comfort theory) addressing family experiences, when a loved one is hospitalized in an intensive care unit, *Twohig et al (2015)* found that there was an elevated level of satisfaction among family members in all aspects of client care, including communication and the opportunity to be involved in decision-making.
- ▲ Promote participation in creative arts and activity programs. EB: *Adult education classes in creative arts were found to improve well-being by boosting mood and providing a feeling of belonging. It also supported members in developing self-confidence, in the development of new relationships, and in general, it encouraged more active lives (Pearce, 2017).*
- ▲ Encourage clients to use health information technology (HIT) as needed. EB: *In a European Union study, Internet users in the United Kingdom validated the concept that the Internet was a good option in gaining knowledge of self-care and care of others and was valuable in positive health care outcomes (Marton, 2015).*
- ● Evaluate the effectiveness of all comfort interventions at regular intervals and adjust therapies as necessary. EBN: *In a study by Coelho et al (2016), clients were asked how they sensed a feeling of comfort, and their responses included individualized care, symptom containment, need for a comfortable environment, and hope and relationships. Recognition of these needs gives the nurse the opportunity to construct personalized interventions that meet these needs as well as to evaluate and revise them as needed.*

Geriatric

- ● Refer to previously mentioned interventions for geriatric interventions.

Pediatric

- ● Assess and evaluate the child's level of comfort at frequent intervals. With assessment of pain in children, it is best to use input from the parents or a primary caregiver. EBN: *According to Shaw et al (2017), skillful communication with clients and families is necessary for proficient, personalized comfort care in the pediatric environment.*
- ● Skin-to-skin contact (SSC) in the comfort of newborns, especially those at risk. EBN: Newborn SSC practice is natural and instinctive and has been found to have positive effects on health outcomes and comfort, especially for at-risk newborns in low-support environments (Hubbard & Gattman, 2017).
- ● Encourage parental presence whenever possible. EBN: There is an increasing awareness by health care professionals that parents play a vital function in promoting the positive health outcomes of low-birth-weight and preterm infants (*Franck & O'Brien, 2019*).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Promote use of alternative comforting strategies such as positioning, presence, massage, spiritual care, music therapy, art therapy, and storytelling to enhance comfort when needed. EB: *In their study of comfort measures and sedation/analgesics used in pediatric intensive care units (PICUs), Guerra et al (2016) found that enhanced comfort care is offered through music, swaddling, pacifiers, television, and sucrose solutions.*
- Support the child's spirituality. EBN: It is becoming generally acknowledged that spiritual care for children with chronic illness is necessary to support them in dealing with their illness and/or disabilities (Bakker et al, 2018).

Multicultural

- Identify cultural beliefs, values, lifestyles, practices, and problem-solving strategies when assessing a client's comfort. EBN: *According to Moore (2017), it is a necessity for nurses to recognize that culture and language are the basis for the realization of health awareness and should make it a goal to work within the cultural perspective of the client.*
- Enhance cultural knowledge by actively seeking out information regarding different cultural and ethnic groups EBN: *As the multicultural population of the United States continues to expand, there is a growing need for outreach and culturally sensitive education that will better serve these communities (Sanchez Elminowski, 2015).*

▲ Recognize the impact of culture on communication styles and techniques EBN: *Livesay et al (2017) surmised that growing diversification of societies places increasing emphasis on the demand for culturally suitable communication, which both addresses the needs of the health care consumer and the provider.*

Home Care

- The nursing interventions described for Readiness for Enhanced **Comfort** may be used with clients in the home care setting. When needed, adaptations can be made to meet the needs of specific clients, families, and communities.

▲ Make appropriate referrals to other organizations or health care providers as needed to enhance comfort. EBN: *Nurses performing holistic assessments as the center of client care and then making appropriate referrals and providing beneficial health promotions, have made a noticeable improvement in the physical health outcomes for people with mental illness (Tranter & Robertson, 2019).*

▲ Promote an interdisciplinary (e.g., home care nurses, physicians, pharmacy) approach to home care. EBN: *Imhof et al (2016), in their study of nurse-led interdisciplinary team approach to palliative care, found that the nurse specialist was an important player in establishing and sustaining an interdisciplinary complex system of care.*

- Evaluate regularly if enhanced comfort is attainable in the home care setting. EB: *A study by Seow et al (2016) found that home care nurses provided comfort and support to cancer clients who wished to die at home and not in the hospital.*

Client/Family Teaching and Discharge Planning

- Teach client how to regularly assess levels of comfort.
- Instruct client that a variety of interventions may be needed at any given time to enhance comfort. EBN: *Health care professionals involved in home care should be proficient in medical technology to preserve a feeling of safety and allay fears in both clients and their caregivers (Munck & Sandgren, 2017).*

Readiness for Enhanced Communication

Domain 5 Perception/cognition Class 5 Communication

Stacey M. Carroll, PhD, APRN-BC and Suzanne White, DNP, RN, PHCNS-BC

NANDA-I

Definition

A pattern of exchanging information and ideas with others, which can be strengthened.

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Defining Characteristics

Expresses desire to enhance communication

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Communication; Communication: Expressive, Receptive

Example NOC Outcome with Indicators

Communication as evidenced by the following indicators: Use of spoken language/Use of written language/Acknowledgment of messages received/Exchanges messages accurately with others. (Rate the outcome and indicators of **Communication:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Express willingness to enhance communication
- Demonstrate ability to speak or write a language
- Form words, phrases, and language
- Express thoughts and feelings
- Use and interpret nonverbal cues appropriately
- Express satisfaction with ability to share information and ideas with others

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening; Communication Enhancement: Hearing Deficit; Communication Enhancement: Speech Deficit

Example NIC Activities—Communication Enhancement

Hearing Deficit
Listen attentively; Allow patient adequate time to process communication and respond; Verify what was said or written using patient's response before continuing

Nursing Interventions and *Rationales*

- Assess the client's health literacy level so information can be tailored accordingly. EBN: *The Rapid Estimate of Adult Literacy in Medicine–Short Form (REALM-SF) provides a quick, valid assessment (Nowak, 2019).*
- ▲ Provide resources for communication for those who are deaf or hard of hearing, ensuring applications are HIPAA compliant. For a comprehensive list of available resources, see http://connect-hear.com/.
- ▲ Refer clients with autism spectrum disorder (ASD) to augmentative and alternative communication (AAC) specialists for employment, as appropriate. EB: *Clients with ASD who used mobile AAC devices in their place of employment had increased communicative support and participation (Richardson et al, 2019).*
- ▲ Refer couples in maladjusted relationships for psychosocial intervention and social support to strengthen communication; consider nurse specialists. EB: *The Couple Communication Satisfaction Scale showed high levels of reliability across genders (Jones et al, 2018).*
- ▲ Encourage communication partner training. EB: *Unresponsive partner communication led to negative emotional responses in people with aphasia (Harmon et al, 2020).* **EB:** *Communication skills training of clients with traumatic brain injuries and their partners resulted in improved communication in both parties (Rietdijk et al, 2020).*
- Use social media as a means to facilitate communication. EB: *Individuals who use AAC methods may benefit from integration of social media to further enhance communication (Caron, 2016).*
- Teach clients mindfulness meditation. EB: *Mindfulness meditation enhanced language production in clients with aphasia (Dickinson et al, 2017).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

- Use photographs as a communication aid. EB: *Use of photographs during conversation resulted in people with aphasia talking more about the topic and staying on that topic (Ulmer et al, 2017).*
- Encourage clients with aphasia to join communication groups. EB: *Gavel Clubs, emphasizing public speaking and leadership skills, increased quality of communication life and communication confidence in clients with aphasia, regardless of aphasia severity (Plourde et al, 2019).*

▲ Use telephonic (with or without video) health care to promote communication, especially in areas with lower access or when infection control precautions are in place. EBN: *Registered nurses effectively practiced person-centered care, including communication and presence, in telehealth (Boström et al, 2020).* EB: *Telehealth was equivalent to in-person delivery of social communication training for people with traumatic brain injury and their communication partners (Rietdijk et al, 2020).*

▲ Refer transgender clients for voice therapy if the client desires voice modification. EB: *Voice therapy assisted transgender clients in adjusting their voice to match their identified gender (Smith, 2020).*

- See care plan for Impaired Verbal **Communication.**

Pediatric

- Use social media as appropriate. EB: *Russell et al (2016) identified social media as a method for pediatric communication having numerous benefits, including increasing accessibility, interactions with others, and access to information.*
- Implement a collaborative approach to communication. EBN: *McKean et al (2017) found that when practitioners embraced services and systems that enabled more fluid forms of collaboration, trust and reciprocity developed.*
- See care plan for Impaired Verbal **Communication.**

Geriatric

- Facilitate communication through reminiscence. EB: *Reminiscence improved cognitive abilities and social engagement in older adults (Shropshire, 2020).* EB: *Clients with dementia used life story work to communicate memories with others (O'Philbin et al, 2020).*

▲ Encourage group singing activities and music therapy interventions in clients with dementia. EB: *"Singing for the Brain" is a group singing activity developed by the Alzheimer's Society and the program resulted in increased social inclusiveness and improvements in relationships (Osman et al, 2016).*

- Encourage drawing by caregivers of clients with dementia. EBN: *Drawing by caregivers of clients with dementia enhanced the communication experience (McEvoy & Bellass, 2017).*
- See care plan for Impaired Verbal **Communication.**

Multicultural

- See care plan for Impaired Verbal **Communication.**

Home Care and Client/Family Teaching and Discharge Planning

- The interventions described previously may be used in home care, discharge planning, and client and family teaching.
- See care plan for Impaired Verbal **Communication.**

Impaired Verbal Communication

Domain 5 Perception/cognition Class 5 Communication

Stacey M. Carroll, PhD, APRN-BC and Suzanne White, DNP, RN, PHCNS-BC

NANDA-I

Definition

Decreased, delayed, or absent ability to receive, process, transmit, and/or use a system of symbols.

Defining Characteristics

Absence of eye contact; agraphia; alternative communication; anarthria; aphasia; augmentative communication; decline of speech productivity; decline of speech rate; decreased willingness to participate in social interaction; difficulty comprehending communication; difficulty establishing social interaction; difficulty maintaining communication; difficulty using body expressions; difficulty using facial expressions; difficulty with selective attention; displays negative emotions; dysarthria; dysgraphia; dyslalia; dysphonia; fatigued by conversation; impaired ability to speak; impaired ability to use body expressions; impaired ability to use facial expressions; inability to speak language of caregiver; inappropriate verbalization; obstinate refusal to speak; slurred speech

Related Factors

Altered self-concept; dyspnea; emotional lability; environmental constraints; inadequate stimulation; low self-esteem; perceived vulnerability; psychological barriers; values incongruent with cultural norms

At-Risk Population

Individuals facing physical barriers; individuals in the early postoperative period; individuals unable to verbalize; individuals with communication barriers; individuals without a significant other

Associated Conditions

Altered perception, developmental disabilities; flaccid facial paralysis; hemifacial spasm; motor neuron disease; neoplasms; neurocognitive disorders; oropharyngeal defect; peripheral nervous system diseases; psychotic disorders; respiratory muscle weakness; sialorrhea; speech disorders; tongue diseases; tracheostomy; treatment regimen; velopharyngeal insufficiency; vocal cord dysfunction

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Communication; Communication: Expressive, Receptive

C

Example NOC Outcome with Indicators

Communication as evidenced by the following indicators: Use of spoken and written language/Acknowledgment of messages received/Exchanges messages accurately with others. (Rate the outcome and indicators of **Communication:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Use effective communication techniques
- Use alternative methods of communication effectively
- Demonstrate congruency of verbal and nonverbal behavior
- Demonstrate understanding even if not able to speak
- Express desire for social interactions

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening; Communication Enhancement: Hearing Deficit; Communication Enhancement: Speech Deficit; Presence; Touch

Example NIC Activities—Communication Enhancement

Hearing Deficit
Listen attentively; Allow client adequate time to process communication and respond; Verify what was said or written using client's response before continuing

Nursing Interventions and *Rationales*

- Use a comprehensive nursing assessment to determine the language spoken, cultural considerations, satisfaction with communication, literacy level, cognitive level, and use of glasses and/or hearing aids; avoid making assumptions about clients' communication preferences. EB: *Asking specific assessment questions, including assessing client understanding, can garner more variable and useful responses from clients (Street & Mazor, 2017).* EB: *Clients want to be involved in decisions about their health through communication with providers (Ninnoni, 2019).*
- Determine client's own perception of communication difficulties and potential solutions, in accordance with the Healthy People 2030 goal to decrease the number of clients who report poor client–provider communication. EB: *The Communication Confidence Rating Scale for Aphasia (CCRSA) was used to measure self-reported communication confidence in clients with aphasia (Plourde et al, 2019).* EB: *The Healthcare Communication Distress Scale showed preliminary reliability and validity in assessing client distress with communication in healthcare (Lum et al, 2020).*
- Involve a familiar person when attempting to communicate with a client who has difficulty with communication, if accepted by the client. EB: *Training communication partners of clients with traumatic brain injury improved the communication experience of the client and family member (Togher et al, 2016).* EB: *Retaining valued relationships facilitated communication in people with dementia (Alsawy et al, 2017).*
- Listen carefully and validate verbal and nonverbal expressions particularly when dealing with pain and use appropriate scales for pain when appropriate. EBN: *The Pain Assessment Tool in Cognitively Impaired Elders showed preliminary reliability and validity for assessing nonverbal pain behaviors in African American and Caucasian nursing home residents with dementia (Richey et al, 2020).* EB: *The Revised Nonverbal Pain Scale and the Original Nonverbal Pain Scale both demonstrated reliability and validity for assessing pain in clients who are nonverbal and ventilated (Chookalayi et al, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Use communication programs to improve communication in clients who are nonvocal and mechanically ventilated. EB: *Implementing a program to facilitate communication with clients who are nonvocal significantly increased ease of communication scores (Trotta et al, 2020).*
- Be mindful of word choice when communicating with clients. EBN: *Using neutral and nonjudgmental terms facilitates respect and empowerment in vulnerable populations (Carroll, 2019).*
- Avoid ignoring the client with verbal impairment and place call light within reach of client who cannot verbally call for help, in order to promote safety and concern. EB: *Clients perceived being ignored when health professionals' nonverbal communication did not convey active presence (Timmerman et al, 2017).*
- Validate clients' feelings, focus on their strengths, and assist them in gaining confidence in identifying needs. EBN: *Viewing clients with communicative difficulties in a holistic manner cultivates empowering communication (Parsloe & Carroll, 2020).*
- Explain all health care procedures, be persistent in deciphering what the client is saying, and do not pretend to understand when the message is unclear. CEBN: *Persons who were nonvocal and ventilated appreciated persistence on the nurses' part with respect to being understood, found it bothersome when others pretended to understand them, and appreciated explanations from the nurse (Carroll, 2007).*

▲ Use an individualized and creative multiprofessional approach to augmentative and alternative communication (AAC) assistance and other communication interventions. EB: *Speech-language pathologists (SLPs) often introduce AAC measures, and the multiprofessional team needs to be aware of the client's attitude, socioeconomic status, and culture when choosing AAC (Moorcroft et al, 2019).* EB: *High-technology AAC use by those with intellectual and development disabilities and complex communication needs resulted in some positive effects on communication outcomes (Ganz et al, 2017).*

- Use consistent nursing staff for those with communication impairments. EB: *Among linguistically and culturally diverse clients with dementia, other communication methods (e.g., body language) along with spoken language can develop over time, indicating the importance of the continuity of providers (Strandroos & Antelius, 2017).*

▲ Consult communication specialists from various disciplines as appropriate. SLPs, audiologists, and translators provide comprehensive communication assistance for those with impaired communication. EBN: *Use of interpreter services increased clients' perception that their communication needs were met (Lopez-Bushnell et al, 2020).*

▲ When the client is having difficulty communicating, assess and refer for audiology consultation for hearing loss (American Academy of Audiology, 2021). Suspect hearing loss when:
  - ❍ Client frequently complains that people mumble and that others' speech is not clear.
  - ❍ Client often asks people to repeat what they said and hears only parts of conversations.
  - ❍ Client's friends or relatives state that the client does not seem to hear very well or plays the television or radio too loudly.
  - ❍ Client does not laugh at jokes because of missing too much of the story.
  - ❍ Client needs to ask others about the details of a meeting that the client attended.
  - ❍ Client cannot hear the doorbell or the telephone.
  - ❍ Client finds it easier to understand others when facing them, especially in a noisy environment.

- When communicating with a client with a hearing loss:
  - ❍ Obtain client's attention before speaking and face toward his or her unaffected side or better ear while allowing client to see the speaker's face at a reasonably close distance, provide sufficient light, do not stand in front of a window, use gestures as appropriate to aid in communication, do not raise voice or over enunciate, and minimize extraneous noise. *Correct positioning and an optimal listening environment increase the client's awareness of the interaction and enhance the client's ability to communicate. Light facing the speaker makes expressions and lip movements clearer whereas light behind the speaker causes glare, impeding visibility of the speaker's face (UCSF Health, 2020).*
  - ❍ Encourage the client to wear hearing aids, if appropriate. EB: *Hearing aids reduced communicative efforts of those with hearing loss and their communicative partners (Beechey et al, 2020).*
  - ❍ Remove masks if safe, or use see-through anti-fog masks to allow for visibility of the mouth and less muffling of sound which enhances communication. *For information on see-through masks, see www.amphl.org.*

Pediatric

- Observe behavioral communication cues in infants. EB: *Kupán et al (2017) found that infants' choice behavior is affected by the adult's presence or absence.*

C

- Identify and define at least two forms of augmentative and alternative communication modalities that may be used by children with significant disabilities. EB: *Drager et al (2019) found that augmentative and alternative communication with visual scene displays and Just In Time programming may be effective in increasing symbolic communication for students with severe developmental disability.* EB: *Pitt and Brumberg (2018) determined that brain–computer interfaces (BCIs) have the potential to provide an alternate modality for accessing augmentative and alternative communication for individuals with profound speech and motor impairments, including paralysis and akinetic mutism.*
- Teach children with severe disabilities functional communication skills. EB: *Quinn and Kidd (2019) found that symbolic play provides a rich context for the exchange and negotiation of meaning, and thus may contribute to the development of important skills underlying communicative development.*

▲ Refer children with primary speech and language delay/disorder for speech and language therapy interventions. EB: *McManus et al (2020) determined that early intervention is needed to improve integrated systems of care affecting primary care processes and coordination.*

Geriatric

- Be aware of nonverbal communication. EBN: *Older adults had both positive and negative responses to nurses' nonverbal communication (Wanko Keutchafo et al, 2020).*
- Perform hearing screenings and refer for hearing evaluations in accordance with Healthy People 2030 goal to encourage increasing both the proportion of older adults having hearing examination and the number of referrals for hearing evaluation and treatment. EBN: *Hearing loss was often missed during admission and nursing assessments of older adults, necessitating the increased use of screening measures (Mormer et al, 2020).* EB: *Simple screening procedures such as questioning about hearing loss, the finger-rub test, and the whisper test can be used for identification of hearing loss in older adults and referrals for evaluation (Strawbridge & Wallhagen, 2017).*
- Avoid use of "elderspeak," which is a speech style similar to baby talk. EB: *Avoiding elderspeak reduces resistiveness to care in clients with dementia (Zhang et al, 2020).* EB: *A brief communication training intervention resulted in lower use of elderspeak by staff and less resistiveness to care among clients with dementia (Williams et al, 2018).*
- Initiate communication with the client with dementia and give client time to respond, use eye contact, speak in shorter sentences, and use music. EBN: *The Verbal and Nonverbal Interaction Scale is valid and reliable and can assess sociable and unsociable communication in clients with dementia (Williams et al, 2017).* EB: *Using music in people with late stage dementia resulted in an increase in their nonverbal communication and quality of life (Clare et al, 2020).*

  Use touch, a therapeutic communication strategy, as appropriate. EBN: *Touch resulted in positive responses from older adults (Wanko Keutchafo et al, 2020).*

Multicultural

▲ Attend to the meaning of a culture's nonverbal communication modes, such as eye contact, facial expression, touch, and body language. EB: *Attending to nonverbal interactions facilitated communication among culturally and linguistically diverse clients with dementia (Strandroos & Antelius, 2017).*

▲ Use instruments to determine culturally appropriate therapeutic communication. EBN: *The Global Interprofessional Therapeutic Communication Scale measures culturally appropriate client–provider communication and has demonstrated preliminary reliability and validity (Campbell & Aredes, 2019).*

▲ Assess for the influence of cultural beliefs, norms, and values on the client's communication process. EBN: *Misunderstandings and conflicts can arise when there is a difference in language and/or culture of the provider and client (Crawford et al., 2017).*

▲ Assess personal space needs, acceptable communication styles, acceptable body language, interpretation of eye contact, perception of touch, and use of paraverbal modes when communicating with the client. EB: *When caring for clients of varied ethnicities and languages, nurses used nonverbal means such as pointing, smiling, modeling, and touch to convey information and calm clients in long-term care (Small et al, 2015).*

▲ Assess how language barriers contribute to health disparities among ethnic and racial minorities. EBN: *Client safety was compromised when language barriers were present (van Rosse et al, 2016).*

▲ The Office of Minority Health of the U.S. Department of Health and Human Services' national standards on culturally and linguistically appropriate services (CLAS) in health care should be used. EB: *CLAS standards aim to improve health care quality and advance health equity by establishing a framework for*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

organizations to serve the nation's increasingly diverse communities (Office of Minority Health, U.S. Dept. of Health & Human Services, n.d.).

Home Care

- The interventions described previously may be adapted for home care use.

Client/Family Teaching and Discharge Planning

▲ Refer the client to a SLP or audiologist. Audiological assessment quantifies and qualifies hearing in terms of the degree of hearing loss, the type of hearing loss, and the configuration of the hearing loss. Once a particular hearing loss has been identified, a treatment and management plan can be put into place by an SLP. EB: *Audiological services can improve communication in clients with dementia and hearing loss (Mamo et al, 2017).* EB: *SLPs often introduce AAC to those with communication needs but this needs to be done in collaboration with a multiprofessional team (Moorcroft et al, 2019).*

C

Acute Confusion

Domain 5 Perception/cognition Class 4 Cognition

Kimberly S. Meyer, PhD, ACNP-BC, CNRN

NANDA-I

Definition

Reversible disturbances of consciousness, attention, cognition, and perception that develop over a short period of time, and which last less than 3 months.

Defining Characteristics

Altered psychomotor functioning; difficulty initiating goal-directed behavior; difficulty initiating purposeful behavior; hallucinations; inadequate follow-through with goal-directed behavior; inadequate follow-through with purposeful behavior; misperception; neurobehavioral manifestations; psychomotor agitation

Related Factors

Altered in sleep-wake cycle; dehydration; impaired physical mobility, inappropriate use of physical restraint; malnutrition, pain, sensory deprivation; substance misuse; urinary retention

At-Risk Population

Individuals aged ≥60 years; individuals with history of cerebral vascular accident; men

Associated Conditions

Decreased level of consciousness; impaired metabolism; infections; neurocognitive disorders; pharmaceutical preparations

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Improved Cognitive Function; Improved Sensory Perception; Improved Thought Processes

Example NOC Outcome with Indicators

Cognition as evidenced by the following indicators: Communication clear for age/Comprehension of the meaning of situations/Attentiveness/Concentration/Cognitive orientation. (Rate the outcome and indicators of **Cognition:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate restoration of cognitive status to baseline
- Be oriented to time, place, and person
- Demonstrate appropriate motor behavior
- Maintain functional capacity
- Remain free from injury

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Delirium Management; Delusion Management

Example NIC Activities—Delirium Management

Inform client of time, place, and person as needed; Provide information slowly and in small doses with frequent rest periods; Ensure client has appropriate assistive sensory devices (e.g., glasses, hearing aids)

Nursing Interventions and *Rationales*

- Recognize that delirium is characterized by an acute onset, a fluctuating course, inattention, and disordered thinking. EBN: *Delirium is often underrecognized and can have significant adverse consequences for clients, including increase in length of hospitalization, cognitive deficits, and increased mortality. Common conditions that place clients at risk for delirium include advanced age, pain, dehydration, infections, metabolic disturbances, medication use/withdrawal, mechanical ventilation, invasive lines, and surgery (Xing et al, 2019; Wilson et al, 2020).*
- Use a validated screening tool to assess for delirium. EBN: *The Confusion Assessment Method (CAM) and the Delirium Observation Screening (DOS) Scale are brief evaluations that can be used for the assessment of delirium in most clients. The CAM-ICU can be used to screen for delirium in critically ill clients (Ho et al, 2020).*
- Identify the three distinct types of delirium: hyperactive (easy to recognize), hypoactive (commonly missed), and mixed (the most commonly occurring) (Wilson et al, 2020).
  - Hyperactive: delirium characterized by restlessness, agitation, irritability, hypervigilance, hallucinations, and delusions; client may be combative or may attempt to remove tubes, lines.
  - Hypoactive: delirium characterized by decreased motor activity, decreased vocalization, detachment, apathy, lethargy, somnolence, reduced awareness of surroundings, and confusion.
  - Mixed: delirium characterized by the client fluctuating between periods of hyperactivity and agitation and hypoactivity and sedation. EB: *Delirium is underrecognized by both medical and nursing staff, particularly the hypoactive form (Morandi et al, 2020).*
- Perform a comprehensive nursing assessment and mental status examination that includes the following assessment (Solà-Miravete et al, 2018):
  - History from a reliable source that documents an acute and fluctuating change in cognitive function, attention, and behavior from baseline.

C

- ❍ Cognition as evidenced by level of consciousness; orientation to time, person, and place; thought process (thinking may be disorganized, distorted, fragmented, slow, or accelerated with delirium; conversation may be irrelevant or rambling); and content (perceptual disturbances such as visual, auditory, or tactile delusions or hallucinations).
- ❍ Level of attention (may be decreased or may fluctuate with delirium; may be unable to focus, shift, or sustain attention; may be easily distracted or may be hypervigilant).
- ❍ Behavior characteristics and level of psychomotor behavior (activity may be increased or decreased and may include restlessness, finger tapping, picking at bedclothes, changing position frequently, spastic movements or tremors, or decreased psychomotor activity such as sluggishness, staring into space, remaining in the same position for prolonged periods).
- ❍ Level of consciousness (may be easily aroused, lethargic, drowsy, difficult to arouse, unarousable, hyperalert, easily startled, and overly sensitive to stimuli).
- ❍ Mood and affect (may be paranoid or fearful with delirium; may have rapid mood swings).
- ❍ Insight and judgment (may be impaired).
- ❍ Memory (recent and immediate memory is impaired with delirium; unable to register new information).
- ❍ Language (may have rapid, rambling, slurred, incoherent speech).
- ❍ Altered sleep-wake cycle (insomnia, excessive daytime sleepiness).
- ❍ Nutrition status.
- ❍ Bowel and bladder elimination habits.
- ❍ Mobility status.

EBN: *Establishing the client's baseline mental status by obtaining an accurate history and performing a brief cognitive assessment observing for key diagnostic criteria are important in the diagnosis of delirium (Solà-Miravete et al, 2018). Encourage family presence to facilitate assessment of subtle changes in cognition (Devlin et al, 2018).*

- ● Identify predisposing factors that may precede the development of delirium: dementia, cognitive impairment, functional impairment, visual impairment, alcohol misuse, multiple comorbidities, severe illness, history of transient ischemic attack or stroke, depression, history of delirium, and advanced age (older than 65). EB: *Delirium is a multifactorial syndrome most commonly seen in the intensive care unit (ICU), palliative care, and postoperative settings; identification of risk factors is important for prevention (Devlin et al, 2018).*
- ● Surgical procedures increase the risk of delirium postoperatively. EB: *Assess the client for risk factors and implement interventions to reorient client postoperatively. Effectively treat pain and anxiety with the lowest effective dose. Avoid benzodiazepine agents if possible (Devlin et al, 2018).*
- ● Identify iatrogenic factors that may precede the development of delirium, especially for individuals with predisposing factors: use of restraints, indwelling bladder catheter, metabolic disturbances, polypharmacy, pain, infection, dehydration, blood loss, constipation, electrolyte imbalances, immobility, general anesthesia, mechanical ventilation, hospital admission for fractures or hip surgery, anticholinergic medications, anxiety, sleep deprivation, lack of use of vision and/or hearing aids, and environmental factors. EB: *Prevention of delirium needs to remain a high priority in light of frequency of occurrence, high treatment costs, longer hospital length of stay, higher rates of functional decline and resultant institutional care, and greater mortality; delirium may persist and lead to long-term cognitive decline (Davidson et al, 2015).*
- ● Facilitate appropriate extended visitation for clients at risk of delirium. EBN: *Extended visitation is associated with decreased incidence of delirium and shorter length of stay (Liang et al, 2021). In the absence of family availability, simulated presence using prerecorded video or audio messages may decrease agitation (Waszynski et al, 2018).*
- ▲ Assess for and report possible physiological alterations (e.g., sepsis, hypoglycemia, hypoxia, hypotension, infection, changes in temperature, fluid and electrolyte imbalance, use of medications with known cognitive and psychotropic side effects). CEB: *Systemic disturbances, including immunological, metabolic, neuroinflammatory, endocrinological, and neurological factors, lead to alterations in neurotransmitter synthesis and availability, which leads to delirium (Maldonado, 2013).*
  - ❍ Treat the underlying risk factors or the causes of delirium in collaboration with the health care team: establish/maintain normal fluid and electrolyte balance, normal body temperature, normal oxygenation (if the client experiences low oxygen saturation, deliver supplemental oxygen), normal blood glucose levels, and normal blood pressure, and address malnutrition and anemia. EB: *Early recognition of risk factors may help to prevent the negative sequelae of delirium (Burry et al., 2019).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- ❍ Monitor for any trends occurring in these manifestations, including laboratory tests. EB: *Careful monitoring of laboratory tests assessing for metabolic abnormities is important to identify the potential etiological factors for delirium (Davidson et al, 2015).*

▲ Conduct a medication review and eliminate unnecessary medications; potentially inappropriate medications for older adults at risk for delirium include anticholinergics, benzodiazepines, corticosteroids, H_2 receptor antagonists, sedative hypnotics, and tricyclic antidepressants (American Geriatrics Society, 2015). EB: *Polypharmacy is associated with delirium, and a elimination of high-risk medications improves agitation and cognitive function (Aloisi et al, 2019).*

▲ Recognize that delirium is frequently treated with antipsychotic medications or sedatives; if there is no other way to keep the client safe, administer these medications cautiously, as ordered, while monitoring for medication side effects. EB: *Studies show that routine use of antipsychotic medications does not decrease the duration and severity of delirium and increases the risk of cardiac side effects (Nikooie et al, 2019).*

- Locate at risk-clients in private (single-bed) rooms when possible. EB: *Studies in the long-term care population suggest that the incidence of delirium is decreased when there is no roommate (Blandfort et al, 2020).*
- Identify, evaluate, and treat pain quickly and adequately (see care plans for Acute **Pain** or Chronic **Pain**). EB: *Untreated pain is a potential cause of delirium (Blair et al, 2019; Daoust et al, 2020). The use of nonopioid analgesia (acetaminophen, antiinflammatory medications) reduces the need for opiates, continuous observation, and the development of delirium (Connolly et al, 2020).*
- Facilitate sleep hygiene. Establish day/night routines and plan care to allow for appropriate sleep-wake cycles (Lu et al, 2019). EBN: *The use of ear plugs and eye masks may improve sleep and decrease the risk of delirium (Hu et al, 2015; Reznik & Slooter, 2019).* EB: *Administration of melatonin is associated with reduced risk of delirium in at-risk ICU and surgical clients (Baumgartner et al, 2019; Campbell et al, 2019).*
- Promote regulation of bowel and bladder function; use bladder scanning to identify retention, avoid prolonged insertion of urinary catheters, and remove catheters as soon as possible (Bounds et al, 2016).
- Ensure adequate nutritional and fluid intake. EB: *Malnutrition is significantly associated with delirium. Attending to correct levels of B vitamins, antioxidants, glucose, water, and lipids may lead to resolution of delirium (Rosted et al, 2018).*
- Promote early mobilization and rehabilitation in a progressive manner. EB: *Early, aggressive mobilization is associated with decreased incidence of delirium (Liang et al, 2021).*
- Promote continuity of care; avoid frequent changes in staff and surroundings. EB: *Changes may contribute to feelings of disorientation and confusion (Mazur et al, 2016).*
- Facilitate appropriate sensory input by having clients use aids (e.g., glasses, hearing aids, dentures) as needed; check for impacted ear wax. EB: *Delirium can be addressed with nonpharmacological interventions, such as decreasing sensory impairment (Javedan & Tulebaev, 2014; Burry et al, 2019) or avoiding sensory overload for clients with agitation.* EB: *A systematic review of interventions to help reduce delirium risk included multicomponent interventions, such as encouraging use of vision and hearing aids, and may assist in the prevention of delirium in individuals who are not cognitively impaired (Trogrlić et al, 2015).*
- Modulate sensory exposure; eliminate excessive noise, use appropriate lighting based on the time of day, and establish a calm environment.
- Provide cognitive stimulation through conversation about current events, viewpoints, and relationships and encourage reminiscence or word games. EBN: *Daily cognitive stimulation can prevent cognitive decline and promote cognitive recovery (Trogrlić et al, 2015).*
- Provide reality orientation, including identifying self by name at each encounter with the client, calling the client by their preferred name, and the gentle use of orientation techniques; when reorientation is not effective, use distraction. Gently correct misperceptions. EB: *Efforts to reorient may agitate some clients; changing the subject may help calm the client (Davidson et al, 2015; Trogrlić et al, 2015).*
- Provide clocks and calendars, update dry erase white boards each shift, encourage family to visit regularly and to bring familiar objects from home, such as family photos or an afghan. EB: *Persons at risk for delirium should be provided clocks and calendars that are easily visible; family and friends may help with reorientation (Bannon et al, 2016).*
- Use gentle, caring communication; provide reassurance of safety; and give simple explanations of procedures.
- Provide supportive nursing care, including meeting basic needs, such as feeding, regular toileting, and ensuring adequate hydration; closely observe behaviors that provide clues as to what might be distressing the client. Delirious clients are unable to care for themselves because of their confusion. EB: *Understanding and anticipating behaviors promotes client comfort and safety (Faught, 2014).*

- If clients know that they are not thinking clearly, acknowledge the concern. Fear is frequently experienced by people with delirium. EB: *Confusion is frightening; the memory of the delirium can be distressing to clients and families (Bannon et al, 2016).*

Critical Care

- Recognize admission risk factors for delirium. EB: *ICU clients are at increased risk for delirium because of greater use of sedatives, analgesics, severity of illness, age, infection, multiorgan failure, sleep deprivation, surgery, fracture, restraint use, immobility, tubes, catheters, hypovolemia, polypharmacy, malnutrition, electrolyte imbalance, and stroke (Devlin et al, 2018).*
- Assess level of arousal using the Richmond Agitation Sedation Scale (RASS); clients receiving a score of −5 to −4 are comatose and unable to be assessed for delirium. CEB: *Establishing level of arousal before using the CAM for the ICU (CAM-ICU) decreases the incidence of inappropriate "unable to assess" (UTA) ratings on the CAM-ICU; it was found that noncomatose clients were inappropriately determined to be UTA (Swan, 2014).*
- Assess for pain every 2 to 3 hours or more frequently as needed with a standardized assessment tool, which includes either a numerical rating scale or one with behavioral indicators, such as the Behavioral Pain Scale (BPS) or Critical Care Pain Observation Tool (CPOT). EB: *Behavioral pain scales provide reliable assessments in critically ill clients (Bouajram et al, 2020).* EBN: *Uncontrolled pain is associated with a threefold increase in the development of delirium (Daoust et al, 2020).*

▲ Incorporate the Awakening and Breathing Coordination, Delirium Monitoring and Management, and Early Mobility (ABCDE) ICU delirium and weakness prevention bundle in conjunction with the interdisciplinary team. EB: *Implementation of the ABCDE bundle leads to fewer incidence of ICU delirium and short durations of delirium (Bounds et al, 2016).*

- ❍ Assess safety and implementation of a spontaneous awakening trial (SAT) using an established protocol. EB: Daily interruption of sedation may be beneficial when it results in a reduced total dose of sedative administered; minimizing the depth and duration of sedation is beneficial for reducing delirium (*Bounds et al, 2016*).
- ❍ Assess sedation and agitation level using a valid and reliable tool; titrate sedation to target sedation level. EB: Sedatives and analgesics prescribed to improve client–ventilator dyssynchrony and treat anxiety and pain may precipitate delirium (*Davidson et al, 2015*).

Geriatric

- The interventions described previously are relevant to the geriatric client.
- Recognize that delirium may be superimposed on dementia; the nurse must be aware of the client's baseline cognitive function. EB: *Dementia increases the risk and severity of delirium, and current research suggests delirium is an independent risk for subsequent dementia (Parrish, 2019).*
- Understand that delirium is common in frail, older adults and leads to increased lengths of stay and mortality. EBN: *Delirium is underrecognized in older adults but routine screening improves identification and treatment (Geriatric Medicine Research Collaborative, 2019).*
- Provide feeding assistance as needed. See care plan for Imbalanced **Nutrition:** Less than Body Requirements. EB: *Modified food consistencies and nutritional supplements can improve nutritional status and decrease development of delirium in older adults (Volkert et al, 2019).*
- Promote adequate hydration; keep a glass of water within easy reach of the client and offer fluids frequently. EBN: *Older adults are at high risk for dehydration (Volkert et al, 2019).*
- Avoid use of restraints; remove all nonessential equipment such as telemetry, blood pressure cuffs, catheters, and intravenous lines as soon as possible. EBN: *The use of restraints contributes to the development of delirium and posttraumatic stress disorder in critically ill clients (Franks et al, 2021).*
- Consider use of music to decrease the development of delirium, especially in surgical clients. EB: *Listening to music has been found to decrease delirium during acute hospitalization of older clients (Cheong et al, 2016).*

▲ Assess risk for falls and implement fall prevention strategies. EB: *Falls are an independent predictor of delirium-inducing hospitalizations and a consequence of delirium in the hospitalized client (Mazur et al, 2016).*

▲ Determine whether the client is nourished; watch for protein-calorie malnutrition. Consult with health care provider or dietitian as needed. EB: *Malnutrition is significantly associated with delirium. Attending to*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

correct levels of B vitamins, antioxidants, glucose, water, and lipids may lead to resolution of delirium (Rosted et al, 2018).

- Explain hospital routines and procedures slowly and in simple terms; repeat information as necessary.
- Educate family members about delirium assessment and strategies to use to prevent and lessen delirium. EBN: *Delirium increases caregiver burden (Fong et al, 2019).*

Home Care

- The interventions described previously are relevant to home care use.
- Assess and monitor for acute changes in cognition and behavior.
- Recognize that delirium is reversible but can contribute to early cognitive decline in many clients (Goldberg et al, 2020).
- Avoid preconceptions about the source of acute confusion; assess each occurrence on the basis of available evidence.

▲ Institute case management of frail elderly clients to support continued independent living if possible once delirium has resolved.

Client/Family Teaching and Discharge Planning

- Teach the family to recognize signs of early confusion and seek medical help.
- Counsel the client and family regarding the management of delirium and its sequelae. Increased care requirements at discharge may be needed for clients who have experienced delirium. EB: *Frailty and delirium can lead to functional decline and institutionalization (Geriatric Medicine Research Collaborative, 2019; Goldberg et al, 2020).*

Chronic Confusion

Domain 5 Perception/cognition Class 4 Cognition

Linda J. Hassler, DNP, RN, GCNS-BC, FGNLA, Philemon Tedros, BSN, RN, and Olga F. Jarrín, PhD, RN

NANDA-I

Definition

Irreversible, progressive, insidious disturbances of consciousness, attention, cognition, and perception, which last more than 3 months.

Defining Characteristics

Altered personality; difficulty retrieving information when speaking; difficulty with decision-making; impaired executive functioning skills; impaired psychosocial functioning; inability to perform at least one daily activity; incoherent speech; long-term memory loss; marked change in behavior; short-term memory loss

Related Factors

Chronic sorrow; sedentary lifestyle; substance misuse

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

At-Risk Population

Individuals aged ≥60 years

Associated Conditions

Human immunodeficiency virus infections; mental disorders; neurocognitive disorders; stroke

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Cognition; Cognitive Orientation; Agitation Level; Comfort Status; Dementia Level; Dementia Management; Social Support

Example NOC Outcome with Indicators

Cognition as evidenced by the following indicators: Cognitive orientation/Communicates clearly for age/Comprehends the meaning of situations/Attentiveness/Concentration. (Rate the outcome and indicators of **Cognition:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain content and free from harm
- Function at maximal cognitive level
- Participate in activities of daily living at the maximum of functional ability
- Have minimal episodes of agitation (agitation occurs in up to 70% of clients with dementia)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Dementia Management; Environmental Management; Surveillance: Safety; Validation Therapy

Example NIC Activities—Dementia Management

Use distraction rather than confrontation to manage behavior; Give one simple direction at a time

Nursing Interventions and *Rationales*

Note: Nursing science has a rich history of conceptualizing behavioral and psychological symptoms of dementia (BPSD), which include delusions, hallucinations, misidentification of depression, sleeplessness, anxiety, physical aggression, wandering, restlessness, agitation, pacing, screaming, culturally inappropriate behavior, sexual disinhibition, crying, cursing, apathy, repetitive questioning, and shadowing (stalking), as expressions of unmet pathophysiological and psychological needs related to environmental and caregiver factors (Kolanowski et al, 2017).

- Assess for BPSD using the BEHAVE-AD or Neuropsychiatry Inventory (NPI-Q), and determine cause(s) of symptoms, which may include changes in the environment, caregiver, or routine; demands to perform beyond capacity; multiple competing stimuli, including discomfort. EBN: *Agitated behaviors can be an expression of a need that is not being met; needs assessment is facilitated through methods to enhance communication so that needs may be expressed (Kolanowski et al, 2017).*
- Assess the client for delirium (physiological causes of delirium include acute hypoxia, pain, medication effects, malnutrition, and infections such as urinary tract infection, fatigue, electrolyte disturbances, constipation, and urinary retention). EB: *Delirium is a medical emergency that can often be confused for chronic confusion and lead to increased mortality/morbidity rates, thus screening for delirium superimposed on dementia is fundamental to client safety (Steensma et al, 2019).*
- If the client is suspected of delirium (presenting as inattention, and impaired arousal or vigilance), initiate three-part delirium screener, which includes questions: "What are the days of the week backward?" and

"What type of place is this?" If either question is incorrect or the client appears sleepy proceed to diagnostic delirium testing such as the Confusion Assessment Method (CAM). EB: *Delirium superimposed on dementia is a common clinical syndrome in hospital and institutional settings that often results in poor outcomes (Morandi et al, 2017).*

- Assess the client for signs of depression and anxiety (including sadness, irritability, agitation, somatic complaints, tension, loss of concentration, insomnia, poor appetite, apathy, flat affect, and withdrawn behavior) with an instrument appropriate for the cognitive level. EB: *The Cornell Scale for Depression in Dementia (CSDD) and Hamilton Depression Rating Scale (HDRS) have the highest sensitivity for screening clients with dementia (Goodarzi et al, 2017). The Geriatric Anxiety Inventory (GAI), Hospital Anxiety and Depression Scale (HADS-A), and Rating Anxiety in Dementia (RAID) scale are reliable and valid instruments for identifying and measuring anxiety in dementia (Creighton et al, 2019).*
- Assess for pain, including pain with movement, using a method appropriate to the client's level of cognition. EBN: *Pain assessment tools appropriate for client's living with cognitive impairments include the Pain Assessment in Advanced Dementia Scale (PAINAD) (Masman et al, 2018) and the Rotterdam Elderly Pain Observation Scale (REPOS) for noncommunicative clients (Boerlage et al, 2019).*
- Begin each interaction with the client calmly and empathetically, maintain eye contact, identify yourself, and call the client by their name; talk slowly, keep communication simple, give clear choices, and one-step instructions; if indicated, use gestures, prompts, cues, or visual aids. CEB: *These communication techniques assist in focusing attention, incorporate nonverbal means of communication, simplify memory demands, compensate for cognitive slowing, and assist with retrieval and comprehension (Feil & de Klerk-Rubin, 2012).*
- To promote completion of activity of daily living tasks, focus on what the client can still do (e.g., comb their hair, brush their teeth), as opposed to what they cannot do. Using a hand-under-hand technique, a caregiver can guide the client to complete tasks with less challenging behaviors exhibited, giving the client a sense of independence and completion of a task. EB: *By focusing on the retained skills, the caregiver is better able to accomplish other tasks and establish positive relationships between the client and caregiver (Batchelor-Murphy et al, 2015; Snow, 2019).*
- Promote person-centered care, which includes getting to know the unique and complete person, recognizing/accepting the person's reality, supporting their ongoing opportunities for meaningful engagement, and evaluating care practices regularly. EBN: *Understanding the individual's past and sharing memories enhances communication and client and staff satisfaction (Scales et al, 2018).*
- Obtain information about the client's life history, interests, routines, needs, and preferences from the family or significant others to plan care and facilitate reminiscence and validation therapy; collaborate with family members to engage in reminiscence using personal photographs and belongings to stimulate memories and improve sense of self. CEB: *When more recent memory fails, earlier memories are retrieved to restore balance; when eyesight fails, the mind's eye is used to see; when hearing goes, sounds from the past are heard (Feil & de Klerk-Rubin, 2012).*
- Utilize validation therapy techniques to meet clients where they are in their mind; instead of correcting their thoughts, guide them through the reminiscence of that thought. CEB: *Painful feelings that are expressed, acknowledged, and validated by a trusted listener will diminish, and those that are ignored or suppressed will gain strength; decreasing stress of both the care recipient and the family/caregiver (Feil & de Klerk-Rubin, 2012).*
- Facilitate the use of music therapy via activities staff, or electronic sources (e.g., Amazon Echo/Alexa and Google Home); identify the client's music preferences and interview family members if necessary. EB: *Music therapy is beneficial and improves behavior disorders, anxiety, depression, and agitation in people living with dementia (Moreno-Morales et al, 2020).*
- Use multisensory stimulation (e.g., exercise, nature, arts, group activities, music, aromas) to improve mood, behavior, and quality of life; engage assistance of volunteers and family caregivers in one-on-one activities. EB: *Multisensory interventions can improve mood, behaviors, and quality of life, particularly when a personalized approach is taken. Do not correct their thoughts, but guide, when cognitive stimulation is combined with recreational activities, occupational therapy, and physical exercise (Zucchella et al, 2018; Cheng et al, 2019).*
- Promote regular, supervised physical activity and exercise. EB: *Regular physical exercise is recommended for all adults and may improve physical and mental health, reduce frailty, and improve cognitive function (Groot, 2016; Zucchella et al, 2018).*
- Provide opportunities for contact with nature gardens or nature-based stimuli, such as facilitating time spent outdoors with a safe walking path or indoor gardening. EBN: *Improvements in mood among clients*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

with dementia were associated with exposures to nature of relatively short duration (Scales et al, 2018; White et al, 2018).

- Facilitate the use of doll therapy for clients with advanced dementia and challenging dementia related behaviors. EB: *Doll therapy is associated with reducing cognitive, behavioral, and emotional symptoms of dementia; improving overall well-being; and the ability to relate with an external environment (Ng et al, 2017).*
- Provide pet therapy and other animal-assisted activities when possible. EBN: *Animal-assisted activities and interventions (including use of centrally located aquariums) showed a strong positive effect on social behaviors, physical activity, and dietary intake in dementia clients and a positive effect on agitation/aggression and quality of life (Scales et al, 2018; Yakimicki et al, 2019).*
- Use individual or group reminiscence therapy. EBN: *Reminiscence therapy can positively affect quality of life, attitudes toward old age, and symptoms of depression in elderly adults with cognitive impairment (Scales et al, 2018).*
- Use an environmental audit tool to evaluate and optimize the living environment in group home and assisted living facilities (e.g., provide unobtrusive safety features, reduce unnecessary stimulation, enhance useful stimulation, provide wayfinding cues, and encourage safe wandering). EB: *Moderate evidence supports environmental design, noise/sound and light regulation, and the use of cognitively stimulating activity stations (such as folding towels or socks and setting the table) and memory boxes (with personal photos and mementos) to support well-being, daytime activity, nighttime sleep, and wayfinding (Jensen & Padilla, 2017). The Built Environment Assessment Tool (BEAT-D) is a free app for iOS and Google/Android that includes original versions of the Environmental Assessment Tool (EAT and EAT-HC).*
- Use appropriate lighting to support regulation of sleep-wake patterns and associated behavioral issues. EB: *Ambient lighting and bright light therapy interventions encourage proper sleep-wake cycles and improve sleep efficiency in persons with dementia and their caregivers, and may help prevent sundowning (confusion in late afternoon and evening) (Figueiro et al, 2019).*
- Provide the client and family information regarding advance directives, palliative and hospice care options, and discuss/document goals of care in the early stages of illness when further cognitive decline is anticipated. EB: *Discussion of delicate and important end-of-life issues should be discussed with clients early in the course of their illness, when decision-making capacity is less likely to be impaired, so that goals of care may more accurately reflect their true personal preferences (Abu Snineh et al, 2017).* EBN: *Advantages of advanced care planning with dementia include increased communication and documentation about end-of-life care preferences; increased concordance between care preferences documented and provided; and lower rates of unwanted, burdensome treatments at end of life (Kim et al, 2015).*
- Refer to the care plans for Impaired **Memory, Wandering,** Feeding **Self-Care** Deficit, Dressing **Self-Care** Deficit, Toileting **Self-Care** Deficit, and Bathing **Self-Care** Deficit as needed.

Geriatric

Note: All interventions are appropriate for geriatric clients.

Multicultural

- Provide culturally and linguistically appropriate care. EB: *Linguistic and cultural isolation may cause or worsen agitation in people living with dementia (Cooper et al, 2018).*
- Facilitate cultural congruity, defined as the match of the client's cultural values, preferences (language, food, music, customs), and traditions within the care environment, which may include companion care, adult day care, board and care homes, or nursing homes, including state veterans' homes. EB: *Culturally congruent care is associated with greater satisfaction, well-being, social stimulation, and happiness (Martin et al, 2019; Richardson et al, 2019).*
- Assess for the influence of cultural beliefs, norms, and values on the client and the family's understanding of chronic confusion or dementia; assist the family or caregiver in identifying and accessing available social services or other supportive services. EB: *In some cultures, traditional family caregiving (which may be the responsibility of an adult child) is both an obligation and provided from one's heart, which may complicate discussions regarding topics of caregiver role strain, caregiver burnout, or decisions related to use of nursing home level care (Richardson et al, 2019; Yaghmour et al, 2019).*

Home Care

- The interventions described previously may be adapted for home care use.

- Provide education and support to the family regarding effective communication, home safety, fall prevention, engagement in meaningful activities, ways to manage cognitive and behavioral changes, and comprehensive health care for both client and caregiver(s), including screening for depression and caregiver role strain. EB: *Among clients with mild-to-moderate dementia living in the community, a multimodal occupational therapy approach (including cognitive and behavioral interventions for clients and their caregivers) was effective in improving clients' ability to participate in activities of daily living and reducing caregiver burden (Zucchella et al, 2018).*
- Provide information about respite care to family caregivers. EB: *Although many caregivers report that they derive significant emotional and spiritual rewards from their caregiving role, many also experience physical and emotional problems directly related to the stress and demands of daily care. Caregiver resilience can be enhanced through the use of respite programs, including day care, overnight respite, support groups, and counseling services (Roberts & Struckmeyer, 2018).*
- Refer to the care plans for Feeding **Self-Care Deficit;** Dressing **Self-Care** Deficit; Toileting **Self-Care** Deficit; Bathing **Self-Care** Deficit; and **Caregiver Role Strain** as needed.

Client/Family Teaching and Discharge Planning

- In the client's early stages of dementia, provide the caregiver with information on illness processes, needed care, available services, role changes, and importance of advance directives discussion; facilitate family cohesion. EBN: *Education provided to caregivers early in the disease trajectory may assist them to anticipate care needs and role changes and to facilitate involving the individual with dementia in care decisions (Kim et al, 2015; Abu Snineh et al, 2017).*
- Provide education and support to the family regarding effective communication, home safety, fall prevention, engagement in meaningful activities, ways to manage cognitive and behavioral changes, and comprehensive health care, including screening for depression. Be prepared to offer support and information to family members who also live at a distance. EB: *The need for care, services, and support for individuals in the community with dementia and their caregivers is often unmet; evaluation and diagnosis of dementia, personal and home safety, physical and mental health care, advanced care planning, and legal issues are needs that should be addressed (Roberts & Struckmeyer, 2018).*
- Refer for home care services before discharge as needed.

Risk for Acute Confusion

Domain 5 Perception/cognition Class 4 Cognition

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to reversible disturbances of consciousness, attention, cognition, and perception that develop over a short period of time, which may compromise health.

Risk Factors

Alteration in sleep-wake cycle; dehydration; impaired physical mobility; inappropriate use of physical restraint; malnutrition; pain; sensory deprivation; substance misuse; urinary retention

At-Risk Population

Individuals aged ≥60 years; individuals with history of cerebral vascular accident; men

Associated Conditions

Decreased level of consciousness; impaired metabolism; infections; neurocognitive disorders; pharmaceutical preparations

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching, and References

Refer to care plan for Acute **Confusion.**

Constipation Domain 3 Elimination and exchange Class 2 Gastrointestinal function

Amanda Andrews, BSc (Hons), MA and Bernie St Aubyn, BSc (Hons), MSc

C

NANDA-I

Definition

Infrequent or difficult evacuation of feces.

Defining Characteristics

Evidence of symptoms in standardized diagnostic criteria; hard stools; lumpy stools; need for manual maneuvers to facilitate defecation; passing fewer than three stools a week; sensation of anorectal obstruction; sensation of incomplete evacuation; straining with defecation

Related Factors

Altered regular routine; average daily physical activity is less than recommended for age and gender; communication barriers; habitually suppresses urge to defecate; impaired physical mobility; impaired postural balance; inadequate knowledge of modifiable factors; inadequate toileting habits; insufficient fiber intake; insufficient fluid intake; insufficient privacy; stressors; substance misuse

At-Risk Population

Individuals admitted to hospital; individuals experiencing prolonged hospitalization; individuals in aged care settings; individuals in the early postoperative period; older adults; pregnant women; women

Associated Conditions

Blockage in the colon; blockage in the rectum; depression; developmental disabilities; digestive system diseases; endocrine diseases; heart diseases; mental disorders; muscular diseases; nervous system diseases; neurocognitive disorders; pelvic floor disorders; pharmaceutical preparations; radiotherapy; urogynecological disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Bowel Elimination; Hydration

Example NOC Outcome with Indicators

Bowel Elimination as evidenced by the following indicators: Elimination pattern/Stool soft and formed/Passage of stool without aids/Ease of stool passage. (Rate each indicator of **Bowel Elimination:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain passage of soft, formed stool (i.e., Bristol Stool Scale Type 4) every 1 to 3 days without straining
- State relief from discomfort of constipation
- Identify measures that prevent or treat constipation

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Constipation/Impaction Management

Example NIC Activities—Constipation/Impaction Management

Identify factors (e.g., medications, bed rest, diet) that may cause or contribute to constipation/impaction; Institute a toileting schedule, as appropriate

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Nursing Interventions and *Rationales*

- Introduce yourself to the client and any companions and inform them of your role. *Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the basis for building trust on which to base the provision of care (Ellis et al, 2020).*
- Gain consent to perform care before proceeding further with the assessment. *Clients have the right of autonomy both legally and morally and therefore should be fully involved in the decision-making process (Griffith & Tengnah, 2020).*
- Wash hands using a recognized technique. EB: *Performing strict hand-hygiene regimens significantly reduces the incidence of infection with methicillin-resistant Staphylococcus aureus and Clostridium difficile infection (Goldberg, 2017).*
- Assess usual pattern of defecation and establish the extent of the constipation problem. EB: *A thorough and holistic assessment of the client enables effective treatment of constipation to be delivered. A thorough assessment allows the nurse to identify the cause, plan interventions, monitor outcomes, and evaluate care (Mitchell, 2019).*
- Assess the client's bowel habits:
  - Time of day of bowel evacuation
  - Amount and frequency of stool
  - Consistency of stool (using the Bristol Stool Scale)
  - Bleeding/passing mucus on defecation
  - History of bowel habits and/or laxative use

  EB: *Assess usual pattern of defecation, including time of day; amount and frequency of stool; consistency of stool; history of bowel habits or laxative use; and diet, including fiber and fluid intake. A nursing assessment that identifies the client's usual bowel habits will assist in the identification and management of their constipation (Lee, 2015).*
- Assess the client's lifestyle factors that may influence constipation:
  - Fiber content in diet
  - Daily fluid intake
  - Exercise patterns
  - Personal remedies for constipation
  - Recently stopped smoking
  - Alcohol consumption/recreational drug use

  EB: *When undertaking an assessment of a client with suspected constipation, it is important to discuss their lifestyle factors, which can be useful in establishing a clinical diagnosis. The main lifestyle factors to consider and record include the client's food and fluid intake, the fiber content of their diet, smoking, physical activity level, and mood (Andrews & St Aubyn, 2020).*
- Review the client's medical history:
  - Obstetrical/gynecological/urological history and surgeries
  - Diseases that affect bowel motility
  - Bleeding/passing mucus on defecation
  - Current medications

  EB: *Review the client's medical history for conditions that may contribute to constipation, obstetrical/gynecological history, surgeries, diseases that affect bowel motility, alterations in perianal sensation, and the present bowel regimen. It is imperative to establish a nursing history that identifies the client's bowel habits because this will assist in the identification and management of their constipation (Lee, 2015).*
- Assess the client for emotional influences that may be contributing to constipation:
  - Anxiety and depression
  - Long-term defecation issues
  - Stress

  EB: *Consider emotional influences (e.g., depression and anxiety) on defecation. Anxiety and depression are related to the occurrence of constipation; however, this is often a neglected aspect of client assessment and care in clinical practice (Jing & Jia, 2019).*
- Complete a physical examination (palpation for abdominal distention, percussion for dullness, and auscultation for bowel sounds). EB: *Research recommends the use of a standardized constipation assessment and management pathway. The key elements of such a pathway include a physical examination for the detection of any palpable fecal mass or abnormalities (Sandweiss et al, 2018).*

- Complete a digital rectal examination (DRE) if competent and suitably trained to do so, to identify hemorrhoids, rectal prolapse, anal fissure, rectocele, the anal tone, and fecal impaction. EBN: *A DRE should be performed by nurses who have received suitable training and demonstrated a level of competence determined by their professional governing body (Mitchell, 2019). A DRE is essential aid to identify any abnormalities and/or constipation (Bardsley, 2017).*
- Check for impaction; if present, use a combination of oral laxatives and enemas initially to remove fecal loading and impaction (National Institute for Health and Care Excellence, 2020). Clients with neurogenic bowel dysfunction (e.g., spinal cord injury) commonly require manual evacuation of stool (McClurg & Norton, 2016).
- Encourage the client or family to keep a 7-day diary of bowel habits, including time of day, length of time spent on the toilet, consistency, amount and frequency of stool, and any straining (using the Bristol Stool Scale). EBN: *Keeping a diary helps establish a client's bowel pattern and helps with recall and accuracy (Andrews & St Aubyn, 2020).*
- Encourage the client or family to keep a 7-day diary of lifestyle issues in relation to bowel habits, including fluid consumption, fiber content in diet, usual bowel stimulus, and exercise regimen. EB: *The use of bowel diaries for efficiently and reliably characterizing bowel habits cannot be over emphasized (Bharucha & Wald, 2019).*
- Use the Bristol Stool Scale to assess stool consistency. EB: The Bristol Stool Scale is widely used as a more objective measure to describe stool consistency (DerSarkissian, 2020).

▲ Review the client's current medications. EB: *A review of current medication should be requested, including recently started medications and any over-the-counter or herbal medications the client is taking. Medications associated with chronic constipation include opioid analgesics, anticholinergics, antipsychotics, antispasmodics, and calcium channel blockers (Joint Formulary Committee, 2016). This baseline information is key to gaining a comprehensive client assessment (Bardsley, 2017).*

- Discuss with clients already taking opioids (temporarily or long term) that constipation is a common side effect. If the client is receiving temporary opioids (e.g., for acute postoperative pain), request an order for routine stool softeners from the primary care provider, monitor bowel movements, and request a laxative for the client if constipation develops. If the client is receiving around-the-clock opiates (e.g., for palliative care), laxatives, then softeners, stimulants, or osmotic laxatives should be requested. EB: *Constipation is the most common opioid-related adverse effect. Opioids cause a lack of peristalsis in the large intestine and decrease fluid in the stool and increase anal muscle tone. Clients should be prescribed a stool softener and a bowel stimulant prophylactically to prevent constipation (Brant, 2018).*

▲ If the client is terminally ill and is receiving around-the-clock opioids for palliative care, speak with the prescribing health care provider about ordering low-dose naloxone, which is a drug that blocks opioid effects on the gastrointestinal tract without interfering with analgesia *(Sanders et al, 2015).*

- If new onset of constipation, determine whether the client has recently stopped smoking. EB: *Constipation is common, but usually transient, when people stop smoking. A 2016 study surveyed 16,840 individuals between 45 and 75 years of age and found that smoking was associated with abdominal pain, bloating, and constipation (Lundström et al, 2016).*

▲ Advise a fiber intake of 18 to 25 g daily and suggest foodstuffs high in fiber (e.g., prune juice, leafy green vegetables, whole meal bread and pasta). EB: *Fiber creates bulky feces and stretches the bowel wall to stimulate peristalsis, thus shortening bowel transit time (Bardsley, 2017).*

- Add fiber gradually to the diet to decrease bloating and flatus. EB: *The National Institute for Care and Excellence recommends that fiber intake must be increased slowly to minimize bloating and flatulence, enhancing Client comfort (NICE Guidelines, 2020).*
- Recommend prunes or prune juice daily. Each 100 g of prunes contains about 6 g of fiber, 15 g of sorbitol, and 184 mg of polyphenol, which all have laxative effects. EB: *Prunes are generally perceived to have a laxative effect. They are high in fiber, including hemicellulose, pectin, and cellulose. These fibers resist colonic fermentation and increase stool water and volume (Lever et al, 2019).*
- Advise a fluid intake of 1.5 to 2 L of fluid per day (ideally, 6–8 glasses of water), unless contraindicated by comorbidities, such as kidney or heart disease. *The recommended intake of fluid is 1.5 to 2 L daily, if the client presents with clinical signs of dehydration (Shen et al, 2019).*

▲ If the client is uncomfortable or in pain because of constipation or has acute or chronic constipation that does not respond to increased fiber, fluid, activity, and appropriate toileting, refer the client to the primary care provider for an evaluation of bowel function and health status. EB: *The main aim of referral is to rule out any serious causes of changes in bowel habits (e.g., the presence of tumors, old scarring, and megacolon).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Red flags (anemia, rectal bleeding, and a family history of bowel cancer or inflammatory bowel disease) are commonly used in general practice to identify the need for further referral (Lee, 2015).

- Encourage physical activity within the client's current ability to mobilize. Encourage turning and changing position in bed if immobile. For clients with reduced mobility, encourage knee to chest raises, waist twists, and stretching the arms away from the body. For fully mobile clients, encourage walking and swimming. EB: *Physical activity can help stimulate peristaltic waves in the colon and encourage the transit of feces to the rectum (Mihara et al, 2020).*
- Demonstrate the use of gentle external abdominal massage, following the direction of colon activity. EB: *Abdominal massage accelerates peristalsis by changing the intraabdominal pressure, thereby mechanically and reflexively acting on the intestines to evacuate the intestine (Okuyan & Bilgili, 2019).*
- Recommend that clients establish a regular elimination routine that includes activity, diet and fluids, and scheduled toilet visits. If required, assist clients to the bathroom at the same time every day; always be mindful of the need for privacy (closing of bathroom doors). EBN: *A daily routine should begin with mild physical activity, consumption of a hot and preferably caffeinated beverage, and a breakfast that includes a form of soluble fiber to induce peristaltic contractions to take advantage of colonic motility and the gastrocolic reflex (Baffy et al, 2017).*
- Educate the client about how to adopt the best posture for defecation. Keep knees slightly higher than hips, keep feet flat on the floor, and lean forward, putting elbows onto knees, thus adopting a squatting position. EB: *Adopting the squatting position helps with the angle of the anorectal section of the colon by lifting the sigmoid colon. The puborectalis muscles work most effectively when they are able to relax in the squatting position (Mercola, 2018).*
- Teach clients about the importance of responding promptly to the urge to defecate. EB: *The body's natural "call to stool" should be heeded in that it is a response to the stimulation of nerve endings in the rectum when a stool is present. Failure to respond to the urge of defecation or waiting until a more suitable time leads to stool retropulsion and worsening of the constipation (George & Borello-France, 2017).*
- Consider the use of laxatives, suppositories, enemas, and bowel irrigation as required if other more natural interventions are not effective. EBN/EB: *The overall aim of laxative therapy is to enable the client to defecate in a manner that promotes comfort and enhances symptom management. A fast active stimulant laxative should be considered to provide short-term relief and longer term management, including the use of an osmotic laxative (Andrews & St Aubyn, 2020). A systematic review identified that bowel irrigation is effective for chronic constipation in around 50% of clients (Emmett et al, 2015).*
- Discourage the use of long-term laxatives and enemas and advise clients to gradually reduce their use if taken regularly. EB: *Long-term use or overuse of laxatives can cause health problems (e.g., electrolyte imbalance) or hide symptoms that may be from a serious medical condition. The evidence base does not support use of stimulant laxatives for more than 4 weeks as associated with long-term colonic effects and possible carcinogenic risks (Noergaard et al, 2019).*

Geriatric

- Assess older adults for the presence of factors that contribute to constipation, including dietary fiber and fluid intake (<1.5 L/day), physical activity, use of constipating medications, and diseases that are associated with constipation. EB: *Constipation is a private problem and the need for health care professionals to be attentive to this issue and initiate assessment with clients in order to advise on the management of constipation is paramount to person-centered care (Munch et al, 2016).*
- Explain the importance of adequate fiber intake, fluid intake, activity, and established toileting routines to ensure soft, formed stool. EB: *In the prevention of constipation in older adults, evidence suggests that the majority of clients would respond to lifestyle modifications reinforced by bowel training measures (De Giorgio et al, 2015).*
- Determine the client's perception of normal bowel elimination and laxative use; promote adherence to a regular schedule. EB: *A systematic review on older people's experiences of living with constipation showed that older people had individual and personal strategies relative to their own beliefs. Clients reported bodily experiences of everyday life shadowed by constipation and adverse psychological effects, which need to be explored to prevent and treat constipation (Tvistholm et al, 2017).*
- Explain why straining (Valsalva maneuver) should be avoided. EB: *Excessive straining can cause syncope or cardiac dysrhythmias in susceptible people (Pstras et al, 2016).*
- Respond quickly to the client's call for assistance with toileting.

- Offer food, fluids, activity, and toileting opportunities to older clients who are cognitively impaired. EB: *Even cognitively impaired individuals who are unable to initiate a request for food, fluids, and so forth may respond when opportunities are offered. A recent research study concluded that 25% of the studied population had functional constipation with the most important risk factors being cited as nutritional impairment and cognitive impairment with advanced age (Farahat et al, 2019).*
- Avoid regular use of enemas in older adults. EB: *Enemas can cause fluid and electrolyte imbalances and damage to the colonic mucosa. However, judicious enema use may help prevent impactions (De Giorgio et al, 2015).*
- Advise the client against attempting to remove impacted feces on his or her own. *Older or confused clients in particular may attempt to remove feces and cause rectal damage.*

▲ Use opioids cautiously. EB: *Intestinal constipation is the main secondary effect to the use of opioids (Bezerra de Lima & Pereira, 2017).*

- Position the client on the toilet or commode and place a small footstool under the feet. *Placing a small footstool helps the client assume a squatting posture to facilitate defecation.*

Home Care

- The interventions described previously may be adapted for home care use.
- Take complaints seriously and evaluate claims of constipation in a matter-of-fact manner.
  EB: *Continued constipation can lead to bowel obstruction, which is a medical emergency. Use of a matter-of-fact manner will limit positive reinforcement of the behavior if actual constipation does not exist. (Tvistholm et al, 2017).*
- Assess the self-care management activities the client is already using. EB: *Many older adults seek solutions to constipation, with laxative use a frequent remedy that creates its own problems (Tvistholm et al, 2017).*
- Offer the following treatment recommendations:
  - ❍ Acknowledge the client's lifelong experience of bowel function; respect beliefs, attitudes, and preferences, and avoid patronizing responses.
  - ❍ Make available comprehensive, useful written information about constipation and possible solutions.
  - ❍ Make available empathetic and accessible professional care to provide treatment and advice; a multiprofessional approach (including health care provider, nurse, and pharmacist) should be used.
  - ❍ Institute a bowel management program.
  - ❍ Consider affordability when suggesting solutions to constipation; discuss cost-effective strategies.
  - ❍ Discuss a range of solutions to constipation and allow the client to choose the preferred options.
  - ❍ Have orders in place for a suppository and enema as needed. As part of a bowel management program, suppositories or enemas may become necessary.
- Although the use of a bedside commode may be necessitated by the client's condition, allow the client to use the toilet in the bathroom when possible and provide assistance. *Bowel elimination is a private act, and a lack of privacy can contribute to constipation.*
- In older clients, routinely advise consumption of fluids, fruits, and vegetables as part of the diet, and ambulation if the client is able.
  EB: *Introduce a bowel management program at the first sign of constipation. Constipation is a major problem for terminally ill or hospice clients who may need very high doses of opioids for pain management (De Giorgio et al, 2015).*

▲ Refer for consideration of the use of polyethylene glycol 3350 (PEG-3350) for constipation. EB: *There is good evidence to support the use of PEG-3350 for both chronic constipation and constipation associated with irritable bowel syndrome. PEG 3350 resolved constipation in the short term, was well tolerated, and led to sustained improvement in bowel function in the long-term treatment of clients with chronic constipation (Nakajima et al, 2019).*

- Use a bowel program to establish a pattern that is regular, thereby allowing the client to be part of the family unit.
  EB: *Regularity of the program promotes psychological and/or physiological readiness to evacuate stool. Families of home care clients often cannot proceed with normal daily activities until bowel programs are complete (Tvistholm et al, 2017).*

Client/Family Teaching and Discharge Planning

- Instruct the client on normal bowel function and the need for adequate fluid and fiber intake, activity, and a defined toileting pattern in a bowel program.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Encourage the client to heed defecation warning signs and develop a regular schedule of defecation by using a stimulus such as a warm drink or prune juice. *Most cases of constipation are mechanical and result from habitual neglect of impulses that signal the appropriate time for defecation.*
- Encourage the client to avoid long-term use of laxatives and enemas and to gradually withdraw from their use if they are used regularly. EB: *Long-term use or overuse of laxatives can cause health problems (e.g., electrolyte imbalance) or hide symptoms that may be from a serious medical condition. The evidence base does not support use of stimulant laxatives for more than 4 weeks as associated with long-term colonic effects and possible carcinogenic risks (Noergaard et al, 2019).*
- If not contraindicated, teach the client how to do bent-leg sit-ups to increase abdominal tone; also encourage the client to contract the abdominal muscles frequently throughout the day. Help the client develop a daily exercise program to increase peristalsis.
- Provide client with comprehensive written information about constipation and its management. EB: *Providing clients with well-written, evidence-based information about their condition and treatment can have a beneficial effect on the outcomes of treatment. A research study suggests that the use of family-friendly colorful and informative leaflets can have a direct effect on health-related issues (Shabde & Harrison, 2016).*

▲ Collaborate with members of the multiprofessional team to provide treatment and advice to clients and caregivers. EB: *Teamwork is a central process in health care organizations. Effective organization and delivery of health care services depends on a wide range of professionals, families, clients, and carers working together to achieve the best health outcomes and quality of life (Flynn & Mercer, 2018).*

▲ Consider referral to other specialist practitioners if constipation persists. **EB:** *A diagnosis of primary chronic constipation is made after the exclusion of secondary causes of constipation and managed effectively. If unsuccessful, subspecialist referrals should be considered (Rao et al, 2016).*

- Document all care and advice given in a factual and comprehensive manner. EB: *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (St Aubyn & Andrews, 2015).*

Risk for Constipation

Domain 3 Elimination and exchange Class 2 Gastrointestinal function

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to infrequent or difficult evacuation of feces, which may compromise health.

Risk Factors

Altered regular routine; average daily physical activity is less than recommended for age and gender; communication barriers; habitually suppresses urge to defecate; impaired physical mobility; impaired postural balance; inadequate knowledge of modifiable factors; inadequate toileting habits; insufficient fiber intake; insufficient fluid intake; insufficient privacy; stressors; substance misuse

At-Risk Population

Individuals admitted to hospital; individuals experiencing prolonged hospitalization; individuals in aged care settings; individuals in the early postoperative period; older adults; pregnant women; women

Associated Conditions

Blockage in the colon; blockage in the rectum; depression; developmental disabilities; digestive system diseases; endocrine system diseases; heart diseases; mental disorders; muscular diseases; nervous system diseases; neurocognitive disorders; pelvic floor disorders; pharmaceutical preparations; radiotherapy; urogynecological disorders

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching, and References

Refer to care plan for **Constipation.**

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Perceived Constipation

Domain 3 Elimination and exchange Class 2 Gastrointestinal function

Amanda Andrews, BSc (Hons), MA and Bernie St Aubyn, BSc (Hons), MSc

NANDA-I

Definition

Self-diagnosis of infrequent or difficult evacuation of feces combined with abuse of methods to ensure a daily bowel movement.

Defining Characteristics

Enema misuse; expects bowel movement at same time daily; laxative misuse; suppository misuse

Related Factors

Cultural health beliefs; deficient knowledge about normal evacuation patterns; disturbed thought processes; family health beliefs

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Bowel Elimination; Health Beliefs; Health Beliefs: Perceived Threat

Example NOC Outcome with Indicators

Bowel Elimination as evidenced by the following indicators: Elimination pattern/Stool soft and formed/Passage of stool without aids/Ease of stool passage. (Rate each indicator of **Bowel Elimination:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Regularly defecate soft, formed stool without use of aids (i.e., Bristol Stool Scale Type 4) every 1 to 3 days without straining
- Understand the need to decrease or eliminate the use of stimulant laxatives, suppositories, and enemas
- Identify alternatives to stimulant laxatives, enemas, and suppositories for ensuring defecation
- Understand that defecation does not have to occur every day

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Bowel Management; Medication Management

Example NIC Activities—Bowel Management

Note preexistent bowel problems, bowel routine, and use of laxatives; Initiate a bowel training program, as appropriate

Nursing Interventions and *Rationales*

- Introduce yourself to the client and any companions and inform them of your role. EB: *Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the basis for building trust on which to base the provision of care (Ellis et al, 2020).*
- Gain consent to perform care before proceeding further with the assessment. EB: *Clients have the right of autonomy both legally and morally and therefore should be fully involved in the decision-making process (Griffith & Tengnah, 2020).*

- Wash hands using a recognized technique. EB: *Performing strict hand-hygiene regimens significantly reduces the incidence of infection with methicillin-resistant* Staphylococcus aureus *and* Clostridium difficile (i.e., *Clostridioides difficile*) *infections (Goldberg, 2017).*
- Assess usual pattern of defecation and establish the extent of the perceived constipation problem. Assess the client's bowel habits:
  - ❍ Time of day
  - ❍ Amount and frequency of stool
  - ❍ Consistency of stool (using the Bristol Stool Scale)
  - ❍ Bleeding/passing mucus on defecation
  - ❍ Client history of bowel habits and/or laxative use
  - ❍ Family history of bowel habits and/or laxative use

  EB: *A nursing assessment that identifies the client's usual bowel habits will assist in the identification and management of their constipation (Lee, 2015).*

▲ Assess the client's lifestyle factors that may affect bowel function:
  - ❍ Fiber content in diet
  - ❍ Daily fluid intake
  - ❍ Exercise patterns
  - ❍ Personal remedies for constipation
  - ❍ Cultural remedies for constipation
  - ❍ Recently stopped smoking
  - ❍ Alcohol consumption/recreational drug use

  EB: *One of the key causes of constipation is dehydration of stools. A lack of water in the bowel leads to hard fecal matter, which is difficult to pass (Bardsley, 2017). Alcohol has a dehydrating effect on the body.*

▲ Review the client's medical history:
  - ❍ Obstetrical/gynecological/urological history and surgeries
  - ❍ Diseases that affect bowel motility
  - ❍ Bleeding/passing mucus on defecation
  - ❍ Current medications

  EB: *Review the client's medical history for conditions that may contribute to constipation, obstetrical/gynecological history, surgeries, diseases that affect bowel motility, alterations in perianal sensation, and the present bowel regimen (Lee, 2015).*

▲ Emotional influences:
  - ❍ Anxiety and depression/psychological disorders
  - ❍ History of eating disorders
  - ❍ History of physical/or sexual abuse
  - ❍ Long-term defecation issues
  - ❍ Stress

  EB: *Consider emotional influences (e.g., depression and anxiety) on defecation. Anxiety and depression are related to the occurrence of constipation; however, this is often a neglected aspect of client assessment and care in clinical practice (Jing & Jia, 2019).*

- Encourage the client or family to keep a 7-day diary of bowel habits, including time of day, length of time spent on the toilet, consistency, amount and frequency of stool, and any straining (using the Bristol Stool Scale). EBN: *Keeping a diary helps establish a client's bowel pattern and helps with recall and accuracy (Andrews & St Aubyn, 2020).*
- Encourage the client or family to keep a 7-day diary of lifestyle issues in relation to bowel habits, including fluid consumption, fiber content in diet, usual bowel stimulus, and exercise regimen. EB: *Enabling clients to present their condition in their own words ensures that they feel the health care professionals understand their concerns (Bharucha & Wald, 2019).*
- Educate the client that it is not necessary to have a daily bowel movement. EB: *A healthy bowel function can vary from three stools each day to three stools each week. The criteria of choice used for establishing a diagnosis of constipation are often the Rome IV criteria. The criteria-based definition calls for the presence of two or more of the symptoms for at least 3 months for a definition of constipation (Drossman, 2016).*
- Encourage the client to record use of laxatives, suppositories, or enemas, and suggest replacing them with an increase in fluid and fiber intake. EB: *Laxatives available for the treatment of constipation are generally safe when used at established doses under medical supervision. Their long-term use should be monitored by*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

health care professionals and clients to optimize treatment on an individualized basis, enhancing efficacy and minimizing adverse effects (Serrano-Falcón & Rey, 2017).

- Advise a fiber intake of 18 to 30 g daily in adults and suggest foodstuffs high in fiber (e.g., prune juice, leafy green vegetables, whole meal bread and pasta). EB: *Fiber creates bulky feces and stretches the bowel wall to stimulate peristalsis, thus shortening bowel transit time (Bardsley, 2017). For further information on use of fiber, see the care plan for* ***Constipation.***
- Advise a fluid intake of 1.5 to 2 L of fluid per day (ideally, 6–8 glasses of water), unless contraindicated by comorbidities, such as kidney or heart disease. EB: *Water passes into the gut to promote the formation of a softer fecal mass and provides lubrication to prevent a blockage of the gut. The recommended intake of fluid is 1.5 to 2 L daily, if the client presents with clinical signs of dehydration (Shen et al, 2019).*
- Obtain a referral to a dietitian for analysis of the client's diet and fluid intake *to provide strategies to improve diet and nutrition.*
- Encourage physical activity within the client's current ability to mobilize. Encourage turning and changing position in bed if immobile. For clients with reduced mobility, encourage knee to chest raises, waist twists, and stretching the arms away from the body. For fully mobile clients, encourage walking and swimming. EB: *Physical activity can help stimulate peristaltic waves in the colon and encourage the transit of feces to the rectum (Mihara et al, 2020).*
- Demonstrate the use of gentle external abdominal massage, using aroma therapy oils, following the direction of colon activity. EB: *Abdominal massage accelerates peristalsis by changing the intraabdominal pressure, thereby mechanically and reflexively acting on the intestines to evacuate the intestine (Okuyan & Bilgili, 2019).*
- Recommend that clients establish a regular elimination routine that includes activity, diet and fluids, and scheduled toilet visits. If required, assist clients to the bathroom at the same time every day; always be mindful of the need for privacy (closing of bathroom doors). EB: *A daily routine should begin with mild physical activity, consumption of a hot and preferably caffeinated beverage, and a breakfast that includes a form of soluble fiber to induce peristaltic contractions to take advantage of colonic motility and the gastrocolic reflex (Baffy et al, 2017).*
- Observe for the presence of an eating disorder by using laxatives to control or decrease weight; refer for counseling if needed. *People with eating disorders suffer from constipation and other gastrointestinal symptoms, or use laxatives as part of inducing weight loss (Sato & Fukudo, 2015).*
- Observe family cultural patterns related to eating and bowel habits. Cultural patterns may control bowel habits.

Client/Family Teaching and Discharge Planning

- Educate the client about how to adopt the best posture for defecation. Keep knees slightly higher than hips, keep feet flat on the floor, and lean forward putting elbows onto knees, thus adopting a squatting position. EB: *Adopting the squatting position helps with the angle of the anorectal section of the colon by lifting the sigmoid colon. The puborectalis muscles work most effectively when they are able to relax in the squatting position (Mercola, 2018).*
- Teach clients about the importance of responding promptly to the urge to defecate. EB: *The body's natural "call to stool" should be heeded in that it is a response to the stimulation of nerve endings in the rectum when a stool is present. Failure to respond to the urge of defecation or waiting until a more suitable time leads to stool retropulsion and worsening of the constipation (George & Borello-France, 2017).*
- Discourage the use of long-term laxatives and enemas and explain the potential harmful effects of the continual use of defecation aids such as laxatives and enemas. EB: *"Lazy bowel syndrome" may occur if laxatives are used too frequently, causing the bowel to become dependent on laxatives to stimulate a bowel movement. Overuse of laxatives can also lead to poor absorption of vitamins and other nutrients, and to damage of the gastrointestinal tract (Elran-Barak et al, 2017).*
- Discourage the long-term use of laxatives and enemas and advise clients to gradually reduce their use if taken regularly. EB: *Long-term use or overuse of laxatives can cause health problems (e.g., electrolyte imbalance) or hide symptoms that may be from a serious medical condition. The evidence base does not support use of stimulant laxatives for more than 4 weeks as associated with long-term colonic effects and possible carcinogenic risks (Noergaard et al, 2019).*
- Provide client with comprehensive written information about constipation and its management. EB: *Providing clients with well-written, evidence-based information about their condition and treatment can have a beneficial effect on the outcomes of treatment. A research study suggests that the use of family-friendly colorful and informative leaflets can have a direct effect on health-related issues (Shabde & Harrison, 2016).*

- Collaborate with members of the multiprofessional team to provide treatment and advice to clients and caregivers. *Teamwork is a central process in health care organizations. Effective organization and delivery of health care services depends on a wide range of professionals, families, clients, and carers working together to achieve the best health outcomes and quality of life (Flynn & Mercer, 2018).*
- Document all care and advice given in a factual and comprehensive manner. *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (St Aubyn & Andrews, 2015).*

Chronic Functional Constipation

Domain 3 Elimination and exchange Class 2 Gastrointestinal function

Amanda Andrews, BSc (Hons), MA and Bernie St Aubyn, BSc (Hons), MSc

NANDA-I

Definition

Infrequent or difficult evacuation of feces, which has been present for at least 3 of the prior 12 months.

Defining Characteristics

General

Distended abdomen; fecal impaction; leakage of stool with digital stimulation; pain with defecation; palpable abdominal mass; positive fecal occult blood test; prolonged straining; Type 1 or 2 on Bristol Stool Chart

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Adult: *Presence of ≥2 of the following symptoms on Rome III classification system:*

Lumpy or hard stools in ≥25% defecations; manual maneuvers to facilitate ≥25% of defecations (digital manipulation, pelvic floor support); sensation of anorectal obstruction/blockage for ≥25% of defecations; sensation of incomplete evacuation for ≥25% of defecations; ≤3 evacuations per week

Child >4 years: *Presence of ≥2 criteria on the Rome III Pediatric classification system for ≥2 months:*

Large diameter stools that may obstruct the toilet; painful or hard bowel movements; presence of large fecal mass in the rectum; stool retentive posturing; ≤2 defecations per week; ≥1 episode of fecal incontinence per week

Child ≤4 years: *Presence of ≥2 criteria on the Rome III Pediatric classification system for ≥1 month:*

Large diameter stools that may obstruct the toilet; painful or hard bowel movements; presence of large fecal mass in the rectum; stool retentive posturing; ≤2 defecations per week; ≥1 episode of fecal incontinence per week

C

Related Factors

Decreased food intake; dehydration; diet disproportionally high in fat; diet disproportionally high in protein; frail elderly syndrome; habitually suppresses urge to defecate; impaired physical mobility; inadequate dietary intake; inadequate knowledge of modifiable factors; insufficient fiber intake; insufficient fluid intake; low caloric intake; sedentary lifestyle

At-Risk Population

Older adults; pregnant women

Associated Conditions

Amyloidosis; anal fissure; anal stricture; autonomic neuropathy; chronic intestinal pseudo-obstruction; chronic renal insufficiency; colorectal cancer; depression; dermatomyositis; diabetes mellitus; extra intestinal mass; hemorrhoids; Hirschsprung's disease; hypercalcemia; hypothyroidism; inflammatory bowel disease; ischemic stenosis; multiple sclerosis; myotonic dystrophy; neurocognitive disorders; panhypopituitarism; paraplegia; Parkinson's disease; pelvic floor disorders; perineal damage; pharmaceutical preparations; polypharmacy; porphyria; postinflammatory stenosis; proctitis; scleroderma; slow colon transit time; spinal cord injuries; stroke; surgical stenosis

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Bowel Elimination; Symptom Severity

Example NOC Outcome with Indicators

Bowel Elimination as evidenced by the following indicators: Elimination pattern/Stool soft and formed/Passage of stool without aids/Ease of stool passage. (Rate each indicator of **Bowel Elimination:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain passage of soft, formed stool (i.e., Bristol Stool Scale Type 4) every 1 to 3 days without straining.
- Identify measures that prevent or treat constipation

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Constipation/Impaction Management

Example NIC Activities—Constipation/Impaction Management

Identify factors (e.g., medications, bed rest, diet) that may cause or contribute to constipation/impaction; Institute a toileting schedule, as appropriate

Nursing Interventions and *Rationales*

All Client Ages

- Introduce yourself to the client and any companions and inform them of your role. EB: *Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the basis for building trust on which to base the provision of care (Ellis et al, 2020).*
- Gain consent to perform care before proceeding further with the assessment. EB: *Clients have the right of autonomy both legally and morally and therefore should be fully involved in the decision-making process (Griffith & Tengnah, 2020).*
- Wash hands using a recognized technique. EB: *Performing strict hand-hygiene regimens significantly reduces the incidence of infection with methicillin-resistant* Staphylococcus aureus *and* Clostridium difficile *infection (Goldberg, 2017).*
- Assess usual pattern of defecation and establish the extent of the constipation problem. EB: *A thorough and holistic assessment of the client enables effective treatment of constipation to be delivered. A thorough assessment allows the nurse to identify the cause, plan interventions, monitor outcomes, and evaluate care (Mitchell, 2019).*
- Assess bowel habits:
  - Time of day
  - Amount and frequency of stool
  - Consistency of stool (using the Bristol Stool Scale)
  - Bleeding/passing mucus on defecation
  - History of bowel habits and/or laxative use
  - Assess children younger than 4 years using the Rome III pediatric classification (for at least 1 month)
  - Assess children older than age 4 years using the Rome III pediatric classification (for at least 2 months)

  EB: *Assess adults using the Rome IV classification. The Rome Foundation updated the criteria with the release of Rome IV criteria, devised in 2016, which specify that clients must be symptomatic with at least two or more of the criteria that are relevant to their specific age range (Drossman, 2016).*
- ▲ Assess the client's lifestyle factors that may affect bowel function:
  - Fiber content in diet
  - Daily fluid intake
  - Exercise patterns
  - Personal remedies for constipation
  - Recently stopped smoking
  - Alcohol consumption/recreational drug use
  - Personal habits related to defecation

  EB: *Alcohol has a dehydrating effect on the body. One of the key causes of constipation is dehydration of stools. A lack of water in the bowel leads to hard fecal matter, which is difficult to pass (Bardsley, 2017). When undertaking an assessment of a client with suspected constipation, it is important to discuss their lifestyle factors, which can be useful in establishing a clinical diagnosis. The main lifestyle factors to consider and record include the client's food and fluid intake, the fiber content of their diet, smoking, physical activity level, and mood (Andrews & St Aubyn, 2020).*
- ▲ Review the client's medical history:
  - Obstetrical/gynecological/urological history and surgeries
  - Existing anatomical anomalies (e.g., anal fissures, anal strictures and hemorrhoids)
  - Diseases that affect bowel motility (e.g., colorectal cancer, chronic intestinal pseudo-obstruction, and Hirschsprung's disease)
  - Bleeding/passing mucus on defecation
  - Current medications

  EB: *A full review of a client's medical history is essential. Within this assessment the inclusion of family history of inflammatory bowel disease or colorectal cancer will identify red flag symptoms leading to the need for further investigations and referral (Mitchell, 2019).*
- ▲ Review emotional influences with the client:
  - Anxiety and depression
  - Long-term defecation issues
  - Stress

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

EB: *A detailed and accurate assessment of the client enables the nurse to plan interventions, monitor outcomes, and evaluate care, ensuring no unnecessary treatment is performed. Consider emotional influences (e.g., depression and anxiety) on defecation. Anxiety and depression are related to the occurrence of constipation; however, this is often a neglected aspect of client assessment and care in clinical practice (Jing & Jia, 2019).*

- Complete a physical examination (palpation for abdominal distention, percussion for dullness, and auscultation for bowel sounds). EB: *Research recommends the use of a standardized constipation assessment and management pathway. The key elements of such a pathway include a physical examination for the detection of any palpable fecal mass or abnormalities (Sandweiss et al, 2018).*
- Encourage the client or family to keep a 7-day diary of bowel habits, including time of day, length of time spent on the toilet, consistency, amount and frequency of stool, and any straining (using the Bristol Stool Scale). EBN: *Keeping a diary helps establish a client's bowel pattern and helps with recall and accuracy (Andrews & St Aubyn, 2020).*
- Encourage the client or family to keep a 7-day diary of lifestyle issues in relation to bowel habits, including fluid consumption, fiber content in diet, usual bowel stimulus, and exercise regimen. EB: *The importance of using bowel diaries for efficiently and reliably characterizing bowel habits cannot be overemphasized (Bharucha & Wald, 2019).*
- Actively encourage children and families to attend bowel management programs to aid the establishment of regular bowel routines. EB: *Research shows that children who followed a structured program can experience successful treatment of severe constipation (Kilpatrick et al, 2020).*
- Discuss with clients already taking opioids (temporarily or long term) that constipation is a common side effect. If the client is receiving temporary opioids (e.g., for acute postoperative pain), request an order for routine stool softeners from the primary care provider, monitor bowel movements, and request a laxative for the client if constipation develops. If the client is receiving around-the-clock opiates (e.g., for palliative care), laxatives, then softeners, stimulants, or osmotics, should be requested. EB: *Constipation is the most common opioid-related adverse effect. Opioids cause a lack of peristalsis in the large intestine and decrease fluid in the stool and increase anal muscle tone. Clients should be prescribed a stool softener and a bowel stimulant prophylactically to prevent constipation (Brant, 2018).*
- Advise a fiber intake of 18 to 30 g of fiber daily in adults and suggest foodstuffs to facilitate this diet (e.g., prune juice, leafy green vegetables, whole meal bread and pasta). EB: *Fiber creates bulky feces and stretches the bowel wall to stimulate peristalsis, thus shortening bowel transit time (Bardsley, 2017).*
- Advise clients to drink at least 6–8 glasses of water a day, unless contraindicated by comorbidities, such as kidney or heart disease. EB: *The recommended intake of fluid is 1.5 to 2 L daily (e.g., 6-8 glasses), if the client presents with clinical signs of dehydration (Shen et al, 2019).*
- Encourage physical activity within the client's current ability to mobilize. Encourage turning and changing position in bed if immobile. For clients with reduced mobility, encourage knee to chest raises, waist twists, and stretching the arms away from the body. For fully mobile clients, encourage walking and swimming. EB: *Physical activity can help stimulate peristaltic waves in the colon and encourage the transit of feces to the rectum (Mihara et al, 2020).*
- Demonstrate the use of gentle external abdominal massage, following the direction of colon activity. EB: *Abdominal massage accelerates peristalsis by changing the intraabdominal pressure, thereby mechanically and reflexively acting on the intestines to evacuate the intestine (Okuyan & Bilgili, 2019).*
- Recommend that clients establish a regular elimination routine that includes activity, diet and fluids, and scheduled toilet visits. If required, assist clients to the bathroom at the same time every day; always be mindful of the need for privacy (closing of bathroom doors). EB: *A daily routine should begin with mild physical activity, consumption of a hot and preferably caffeinated beverage, and a breakfast that includes a form of soluble fiber to induce peristaltic contractions to take advantage of colonic motility and the gastrocolic reflex (Baffy et al, 2017).*
- Educate the client about how to adopt the best posture for defecation. Keep knees slightly higher than hips, keep feet flat on the floor, and lean forward putting elbows onto knees, thus adopting a squatting position. EB: *Adopting the squatting position helps with the angle of the anorectal section of the colon by lifting the sigmoid colon. The puborectalis muscles work most effectively when they are able to relax in the squatting position (Mercola, 2018).*
- Consider the teaching of biofeedback therapy to encourage a "new normal" bowel routine for clients to adopt. EB: *A literature review concluded that the use of biofeedback therapy in chronic constipation was successful and remains the safest option to successfully manage chronic constipation (Chiarioni, 2016).*

- Teach clients about the importance of responding promptly to the urge to defecate. EB: *The body's natural "call to stool" should be heeded in that it is a response to the stimulation of nerve endings in the rectum when a stool is present. Failure to respond to the urge of defecation or waiting until a more suitable time leads to stool retropulsion and worsening of the constipation (George & Borello-France, 2017).*
- Consider the use of laxatives, suppositories, enemas, and bowel irrigation as required if other more natural interventions are not effective. EB: *The overall aim of laxative therapy is to enable the client to defecate in a manner that promotes comfort and enhances symptom management. A fast active stimulant laxative should be considered to provide short-term relief and longer-term management including the use of an osmotic laxative (Andrews & St Aubyn, 2020). A systematic review identified that bowel irrigation is effective for chronic constipation in around 50% of clients (Emmett et al, 2015).*
- Discourage the long-term use of laxatives and enemas and advise clients to gradually reduce their use if taken regularly. EB: *Long-term use or overuse of laxatives can cause health problems (e.g., electrolyte imbalance) or hide symptoms that may be from a serious medical condition. The evidence base does not support use of stimulant laxatives for more than 4 weeks as associated with long-term colonic effects and possible carcinogenic risks (Noergaard et al, 2019).*
- Provide client with comprehensive written information about constipation and its management. EB: *Providing clients with well-written, evidence-based information about their condition and treatment can have a beneficial effect on the outcomes of treatment. A research study suggests that the use of family-friendly colorful and informative leaflets can have a direct effect on health-related issues (Shabde & Harrison, 2016).*
- Provide written instructions for children about taking their medication and about how the bowel works. *Written clear information provided to children with chronic functional constipation will help them understand and therefore recognize when they are at risk for constipation recurrence (National Institute for Health and Care Excellence, 2017).*
- Collaborate with members of the multiprofessional team to provide treatment and advice to clients and caregivers. EB: *Teamwork is a central process in health care organizations. Effective organization and delivery of health care services depends on a wide range of professionals, families, clients, and carers working together to achieve the best health outcomes and quality of life (Flynn & Mercer, 2018).*
- Consider referral to other specialist practitioners if constipation persists. *A diagnosis of primary chronic constipation is made after the exclusion of secondary causes of constipation and managed effectively. If unsuccessful, subspecialist referrals should be considered (Rao et al, 2016).*
- Document all care and advice given in a factual and comprehensive manner. EBN: *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (St Aubyn & Andrews, 2015).*

Risk for Chronic Functional Constipation

Domain 3 Elimination and exchange Class 2 Gastrointestinal function

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to infrequent or difficult evacuation of feces, which has been present nearly 3 of the prior 12 months, which may compromise health.

Risk Factors

Decreased food intake; dehydration; diet disproportionally high in fat; diet disproportionally high in protein; frail elderly syndrome; habitually suppresses urge to defecate; impaired physical mobility; inadequate dietary intake; inadequate knowledge of modifiable factors; insufficient fiber intake; insufficient fluid intake; low caloric intake; sedentary lifestyle

At-Risk Population

Older adults; pregnant women

Associated Conditions

Amyloidosis; anal fissure; anal stricture; autonomic neuropathy; chronic intestinal pseudo-obstruction; chronic renal insufficiency; colorectal cancer; depression; dermatomyositis; diabetes mellitus; extra intestinal mass; hemorrhoids; Hirschsprung's disease; hypercalcemia; hypothyroidism; inflammatory bowel disease; ischemic stenosis; multiple sclerosis; myotonic dystrophy; neurocognitive disorders; panhypopituitarism; paraplegia; Parkinson's disease; pelvic floor disorders; perineal damage; pharmaceutical preparations; polypharmacy; porphyria; postinflammatory stenosis; proctitis; scleroderma; slow colon transit time; spinal cord injuries; stroke; surgical stenosis

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Chronic Functional **Constipation.**

Contamination Domain 11 Safety/protection Class 4 Environmental hazards

Pauline McKinney Green, PhD, RN, CNE

C

NANDA-I

Definition

Exposure to environmental contaminants in doses sufficient to cause adverse health effects.

Defining Characteristics

Pesticides

Dermatological effects of pesticide exposure; gastrointestinal effects of pesticide exposure; neurological effects of pesticide exposure; pulmonary effects of pesticide exposure; renal effects of pesticide exposure

Chemicals

Dermatological effects of chemical exposure; gastrointestinal effects of chemical exposure; immunological effects of chemical exposure; neurological effects of chemical exposure; pulmonary effects of chemical exposure; renal effects of chemical exposure

Biologics

Dermatological effects of biologic exposure; gastrointestinal effects of biologic exposure; neurological effects of biologic exposure; pulmonary effects of biologic exposure; renal effects of biologic exposure

Pollution

Neurological effects of pollution exposure; pulmonary effects of pollution exposure

Waste

Dermatological effects of waste exposure; gastrointestinal effects of waste exposure; hepatic effects of waste exposure; pulmonary effects of waste exposure

Radiation

Genetic effects of radiotherapy exposure; immunological effects of radiotherapy exposure; neurological effects of radiotherapy exposure; oncological effects of radiotherapy exposure

Related Factors

External Factors

Carpeted flooring; chemical contamination of food; chemical contamination of water; flaking, peeling surface in presence of young children; inadequate breakdown of contaminant; inadequate household hygiene practices; inadequate municipal services; inadequate personal hygiene practices; inadequate protective clothing; inappropriate use of protective clothing; individuals who ingested contaminated material; playing where environmental contaminants are used; unprotected exposure to chemical; unprotected exposure to heavy metal; unprotected exposure to radioactive material; use of environmental contaminant in the home; use of noxious material in inadequately ventilated area; use of noxious material without effective protection

Internal Factors

Concomitant exposure; malnutrition; smoking

At-Risk Population

Children aged <5 years; economically disadvantaged individuals; individuals exposed perinatally; individuals exposed to areas with high concomitant level; individuals exposed to atmospheric pollutants; individuals exposed to bioterrorism; individuals exposed to disaster; individuals with history of exposure to contaminant; older adults; pregnant women; women

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Associated Conditions

Pre-existing disease; radiotherapy

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Community Health Status; Family Physical Environment; Anxiety Level; Fear Level

Example NOC Outcome with Indicators

Community Health Status as evidenced by the following indicators: Evidence of health protection measures/Compliance with environmental health standards/Health status of population. (Rate the outcome and indicators of **Community Health Status:** 1 = poor, 2 = fair, 3 = good, 4 = very good, 5 = excellent [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Have minimal health effects associated with contamination
- Cooperate with appropriate decontamination protocol
- Participate in appropriate isolation precautions
- Use health surveillance data system to monitor for contamination incidents
- Use disaster plan to evacuate and triage affected members
- Have minimal health effects associated with contamination
- Use measures to reduce household environmental risks

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Triage: Disaster; Infection Control; Anxiety Reduction; Crisis Intervention; Health Education

Example NIC Activities—Triage: Disaster

Initiate appropriate emergency measures, as indicated; Monitor for and treat life-threatening injuries or acute needs

Nursing Interventions and Rationales

▲ Help individuals cope with contamination incident by doing the following:
  - ❍ Use organizations and groups that have survived terrorist attacks as a useful resource for victims
  - ❍ Provide accurate information on risks involved, preventive measures, and use of antibiotics and vaccines
  - ❍ Assist to deal with feelings of fear, vulnerability, and grief
  - ❍ Encourage individuals to talk to others about their fears
  - ❍ Assist victims to think positively and to move toward the future

▲ In a crisis situation, interventions aimed at supporting an individual's coping help the person deal with feelings of fear, helplessness, and loss of control that are normal reactions in a crisis situation.

● Triage, stabilize, transport, and treat affected community members. EB: *Accurate triage and early treatment provide the best chance of survival to affected persons (Goodwin Veenema, 2019).*

● Prioritize mental health care for highly vulnerable risk groups or those with special needs (women, older persons, children and adolescents, displaced persons, especially those living in shelters; persons with preexisting mental health disorders, including those living in institutions, those significantly exposed to contaminants). CEB: *Persons with special needs are vulnerable to marginalization during emergencies and are exposed to greater stress (Pan American Health Organization, 2012).*

✱ Collaborate with members of the health care delivery system and outside agencies (local health department, emergency medical services [EMS], state and federal agencies). EB: *Communication among agencies increases the ability to handle a crisis efficiently by disseminating evidence-based information (Centers for Disease Control and Prevention [CDC], 2018; Goodwin Veenema, 2019).*

- Use approved procedures for decontamination of persons, clothing, and equipment. *Victims may first require decontamination before entering health facility to receive care to prevent the spread of contamination (U.S. Army Medical Research Institute of Infectious Diseases, 2014).*
- Use appropriate isolation precautions: universal, airborne, droplet, and contact isolation to prevent cross-contamination by contaminating agents (U.S. Army Medical Research Institute of Infectious Diseases, 2014). EB: *Client contact is a major risk factor for provider contamination and transmission (Jackson et al, 2018).*
- Monitor individuals for therapeutic effects, side effects, and compliance with postexposure drug therapy that may extend over a long period of time and require monitoring for compliance and for therapeutic and side effects (Adalja, Toner, & Inglesby, 2015; Goodwin Veenema, 2019).
- Perform effective handwashing using 60% to 90% alcohol-based hand rub before and after touching a client, after touching client's immediate environment, aseptic tasks, contact with body fluids or contaminated surfaces, and immediately after glove removal (CDC, 2020a).
- Prevent cross-contamination by systematically disinfecting stethoscopes (diaphragm and tubing) after each use. EB: *A descriptive study using cultures and bioluminescence to visualize contamination demonstrated improve stethoscope hygiene among providers (Holleck et al, 2020).*
- Minimize occupational exposure to antineoplastic agents by following National Institute for Occupational Safety and Health (NIOSH) guidelines regarding personal protective equipment (PPE) and correct handling of hazardous drugs. CEB: *Nurse safety is directly related to knowledge of hazard assessment, decontamination, and proper use of PPE (NIOSH, 2013; Crickman, 2017).*
- Adhere to standards and transmission-based precautions when caring for clients with SARS-CoV-2 and use correct donning and doffing procedure with PPE (CDC, 2020b).
- Follow institutional policy and procedure for optimizing supply of PPE during surges or instances of low or inadequate PPE (CDC, 2020b).

Geriatric

- Help the client identify age-related factors that may affect response to contamination incidents.
- Advise older adults to follow public notices related to drinking water. *Contaminated water can harm the health of older persons and those with chronic conditions (CDC, 2014).*
- Encourage older adults to receive influenza vaccination when it is available, beginning as early as late August and continuing through the end of February. *Flu vaccination protects persons against influenza, protects those in proximity who are more vulnerable to serious flu illness, and reduces flu-associated hospitalizations among older adults (CDC, 2019a).*
- Instruct older adults with special needs or chronic conditions to create and share a plan with family and friends for emergencies and keep medications, prescriptions, and special devices on hand. *Sharing a plan for emergencies helps older adults create a social network that will be available for support and assistance* (*Federal Emergency Management Agency, 2020*).

Pediatric

- Provide environmental health hazard information. *Developing children are more vulnerable to environmental toxicants because of greater and longer exposure and particular susceptibility windows (Children's Environmental Health Network, 2017).*
- Reduce risks from exposure to environmental contaminants by identifying the ages and life stages of children. CEB: *Coordinate hazard and exposure assessment using children's ages and life stages to accommodate for children's physiology and developmental stage, which contribute to opportunities for environmental exposure and contamination (Hubal et al, 2014).*
- Screen newly arrived immigrant and refugee children, adolescents, pregnant and lactating women, and children for elevated blood lead levels secondary to lead hazards in country of origin and residence in older housing. EB: *Lead exposure is common in newly arrived refugees and those residing in older housing (CDC, 2020c).*
- Be aware that the risk for lead exposure is much higher in many countries from which children are adopted than in the United States; screening should then be conducted for those identified from 6 months and up to 16 years of age (CDC, 2019b).
- The current reference level of 5 µg/dL is used to identify children and environments associated with lead-exposure hazards. EB: *The CDC currently recommends using 5 µg/dL as the reference value in place of the previously recommended level of 10 µg/dL; reference values are updated every 4 years based on the most recent population-based blood lead surveys among children (CDC, 2020d).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Encourage flu vaccination among children. CEB: *Children vaccinated against flu were 74% less likely to be admitted to a pediatric intensive care for influenza compared with controls (Ferdinands et al, 2014).*

Multicultural

- Ask about use of imported or culture-specific products that contain lead, such as greta and azarcon (Hispanic folk medicine for upset stomach and diarrhea), ghasard (Indian folk medicine tonic), ba-baw-san (Chinese herbal remedy), and daw-tway (Thai and Myanmar [Burmese] remedy). *Immigrant children are at increased risk for contamination, particularly from lead related to exposure to imported culture-specific products (CDC, 2019c).*
- ✱ Nurses need to consider the cultural and social factors that affect access to and understanding of the health care system, particularly for groups such as migrant workers who do not have consistent health care providers. CEB: *Subtle cultural biases in how nurses approach care can affect outcomes (Holmes, 2012; Hubal et al, 2014).*

Home Care

- Assess current environmental stressors and identify community resources. *Accessing resources decreases stress and increases ability to cope.*
- Recognize that relocated and unemployed individuals/families are at risk for psychological distress. EB: *People who lose their social network are at a very high risk for postevent psychological distress and require appropriate care and resources to respond and recover from disasters (Substance Abuse and Mental Health Services Administration [SAMHSA], 2020).*
- Support policy and program initiatives that integrate case identification, triage, and mental health interventions into emergency care response following large scale disaster events. EB: *A skills-based mental health program using front-line workers was found feasible and beneficial in reducing psychological symptoms among disaster survivors (O'Donnell et al, 2020).*
- Instruct community members concerned about lead in drinking water from plumbing pipes and fixtures to have the water tested by calling the US Environmental Protection Agency (EPA) drinking water hotline at 1-800-424-8802.
- Educate community members to reduce exposure to lead by inquiring about lead-based paint before buying a home or renting an apartment built before 1978; *federal law requires disclosure of known information about lead-based paint (U. S. EPA, 2020).*
- Instruct individuals and families that food contamination occurs through a variety of mechanisms and that food safety is associated with proper washing of hands, surfaces, and utensils; prompt refrigeration of food; and cooking foods at the correct temperature. EB: *Pathogens can be introduced into food from infected humans who handle food without thoroughly washing their hands, from food that touches surfaces or utensils contaminated by pathogens in raw food, and improper refrigeration or heating of food (CDC, 2020e).*

Client/Family Teaching and Discharge Planning

- Provide truthful information to the person or family affected.
- Discuss signs and symptoms of contamination.
- Explain decontamination protocols.
- Explain need for isolation procedures.
- *Well-managed efforts at communication of contamination information ensure messages are correctly formulated, transmitted, and received and result in meaningful actions.*
- Emphasize the importance of prehospital exposure and postexposure treatment of contamination. CEB: *Early treatment decreases associated complications related to contamination (Agency for Toxic Substances and Disease Registry [ATSDR], 2014).*
- Provide parents with actionable information to reduce environmental contamination in the home. CEBN: *A randomized educational intervention to reduce contamination in the home demonstrated significant reduction in biomarker levels and improved environmental health self-efficacy and precaution adoption (Butterfield et al, 2011).*

Risk for Contamination

Domain 11 Safety/protection Class 4 Environmental hazards

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to exposure to environmental contaminants, which may compromise health.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Risk Factors

External Factors

Carpeted flooring; chemical contamination of food; chemical contamination of water; flaking, peeling surface in presence of young children; inadequate breakdown of contaminant; inadequate household hygiene practices; inadequate municipal services; inadequate personal hygiene practices; inadequate protective clothing; inappropriate use of protective clothing; individuals who ingested contaminated material; playing where environmental contaminants are used; unprotected exposure to chemical; unprotected exposure to heavy metal; unprotected exposure to radioactive material; use of environmental contaminant in the home; use of noxious material in inadequately ventilated area; use of noxious material without effective protection

Internal Factors

Concomitant exposure; malnutrition; smoking

At-Risk Population

Children aged <5 years; economically disadvantaged individuals; individuals exposed perinatally; individuals exposed to areas with high contaminant level; individuals exposed to atmospheric pollutants; individuals exposed to bioterrorism; individuals exposed to disaster; individuals with history of exposure to contaminant; older adults; pregnant women; women

Associated Conditions

Pre-existing disease; radiotherapy

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching, and References

Refer to care plan for **Contamination.**

Impaired Bowel Continence

Domain 3 Elimination and exchange Class 2 Gastrointestinal function

Kim L. Paxton, DNP, APRN, ANP-BC, LHIT-C

NANDA-I

Definition

Inability to hold stool, to sense the presence of stool in the rectum, to relax and store stool when having a bowel movement is not convenient.

Defining Characteristics

Abdominal discomfort; bowel urgency; fecal staining; impaired ability to expel formed stool despite recognition of rectal fullness; inability to delay defecation; inability to hold flatus; inability to reach toilet in time; inattentive to urge to defecate; silent leakage of stool during activities

Related Factors

Avoidance of non-hygienic toilet use; constipation; dependency for toileting; diarrhea; difficulty finding the bathroom; difficulty obtaining timely assistance to bathroom; embarrassment regarding toilet use in social situations; environmental constraints that interfere with continence; generalized decline in muscle tone; impaired physical mobility; impaired postural balance; inadequate dietary habits; inadequate motivation to maintain continence; incomplete emptying of bowel; laxative misuse; stressors

At-Risk Population

Older adults; women giving birth vaginally; women giving birth with obstetrical extraction

Associated Conditions

Anal trauma; congenital abnormalities of the digestive system; diabetes mellitus; neurocognitive disorders; neurological diseases; physical inactivity; prostatic diseases; rectum trauma; spinal cord injuries; stroke

C

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Bowel Continence; Bowel Elimination

Example NOC Outcome with Indicators

Bowel Continence as evidenced by the following indicators: Maintains predictable pattern of stool evacuation/Maintains control of stool passage/Evacuates stool at least every 3 days. (Rate the outcome and indicators of **Bowel Continence:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Have regular, complete evacuation of fecal contents from the rectal vault (pattern may vary from every day to every 3 days)
- Have regulation of stool consistency (soft, formed stools)
- Reduce or eliminate frequency of incontinent episodes
- Exhibit intact skin in the perianal/perineal area
- Demonstrate the ability to isolate, contract, and relax pelvic muscles (when incontinence related to sphincter incompetence or high-tone pelvic floor dysfunction)
- Increase pelvic muscle strength (when incontinence related to sphincter incompetence)
- Identify triggers that precipitate change in bowel continence

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Bowel Incontinence Care; Bowel Incontinence Care: Encopresis; Bowel Training

Example NIC Interventions—Bowel Incontinence Care

Determine physical or psychological cause of fecal incontinence; Instruct client/family to record fecal output, as appropriate

Nursing Interventions and *Rationales*

- In a private setting, directly question client about the presence of fecal incontinence. If the client reports altered bowel elimination patterns, problems with bowel control, or "uncontrollable diarrhea," complete a focused nursing history including previous and present bowel elimination routines, dietary history, frequency and volume of uncontrolled stool loss, and aggravating and alleviating factors. EB: *Unless questioned directly or the client is experiencing bothersome fecal incontinence, clients are often hesitant or withhold reporting the presence of fecal incontinence (Menees et al, 2018). The nursing history determines the patterns of stool elimination, to characterize involuntary stool loss and the possible causation of the incontinence (Yates, 2018).*
- Recognize that risk factors for fecal incontinence include older individuals, female sex, impaired mobility, cognitive impairment, obesity, individuals who have undergone pelvic surgery, diabetes, and structural or functional impairment of bowel function and medications (Young et al, 2017; Menees et al, 2018). *Although fecal incontinence is more common in women, it is also a problem for men and should not be overlooked when obtaining a health history. Men are more likely to report increased frequency of stool leakage episodes compared with women (Young et al, 2017; Menees et al, 2018).*
- Physiological changes of the female pelvis that occur with aging, along with those that occur with childbirth and anoreceptive intercourse increase the risk of elimination problems, both constipation and

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

incontinence (Young et al, 2017; Brown et al, 2020). EBN: *While most people associate incontinence automatically with urinary incontinence, it is often forgotten that at least 1 out of 10 women suffers from fecal incontinence as well who are over the age of 20 (Gass et al, 2019).*

- Recognize that additional risk factors for bowel incontinence in hospitalized clients include antibiotic therapy, medications, enteral feeding, indwelling urinary catheter placement, immobility, inability to communicate elimination needs, acute disease processes and procedures (e.g., cancer, abdominal surgery), sedation, and mechanical ventilation (Eman & Lohrmann, 2015; Pitta et al, 2019).

▲ Conduct a health history assessment that includes a review of current bowel patterns/habits, including constipation and use of laxatives; diarrhea; pelvic floor injury with childbirth; acute trauma to organs, muscles, or nerves involved in defecation; gastrointestinal inflammatory disorders; functional disability; and medications (Whitehead et al, 2016; Musa et al, 2019).

- Closely inspect the perineal skin and skinfolds for evidence of skin breakdown in clients with incontinence. EBN: *An expert consensus statement defined moisture-associated skin damage as inflammation and erosion of the skin caused by prolonged exposure to various sources of moisture (Coyer et al, 2017; McNichol et al, 2018). Incontinence-associated dermatitis (IAD) is a form of skin irritation that develops from chronic exposure to urine or liquid stool (Bliss et al, 2015; Coyer et al, 2017; McNichol et al, 2018). A recent meta-analysis found a strong association between IAD and a client developing a pressure ulcer (Manderlier et al, 2019).*
- Use a validated tool that focuses on bowel elimination patterns. EB: *Valid and reliable assessment tools help provide a clearer understanding of the client's individual challenges and perceptions of symptoms associated with fecal incontinence (Brown et al, 2020; McNichol et al, 2018).*
- Complete a focused physical assessment, including inspection of perineal skin, pelvic muscle strength assessment, digital examination of the rectum for the presence of impaction and anal sphincter strength, and evaluation of functional status (mobility, dexterity, and visual acuity).
- Complete an assessment of cognitive function; explore for a history of dementia, delirium, or acute confusion (Bliss et al, 2015; Blekken et al, 2018). EBN: *A study found that critically ill clients who were less cognitively aware were 50% more likely to develop IAD than clients who were more cognitively aware (Bliss et al, 2015; McNichol et al, 2018).*
- Document patterns of stool elimination and incontinent episodes through a bowel record, including frequency of bowel movements, stool consistency, frequency and severity of incontinent episodes, precipitating factors, and dietary and fluid intake. EB: *Documented patterns of elimination are used to narrow the likely etiology of stool incontinence and serve as a baseline to evaluate treatment efficacy (Rao et al, 2016; Yates, 2018).*
- Assess stool consistency and its influence on risk for stool loss. Several classification systems for stool exist and may assist the nurse and client to differentiate among normal soft, formed stool, hardened stools associated with constipation, and liquid stools associated with diarrhea. EB/EBN: *A study of stool consistency found good reliability when evaluated by nurses and clients. Word-only descriptors yielded equivocal consistency when assessed by subjects, as did tools that combined words with illustrations of various stool consistencies (Bliss et al, 2015). Less well-formed (loose or liquid) stool is associated with an increased severity and frequency of fecal incontinence episodes and potential for compromised skin integrity (Bliss et al, 2015; Beeckman, 2017; Coyer et al, 2017; Yates, 2018).*
- Identify conditions contributing to or causing fecal incontinence. *Fecal incontinence is frequently multifactorial. Accurate assessment of the probable etiology of fecal incontinence is necessary to select a treatment plan likely to control or eliminate the condition (Yates, 2018; Pitta et al, 2019).*
- Improve access to toileting:
  - ❍ Identify usual toileting patterns and plan opportunities for toileting accordingly.
  - ❍ Provide assistance with toileting for clients with limited access or impaired functional status (mobility, dexterity, and access).
  - ❍ Institute a prompted toileting program for persons with impaired cognitive status.
  - ❍ Provide adequate privacy for toileting.
  - ❍ Respond promptly to requests for assistance with toileting.

  EB: *Acute or transient fecal incontinence frequently occurs in the acute care or long-term care facility secondary to cognition changes, mentation changes associated with environment change, inadequate access to toileting facilities, insufficient assistance with toileting, inability to perform activities of daily living, or inadequate privacy when attempting to toilet (Blekken et al, 2016; Musa et al, 2019).*
- Review the client's nutritional history and evaluate methods to normalize stool consistency with dietary adjustments (e.g., avoiding high-fat foods) and use of fiber along with assessing for use of caffeine, lactose,

and sugar replacements (Paquette et al, 2017; Da Silva & Sirany, 2019; International Foundation for Functional Gastrointestinal Disorders [IFFGD], 2019; O'Donnell, 2020). EB: *Diet modifications have been found to be helpful in the management of fecal incontinence, including restrictions of some foods, adding fiber to the diet, and establishing consistent eating patterns (National Institute for Diabetes and Digestive and Kidney Diseases, 2017; Da Silva & Sirany, 2019; O'Donnell, 2020).*

- Encourage the client to keep a nutrition log to track foods that irritate the bowel (Paquette et al, 2017).
- For hospitalized clients with tube feeding–associated fecal incontinence, involve the nutrition specialist to evaluate the formula composition, osmolality, and fiber content.
- For the client with intermittent episodes of fecal incontinence related to acute changes in stool consistency, begin a bowel reeducation program consisting of the following:
  - Cleansing the bowel of impacted stool if indicated
  - Normalizing stool consistency by adequate intake of fluids (30 mL/kg of body weight per day) and dietary or supplemental fiber
  - Establishing a regular routine of fecal elimination based on established patterns of bowel elimination (patterns established before onset of incontinence)

  EB: *Education on bowel patterns and strategies to establish normal defecation patterns and stool consistency to reduce or eliminate the risk of recurring fecal incontinence have been found to be beneficial in controlling fecal incontinence associated with changes in stool consistency (NHS Choices Information, 2018; IFFGD, 2019).*
- Implement a scheduled stimulation defecation program for persons with neurological conditions causing fecal incontinence:
  - Cleanse the bowel of impacted fecal material before beginning the program.
  - Implement strategies to normalize stool consistency, including adequate intake of fluid and fiber and avoidance of foods associated with diarrhea.
  - Determine a regular schedule for bowel elimination (typically every day or every other day) based on prior patterns of bowel elimination.
  - Provide a stimulus before assisting the client to a position on the toilet; digital stimulation, a stimulating suppository, "mini-enema," or pulsed evacuation enema may be used for stimulation.

  EB: *The scheduled, stimulated program relies on consistency of stool and a mechanical or chemical stimulus to produce a bolus contraction of the rectum with evacuation of fecal material (Duelund-Jakobsen et al, 2016; Paquette et al, 2017).*
- Begin a reeducation or pelvic floor muscle exercise program for the person with sphincter incompetence or high-tone pelvic floor muscle dysfunction of the pelvic muscles, or refer persons with fecal incontinence related to sphincter dysfunction to a nurse specialist or other therapist with clinical expertise in these techniques of care. EB: *Although evidence of overall effectiveness of pelvic floor muscle exercise programs is inconclusive as a treatment strategy for fecal incontinence, the programs are not harmful (Brown et al, 2020).*

▲ Consider a sacral nerve stimulation program in clients with urgency to defecate and fecal incontinence related to weakened sphincter muscles or sphincter defect. EB: *Sacral nerve stimulation has been found to significantly reduce incontinence for some clients (Da Silva & Sirany, 2019; Brown et al, 2020).*

- Institute a structured skin care regimen that incorporates three essential steps: cleanse, moisturize, and protect:
  - Select a cleanser with a pH range comparable to that of normal skin (usually labeled "pH balanced").
  - Moisturize with an emollient to replace lipids removed with cleansing and protect with a skin. Products containing petrolatum, dimethicone, or zinc oxide base or a no-sting skin barrier should be used.
  - Routine incontinence care should include daily perineal skin cleansing and after each episode of incontinence.
  - When feasible, select a product that combines two or all three of these processes into a single step. Ensure that products are available at the bedside when caring for a client with total incontinence in an inpatient facility.
- Use of absorptive pads or adult containment briefs that are applied next to the client's skin increases the risk of IAD. Absorbent underpads that wick moisture away from skin may be used with immobile clients. EB/EBN: *A structured skin care regimen based on a three-step process (cleanse, moisturize, and protect) is effective for the prevention of IAD (Gray et al, 2016; Beeckman, 2017; Coyer et al, 2017; Manderlier et al, 2019).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ Consult the provider if a fungal infection is suspected. An antifungal cream or powder beneath a protective ointment may be indicated (Gray et al, 2016; Coyer et al, 2017).

- Assist the client to select and apply a containment device for occasional episodes of fecal incontinence. A fecal containment device will prevent soiling of clothing and reduce odors in the client with uncontrolled stool loss. EBN: *A study of community persons with fecal incontinence who used an absorptive dressing to contain mucus and stool leakage after surgery revealed that the device was preferred over traditional pads by 92% (Bliss et al, 2015).*
- In the client with frequent episodes of fecal incontinence and limited mobility, monitor the sacrum and perineal area for pressure ulcerations. EBN: *Limited mobility, particularly when combined with fecal incontinence and increased moisture, increases the risk of pressure ulceration. Routine cleansing, pressure reduction techniques, and management of fecal and urinary incontinence reduce this risk (Beeckman, 2017; Manderlier et al, 2019).*
- With acutely ill clients, anticipate and evaluate the cause of acute diarrhea. Anticipate diarrhea associated with treatment or specific interventions (e.g., medications, initiation of tube feedings). *Interventions to manage acute diarrhea include use of absorbent pads and skin protectant moisturizers or fecal collector/pouch (Beeckman, 2017; Pather et al, 2017).*

▲ Consult a provider or the standing orders before inserting a bowel management system (BMS) in the critically ill client when conservative measures have failed and fecal incontinence is excessive and/or produces perianal skin injury or IAD. *Indwelling BMSs, also called fecal management systems (FMSs), are commercially available and designed to direct, collect, and contain liquid stool in immobile clients. BMS devices are approved by the Food and Drug Administration for up to 29 days for management of liquid stool (Da Silva & Sirany, 2019).* EBN: *Devices other than BMSs should not be used for indwelling bowel/feces diversion (Da Silva & Sirany, 2019).*

Geriatric

- Evaluate all older clients for established or acute fecal incontinence when the older client enters the acute or long-term care facility and intervene as indicated. EB: *Fecal incontinence often coexists with urinary incontinence, necessitating evidence-based interventions to prevent skin breakdown and/or pressure ulcer development in the older client (Shahin & Lohrmann, 2015; Blekken et al, 2018; McNichol et al, 2018).*
- Determine the client's cognitive level using a screening tool such as the Mini-Mental State Exam (MMSE), Montreal Cognitive Assessment (MoCA), the Confusion Assessment Method (CAM), or Mini-Cog. EB: *Use of a standard evaluation tool such as the MMSE or MoCA can help determine the client's abilities and assist in planning appropriate nursing interventions. Acute or established dementias increase the risk of fecal incontinence among older adults (Jerez-Roig et al, 2015; Trzepacz et al, 2015).*
- Teach nursing colleagues, nonprofessional care providers, family, and clients the importance of providing toileting opportunities and adequate privacy for the client in an acute or long-term care facility.

Home Care

- The preceding interventions may be adapted for home care use.
- Assess and teach a bowel management program to support continence. Address timing, diet, fluids, and actions taken independently to deal with bowel incontinence. *Identifying factors that change level of incontinence may guide interventions. If the client has been taking over-the-counter medications or home remedies, it is important to consider their influence.*
- Instruct the caregiver to provide clothing that is nonrestrictive, can be manipulated easily for toileting, and can be changed with ease. *Avoidance of complicated maneuvers increases the chance of success in toileting programs and decreases the client's risk for embarrassing incontinent episodes.*
- Evaluate self-care strategies of community-dwelling older adults, strengthen adaptive behaviors, and counsel older adults about altering strategies that compromise general health.
- Assist the family in arranging care in a way that allows the client to participate in family or favorite activities without embarrassment. *Careful planning can both help the client retain dignity and maintain integrity of family patterns.*

▲ If the client is limited to bed (or bed and chair), provide a commode or bedpan that can be easily accessed. Involve occupational and physical therapy services as indicated to promote safe transfers.

▲ If the client is frequently incontinent, refer for home health aide services to assist with hygiene and skin care.

▲ Refer the family to support services to assist with in-home management of fecal incontinence as indicated.

- Refer to care plans for **Diarrhea** and **Constipation** for detailed management of these related conditions.

Risk for Adverse Reaction to Iodinated Contrast Media Domain 11

Safety/protection Class 5 Defensive processes

Pauline McKinney Green, PhD, RN, CNE

NANDA-I

Definition

Susceptible to noxious or unintended reaction that can occur within seven days after contrast agent injection, which may compromise health.

Risk Factors

Dehydration; generalized weakness

At-Risk Population

Individuals at extremes of age; individuals with history of adverse effect from iodinated contrast media; individuals with a history of allergy

Associated Conditions

Chronic disease; concurrent use of pharmaceutical preparations; decreased level of consciousness; individuals with fragile veins

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Perfusion: Renal; Kidney Function

Example NOC Outcome with Indicators

Kidney Function as evidenced by 24-hour intake and output balance/Blood urea nitrogen/Serum creatinine/Urine color/Serum electrolytes. (Rate the outcome and indicators of **Kidney Function:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain normal blood urea nitrogen and serum creatinine levels
- Maintain urine output of 0.5 mL/kg/hr
- Maintain serum electrolytes (K^+, PO_4, Na^+) within normal limits

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Fluid/Electrolyte Management; Laboratory Data Interpretation

Example NIC Activities—Fluid/Electrolyte Management

Monitor for serum electrolytes levels, as available; Weigh daily and monitor trends; Monitor vital signs, as appropriate

Nursing Interventions and *Rationales*

Recognize that iodinated contrast media can be harmful to clients in a number of ways, including onset of contrast-induced nephropathy (CIN), allergic reactions to the dye, and damage to veins and vascular access devices.

C

Contrast-Induced Nephropathy

Protect clients from contrast media-induced nephropathy by taking the following actions:

- Advocate for high-risk clients who are prone to develop contrast-induced acute kidney injury.
- Assess client's baseline kidney function, including serum creatinine, creatinine clearance, estimated glomerular filtration rate, and blood urea nitrogen (Nahar, 2017). EB: *Baseline renal values are critical for comparison purposes following contrast media; estimated glomerular filtration rate is a biomarker for CIN risk (American College of Radiology, 2021).*
- ▲ Assess clients for risk factors for adverse reactions to contrast media: preexisting renal insufficiency, diabetes mellitus, dehydration, cardiovascular disease, diuretic use, advanced age, multiple myeloma, hypertension, hyperuricemia, multiple doses of iodinated contrast media in less than 24 hours (American College of Radiology, 2021).
- Communicate information about at-risk clients to provider and procedure team in the hand-off report and electronic medical record. EBN: *A study of clients undergoing percutaneous coronary interventions with contrast media demonstrated significant reduction in acute kidney injury rates when evidence-based practices in nursing were introduced/standardized (Lambert et al, 2017).*
- ▲ Ensure that clients having diagnostic testing with contrast are well hydrated with isotonic intravenous (IV) fluids for volume expansion as ordered before and after the examination. EB: *Incidence of CIN is reduced by IV hydration with isotonic fluids (lactated Ringer's solution or 0.9% normal saline) before and after IV contrast administration (American College of Radiology, 2021).*
- ▲ Assess clients with symptoms of heart failure on an individual basis to determine tolerance for IV fluids used for hydration in the periprocedure period (Lambert et al, 2017).
- ▲ Monitor for and report signs of acute kidney injury for 48 hours after iodinated contrast administration in clients at risk: absolute serum creatinine increase ≥0.3 mg/dL, percentage increase in serum creatinine ≥50%, or urine output reduced to ≤0.5 mL/kg/hr for at least 6 hours. (Refer to your institution policy for specific clinical parameters.) *These clinical parameters are suggestive of acute kidney injury (Mehta et al, 2007; American College of Radiology, 2021).*
- ▲ Clients known to have acute kidney injury who are taking metformin should temporarily discontinue its use at the time of or before the procedure using contrast media, withhold metformin for 48 hours following, and reinstitute use only when renal function is found to be normal (Rose & Choi, 2015; American College of Radiology, 2021).

Allergic Reaction to Contrast Media

- ▲ Previous allergic reactions to contrast material, history of asthma, and other allergies are factors that may increase the client's risk of developing an adverse reaction. Discuss premedication with prednisone, methylprednisolone, or hydrocortisone with the provider for clients who have had previous reactions to contrast media or known asthma or allergies. EB: *Premedication may reduce the incidence of allergic reaction in some clients (Wang & Soloff, 2020; American College of Radiology, 2021).*
- Monitor carefully for symptoms of a hypersensitivity reaction, which can be mild, moderate, or severe. Report all symptoms to the provider because symptoms can advance rapidly from mild to severe.
  - ❍ *Mild reactions:* Nausea, vomiting, headache, itchy throat or eyes, flushing, mild skin rash, or hives.
  - ❍ *Moderate reactions:* Diffuse skin rash or hives, itchiness, erythema, wheezing but no hypoxia, facial edema but no dyspnea, throat tightness but no dyspnea.
  - ❍ *Severe reactions:* Diffuse hives with hypotension, diffuse itchiness or erythema with hypotension, diffuse edema including facial edema, wheezing with hypoxia, laryngeal edema with stridor and or hypoxia, anaphylactic shock (hypotension and tachycardia).
  - ❍ *Both allergic and allergic-like (anaphylactoid) reactions can occur. Life-threatening events usually occur within 20 minutes after injection. Delayed reactions may occur with rash that appears hours or days afterward (American College of Radiology, 2021).*

Vein Damage and Damage to Vascular Access Devices

- Recognize that *only* vascular access devices labeled "power injectable" can be used to administer power-injected contrast media. These include a power port, a power peripherally inserted central catheter (PICC) line, and a power central venous catheter (UCSF Department of Radiology and Biomedical Imaging, 2020a). *A regular vascular access device used for administration of contrast media can rupture from the high pressures used to administer the contrast media.*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Reduce the risk of vein and vascular access device damage with the following:
  - Maintain constant communication with the client during the injection and monitor client for report of pain or swelling at the injection site, paresthesia, or tenderness. *These are signs of complications that require the injection to be discontinued (American College of Radiology, 2021).*
  - Monitor access site for extravasation during and after the procedure; be vigilant for clients at increased risk of extravasation. *Clients at increased risk include those who cannot communicate, such as infants, older adults, or those with altered consciousness; severely ill or debilitated clients; clients with abnormal circulation in the affected limb; clients receiving the injection via a peripheral IV line that has been in place for more than 24 hours or into a vein that has been punctured multiple times; and clients with arterial insufficiency or compromised venous or lymphatic drainage in the affected extremity (American College of Radiology, 2021).*
  - Assess for venous backflow before injecting contrast. *If backflow is not obtained, the catheter may need adjustment (American College of Radiology, 2021).*
  - Directly monitor and palpate the venipuncture site during the first 15 seconds of injection. *A critical step in preventing significant extravasation is direct monitoring of the venipuncture site (American College of Radiology, 2021).*

Geriatric

- Screen the older client thoroughly before diagnostic testing using contrast media. *Adults over 60 years of age are considered at risk for acute adverse reactions to contrast media (Beckett, Moriority, & Langer, 2015).*

Pediatric

- Contrast medium can be safely administered intravenously by power injector at high flow rates of up to 2 mL/second (depending on size of client). A short peripheral IV catheter in the antecubital or forearm is the preferred route for intravenous contrast administration (UCSF Department of Radiology and Biomedical Imaging, 2020b). *Neonates and small children are especially susceptible to fluid shifts and have lower tolerance for intravascular osmotic loads compared with adults (American College of Radiology, 2021).* EB: *A retrospective study of pediatric clients who underwent computed tomography scan with iodinated contrast media injection found CIN incidents of 10.3% and 30-day unfavorable outcomes in 45.8% of clients (Cantais et al, 2016).*

Client/Family Teaching and Discharge Teaching

✱ Discharge instructions should include the importance of self-hydration after the procedure; reporting of symptoms of fluid retention or decrease in urine output; identifying which medications to take, withhold, or discontinue; scheduling laboratory evaluation 48 to 72 hours after the procedure; and scheduling follow-up with the provider (Lambert et al, 2017). *Client education contributes to client safety and greater compliance with self-care measures.*

Readiness for Enhanced Community Coping

Domain 9 Coping/stress tolerance Class 2
Coping responses

Marina Martinez-Kratz, MS, RN, CNE

C

NANDA-I

Definition

A pattern of community activities for adaptation and problem-solving for meeting the demands or needs of the community, which can be strengthened.

Defining Characteristics

Expresses desire to enhance availability of community recreation programs; expresses desire to enhance availability of community relaxation programs; expresses desire to enhance communication among community members; expresses desire to enhance communication between groups and larger community; expresses desire to enhance community planning for predictable stressors; expresses desire to enhance community resources for managing stressors; expresses desire to enhance community responsibility for stress management; expresses desire to enhance problem-solving for identified issue

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Community Competence; Community Health Status

Example NOC Outcome with Indicators

Community Health Status as evidenced by the following indicators: Prevalence of health promotion programs, health status of infants, children, adolescents, adults, elders, participation rates in community health programs. (Rate the outcome and indicators of **Community Health Status:** 1 = poor, 2 = fair, 3 = good, 4 = very good, 5 = excellent [see Section I].)

Community Outcomes

Community Will (Specify Time Frame)

- Develop enhanced coping strategies
- Maintain effective coping strategies for management of stress

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Environmental Management: Community; Health Policy Monitoring: Program Development

Example NIC Activities—Program Development

Assist the group or community in identifying significant health needs or problems; Identify alternative approaches to address the need(s) or problem(s)

Nursing Interventions and *Rationales*

Note: Interventions depend on the specific aspects of community coping that can be enhanced (e.g., planning for stress management, communication, development of community power, community perceptions of stress, community coping strategies).

▲ Establish a collaborative partnership with the community. EB: A recent study found that counties whose Area Agencies for the Aging (AAAs) maintained informal partnerships with a broad range of organizations in health care and other sectors had significantly lower hospital readmission rates compared with counties whose AAAs had informal partnerships with fewer types of organizations (Brewster et al, 2018).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Assess community needs with the use of concept mapping methodology. EB: *The findings of a recent study showed that an integration of several concept mapping methods into a community engagement process was able to increase the input from a wide range of populations (Velonis et al, 2018).*
- Assess for the impact of social determinants of health on community health. EB: *A validated multivariate social determinants of health index score was used to accurately classify counties with high cardiovascular burden (Hong & Mainous, 2020).*
- Encourage participation in faith-based organizations that want to improve community stress management. EBN: *A recent study showed that coaching by faith community nurses created an environment of sustained support that promoted improved lifestyles and blood pressure changes over time (Cooper & Zimmerman, 2017).*

▲ Identify the health services and information resources that are currently available in the community through network analysis. EB: *A study found that network analysis served as a useful tool to evaluate community partnerships and facilitate coalition building (An et al, 2017).*

- Work with community members to increase problem-solving abilities. EBN: *Problem-solving is essential for effective coping. Findings from a recent study showed positive outcomes from a direct and tailored problem-solving training program (Easom et al, 2018).*
- Provide support to the community and help community members identify and mobilize additional supports. EB: *A community mobilization project demonstrated how cross-sector, coordinated efforts focused on vulnerable populations can leverage local strengths to establish and enhance breastfeeding support services customized to local needs (Colchamiro et al, 2015).*
- Advocate for the community in multiple arenas (e.g., multimedia, social media, and governmental agencies). EB: *A recent study explored how social media can help community organizations engage in advocacy work (Guo et al, 2018).*
- Work with communities to ensure that vulnerable individuals with access and functional needs are included in preparations for, response to, and recovery from disasters. EB: *Analysis of recent disasters has identified that a combination of strategic and operational methods, appropriate planning tools, and planning for the entire community will prevent individuals with access and functional needs from being disproportionately and negatively affected by disasters (Franks & Seaton, 2017).*
- Partner with community pharmacies to provide community education and health prevention services. EB: *A review of reviews found support for the development of community pharmacy health services focused on primary disease prevention (Thomson et al, 2019).*

Pediatric

- Protect children and adolescents from exposure to community violence. EB: *A systematic review found evidence for a positive association between community violence exposure and cardiovascular and sleep problems in children and adolescents (Wright et al, 2017).*
- Assess children and adolescents for the effects of direct and indirect crime exposure rather than only focusing solely on violent victimization. EB: *A study found poor behavioral health outcomes for adolescents with self-reported crime exposure (Grinshteyn et al, 2018).*

Multicultural

- Acknowledge the stressors unique to racial/ethnic communities. EB: *A recent study of Hispanic and African American women found that neighborhood context was an important factor in examining the determinants of health, survivorship, and quality of life outcomes among cancer clients (Wu et al, 2018).*
- Identify community strengths with community members. EBN: *A community-based participatory research approach was used to obtain Native American community input and identify strengths to address youth suicide and substance abuse. The results led to the development of a strengths-based intervention incorporating the Gathering of Native Americans curriculum (Holliday et al, 2018).*
- Use an empowerment approach to address health behaviors in diverse communities. An empowerment approach includes increasing clients' self-efficacy and capacity to make informed decisions about their health care. EB: *A recent study found use of an empowerment approach was effective in changing nonadherent Latinas' breast screening behaviors and promoting them to become agents of change in their communities (Molina et al, 2018). The empowerment intervention has three sessions focused on early detection, sharing information with family/friends, and health volunteerism.*

C

- Work with members of the community to prioritize and target health goals specific to the community. EB: *Recent research found that members of underserved communities, in informed deliberations, prioritized research on quality of life, client-doctor, special needs, access, and compare approaches (Goold et al, 2017).*
- Establish and sustain partnerships with key individuals within communities when developing and implementing programs. EB: *A study of community engagement strategies found the following techniques to be effective: proactively engaging stakeholders in informational meetings, webinars, social media, the promising practice process, and community advisory council meetings (D'Angelo et al, 2017).*
- Use mentoring strategies for community members. EB: *A recent study showed parent mentors are highly effective in insuring uninsured Latino children and eliminating disparities (Flores et al, 2018).*
- Use community church settings as a forum for advocacy, teaching, and program implementation. EBN: *A recent study found that trust, respect, open dialog with participants, and commitment to address community health needs contributed to successful engagement and recruitment of African American churches to serve as participants in cancer research projects (Slade et al, 2018).*

Defensive Coping

Domain 9 Coping/stress tolerance Class 2 Coping responses

Arlene T. Farren, PhD, RN, AOCN, CTN-A

NANDA-I

Definition

Repeated projection of falsely positive self-evaluation based on a self-protective pattern that defends against underlying perceived threats to positive self-regard.

Defining Characteristics

Altered reality testing; denies problems; denies weaknesses; difficulty establishing interpersonal relations; difficulty maintaining interpersonal relations; grandiosity; hostile laughter; hypersensitivity to a discourtesy; hypersensitivity to criticism; inadequate follow through with treatment regimen; inadequate participation in treatment regimen; projection of blame; projection of responsibility; rationalization of failures; reality distortion; ridicules others; superior attitude toward others

Related Factors

Conflict between self-perception and value system; fear of failure; fear of humiliation; fear of repercussions; inadequate confidence in others; inadequate psychological resilience; inadequate self-confidence; inadequate social support; uncertainty; unrealistic self-expectations

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Decision-Making; Impulse Self-Control; Information Processing

Example NOC Outcome with Indicators

Coping as evidenced by the following indicators: Identifies effective and ineffective coping patterns/ Modifies lifestyle to reduce stress. (Rate the outcome and indicators of **Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Acknowledge need for change in coping style
- Accept responsibility for own behavior
- Establish realistic goals with validation from caregivers
- Solicit caregiver validation in decision-making

NIC (Nursing Interventions Classification)

Suggested Nursing Interventions

Body Image Enhancement; Complex Relationship Building; Coping Enhancement; Patient Contracting; Resiliency Promotion; Self-Awareness Enhancement; Self-Esteem Enhancement; Socialization Enhancement; Surveillance

Example NIC Activities—Self-Awareness Enhancement

Encourage client to recognize and discuss thoughts and feelings; Assist client in identifying behaviors that are self-destructive

Nursing Interventions and *Rationales*

- Assess for possible symptoms associated with defensive coping: depressive symptoms, excessive self-focused attention, negativism and anxiety, hypertension, posttraumatic stress disorder (e.g., exposure

to terrorism), substance use symptoms, unjust world beliefs. EBN: *In one study, 45% of nurse educators (212/470) experienced workplace bullying and coped with avoidance behaviors such as disengagement; the researcher recommended development of more effective ways to assess workplace bullying and further research exploring coping strategies in this population (Wunnenberg, 2020).* EBN: *Toxic stress may be associated with physiological disruptions that play roles of stressor, promotor of effects of stressful environments, and inhibitor of positive coping responses in mothers with personal history of trauma (Condon & Sadler, 2019).*

▲ Use cognitive behavioral interventions. EBN: *Cajanding (2016) conducted a randomized control trial of a nurse-led cognitive behavioral intervention in Filipino heart failure* (n =100) *clients (48-control group and 52-intervention group participants) and found a positive effect on quality of life, self-esteem, and improved mood.*

- Ask appropriate questions to assess whether denial (defensive coping) is being used in association with health problems including alcoholism, myocardial infarction (MI), or other diagnoses EBN: *Rogers et al (2017) conducted a study of 244 newly diagnosed colorectal cancer clients to determine coping with symptoms before diagnosis and found that denial was used by those with lower education and income levels and that denial was a factor in delaying care and time to diagnosis.*
- Promote interventions with multisensory stimulation approaches (MSA). EB: *MSA has been studied in a variety of health situations including anorexia (Provenzano et al, 2019) and in a review of randomized controlled trials in older adults (Silva et al, 2018) both suggesting MSA provides promise as interventions to reduce negative coping strategies such as denial, distortions, agitation, and anxiety; researchers recommend future research.*
- Empower the client/caregiver's self-knowledge. EB: In a qualitative study of adults receiving medications for rheumatoid arthritis, researchers found that self-efficacy in managing the medication regimen was associated with self-knowledge and medication knowledge and was influenced by initial denial and future acceptance (*Oshotse et al, 2018*).

Geriatric

▲ Identify problems with alcohol in older adults with the appropriate tools and make suitable referrals. EB: *Using valid and reliable tools including the Daily Drinking Questionnaire (DDQ) revised version subscale of drinking to cope motives, researchers found that older adults* (n = *98) with higher drinking to cope motives and low expectancies drank more; the researchers recommended examining drinking to cope motives so more targeted interventions could be formulated (Wilson et al, 2019).* CEB: *Tools such as the Alcohol Use Disorders Identification Test (AUDIT), Michigan Alcohol Screening Test—Geriatric Version (MAST-G), and the Alcohol-Related Problems Survey (ARPS) may have additional use in this population. Brief interventions have been shown to be effective in producing sustained abstinence or reducing levels of consumption, decreasing hazardous and harmful drinking (Culberson, 2006).*

- Encourage exercise for positive coping. EB: *In a pilot randomized clinical trial of a physical activity intervention in sedentary obese older adults* (n = *66), researchers found the intervention improved activity levels and coping while reducing stress; researchers recommended future research of the intervention (Matson et al, 2019).*
- Use individual and/or group reminiscence therapy (RT). EBN: *In a literature review of studies examining both individual and group RT in older adults without dementia, findings indicated that both approaches to RT showed promise for enhancing coping and social engagement and reducing depressive symptoms (Shropshire, 2020).*

Multicultural

- Acknowledge racial/ethnic differences at the onset of care. EB: *In a quantitative study of women who experienced intimate partner violence (IPV), researchers found racial/ethnic differences in the use of coping strategies such that African American women used more problem solving and avoidance coping than their Latina and White participants; researchers reported that their findings were consistent with earlier studies in the literature (Weiss et al, 2017).*
- Assess an individual's sociocultural backgrounds in teaching self-management and self-regulation. EB: *A study of problem gambling in South Pacific and Asian cultures found a relationship between problem gambling between parents and participants, such that expectancies and motives about gambling may help targeted interventions for offspring of problem gamblers (Dowling et al, 2018).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Encourage the client to use spiritual coping mechanisms such as faith and prayer. EBN: *In a qualitative study of Hispanic older adults (n = 17) and coping with mental health issues most participants described spiritual beliefs and religious practices, including a reliance on God, deep faith, and prayer, as their primary coping strategies (Curtin et al, 2019).* EB: *In a study of renal cell carcinoma clients' (n = 117) expressive writing, positive religious coping was found to be a common coping strategy; however, negative religious coping was associated with psychological distress (Narayanan et al, 2020).*
- Encourage spirituality as a source of support for coping. EBN: *Experts in hospice and palliative care recommend spiritual assessment and encourage client preferred interventions that may include prayer, meditation, and meaning-focused therapy (Ferrell, 2017).* EB: *In a study of religion and coping with racial discrimination among African Americans (n = 2032) and Caribbean Blacks (n = 857), researchers found that both groups were similar in their likelihood of using prayer for coping with discrimination (Hayward & Krause, 2015).*

Home Care

▲ Refer the client for programs that teach coping skills. EB: *Researchers explored binge drinking in American Indian adolescents and found that in addition to findings supporting previous research about the role of peer influence, cultural identity was associated with the level of binge drinking behavior; recommendations included culturally appropriate coping skills training for youth and their families and identified an effective program, the American Indian Life Skills Development Curriculum for this population (Cwik et al, 2017).*

Client/Family Teaching and Discharge Planning

- Teach coping skills to clients and caregivers. EBN: *In a longitudinal study of a psychoeducation program versus standard education in Spanish clients with Parkinson's disease (n = 140) and their caregivers (n = 127), researchers found that in the short-term the psychoeducation program improved quality of life of clients and coping in caregivers (Navarta-Sánchez et al, 2020).*
- Teach reflexive and expressive writing to address emotions. EBN: *A collaborative diary writing intervention was studied to examine its effectiveness for clients with critical illness at risk of critical care posttraumatic stress (PTS) (n = 66) compared with standard care (n = 68); researchers found the clients in the intervention group had lower incidence of PTS (Torres et al, 2020).* EBN: *Kim-Godwin et al (2020) conducted a mixed method pretest, post-test design study of mothers (n = 37) of children with behavioral or emotional problems and a 6-week journaling intervention; researchers found increases in measures of optimism and gratitude and themes included positive thinking and emotional well-being, leading the researchers to conclude that positive writing intervention can contribute to well-being and self-care.*

Ineffective Coping

Domain 9 Coping/stress tolerance Class 2 Coping responses

Arlene T. Farren, PhD, RN, AOCN, CTN-A

NANDA-I

Definition

A pattern of invalid appraisal of stressors, with cognitive and/or behavioral efforts, that fails to manage demands related to well-being.

Defining Characteristics

Altered affective responsiveness; altered attention; altered communication pattern; destructive behavior toward others; destructive behavior toward self; difficulty organizing information; fatigue; frequent illness; impaired ability to ask for help; impaired ability to attend to information; impaired ability to deal with a situation; impaired ability to meet basic needs; impaired ability to meet role expectation; inadequate follow-through with goal-directed behavior; inadequate problem resolution; inadequate problem-solving skills; reports altered sleep-wake cycle; reports inadequate sense of control; risk-taking behavior; substance misuse

Related Factors

High degree of threat; inability to conserve adaptive energies; inaccurate threat appraisal; inadequate confidence in ability to deal with a situation; inadequate health resources; inadequate preparation for stressor; inadequate sense of control; inadequate social support; ineffective tension release strategies

At-Risk Population

Individuals experiencing maturational crisis; individuals experiencing situational crisis

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Decision-Making; Impulse Self-Control; Information Processing

Example NOC Outcome with Indicators

Coping as evidenced by the following indicators: Identifies effective and ineffective coping patterns/ Modifies lifestyle to reduce stress. (Rate the outcome and indicators of **Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Client Outcomes

Client Will (Specify Time Frame)

- Use effective coping strategies
- Use behaviors to decrease stress
- Remain free of destructive behavior toward self or others
- Report decrease in physical symptoms of stress
- Report increase in psychological comfort
- Seek help from a health care professional as appropriate

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Decision-Making Support

Example NIC Activities—Coping Enhancement

Assist the client in developing an objective appraisal of the event; Explore with the client previous methods of dealing with life problems

Nursing Interventions and *Rationales*

- Appraise the presence of contributing factors for ineffective coping such as poor self-concept, grief, lack of problem-solving skills, lack of support, recent change in life situation, and maturational or situational crises. EBN: *Contributing factors may include experiences such as intimate partner violence in sexual minority men (Goldberg-Looney et al, 2016) and lifestyle behaviors such as high TV viewing in women experiencing trauma with or without symptoms (Jung et al, 2019).*
- Use presence and other verbal and nonverbal therapeutic communication approaches including empathy, active listening, calm approach, and acceptance. EBN: *Clients feel cared for and listened to with nurse presence as measured by the Presence of Nursing Scale (PONS) (Hansbrough & Georges, 2019).*
- Collaborate with the client to identify strengths such as the ability to relate the facts and to recognize the source of stressors. EBN: *Strength-based nursing (SBN) is a philosophical approach that includes eight values, including a collaborative partnership with clients and families (Gottlieb & Gottlieb, 2017).* EB: *Self-compassion in parents (n = 139) of children with autism spectrum disorders was associated with decreased stress and improved quality of life (Bohadana et al, 2019).*
- Explore the client's previous stressors and coping methods. EBN: *Caregivers of young adults with early psychosis experience stress due to client's behaviors and fear of harm to the client or themselves (Cheng et al, 2020b).* EB: *A review examining endometriosis and behavioral, cognitive, and emotional coping strategies demonstrated that despite mixed results, clinicians should engage in an evaluation of women's coping strategies to promote well-being and minimize poor mental health outcomes (Zarbo et al, 2018).*
- Provide opportunities to discuss the meaning the situation might have for the client. EBN: *A qualitative study of the coping experiences of spouses of people with dementia found that spouses search each day for meaning while experiencing stress and using coping strategies (Myhre et al, 2018).*
- Assist the client to set realistic goals and identify personal skills and knowledge. EBN: *Setting realistic goals is recommended as part of the support needed during weight loss programs (Fruh, 2017).* EB: *In a qualitative study of nurses and other health care providers (n = 10), researchers found that assisting clients to set realistic goals was essential to successful coaching interventions (Brandt et al, 2018).*
- Provide information regarding care, including diagnoses, treatments, and anticipated expectations. EBN: *Clients and caregivers of persons hospitalized for a cancer diagnosis reported that meeting their information needs assisted them to cope with (Abuatiq et al, 2020).*
- Discuss changes with the client before making them. EBN: *In a review of evidence about minimally invasive, robotic-assisted cancer surgery, researchers recommended that nursing care should focus on providing information and preparation to clients and families for shorter hospital stays (Sun & Fong, 2017).* EB: *In a study (n = 451) about transfer of clients from an intensive care unit to inpatient unit, clients/family were more satisfied and less stressed if they were informed in advance about impending transfers and nurses met with the client shortly after transfer (Stelfox et al, 2017).*
- Provide mental and physical activities within the client's ability (e.g., reading, television, radio, crafts, outings, movies, dinners out, social gatherings, exercise, sports, games). EB: *In a study of health care workers*

(n = 657) dealing with the stress of the COVID-19 pandemic, physical exercise was the preferred coping strategy for the majority of participants (Shechter et al, 2020).

- Discuss the power of the client and family to change a situation or the need to accept a situation. EBN: *Power as knowing participation in change was statistically significantly associated with client's (n = 98) engagement in health decision-making and resulted in satisfaction with the decisions (Sheikh, 2019).*
- Offer instruction regarding alternative coping strategies. EBN: *Motivational interviewing is a supportive strategy that helps elicit client perspectives and can promote coping (Carr, 2016).* EBN: *Mills, Wong-Anuchit, and Poogpan (2017) conducted a concept analysis of Thum-jai, a Thai coping strategy, and discussed the consequences or outcomes, which include emotional stability, positive thought, and productive change. It is recommended as an alternate coping strategy.*
- Encourage use of spiritual resources as desired. EBN: *Clark and Hunter (2019) conducted a literature review regarding spiritual coping in clients with advanced heart failure and recommended Reed's Theory of Self-Transcendence as a foundation for examining individuals' perspectives of their vulnerability and understanding one's sense of meaning.* EB: *Finding meaning after breast cancer treatment and experiencing posttraumatic growth was a significant source of coping and continued for as long as 2 years after treatment (Hamama-Raz et al, 2019).*
- Encourage use of social support resources. EBN: Based on a study of informal caregivers (n = 108) of persons with dementia, researchers recommended health care providers assist caregivers of persons with dementia build a broad-based support system because availability of social support predicted resilient coping (*Jones et al, 2019*).

▲ Refer for additional or more intensive therapies as needed. EB: *More complex interventions are available to assist with coping; for example, a randomized controlled trial of older adults in the community found that mindfulness and a self-compassion program consisting of 10, 2-hour sessions were successful in improving coping strategies (Perez-Blasco et al, 2016).*

Pediatric

✱ Monitor the client's risk of harming self or others and intervene appropriately. See care plan for Risk for **Suicidal Behavior**. EBN: *In a study of 140 Taiwanese secondary school students, resourcefulness as a coping strategy was inversely associated with depressive symptoms (Yang et al, 2017).*

- Monitor pediatric clients for exposure to community violence. EBN: *Researchers found that stressors such as violence and other traumatic disruptions in early childhood may interfere with the child's stress-response patterns and mental health in later life (Condon & Sadler, 2019).*
- Engage adolescents during stressful periods with comforting activities. EB: *In an experimental study that compared watching a video on cellphone, sitting quietly, or texting a friend after a stressful event, researchers found improved mood and decreased stress in adolescents (average age 12.4 years) only with the texting activity (Yau et al, 2021).*

Geriatric

▲ Assess and report possible physiological alterations (e.g., sepsis, hypoglycemia, hypotension, infection, changes in temperature, fluid and electrolyte imbalances, use of medications with known cognitive and psychotropic side effects). EBN: *Physical and mental comorbidities were found to be stressors for well older adults (ages 55–99) (Rubio et al, 2016) and for caregivers of older adults after stroke (Eeseung et al, 2016).*

- Screen for elder neglect or other forms of elder mistreatment. EBN/EB: *There is no gold standard for assessment of elder neglect, abuse, or mistreatment. There are several literature reviews exploring best practices for assessment and intervention (Hirst et al, 2016; Fearing et al, 2017; Moore & Browne, 2017).*
- Encourage the client to make choices (as appropriate) and participate in planning care and scheduled activities. EB: *Researchers found older adults preferred active engagement in making health care decisions, but the preference may be different for those with four or more comorbidities (Chi et al, 2017).*
- Target selected coping mechanisms for older persons based on client features, use, and preferences. EB: *Qualitative researchers, Birtwell and Dubrow-Marshall (2018), found older adults with mild dementia used coping mechanisms such as engaging in new activities and using humor.* EB: *In a quantitative study, older adult Internet users experiencing lockdown during a pandemic reported improved well-being associated with coping by hobby and interest-based Internet use (Nimrod, 2020).*
- Increase and mobilize support available to older persons by encouraging a variety of mechanisms involving family, friends, peers, and health care providers. EB: *Families give older adults important psychological support for coping with functional disabilities, pain, and other health issues (Honn Qualls, 2016).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Actively listen to complaints and concerns. EBN: *During the working phase of Peplau's theory, holistic communication includes the use of active listening to promote the older adult patient's development of a deeper connection with the nurse; active listening and focusing are essential holistic communication skills (Deane & Fain, 2016).*
- Engage the client in reminiscence. EBN: *A study of older adults with dementia living in a nursing home examined an intervention of music reminiscence therapy with reality orientation techniques, resulting in positive improvements in depression in the intervention group (Onieva-Zafra et al, 2018).*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's perceptions of effective coping. EBN: *One integrative review found evidence to support culture as a factor in coping with multiple chronic conditions; for example, the cultural belief of Arabic people includes multiple chronic conditions as sent by God and a sign of their relation with God (Cheng et al, 2020a).*
- Assess for intergenerational family problems that can overwhelm coping abilities. EBN: *A study of Chinese family caregivers revealed family expectations to provide care, but family resources contributed to coping, and a sense of self-sacrifice by the caregivers (Qiu et al, 2018).*

✱ Negotiate with the client regarding aspects of coping behavior that will need to be modified. EBN: *Adolescents are less likely to engage in help-seeking behaviors, which places them at greater risk for self-harm and suicide; resourcefulness has been found to be negatively and significantly related to self-harm in Taiwanese adolescents (Yang et al, 2017).* EB: *Researchers conducted two studies of Australian adolescents' online coping and found that those who engaged in frequent use of online technology for coping had poorer recovery from worry and jealousy (Duvenage et al, 2020).*

- Refer families experiencing race-based stress and trauma to evidence-based programs. EB: *The EMBRace program is based on racial socialization theory and is used to assist Black youth and their families to develop coping strategies to deal with the stress and trauma of discrimination (Anderson et al, 2019).*
- Identify which family members the client can count on for support. EBN: *In Madurai women who underwent hysterectomy (n = 60), researchers found that family support was associated with coping and quality of life and concluded that support from the partner is especially important to both coping and quality of life (Shanthi & Jeyapal, 2016).*
- Support the inner resources that clients use for coping. EBN: *Researchers in the United States and Asia have found evidence that supports that self-transcendence is an inner resource for coping and well-being in a variety of populations and situations; the effects of inner resources, such as resilience, self-adjustments, and getting out of oneself for the interest of others, are ways to enhance self-transcendence and meaning in life (Ho et al, 2016; Haase et al, 2017).*
- Use an empowerment framework to redefine coping strategies. EBN: *Canadian researchers tested an intervention based on a Caregiver Grief Model that enhanced empowerment and coping in caregivers of people with dementia (MacCourt et al, 2017).*

Home Care

- The interventions described previously may be adapted for home care use.

✱ Assess for suicidal tendencies. Refer for mental health care immediately if indicated.

✱ Identify an emergency plan should the client become suicidal. Ineffective coping can occur in a crisis situation and can lead to suicidal ideation if the client sees no hope for a solution. A suicidal client is not safe in the home environment unless supported by professional help. Refer to the care plan for Risk for **Suicidal Behavior.**

- Discuss preferred coping strategies of family caregivers. EBN: *Researchers found that family caregivers of dying persons used a variety of problem- and emotion-based coping strategies to achieve a sense of death preparedness (Durepos et al, 2019).*
- Encourage clients to participate knowingly in their care. Refer to the care plan for **Powerlessness.** EBN: *Power enhances coping when patients and caregivers participate knowingly to care for others and for those engaged in health care decision-making (Leveille-Tulce, 2017; Sheikh, 2019).*

▲ Refer the client and family to support groups. EB: *In a study of adolescents and adults with neurofibromatosis type 1 (NF1), a genetic, progressive disorder, researchers found that participation in support groups had an influence on self-esteem and recommended that health care professionals inform clients about support groups (Rosnau et al, 2017).*

▲ If monitoring medication use, discuss the barriers and facilitators to adapting and coping with the regimen. EBN: *Researchers found that patients with heart failure have stressors, often associated with social determinants of health that affect their ability to adhere to their medication and treatment regimens (Dickens et al, 2019).*

▲ Institute case management for frail elderly clients to support continued independent living. EBN: *Nurse-led community care for the oldest-old that includes care coordination and follow-up could preserve functioning in the oldest-old in the community (Bleijenberg et al, 2017).* EB: *A study examining tablet and Skype use in a case management program for frail older adults found that the participants had positive experiences with the technology as a means of communicating with case managers (Berner et al, 2016).*

Client/Family Teaching and Discharge Planning

- Teach the client to problem solve. Have the client define the problem and cause, and list the advantages and disadvantages of the options. EB: *A problem-solving intervention that included defining the problem and goals, listing multiple solutions, and selecting a solution found improved task-oriented coping, avoidant coping, and generic health-related quality of life (Visser et al, 2016).*
- Teach relaxation techniques. EBN: *A combination intervention of relaxation techniques and sleep hygiene training statistically significantly reduced insomnia, a source of stress, in postmenopausal women (Duman & Taşhan, 2018).*
- Work closely with the client to develop appropriate educational tools that address individualized needs. EB: *A participatory project to develop client education materials for older adults about lung stereotactic body radiotherapy (SBRT) involved clients at each step of the process. Participants had high health literacy and home Internet access, but researchers found that the participants had a preference for written and verbal teaching about the SBRT procedure (Jewitt et al, 2016).*

▲ Teach the client about available community resources (e.g., therapists, ministers, counselors, self-help groups). EBN: *Easom, Cotter, and Ramos (2018) conducted a post-participation examination of the Resources for Enhancing Alzheimer's Caregiver Health (REACH II) program provided to African American and Caucasian caregivers of people with Alzheimer's disease and found it to be a culturally appropriate and effective program.*

C

Readiness for Enhanced Coping

Domain 9 Coping/stress tolerance Class 2 Coping responses

Arlene T. Farren, PhD, RN, AOCN, CTN-A

NANDA-I

Definition

A pattern of valid appraisal of stressors with cognitive and/or behavioral efforts to manage demands related to well-being, which can be strengthened.

Defining Characteristics

Expresses desire to enhance knowledge of stress management strategies; expresses desire to enhance management of stressors; expresses desire to enhance social support; expresses desire to enhance use of emotion-oriented strategies; expresses desire to enhance use of problem-oriented strategies; expresses desire to enhance use of spiritual resource

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Personal Well-Being; Social Interaction Skills; Quality of life

Example NOC Outcome with Indicators

Coping as evidenced by the following indicators: Identifies effective coping patterns/Uses effective coping strategies. (Rate the outcome and indicators of **Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Acknowledge personal power
- State awareness of possible environmental changes that may contribute to decreased coping
- State that stressors are manageable
- Seek new effective coping strategies
- Seek social support for problems associated with coping
- Demonstrate ability to cope, using a broad range of coping strategies
- Use spiritual support of personal choice

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Health Education; Decision-Making Support

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NIC Activities—Coping Enhancement

Assist client in developing an objective appraisal of the event; Explore with client previous methods of dealing with life problems

C

Nursing Interventions and *Rationales*

- Assess and support positive psychological strengths, that is, hope, optimism, self-efficacy, resiliency, and social support. EB: *Researchers found that young adults demonstrating resilience use coping strategies such as strategic planning, positive refocusing, and restructuring and view situations with an optimistic perspective (Kim & Lee, 2018).*
- Be physically and emotionally present for the client while using a variety of therapeutic communication techniques. EBN: *A qualitative study using focus groups to understand nurses' (N = 27) experiences of presence found empathy, active listening, and use of silence were among the therapeutic communication approaches that were required to implement presence and improve client outcomes (Stockmann et al, 2018).* EBN: *Clients feel cared for and listened to with nurse presence as measured by the Presence of Nursing Scale (PONS) (Hansbrough & Georges, 2019).*
- Empower the client to set realistic goals and to engage in problem-solving. EBN: *Power as knowing participation in change was reported by a sample of adults (n = 98) with at least one chronic condition; the researcher found that freedom to act with intention was associated with engagement and satisfaction with health decisions and recommended that nurses increase their awareness of power as it can enhance person-centered care (Sheikh, 2019).* EB: *In a quantitative study of African American women (n = 290) who successfully increased their physical activity, coping behaviors such as setting goals, self-monitoring, and self-regulation were associated with their success; researchers recommended that the findings can be helpful to create interventions for other African-American women who may need to improve their level of physical activity (Kinsey et al, 2019).*
- Encourage expression of positive thoughts and emotions. EBN: *In a study of nurses working in the Philippines (n = 227), researchers found high levels of optimism and proactive coping; recommendations included creating policies and interventions to ensure continued levels of well-being of nurses to promote quality nursing care (Cruz et al, 2018).* EB: *Positive thinking was found to be associated with health, optimism, and problem-focused coping in a sample of cancer survivors (n = 603); researchers concluded that positive thinking and optimism promote resilience and healthy coping in cancer survivors (Gallagher et al, 2019).*
- Encourage the client to use spiritual coping mechanisms such as faith and prayer. EBN: *In a cross-sectional study of women living with human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS), researchers found that prayer and spirituality were associated with coping and health outcomes (Dalmida et al, 2018).*
- Help the client with serious and chronic conditions such as depression, cancer diagnosis, and chemotherapy treatment to maintain social support networks or assist in building new ones. EBN: *In a secondary analysis of longitudinal data, researchers examined illness uncertainty for clients with prostate cancer and their partners; researchers found social support reduced uncertainty and recommended providers promote social support networks for clients and their partners (Guan et al, 2020).*
- ▲ Refer for cognitive-behavioral therapy (CBT) to enhance coping skills. EBN: *In a randomized control trial of a nurse-led cognitive behavioral intervention in a sample of heart failure clients (n = 48, control, and n = 52, intervention group), researchers found a positive effect on quality of life, self-esteem, and mood (Cajanding, 2016). Refer to the care plans for Readiness for Enhanced* ***Communication*** *and Readiness for Enhanced* ***Spiritual*** *Well-Being.*

Pediatric

- Encourage children and adolescents to engage in diversional activities and exercise to promote self-esteem, enhance coping, and prevent behavioral and other physical and psychosocial problems. EBN: *Researchers examining physical activity in children attending school (n = 133) found that enjoyment and self-efficacy were important influences in promoting physical activity in children (Ling et al, 2015).* EBN: *In a qualitative study of hospitalized children (n = 10) receiving chemotherapy for cancer, researchers found that engaging children in entertaining activities and having fun were among positive coping strategies (Sposito et al, 2015).*
- Provide families of children with chronic illness with education, transitional assistance, and psychosocial support to enhance coping. EBN: *An integrative literature review found that interventions should be*

directed toward education and psychosocial support for clients and families dealing with a new diagnosis of chronic illnesses (Gunter & Duke, 2018).

Geriatric

- Encourage active, meaning-based coping strategies for older adults with chronic illness. EBN: *In a qualitative study of older adults living with HIV* (n = *40) residing in an urban environment, researchers uncovered four themes: accessing support, helping oneself and others, and tapping into their own spirituality. These address successful coping for the participants (DeGrezia & Scrandis, 2015).* EB: *Using a case study and evidence-based approach, experts identified meaning-based interventions to engage older adults, such as life-review, reminiscence, honoring wisdom, and engaging in mindfulness; experts recommended providers encourage these activities with older adults (Yang et al, 2018).*
- Consider the use of Web-based and technological resources for older adults in the community. EBN: *In a pilot study to explore the feasibility of an Internet health education program for older adults, researchers found improved attitudes toward Internet sources of health information and improved e-health literacy; researchers concluded that this educational intervention showed promise for enhancing e-health literacy in older adults (Chang et al, 2021).*
- Refer the older client to self-help support groups that address health, psychosocial, and/or social support. EB: *In a qualitative study of a reading and writing group for the well-being of older adults* (n = *12), researchers categorized themes in relational terms including relation to self with subthemes of acknowledgment and achievement, as well as time for self; the reading and writing allowed for eliciting insight and working on emotions; researchers concluded the group enhanced well-being in older adults and recommended bibliotherapy and writing in a variety of community groups (Malyn et al, 2020).*

Multicultural

- Assess an individual's sociocultural backgrounds to identify factors that support coping. EBN: *Using qualitative, narrative methods to explore positive identity in First Nation men, participants described themselves as living a balanced life that engaged coping approaches such as having positive mentors and connections with positive aboriginal communities; researchers concluded that supporting positive identity and supporting culturally safe care can promote strength-based coping and well-being (Carter et al, 2017).* EB: *Researchers found that in a sample of African American college students* (n = *191), a variety of past messages regarding racial socialization may predict race-specific coping in African-American college students (Blackmon et al, 2016).*
- Encourage spirituality as a source of support for coping. EBN: *Living with the unity of God and nature was one of the essential themes found in a hermeneutic study of Afro-Caribbean adults* (n = *14) using folklore practices for healing and well-being (Joseph, 2020).*
- Facilitate positive ethnocultural identity to enhance coping. EBN: *The importance of a positive ethnocultural identity emerged in the qualitative study of Carter et al (2017) of First Nation men with themes regarding balance in life and engaging with positive aboriginal communities.*
- Foster family support. EBN: *In Madurai women who underwent hysterectomy* (N = *60), researchers found that family support was associated with coping and quality of life and concluded that support from the partner is especially important to both coping and quality of life (Shanthi & Jeyapal, 2016). Refer to the care plan for Ineffective* ***Coping.***

Home Care

- The interventions described previously may be adapted for home care use.
- Engage both clients and their caregivers as a dyad. CEBN: *In a review of a program of research about helping clients and family caregivers cope with cancer, Northouse (2012) related lessons learned about caring for client and family caregiver dyad. Recommendations included identifying strengths; three-way, open communication and alliances; and promoting active coping (versus avoidant coping).*

▲ Institute case management for frail elderly clients to support continued independent living. EBN: *Nurse-led community care for the oldest-old that includes care coordination and follow-up could preserve functioning in the oldest-old in the community (Bleijenberg et al, 2017).* EB: *A study examining tablet and Skype use in a case management program for frail older adults found that the participants had positive experiences with the technology as a means of communicating with case managers (Berner et al, 2016).*

- Refer the client and family to support groups. EB: *A study of adolescents and adults with neurofibromatosis type 1 (NF1), a genetic, progressive disorder, explored knowledge of the disease, self-esteem, and the effect of support groups. Researchers found that participation in support groups had an influence on*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

self-esteem and recommended that health care professionals inform clients about support groups (Rosnau et al, 2017).

- Refer prostate cancer clients and their spouses to family programs that include family-based interventions of communication, hope, coping, uncertainty, and symptom management. EBN: *In their longitudinal secondary data analysis of uncertainty in prostate cancer clients and their partners, Guan et al (2020) found that those with lower social support had greater uncertainty; researchers recommended nurses tailor interventions that include opportunities for social support of clients and their partners.*

▲ Refer military members, veterans, and family members for appropriate health services. EB: *Research found veterans with and without posttraumatic stress disorder (PTSD) enrolled in the Veterans Administration Program of Comprehensive Assistance for Family Caregivers (PCAFC) accessed more mental health, primary, and specialty care services than weighted comparisons (Shepherd-Banigan et al, 2018).*

Client/Family Teaching and Discharge Planning

- Teach the client about available community resources (e.g., therapists, ministers, counselors, self-help groups, family education groups). EBN: *Easom, Cotter, and Ramos (2018) conducted a postparticipation examination of the Resources for Enhancing Alzheimer's Caregiver Health (REACH II) program provided to African American and Caucasian caregivers of people with Alzheimer's disease and found it to be a culturally appropriate and effective program.*
- Teach caregivers using a variety of interventions that contribute to coping. EBN: *In one quasi-experimental study to examine the effectiveness of an education program for informal caregivers of persons with stroke, researchers found the intervention group gained practical skills, reported lower burden levels, and had better general mental health (Araujo et al, 2018).*
- Teach expressive writing, journaling, and education about emotions. EBN: *In a mixed-method study of a 6-week journaling intervention of mothers (n =37), researchers found increases in reports of optimism and gratitude; qualitative themes included positive thinking and emotional well-being (Kim-Godwin et al, 2020).*

Ineffective Community Coping

Domain 9 Coping/stress tolerance Class 2 Coping responses

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

A pattern of community activities for adaptation and problem-solving that is unsatisfactory for meeting the demands or needs of the community.

Defining Characteristics

Community does not meet expectations of its members; deficient community participation; elevated community illness rate; excessive community conflict; excessive community stress; high incidence of community problems; perceived community powerlessness; perceived community vulnerability

Related Factors

Inadequate community problem-solving resources; inadequate community resources; nonexistent community systems

At-Risk Population

Community that has experienced a disaster

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Community Competence; Community Health Status; Community Violence Level

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NOC Outcome with Indicators

Community Competence as evidenced by the following indicators: Participation rates in community activities/Consideration of common and competing interests among groups when solving community problems/Representation of all segments of the community in problem-solving/Effective use of conflict management strategies. (Rate the outcome and indicators of **Community Competence:** 1 = poor, 2 = fair, 3 = good, 4 = very good, 5 = excellent [see Section I].)

C

Community Outcomes

A Broad Range of Community Members Will (Specify Time Frame)

- Participate in community actions to improve power resources
- Develop improved communication among community members
- Participate in problem-solving
- Demonstrate cohesiveness in problem-solving
- Develop new strategies for problem-solving
- Express power to deal with change and manage problems

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Community Health Development; Program Development

Example NIC Activities—Community Health Development

Enhance community support networks; Identify and develop potential community leaders; Unify community members behind a common mission; Ensure that community members maintain control over decision-making

Nursing Interventions and *Rationales*

Note: The diagnosis of Ineffective **Coping** does not apply and should not be used when stress is being imposed by external sources or circumstance. If the community is a victim of circumstances, using the nursing diagnosis Ineffective **Coping** is equivalent to blaming the victim. See the care plan for Readiness for Enhanced Community **Coping.**

▲ Establish a collaborative partnership with the community (see the care plan for Readiness for Enhanced Community **Coping** for additional references). EB: *A recent study found that counties whose Area Agencies for the Aging (AAAs) maintained informal partnerships with a broad range of organizations in health care and other sectors had significantly lower hospital readmission rates compared with counties whose AAAs had informal partnerships with fewer types of organizations (Brewster et al, 2018).*

● Assess community needs with the use of concept mapping methodology. EB: *The findings of a recent study showed that an integration of several concept mapping methods into a community engagement process was able to increase the input from a wide range of populations (Velonis et al, 2018).*

● Assess for the impact of social determinants of health on community health. EB: *A validated multivariate social determinants of health index score was used to accurately classify counties with high cardiovascular burden (Hong & Mainous, 2020).*

● Encourage participation in faith-based organizations that want to improve community stress management. EBN: *A recent study showed that coaching by faith community nurses created an environment of sustained support that promoted improved lifestyles and blood pressure changes over time (Cooper & Zimmerman, 2017).*

▲ Identify the health services and information resources that are currently available in the community through network analysis. EB: *A study found that network analysis served as a useful tool to evaluate community partnerships and facilitate coalition building (An et al, 2017).*

● Work with community members to increase problem-solving abilities. EBN: *Problem-solving is essential for effective coping. Findings from a recent study showed positive outcomes from a direct and tailored problem-solving training program (Easom et al, 2018).*

- Provide support to the community and help community members identify and mobilize additional supports. EB: *A community mobilization project demonstrated how cross-sector, coordinated efforts focused on vulnerable populations can leverage local strengths to establish and enhance breastfeeding support services customized to local needs (Colchamiro et al, 2015).*
- Advocate for the community in multiple arenas (e.g., multimedia, social media, governmental agencies). EB: *A recent study explored how social media can help community organizations engage in advocacy work (Guo & Saxton, 2018).*
- Work with communities to ensure that vulnerable individuals with access and functional needs are included in preparations for, response to, and recovery from disasters. EB: *Analysis of recent disasters has identified that a combination of strategic and operational methods, appropriate planning tools, and planning for the entire community will prevent individuals with access and functional needs from being disproportionately and negatively affected by disasters (Franks & Seaton, 2017).*
- Partner with community pharmacies to provide community education and health prevention services. EB: *A review of reviews found support for the development of community pharmacy health services focused on primary disease prevention (Thomson et al, 2019).*

Pediatric

- Protect children and adolescents from exposure to community violence. EB: *A systematic review found evidence for a positive association between community violence exposure and cardiovascular and sleep problems in children and adolescents (Wright et al, 2017).*
- Assess children and adolescents for the effects of direct and indirect crime exposure rather than only focusing solely on violent victimization. EB: *A study found poor behavioral health outcomes for adolescents with self-reported crime exposure (Grinshteyn et al, 2018).*

Multicultural

- Acknowledge the stressors unique to racial/ethnic communities. EB: *A recent study of Hispanic and African American women found that neighborhood context was an important factor in examining the determinants of health, survivorship, and quality of life outcomes among cancer clients (Wu et al, 2018).*
- Identify community strengths with community members. EBN: *A community-based participatory research approach was used to obtain Native American community input and identify strengths to address youth suicide and substance abuse. The results led to the development of a strengths-based intervention incorporating the Gathering of Native Americans curriculum (Holliday et al, 2018).*
- Use an empowerment approach to address health behaviors in diverse communities. An empowerment approach includes increasing clients' self-efficacy and capacity to make informed decisions about their health care. EB: *A recent study found use of an empowerment approach was effective in changing nonadherent Latinas' breast screening behaviors and promoting them to become agents of change in their communities (Molina et al, 2018). The empowerment intervention has three sessions focused on early detection, sharing information with family/friends, and health volunteerism.*
- Work with members of the community to prioritize and target health goals specific to the community. EB: *Recent research found that members of underserved communities, in informed deliberations, prioritized research categories on quality of life, client-doctor relationships, special needs, access, and compare approaches (Goold et al, 2017).*
- Establish and sustain partnerships with key individuals within communities when developing and implementing programs. EB: *A study of community engagement strategies found the following techniques to be effective: proactively engaging stakeholders in informational meetings, webinars, social media, the promising practice process, and community advisory council meetings (D'Angelo et al, 2017).*
- Use mentoring strategies for community members. EB: *A recent study showed parent mentors are highly effective in insuring uninsured Latino children and eliminating disparities (Flores et al, 2018).*
- Use community church settings as a forum for advocacy, teaching, and program implementation. EBN: *A recent study found that trust, respect, open dialog with participants, and commitment to address community health needs contributed to successful engagement and recruitment of African American churches to serve as participants in cancer research projects (Slade et al, 2018).*

C

Compromised Family Coping

Domain 9 Coping/stress tolerance Class 2 Coping responses

Katherina Nikzad-Terhune, PhD, MSW

NANDA-I

Definition

An usually supportive primary person (family member, significant other, or close friend) provides insufficient, ineffective, or compromised support, comfort, assistance, or encouragement that may be needed by the client to manage or master adaptive tasks related to his or her health challenge.

Defining Characteristics

Client complaint about support person's response to health problem; client reports concern about support person's response to health problem; limitation in communication between support person and client; protective behavior by support person incongruent with client's abilities; protective behavior by support person incongruent with client's need for autonomy; support person reports inadequate knowledge; support

person reports inadequate understanding; support person reports preoccupation with own reaction to client's need; support person withdraws from client; unsatisfactory assistive behaviors of support person

Related Factors

C

Coexisting situations affecting support person; depleted capacity of support person; family disorganization; inaccurate information presented by others; inadequate information available to support person; inadequate reciprocal support; inadequate support given by client to support person; inadequate understanding of information by support person; misunderstanding of information by support person; preoccupation by support person with concern outside of family

At-Risk Population

Families with member with altered family role; families with support person experiencing depleted capacity due to prolonged disease; families with support persons experiencing developmental crisis; families with support persons experiencing situational crisis

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Caregiver Emotional Health; Caregiver-Client Relationship; Family Coping; Family Participation in Professional Care; Family Support During Treatment

Example NOC Outcome with Indicators

Family Coping as evidenced by the following indicators: Confronts family problems/Manages family problems/Reports needs for family assistance. (Rate each indicator of **Family Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Family/Significant Person Will (Specify Time Frame)

- Verbalize internal resources to help deal with the situation
- Verbalize knowledge and understanding of illness, disability, or disease
- Provide support and assistance as needed
- Identify need for and seek outside support

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Caregiver Support; Coping Enhancement; Family Involvement Promotion; Family Mobilization; Family Support; Mutual Goal Setting; Normalization Promotion; Sibling Support

Example NIC Activities—Family Support

Appraise family's emotional reaction to client's condition; Promote trusting relationship with family

Nursing Interventions and *Rationales*

- Assess the strengths and deficiencies of the family system. Consider using Family Systems Nursing, which emphasizes collaboration and a strength-focused relationship between health care professionals and the entire family as a unit of care. **EBN:** *A Family Systems Approach in nursing, as well as multiprofessional collaboration, is effective in facilitating illness management and improving communication and support between family members (Duhamel, 2017).*
- Establish rapport with families by providing accurate communication.
- Assist family members to recognize the need for help and teach them how to ask for it.
- Encourage family members to verbalize feelings. Spend time with them, sit down and make eye contact, and offer coffee and other nourishment.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Provide family support interventions in situations in which caregiving is involved in the family. **EB:** *A comprehensive review of caregiving literature in both the fields of aging and developmental disabilities revealed that family-support interventions improved participant well-being, improved service access and satisfaction, reduced caregiver burden, and delayed institutional placement (Heller, Gibbons, & Fisher, 2015).*
- Provide privacy during family visits. If possible, maintain flexible visiting hours to accommodate more frequent family visits. If possible, arrange staff assignments so the same staff members have contact with the family. Familiarize other staff members with the situation in the absence of the usual staff member. *Providing privacy, maintaining flexible hours, and arranging consistent staff assignments reduce stress, enhance communication, and facilitate the building of trust.*
- Provide education to clients regarding active coping strategies to use in situations involving chronic illnesses. **EB:** *Mindfulness-based activities and cognitive behavioral therapy strategies can improve emotional, behavioral, and cognitive functioning in individuals experiencing various stressors (Gu et al, 2015).*
- Provide psychoeducation interventions and support for families providing palliative care to help reduce caregiver stress and burden. **EB:** *Brief psychoeducation interventions helped reduce stress in caregivers caring for a dying relative (Hudson et al, 2015).*
- Refer the family with ill family members to appropriate resources for assistance as indicated (e.g., counseling, psychotherapy, financial assistance, spiritual support).

Pediatric

- Provide screening for postpartum depression (PPD) during the prenatal period and during the 6-week postpartum checkup to identify symptoms of depression in mothers. **EB:** *The Edinburgh Postnatal Depression Scale (EPDS) is the most widely used screening tool for detecting PPD and has been shown to be effective both prenatally and postnatally for detecting symptoms of depression in women. The EPDS is also considered an adequate tool for identifying depressive symptoms in Spanish pregnant women (Vázquez & Míguez, 2019).*
- Consider medication management and psychosocial interventions, including individual therapy, group therapy, support groups, and brief psychotherapy. **EB:** *These are effective treatment strategies for managing PPD (Stewart & Vigod, 2019).*

▲ Use preventive strategies, such as screening, psychoeducation, postpartum debriefing, and companionship in the delivery room (e.g., community volunteer). Continuing education is also recommended for health care professionals to improve knowledge regarding PPD. **EBN:** *New mothers viewed depression screening and receiving community resource information as a positive part of their care (Logsdon et al, 2018).*

- Use technology-based education to help increase knowledge and support for parents performing care procedures for their children. **EBN:** *Research suggests that smartphone-based education should be considered as an effective educational intervention in providing nursing support for parents of children with respiratory disease (Lee, Kim, & Min, 2017).*
- Use best practices and participate in training to help make communication and environmental adaptations when interacting with children with autism spectrum disorder (ASD) to enhance communication, improve quality of care, and reduce behavioral problems and frustration. **EBN:** *Nursing students who participated in a simulation using a standardized client role-playing an adolescent with ASD reported increased knowledge and improved clinical skills for responding to behavior and communication challenges in children with ASD (McIntosh et al, 2018b).* **EBN:** *School nurses can help reduce and manage problematic behaviors in children with ASD by using extrinsic motivation and reinforcement techniques, as well as communicating clear expectations, providing the child with choices, and using visual activity schedules (McIntosh et al, 2018a).*
- Effectively engaging and collaborating with parents is essential for supporting parents of children with long-term health conditions, and it may enhance the parent–professional relationship and communication. **EBN:** *Smith, Swallow, and Coyne (2015) provided a framework for involving parents in the care of a child with long-term health conditions, which includes valuing the parent's knowledge and expertise of their child, supporting parents in their role, establishing rapport, mutually exchanging information with parents, sharing decisions, collaborating during care planning, and designing services around both the needs of the child and the family.*
- Provide evidence-based psychological therapies for parents with children with chronic conditions. **EB:** *Psychological therapies, such as cognitive behavioral therapy, can lead to improvements in mood and behavior in parents of children diagnosed with attention-deficit hyperactivity disorder (ADHD) (Wong et al, 2018).*
- When performing pediatric diabetes care, be attentive to the mother's experience, including burnout experienced as a result of caregiving for the child. **EBN:** *The well-being of the mother has the potential to*

affect the well-being of the child and the well-being of the family unit. Focusing on the well-being of mothers of children with pediatric diabetes may lead to improvements in overall family functioning, and referrals for appropriate interventions (Lindström et al, 2017).

- Provide options for home-based interventions when severe childhood illnesses make it difficult for children and families to participate in interventions. In-home visits, assessments, and interventions may help improve self-management among the client and family and reduce emergency department visits and inpatient hospitalizations. **EBN:** *The delivery of a home visit program for pediatric asthma clients enhanced early communication, reduced response time between problem identification and resolution, and reduced inpatient care over the course of 1 year (McClure et al, 2017).*

Geriatric

▲ Perform a holistic assessment of all needs of informal family caregivers. **EBN:** *Nurse-led caregiver-centered intervention may help prevent decompensation in caregiver well-being. Results from a recent study reveal that caregivers view a trusting relationship with mental health nurses as being crucial, and that collaboration with nurses can lead to increased well-being in both care recipients and caregivers (Zegwaard et al, 2017).*

▲ Assist informal caregivers with reducing unmet needs by helping them obtain the information, education, and support necessary for caring for an older adult with a chronic health condition. **EB:** *Internet interventions can help meet the educational and support needs of informal dementia caregivers. Results from a systematic review demonstrate that Internet-based interventions can help improve mental health outcomes for informal caregivers of individuals with dementia (Egan et al, 2018).*

- In situations in which familial caregiving is being provided, assess current coping strategies utilized within the family. Provide interventions for family caregivers that are designed specifically to enhance coping skills, including problem-solving strategies and emotional support. **EB:** *Psychosocial interventions that incorporated problem-solving skills, emotional support, knowledge of dementia, and social resources helped caregivers develop more effective coping strategies, which have the potential to reduce caregiver burden (Chen et al, 2015).*

Multicultural

- Acknowledge sociocultural differences and health care disparities at the onset of care. **EBN:** *Consider using Almutairi's critical cultural competence (CCC) model as a comprehensive approach for addressing challenges that may arise from sociocultural and linguistic issues during cross-cultural interactions. Research support use of the Critical Cultural Competence Scale (CCCS) to measure health care providers' perceptions of their CCC (Almutairi & Dahinten, 2017).*
- Use valid and culturally competent assessment tools and procedures when working with families with different racial/ethnic backgrounds. **EBN:** *The cultural information in nursing models and assessments should encompass health beliefs and practices, communication styles, religious orientation, and the degree of acculturation among others (Shen, 2015).*
- Assess for the influence of cultural beliefs, norms, and values on the individual/family/community's perceptions of coping. **EB:** *The Cross-Cultural Depression Coping Inventory (CCD-CI) is recommended to assess how individuals from different cultures prefer to cope with depression. Empirical results designate the CCD-CI as a reliable and valid measure of coping strategies for depression that are appropriate for adults from different ethnic groups (Markova, Sandal, & Guribye, 2020).*
- Provide opportunities for clients and families to discuss spirituality. **EBN:** *Spiritual interventions and coping strategies that focus on meaning, purpose, and connectedness are recommended in the nursing literature, and have been found to be effective in particular with clients experiencing heart failure (Clark & Hunter, 2019).*
- Ensure culturally responsive approaches to end-of-life care. **EBN:** *Providing culturally informed nursing care allows elderly immigrants the opportunity to make choices during their end-of-life care that are congruent with their cultural beliefs and expectations (Johnstone et al, 2016).*

Home Care

- The interventions described previously may be adapted for home care use.
- Assess the reason behind the breakdown of family coping. *Knowledge of the reasons behind compromised coping will assist in identification of appropriate interventions. Refer to the care plan for* ***Caregiver Role Strain.***

▲ During the time of compromised coping, increase visits to ensure the safety of the client, support of the family, and reassurance regarding expectations for prognosis as appropriate.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ Assess the needs of the caregiver in the home, and intervene to meet needs as appropriate; explore all available resources that may be used to provide adequate home care (e.g., parish nursing as an effective adjunct, home health aide services to relieve the caregiver's fatigue).
▲ Encourage caregivers to attend to their own physical, mental, and spiritual health, and give more specific information about the client's needs and ways to meet them.
▲ Refer the family to medical social services for evaluation and supportive counseling. Serve as an advocate, mentor, and role model for caregiving; provide written information for the care needed by the client.
▲ A positive approach and caring by the nurse and concrete task definition and assignment reinforce positive coping strategies and allow caregivers to feel less guilty when tasks are delegated to multiple caregivers.
▲ When a terminal illness is the precipitating factor for ineffective coping, offer hospice services and support groups as possible resources. **EB:** *Research suggests that clients and their families value home hospice care services and report experiencing beneficial outcomes as a result of using hospice services (Ong et al, 2016).*
● Encourage the client and family to discuss changes in daily functioning and routines created by the client's illness, and validate discomfort resulting from changes. *Individuals who live together for a long period tend to become familiar with each other's patterns; for example, meals are expected at certain times or a spouse becomes accustomed to the client's sleep habits.*
● Support positive individual and family coping efforts. *Positive feedback reinforces desired behaviors and supports the family unit.*
● Screen for mental health disorders (MHDs) in the elderly home care population. **EBN:** *Approximately one-third of elderly clients with MHDs received mental health services during a 60-day home care episode. Regular screening and intervention protocols can improve psychiatric care for the homebound elderly (Wang et al, 2016).*
● During home care visits and assessments, provide individuals and families with information for Internet-based interventions, including information on using social media as a health communications tool. **EB:** *A systematic review supports the effectiveness of online interventions (Web and app based) for clients with severe psychiatric disorders as well as their families as evidenced by improvements in knowledge, allowing for experiences to be shared, reported symptom relief for the client, fewer hospitalizations, and an increase in perceived social support (Barbeito et al, 2020).*

Client/Family Teaching and Discharge Planning

● Assess grief in parents who have lost a child to help determine parental needs, especially in the first year after the death of a child. **EB:** *The presentation of grief may differ in mothers and fathers, resulting in different needs during the first year after a child's death (Youngblut et al, 2017).*
▲ Refer women with breast cancer and their family caregivers to support groups (including social network sites and online communities), and to other services that provide assistance with daily coping. **EB:** *Online support groups and communities are feasible and useful tools that may enhance the overall well-being of breast cancer survivors by providing information and opportunities to engage and connect with other cancer survivors (Falisi et al, 2017).*
▲ For families dealing with childhood illnesses, developmental disorders, or other psychosocial stressors, refer parents to training, support, and education groups to provide opportunities for parents to access support, learn new parenting skills, and obtain additional coping resources. **EB:** *Empirical evidence reveals that support groups for parents of children with ASD are effective in reducing stress and enhancing professional knowledge and peer support (Tzur Bitan, 2018). Consider referring parents of children with ASD to parent training programs, which systematic reviews and a randomized clinical trials have revealed are effective for improving parent-child interaction, disruptive behaviors in children, and the mental health of the mother (Iida et al, 2018).* **EBN:** *Since youth present to health care professionals with symptoms related to cyberbullying, a systematic review supports educating both parents and youth on cyberbullying as an evidence-based practice for enhancing coping skills, communication, and digital citizenship (Hutson, Kelly, & Militello, 2018).*
● Provide comprehensive discharge planning for individuals and families to help improve quality of life at home. **EBN:** *Ensuring high-quality discharge planning and assessing parental readiness for discharge can result in identifying at-risk families and mobilizing anticipatory services to support the family's transition home. Assessing discharge readiness is also linked to enhanced parental coping and reduced child hospital readmission (Weiss et al, 2017).* **EB:** *A meta-analysis reveals that when older adults are discharged to a community setting, integrating caregivers into the discharge planning process reduces the risk of hospital readmission (Rodakowski et al, 2017).*

C

- Individuals diagnosed with a developmental disability and a mental illness and their families frequently experience multiple challenges and insufficient resources and support. **EBN:** *Best practices include providing person- and family-centered care; navigation support; prevention strategies; emergency and crisis care services; and housing and vocation assistance to help address gaps in services and enhance familial coping (Nicholas et al, 2017).*
- Nurses can help clients with type 2 diabetes with self-management education and support (DSME/S), which includes the facilitation of knowledge, skills, and abilities necessary to manage diabetes, as well as obtaining the support necessary for executing and maintaining the coping and behavioral skills needed for self-management. **EB:** *Self-management education and support has been shown to improve health outcomes in clients with type 2 diabetes (Powers et al, 2017).*

Disabled Family Coping

Domain 9 Coping/stress tolerance Class 2 Coping responses

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Behavior of primary person (family member, significant other, or close friend) that disables his or her capacities and the client's capacities to effectively address tasks essential to either person's adaptation to the health challenge.

Defining Characteristics

Abandons client; adopts illness symptoms of client; aggressive behaviors; depressive symptoms; difficulty structuring a meaningful life; disregards basic needs of client; disregards family relations; distorted reality about client's health problem; expresses feeling abandoned; family behaviors detrimental to well-being; hostility; impaired individualism; inadequate ability to tolerate client; loss of client independence; neglects treatment regimen; performing routines without regard for client's needs; prolonged hyperfocus on client; psychomotor agitation; psychosomatic symptoms

Related Factors

Ambivalent family relationships; chronically unexpressed feelings by support person; differing coping styles between support person and client; differing coping styles between support persons

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Caregiver Well-Being; Family Coping; Family Normalization; Neglect Recovery

C

Example NOC Outcome with Indicators

Family Normalization as evidenced by the following indicators: Adapts family routines to accommodate needs of affected member/Meets physical and psychosocial needs of family members/Provides activities appropriate to age and ability for affected family member/Uses community support groups. (Rate the outcome and indicators of **Family Normalization:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Family/Significant Person Will (Specify Time Frame)

- Identify normal family routines that will need to be adapted
- Participate positively in the client's care within the limits of his or her abilities
- Identify responses that may be harmful
- Acknowledge and accept the need for assistance with circumstances
- Identify appropriate activities for affected family member

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Family Process Maintenance; Caregiver Support; Family Support; Family Therapy; Respite Care

Example NIC Activities—Family Process Maintenance

Determine typical family processes; Minimize family routine disruption by facilitating family routines and rituals such as private meals together or family discussions for communication and decision-making; Design schedules of home care activities that minimize disruption of family routine

Nursing Interventions and *Rationales*

- Families dealing with acute trauma are susceptible to mild to very severe levels of anxiety. Support should be offered through necessary channels, which are appropriate to the situation, such as providing frequent information, offering social services, or counseling. EB: *Findings from one study suggest that a large percentage of caregivers of clients with trauma suffered from mild to very severe levels of anxiety (Rahnama et al, 2017).*
- Assess coping strategies of family members. EBN: *A study found that assessment of family coping during a hospitalization of their child with cancer can help nurses develop and implement supportive interventions (Lyu et al, 2017).*
- Cancer caregiving interventions should include communication skill building, including strategies for self-care. EB: *Findings from this study confirmed that caregiver quality of life is affected by stress about communication across all domains (Wittenberg et al, 2017).*
- Provide ideas for positive child coping and consider collaboration with mental health providers for children with chronic illnesses who are facing emotional problems. EBN: *One study suggested that negative child coping may have deleterious effects on the family (Woodson et al, 2015).*
- Assess social support of family members caring for survivors of traumatic brain injuries (TBIs). Facilitate realistic expectations about caregiving. EB: *TBI survivors and caregivers had multiple self-reported unaddressed needs after their discharge from facility-based treatment. They expressed the need for further education regarding potential post-TBI challenges and strategies for addressing them, including a need for community and mental health resources (Adams & Dahdah, 2016).*
- Respect and promote the spiritual needs of the client and family. EB: *Spiritual well-being is associated with better mental health and positive coping skills of family caregivers (Kelley & Morrison, 2015).*

Pediatric

- Assist parents and children suffering from chronic illness to develop accommodative coping skills (adapting to stressors rather than attempting to change the stressors). EB: *A study of child and family coping with pediatric inflammatory bowel disease found participants coped through social support, cognitive strategies (positive attitude), behavioral strategies for managing emotions, and confidence in medical care (Easterlin et al, 2020).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Assess discharge readiness of parents of ill children and construct high-quality parent teaching to address educational attainment. EBN: *A study found a sequential effect of the quality of discharge teaching delivery on parent discharge readiness, which is associated with parent coping difficulty and child readmission (Weiss et al, 2017).*

Geriatric

- Assess the emotional well-being of family members who are caring for clients with long-term illnesses, such as stroke. EB: *Ali and Kausar (2016) studied levels of psychological distress experienced by the caregivers of clients who had a stroke, concluding that distress can be reduced by providing greater social support.*
- Be aware of age-related deterioration in coping skills. EB: *A study that compared executive functioning, short-term memory, and coping in a sample of young and older adults found young participants scored higher than older adults on executive functioning and short-term memory (Nieto et al, 2020).*

Multicultural

- Acknowledge racial/ethnic differences at the onset of care. EBN: *Acknowledgment of race/ethnicity issues will enhance communication, establish rapport, and promote treatment outcomes (Giger & Davidhizar, 2021).*
- Be sensitive to the stigma attached to particular illness in various cultures. EB: *Iseselo, Kajula, and Yahya-Malima (2016) studied families coping with mental illness in Tanzania and concluded that the psychosocial challenges of families and caregivers require a collaborative approach.*

Home Care

The interventions described previously may be adapted for home care use:

- Assess for strain in family caregivers.
- Assess for "caregiver fatigue" and provide information related to available respite care.
- Consult social services for available home resources related to the client's age and illness.

Client/Family Teaching and Discharge Planning

- Provide psychoeducational family teaching for families impacted by mental illness. EB: *A study found that psychoeducational family intervention was effective in improving the adaptive coping strategies of relatives of clients with a diagnosis of bipolar I disorder (Sampogna et al, 2018).*
- Involve the client and family in the planning of care as often as possible.
- Recognize that family decision makers may need additional psychosocial support services.

Readiness for Enhanced Family Coping

Domain 9 Coping/stress tolerance Class 2 Coping responses

Keith A. Anderson, PhD, MSW and Marina Martinez-Kratz, MS, RN, CNE

C

NANDA-I

Definition

A pattern of management of adaptive tasks by primary person (family member, significant other, or close friend) involved with the client's health challenge, which can be strengthened.

Defining Characteristics

Expresses desire to acknowledge growth impact of crisis; expresses desire to choose experiences that optimize wellness; expresses desire to enhance connection with others who have experienced a similar situation; expresses desire to enhance enrichment of lifestyle; expresses desire to enhance health promotion

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Family Coping; Health-Seeking Behavior; Participation in Health Care Decisions

Example NOC Outcome with Indicators

Family Coping as evidenced by the following indicators: Confronts and manages family problems/ Cares for needs of all family members. (Rate the outcome and indicators of **Family Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State a plan indicating coping strengths, abilities, and resources, as well as areas for growth and change
- Perform tasks and engage resources needed for growth and change
- Evaluate changes and continually reevaluate plan for continued growth

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Family Integration Promotion; Family Involvement Promotion; Family Support; Mutual Goal Setting

Example NIC Activities—Family Coping

Facilitate communication of concerns and feelings between clients and family or among family members; Provide resources that support and encourage adaptive family coping; Respect and support adaptive coping mechanisms used by family

Nursing Interventions and *Rationales*

▲ Assess the structure, resources, and coping abilities of families and use these assessments in selecting interventions and formulating care plans. EBN: *It is critical to understand the resiliency and coping capabilities of families; the use of established assessment instruments (e.g., Family Assessment Device, Family Assessment Measure) can provide insight into family dynamics, coping styles, and resources of family systems (Sawin, 2016).*

▲ Acknowledge, assess, and support the spiritual needs and resources of families and clients. EB/EBN: *Spirituality has been found to be an important, yet often overlooked, coping resource for families and clients during illness and recovery (Hodge, 2015; Prouty et al, 2016).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- ▲ Establish rapport with families and empower their decision-making through effective communication and person/family-centered care. EBN: *Effective communication and person/family-centered care approaches can help to establish rapport, personalize treatment plans, and empower families in their caregiving activities and decision-making capacities (Mitchell et al, 2016; Coombs et al, 2017).*
- ▲ Provide family members with educational and skill-building interventions to alleviate caregiving stress and to facilitate adherence to prescribed plans of care. EBN: *The provision of psychoeducational and supportive interventions may enable family members to gain a sense of control in the caregiving role and become more comfortable in providing care and making informed decisions (Dockham et al, 2016).*
- ▲ Develop, provide, and encourage family members to use counseling services and interventions. EBN: *Family-centered counseling interventions have been shown to be effective, particularly in situations regarding serious illness and difficult family decisions (Creasy et al, 2015).*
- ▲ Identify and refer to support programs that discuss experiences and challenges similar to those faced by the family (e.g., cancer support groups). EB: *Although there is wide diversity in the format of support programs, couples and family support approaches can be beneficial and enhance coping (Inhestern et al, 2016).*
- ▲ Incorporate the use of emerging technologies to increase the reach of interventions to support family coping. EBN: *Emerging computer and Internet-based supportive and educational interventions may hold promise in enhancing family members' well-being and informational needs (Risling, Risling, & Holtslander, 2017; Salem et al, 2017).*
- ▲ Refer to **Compromised Family Coping** for additional interventions.

Pediatric

- ▲ Identify and assess the management styles of families and facilitate the use of more effective ways of coping with childhood illness. EB: *Understanding the dominant characteristics of each family's coping styles and resources and helping them to use more effective management styles can result in better family functioning and treatment outcomes (McCarthy et al, 2016; Ketelaar et al, 2017).*
- ▲ Provide educational and supportive interventions for families caring for children with illness and disability. EBN: *Providing information, training parents in care management, and offering supportive programs can reduce stress levels in parents and lead to better outcomes for children (Golfenshtein, Srulovici, & Deatrick, 2016).*

Geriatric

- ▲ Encourage family caregivers to participate in counseling and support groups. EB/EBN: *Although a wide variety of programs exist, certain counseling and support group programs have been found to be effective in increasing family resourcefulness and lowering caregiver burden, anxiety, depression, and family conflict (Dam et al, 2016; Muller et al, 2017).*
- ▲ Provide educational and therapeutic interventions to family caregivers that focus on knowledge and skill building. EBN: *Psychoeducational interventions that are accessible and tailored to individual needs can be highly valued and useful to family caregivers (Bakas, McCarthy, & Miller, 2017).*

Multicultural

- ● Acknowledge the importance of cultural influences in families and ensure that assessments and assessment tools account for such cultural differences. EB: *Family coping tends to vary across cultures and may affect the fit, reliability, and validity of existing family functioning and coping assessment tools (Desai, Rivera, & Backes, 2016).*
- ● Understand and incorporate cultural differences into interventions to enhance the impact of family interventions. EB: *Tailoring interventions to the customs, beliefs, preferences, and strengths of specific groups may increase effectiveness (McCalman et al, 2017).*

Readiness for Enhanced Decision-Making

Domain 10 Life principles

Class 3 Value/belief/action congruence

Dawn Fairlie, PhD, NP and Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

A pattern of choosing a course of action for meeting short- and long-term health-related goals, which can be strengthened.

Defining Characteristics

Expresses desire to enhance congruency of decisions with sociocultural goal; expresses desire to enhance congruency of decisions with sociocultural value; expresses desire to enhance congruency of decisions with goal; expresses desire to enhance congruency of decisions with values; expresses desire to enhance decision-making; expresses desire to enhance risk-benefit analysis of decisions; expresses desire to enhance understanding of choices; expresses desire to enhance understanding of meaning of choices; expresses desire to enhance use of reliable evidence for decisions

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Participation in Health Care Decisions; Personal Autonomy

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NOC Outcome with Indicators

Participation in Health Care Decisions as evidenced by the following indicators: Claims decision-making responsibility/Exhibits self-direction in decision-making/Seeks reputable information/Specifies health outcome preferences. (Rate the outcome and indicators of **Participation in Health Care Decisions:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Review treatment options with providers
- Ask questions about the benefits and risks of treatment options
- Communicate decisions about treatment options to providers in relation to personal preferences, values, and goals

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Decision-Making Support; Mutual Goal Setting; Support System Enhancement; Values Clarification

Example NIC Activities—Decision-Making Support

Help client identify the advantages and disadvantages of each alternative; Facilitate collaborative decision-making; Help client explain decisions to others, as needed

Nursing Interventions and *Rationales*

- Support and encourage clients and their representatives to engage in health care decisions. EB: *Decisional conflict was assessed using the Decisional Conflict Scale (DCS) among 186 Dutch mental health clients. They concluded that client participation in decision-making and measuring decisional conflict and knowledge about influencing factors could improve adherence to treatment and clinical outcomes (Metz et al, 2018).* EBN: *Decision aids are intended to help people participate in decisions that involve weighing the benefits and harms of treatment options, often with scientific uncertainty. Hart, Tofthagen, and Hsiao-Lan (2016) developed a decision aid that could be adapted and used in a variety of settings with a focus on initiating a conversation between the client and provider on lung cancer screening. Respect personal preferences, values, needs, and rights.* EBN: *"Clarifying values can be a rewarding exercise, as it not only ensures the best possible decision but demonstrates to patients that we are genuinely interested in incorporating their views and how they value the outcomes from screening options" (Lang et al, 2018, p 29).*
- Provide information that is appropriate, relevant, and timely. EBN: *Decisional conflict was assessed using the DCS among surrogate decision-makers to compare end-of-life terminologies "Do Not Resuscitate" (DNR) and "Allow Natural Death" (AND). Findings included that the framing of the decision influenced decision satisfaction and decision-making. Additionally, prior experience with end-of-life decision-making demonstrated lower mean total DCS scores and lower mean subscores, indicating that prior experience is an important aspect of end-of-life decision-making (Fairlie, 2017).*
- Determine the health literacy of clients and their representatives before helping with decision-making. EB: *An online decision aid for a low health literacy population will be pilot tested with 30 women diagnosed with early breast cancer with the anticipation that the low health literacy decision aid will be useful and acceptable to young women with low health literacy who have been diagnosed with breast cancer and it will be preferred over the high literacy decision aid (Peate et al, 2017).*
- Tailor information to the specific needs of individual clients, according to principles of health literacy. EB: *Altin and Stock (2016) sampled 1125 German adults to examine the contributions of health literacy, shared decision-making, person-centered communication, and satisfaction with care received by the general practitioner. Respondents with sufficient health literacy skills were 2.06 times as likely to be satisfied with their care.*
- Motivate clients to be as independent as possible in decision-making. EB: *A study of shared decision-making and autonomy among clients with multiple sclerosis revealed that person-centered decision-making was most commonly preferred by study participants, followed by shared decision-making (Cofield et al, 2017).*

- Facilitate communication between the client and family members regarding the final decision; offer support to the person actually making the decision. EBN: *A study of surrogate decision-makers' decisional conflict with end-of-life decision-making found that surrogates who had discussed end-of-life preferences with their loved one experienced less decisional conflict than those who had not discussed preferences (Fairlie, 2017).*
- Design educational interventions for decision support. EBN: *The goal of client decision aids is to engage clients in health care decisions by providing evidence-based information in plain language. The goal is to assist clients in understanding the risks and benefits of all available treatment/diagnosis options and engage clients in health care decisions to improve alignment of treatment choices with clients' preferences (Madden & Kleinlugtenbelt, 2017).*

Geriatric

- The previously mentioned interventions may be adapted for geriatric use.
- Facilitate collaborative decision-making. EB: *A systematic review of randomized controlled trials evaluating the efficacy of decision aids compared with the usual care for older adults facing treatment, screening, or care decisions found that decision aids improve older adults' knowledge, increase their risk perception, decrease decisional conflict, and seem to enhance participation in shared decision-making (van Weert et al, 2016).*

Multicultural

- Use existing decision aids for particular types of decisions or develop decision aids as indicated. EB: *Hoffman et al (2017) measured decisional conflict as a primary measure of decision quality and an intermediate measure in the process of screening uptake in a sample of 88 African American males. The purpose of client decision was to prepare clients for a consultation with their doctor. The entertainment–education decision aid significantly improved African American clients' knowledge, reduced their decisional conflict, and increased their sense of self-advocacy regarding colorectal cancer screening.*

Home Care

- The previously mentioned interventions may be adapted for home care use.
- Develop clinical practice guidelines that include shared decision-making. EBN: *Thoma-Lürken et al (2018) reported that people with dementia who wish to age in place are susceptible to nursing home admission. Nurses can intervene by detecting practical problems people with dementia and caregivers face. They identified three domains, decreased self-reliance, safety-related problems, and informal caregiver/social network-related problems, and proposed addressing these domains to facilitate aging in place.*

Client/Family Teaching and Discharge Planning

- Instruct the client and family members to provide advance directives in the following areas:
  - Person to contact in an emergency
  - Preference (if any) to die at home or in the hospital
  - Desire to initiate advance directives, such as a living will or medical power of attorney
  - Desire to donate an organ
  - Funeral arrangements (i.e., burial, cremation)

  EBN: *Shared decision-makers experienced less decisional conflict when they had discussed end-of-life preferences with the client (Fairlie, 2017).*

Decisional Conflict Domain 10 Life principles Class 3 Value/belief/action congruence

Dawn Fairlie, PhD, NP and Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Uncertainty about course of action to be taken when choice among competing actions involves risk, loss, or challenge to values and beliefs.

Defining Characteristics

Delayed decision-making; expresses distress during decision making; physical sign of distress; physical sign of tension; questions moral principle while attempting a decision; questions moral rule while attempting a decision; questions moral values while attempting a decision; questions personal beliefs while attempting a decision; questions personal values while attempting a decision; recognizes undesired consequences of potential actions; reports uncertainty about choices; self-focused; vacillating among choices

Related Factors

Conflict with moral obligation; conflicting information sources; inadequate information; inadequate social support; inexperience with decision-making; interference in decision-making; moral principle supports mutually inconsistent actions; moral rule supports mutually inconsistent actions; moral value supports mutually inconsistent actions; unclear personal beliefs; unclear personal values

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Information Processing; Participation in Health Care Decisions; Personal Autonomy

Example NOC Outcome with Indicators

Decision-Making as evidenced by the following indicators: Identifies relevant information/Identifies alternatives/Identifies potential consequences of each alternative/Identifies needed resources to support each alternative. (Rate the outcome and indicators of **Decision-Making:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State the advantages and disadvantages of choices
- Share fears and concerns regarding choices and responses of others

- Seek resources and information necessary for making an informed choice
- Make an informed choice

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Decision-Making Support

D

Example NIC Activities—Decision-Making Support

Inform client of alternative views or solutions in a clear and supportive manner; Provide information requested by client

Nursing Interventions and *Rationales*

- Observe for factors causing or contributing to conflict (e.g., value conflicts, fear of outcome, poor problem-solving skills). EB: *When studying clients with prostate cancer, Hoffman et al (2018) assessed differences across four treatment groups and asked about decision-making.*
- Provide emotional support. EB: *O'Neill et al (2018) assessed the information needs and levels of distress and correlates of this distress of young women with breast cancer. They reported lower distress and significantly lower decisional conflict and greater endorsement of an array of healthy coping strategies and suggested that young adult women have unmet cancer genetic information and support needs.*
- Use decision aids or computer-based decision aids to assist clients in making decisions. EB: *Baptista et al (2018) found that Web-based decision aids performed similarly to alternative formats for decision-quality outcomes. Additionally, because of anonymity, Web-based decision aids increased access to decision aids that support prostate cancer screening decisions among men. Initiate health teaching and referrals when needed.* EB: *Lopez-Olivo et al (2018) developed and tested multimedia education tools (video tools) for clients with knee osteoarthritis, osteoporosis, and rheumatoid arthritis. They found that multimedia educational tools that incorporate videos increase client understanding and management of their disease.*
- Facilitate communication between the client and family members regarding the final decision; offer support to the person actually making the decision. EBN: *A study of surrogate decision makers' decisional conflict with end-of-life decision-making found that surrogates who had discussed end-of-life preferences with their loved ones experienced less decisional conflict than those who had not discussed their preferences (Fairlie, 2018).*

Geriatric

- Carefully assess clients with dementia regarding ability to make decisions. EBN: *A study of the shared decision-making process of persons with dementia identified a broad spectrum of the shared decision-making process. Results indicated that not all persons with dementia are excluded from participating in the decision-making process. Loizeau et al (2018) tested the effect of fact box decision support tools on decisional conflict and preferences in advanced dementia. They found that fact boxes reduced decisional conflict, increased knowledge, and promoted preferences to forego antibiotics in advanced dementia in decision makers.*
- Discuss the purpose of advance directives such as a living will or medical power of attorney. EB: *Basile et al (2018) studied a Web-based decision aid in clients with severe chronic obstructive pulmonary disease to assist in preparation for decision-making about invasive mechanical ventilation for respiratory failure. Increased knowledge and opportunity to deliberate and discuss treatment choices after using the decision aid improved decision-making at the time of critical illness.*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's decision-making conflict. EB: *A study of couples undergoing genetic counseling found that factors associated with conflict during decision-making included cultural customs, age, emotional state, religious beliefs, and being forced to attend counseling. Provide support for client's decision-making (Schoeffel et al, 2018).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Home Care

- The interventions described previously may be adapted for home care use.
- Encourage discussion of life-sustaining treatments and advance directives. EB: *Torke et al (2019) conducted a feasibility study of the Physician Orders for Life-Sustaining Treatment (POLST) with community-dwelling adults age 65 and older enrolled in a complex care management program. They found that 87.5% of decision makers agreed or strongly agreed that "talking about the (POLST) form helped me think about what I really want."*

Client/Family Teaching and Discharge Planning

- Instruct the client and family members to provide advance directives in the following areas:
  - Person to contact in an emergency
  - Preference (if any) to die at home or in the hospital
  - Desire to initiate advance directives, such as a living will or medical power of attorney
  - Desire to donate an organ
  - Funeral arrangements (i.e., burial, cremation)

  EBN: *Shared decision makers experienced less decisional conflict when they had discussed the client's preferences with the client (Fairlie, 2018).*
- Inform the family of treatment options; encourage and defend self-determination. EB: *Hwang et al (2018) surveyed clients seeking treatment for a lumbar herniated disc and measured decisional conflict using the SURE questionnaire. They found that participants with decisional conflict were less satisfied with their treatment decision and found a high level of decisional conflict when choosing a treatment option. They concluded that there is a need to implement tools and strategies to improve decisional quality, such as decision aids before consultation.*
- Recognize and allow the client to discuss the selection of complementary therapies available, such as spiritual support, relaxation, imagery, exercise, lifestyle changes, diet (e.g., macrobiotic, vegetarian), and nutritional supplementation. EB: *Hippman and Balneaves (2018) studied women's decision-making for treatment of depression during pregnancy and found that women require a nonjudgmental environment when choosing among medications, psychotherapy, electroconvulsive therapy, deep brain stimulation, and complementary and alternative medicine options.*

▲ Provide the POLST form for clients and families faced with end-of-life choices across the health care continuum. EB: *Torke et al (2019) found that a large majority of decision makers agreed or strongly agreed that talking about the (POLST) form helped with decision-making.*

Risk for Elopement Attempt

Domain 1 Health promotion Class 2 Health management

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to leaving a health care facility or a designated area against recommendation or without communicating to health care professionals or caregivers, which may compromise safety and/or health.

Risk Factors

Anger behaviors; exit-seeking behavior; frustration about delay in treatment regimen; inadequate caregiver vigilance; inadequate interest in improving health; inadequate social support; perceived complexity of treatment regimen; perceived excessive family responsibilities; perceived excessive responsibilities in interpersonal relations; perceived lack of safety in surrounding environment; persistent wandering; psychomotor agitation; self-harm intent; substance misuse

At-Risk Population

Economically disadvantaged individuals; homeless individuals; individuals brought to designated area against own wishes; individuals frequently requesting discharge; individuals hospitalized <three weeks; individuals with history of elopement; individuals with history of non-adherence to treatment regimen; individuals with history of self-harm; individuals with impaired judgment; men; older adults with cognitive disorders; unemployed individuals; young adults

Associated Conditions

Autism spectrum disorder; developmental disabilities; mental disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Elopement Propensity Risk; Elopement Occurrence

Example NOC Outcome with Indicators

Elopement Propensity Risk as evidenced by the following indicators: Wanders/Attempts to leave secure area/Attempts to leave with visitors/States wants to go home/Threatens to leave. (Rate the outcome and indicators of **Elopement Propensity Risk:** 1 = consistently demonstrated, 2 = often demonstrated, 3 = sometimes demonstrated, 4 = rarely demonstrated, 5 = never demonstrated [see Section I.)

Client Outcomes

Client Will (Specify Time Frame)

- Remain safely and securely in treatment area
- Remain at scheduled activities
- Identify the consequences of leaving treatment
- Make a commitment to continuing treatment
- Accept discharge date and process

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Elopement Precautions

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NIC Activities—Elopement Precautions

Monitor client for indicators of elopement potential (e.g., verbal indicators, loitering near exits, multiple layers of clothing, disorientation, separation anxiety, and homesickness); Limit patient to a physically-secure environment (e.g., locked or alarmed doors at exits and locked windows); Discuss with patient why he/she desires to leave the treatment setting; Encourage the patient, when appropriate, to make a commitment to continue treatment (e.g., contracting)

Nursing Interventions and *Rationales*

- Identify client factors associated with elopement risk and implement appropriate precautions. EB: *A systematic review regarding elopement in forensic clients found that previous elopements, aggression, substance use, high Historical Clinical Risk Management–20 score, antisocial tendencies, psychiatric symptoms, sexual offending, and poor treatment adherence were factors with predictive value for elopement (Olagunju et al, 2020).*
- Assess the client's stress level and coping. EB: *A retrospective chart review was completed on reported elopement events for over a 2-year period by clients on forensic units in a public psychiatric hospital. Results indicated that the best indicator of a client's risk for elopement was having experienced a stressful, significant event in the 2 weeks before the elopement (Martin et al, 2018).*
- Assess for and ask about the client's responsibilities and commitments outside of the hospital setting. EBN: *A systematic review found that clients who abscond from the hospital view their elopement as a means to meet their needs to address outside responsibilities and commitments (Voss & Bartlett, 2019).*
- Offer the client time and information so they can be involved in decision-making related to their care. EBN: *A systematic review found that clients who abscond from the hospital view their elopement as a positive means to exert power and control over their situation (Voss & Bartlett, 2019).*
- For clients admitted involuntarily to a psychiatric setting, implement elopement precautions to maintain client safety. EB: *Involuntary admission has been identified as a risk factor for elopement (Gowda et al, 2019).*

Pediatric

- Assess for factors associated with risk for elopement. EB: *A study examined predictors of initial elopement from residential care settings (RCSs) in a large sample of youth receiving residential treatment (n = 1261) and found 3 categories of elopement motivation. Youth with a diagnosis of disruptive behavior disorders were most likely to elope as were youth who were motivated by peer influence, escape from negative stimuli inside the RCS, and reinforcing stimuli outside the RCS (Milette-Winfree, Ku, & Mueller, 2017).*
- Counsel families of children diagnosed with autism spectrum disorder (ASD) about the danger related to elopement. EB: *Elopement behavior is exhibited by many children with a diagnosis of ASD. A study of elopement prevention for children diagnosed with ASD identified child and family characteristics that were related to elopement, the use of modifications, and stressed the importance of counseling families about elopement (Pereira-Smith et al, 2019).*

▲ If interested, refer families of children diagnosed with ASD for a consultation regarding electronic tracking device (ETD) technology. EB: *A recent study of families and caregivers of children with ASD found that in current (n = 361) and past (n = 96) ETD users, ETD use was associated with decreased frequency and duration of elopement and decreased risk for serious injury because of elopement (all $p < 0.001$) (McLaughlin et al, 2020).*

Geriatric

- Many of the previous interventions can be adapted for use with geriatric clients.
- Assess for behaviors that may indicate the client with dementia may elope or wander away. EB: *A study found six antecedent behaviors to wandering/elopement: stating intent to leave, door lingering/tampering, preparing to go outside, packing up belongings, calling to be picked up, and draw to outside stimuli (Neubauer & Liu, 2020).*
- Implement elopement precautions for clients who exhibit critical wandering behaviors. EB: *A systematic review calculated a rate of 82 deaths and 61 injuries per 1000 incidents of unexplained absence in nursing home clients (Woolford, Weller, & Ibrahim, 2017).*

- Use a unique room door design for individuals living with dementia in a residential care. EBN: *Internal doors were transformed using a giant adhesive poster created by a commercial graphic designer to replicate the look of traditional front doors. The Revised Algase Wandering Scale (RAWS) was used to identify the effects of introducing the doors on persistent walking, eloping behaviors, and spatial disorientation and found a reduction in all (Varshawsky & Traynor, 2021).*
- Implement a structured physical activity program for with dementia. EBN: *A study found that clients with dementia who participated in a structured physical activity program showed a statistically significant reductions in agitation ($p < 0.001$) and eloping ($p = 0.001$) (Traynor et al, 2018).*

▲ Refer to occupational therapy for assistive technology to address elopement safety for clients diagnosed with dementia. EB: *Study findings suggest that assistive technology devices are often used by occupational therapists to address safety concerns related to elopement with this population (Collins, 2018).*

- See the care plan for **Wandering.**

Multicultural

- The previous interventions can be adapted for use with multicultural clients.

Home Care

- The previous interventions can be adapted for use with home care clients.

▲ Refer families of clients with dementia to smart home technologies to manage nighttime wandering. EB: *The Night-time Wandering Detection and Diversion system detects when the person with dementia gets out of bed and automatically provides cue lighting to guide them safely to the bathroom, uses prerecorded audio prompts if individuals leave their bedroom, and wakes the caregiver when the person with dementia opens an exit door. A study found that the system is successful in supporting the safety of persons with dementia, as well as their caregivers (Ault et al, 2020).*

Client/Family Teaching and Discharge Planning

- Assess family reactions to the client's elopement attempts or wandering behavior. EBN: *A study found caregivers' health outcomes were negatively affected by the client's elopement behaviors. Specifically, clients getting lost outside of the house influenced caregivers' mental fatigue ($\beta = 0–0.215$, $p < .05$) and eloping behavior influenced caregivers' sleep disturbance ($\beta = 0.231$, $p < .05$) (Peng et al, 2018).*
- Provide family and caregivers information about elopement precautions. EB: *A home-based missing incident prevention program (HMIPP) was effective in reducing the number of missing incidents, searching time, and caregivers' stress at 3 months and 1 year. Interventions included dementia education, prescription of assistive devices, on-site skills training, environmental modifications, community service referrals, and redesigning of daily life routine tasks (Lau, Chan, & Szeto, 2019).*

Impaired Emancipated Decision-Making

Domain 10 Life principles Class 3 Value/belief/action congruence

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CNEcl, CHSE, ANEF, FAAN

NANDA-I

Definition

A process of choosing a health care decision that does not include personal knowledge and/or consideration of social norms, or does not occur in a flexible environment, resulting in decisional dissatisfaction.

Defining Characteristics

Delayed enactment of health care option; difficulty choosing a health care option that best fits current lifestyle; expresses constraint in describing own opinion; expresses distress about others' opinion; expresses excessive concern about others' opinions; expresses excessive fear of what others think about a decision; impaired ability to describe how option will fit into current lifestyle; limited verbalization about health care option in others' presence

Related Factors

Decreased understanding of available health care options; difficulty adequately verbalizing perceptions about health care options; inadequate confidence to openly discuss health care options; inadequate information regarding health care options; inadequate privacy to openly discuss health care options; inadequate self-confidence in decision-making; insufficient time to discuss health care options

At-Risk Population

Individuals with limited decision making experience; women accessing health care from systems with patriarchal hierarchy; women living in families with patriarchal hierarchy

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Self-Esteem; Coping; Health Promoting Behavior; Stress Level; Communication; Self-Care Status; Participation in Health Care Decisions; Health-Seeking Processing; Personal Autonomy; Psychosocial Adjustment: Life Change

Example NOC Outcome with Indicators

Participation in Health Care Decisions as evidenced by the following indicator: Claims decision making responsibility. (Rate the outcome and indicators of **Participation in Health Care Decisions:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize option outcomes freely before making a health care decision
- Freely verbalize own opinion with health care providers before making a health care decision
- Choose the health care option that fits his or her lifestyle within an appropriate amount of time that allows enactment of the choice
- Describe how the chosen option fits into his or her current lifestyle before or after the decision has been made
- Verbalizes appropriate concern about others' opinions before making the health care choice
- Remains stress-free when listening to others' opinions before making the health care choice
- Arrives at a decision in a timely manner

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Decision-Making Support; Health Coaching; Cognitive Restructuring; Self-Awareness Enhancement

Example NIC Activities—Emancipated Decision-Making

Assist client in making an emancipated decision about health care options by discussing social norms with the client; Provide a flexible environment; Encourage the client to use personal knowledge

Nursing Interventions and *Rationales*

- Assess client's readiness to openly discussing the decision-making process. EBN: *Using a qualitative approach, Huang et al (2020) studied shared decision-making in clients (n =12) with mental illness. The researchers found that clients preferred to use a shared decision-making approach to issues and actively sought health care information to make decisions.* EB: *Chen (2017) conducted a study with 15 clients with cancer about the decision-making process within three stages of cancer treatment and found that different decision-making approaches to provided information were taken by clients and ranged from informed to paternalistic to shared.*
- Use active listening in a nonjudgmental manner to provide the client with a flexible decision-making environment. EBN: *Through a literature review, van der Heijden et al (2020) found that adults rooming-in with hospitalized family members had a positive emotional effect on clients' well-being.* EB: *Park and colleagues (2020) studied (1) whether clients were invited into clinical decision-making processes and (2) whether administrators fostered person-centered health care and shared decision-making practices. The survey results disclosed that only 23% of substance abuse treatment clinics invited clients into treatment meetings.*
- Use anticipatory guidance by proactively providing the client with information. EB: *Williams et al (2020) completed an integrated review of the literature regarding decisions made by chronically ill clients and found four themes. The themes all suggested that effective communication and having clients involved in care decisions improved affect and promoted positive care outcomes.* CEB: *Wittmann-Price, Fliszar, and Bhattacharya (2011) found in a mixed method study that the majority of pregnant clients (N = 50) reported they had been provided with information prenatally, but not all clients felt they were given enough information at the time of delivery to make an informed choice.*
- Establish a purposeful provider–client relationship. EB: *A mixed methods study with clients who have Parkinson's disease (N = 65) demonstrated that the provider–client relationship was important for the client in the decision-making process (Zizzo et al, 2017).* EBN: *Sun et al (2020) completed a study to examine the relationship of client–provider communication (N = 320) in relation to treatment outcomes and clients' risk perception. The study demonstrated that client–provider communication has a significant influence on client treatment outcomes and their risk perception of the chosen treatments.*

▲ Refer to counseling as needed. EB: *Klausen et al (2017) studied clients in the outpatient setting (N = 25) who were referred for mental health issues and found four key components to shared decision-making: (1) during admission, (2) in individualized treatment, (3) in different treatment contexts, and (4) in user–professional relationships.* CEB: *Wittmann-Price (2006) demonstrated in a quantitative correlational study that women's (N = 97) decision-making was empowered when they were provided resources and information to arrive at an emancipated choice.*

- Provide decision-making support. EBN: *Quinn et al (2020) studied veteran women's (N = 2,302) decisions about contraception and found significant differences in unintended pregnancies and use of specific contraception in different ethnic and racial women. The study highlights the need for improved teaching,*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

decision-making, and access to assist women in reaching their reproductive goals. EBN: *Lazenby et al (2017) studied 15 physicians and 5 nurses about their involvement in end-of-life conversations and decisions with hemodialysis clients and found that advanced decision-making planning was deficit and needed attention to accommodate clients' wishes.*

- Provide a flexible environment by encouraging others to accept the client's choice. EB: *Gerbasi et al (2020) studied women with postpartum depression in a randomized trial and how they reported symptoms in relation to the tool their provider was using. The researchers found that some tools actually promoted shared decision-making for women better than other postpartum assessment tools.* CEB: *Wittmann-Price and Bhattacharya (2008) quantitatively studied pain management decisions for clients in labor (N = 92) and found that a flexible environment was needed for the client to make a supported and emancipated decision.*
- Encourage the client to use personal knowledge as part of the decision-making process to increase decisional satisfaction. CEB: *Women can make health care decisions that are right for them if they can use personal knowledge to overcome oppressive social forces (Stepanuk et al, 2013).* CEB: *Using personal knowledge is the best indicator to making an emancipated decision and correlates strongly and positively with satisfaction with the decision (Wittmann-Price, 2006).*

Pediatric

- When able, involve the client in health care decision-making when possible. EBN: *Sedig et al (2020) studied decision-making in families with terminally ill children (N = 28) and found that the majority (61%) wanted shared decision-making. Being able to participate in end-of-life decision-making for their child significantly affected the parents' perception of the child's death.* EBN: *Craske et al (2017) studied how 12 nurses decide on withdrawal of pediatric sedation and found in complex pediatric cases that there is a variation in assessing client behavior and response to treatment.*
- Provide parental information in the decision-making process. EBN: *Richards et al (2017) performed an integrative review of family-centered behaviors that were experienced in the intensive care unit and found that there were five salient themes needed to engage parents in decision-making: (1) sharing information, (2) hearing parental voices, (3) making decisions for or with parents, (4) negotiating roles, and (5) individualizing communication.* EB: *Lin et al (2020) completed a qualitative study to understand parents' (N = 27) perspectives of shared decision-making for children with complex health care needs. The three themes that emerged from the parental interviews were participation, knowledge, and context.*
- Enhance client decision-making in the critical care setting. EBN: *Petrinec (2017) studied the family decision makers (N = 30) for long-term critical care clients and found they had post–intensive care syndrome, which warrants nursing awareness and interventions to support family decision makers.* EB: *A study completed by Kim et al (2020) compared clients' (N = 58) end-of-life decisions with the recommendations made by the rapid response team. Clients who used a rapid response team intervention were more successful in carrying out their end-of-life preferences for allowing a natural death.*

Geriatric

- Include geriatric clients in the decisional process. EB: *Lippe et al (2020) conducted a pilot study to assess a communication guide on clients' understanding of prognosis. The findings demonstrated that a communication guide can bridge the gap of understanding between provider and client allowing the client a more informed decision-making process.* EB: *Using a case study method, Strohschein et al (2020) found that implementing a program of comprehensive care can promote decision-making, facilitate communication, and contribute to personalization of care.*

Multicultural

- Consider cultural influences on decision-making. EB: *Nogami et al (2020) studied the factors that influenced the decision-making processes of Japanese women (N = 44) facing end-of-life care due to metastatic breast cancer. The study demonstrated that younger clients and those with shorter recurrence-free time had more difficulty with decision-making.* EBN: *Adefris et al (2017) studied women (N = 384) who delayed treatment for uterine prolapse in sub-Saharan Africa and found that it was related to the "social stigma" within the culture.*

Home Care

- Use open communication to assist clients to develop health care plans to which they can adhere. EBN: *An integrative review of the literature by Bayless et al (2017) found that men who choose active surveillance rather than surgical intervention for prostate cancer take a more active, communicative role in the decision-making process.* EB: *Lussier et al (2020) investigated the effects of using ambient assisted living*

(AAL) technologies as part of home care monitoring. The researchers found that AAL monitoring helped health care professionals to have information that they may not have had otherwise and the information gained assisted the health care providers in caring for the clients.

Readiness for Enhanced Emancipated Decision-Making

Domain 10 Life principles Class 3 Value/belief/action congruence

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CNEcl, CHSE, ANEF, FAAN

NANDA-I

Definition

A process of choosing a health care decision that includes personal knowledge and/or consideration of social norms, which can be strengthened.

Defining Characteristics

Expresses desire to enhance ability to choose health care options that enhance current lifestyle; expresses desire to enhance ability to enact chosen health care option; expresses desire to enhance ability to understand all available health care options; expresses desire to enhance ability to verbalize own opinion without constraint; expresses desire to enhance comfort to verbalize health care options in the presence of others; expresses desire to enhance confidence in decision-making; expresses desire to enhance confidence to discuss health care options openly; expresses desire to enhance decision-making; expresses desire to enhance privacy to discuss health care options

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Self-Esteem; Coping; Health Promotion Behavior; Stress Level; Communication; Self-Care; Participation in Health Care Decisions; Health-Seeking Behavior; Knowledge: Treatment Options; Psychosocial Adjustment

Example NOC Outcome with Indicators

Participation in Health Care Decisions as evidenced by the following indicator: Claims decision-making responsibility. (Rate the outcome and indicators of **Participation in Health Care Decisions:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize option of outcomes freely before making a health care decision
- Freely verbalize own opinion with health care providers before making a health care decision
- Choose the health care option that best fits his or her lifestyle within an appropriate amount of time that allows enactment of the choice
- Describe how the chosen option fits into his or her current lifestyle before or after the decision has been made
- Verbalizes appropriate concern about others' opinions before making the health care choice
- Remains stress-free when listening to others' opinions before making the health care choice
- Arrives at a decision in a timely manner

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Decision-Making Support

Example NIC Activities—Emancipated Decision-Making

Assist client in making an emancipated decision about health care options by discussing social norms with the client; Provide a flexible environment; Encourage the client to use personal knowledge

Nursing Interventions and *Rationales*

- Assess client's readiness to choose through active listening. EBN: *Chen et al (2017) applied a home-based, individually tailored intervention, which included nursing education, skills training, listening/counseling, and resources for family caregivers of cognitively impaired individuals. Listening skills and interventions improved caregiving skills and increased the family's quality of life.* EB: *Barnett, Sivam, and Easthall (2020) studied the confidence of pharmacy students in using a person-centered care approach that included shared decision-making. The researchers successfully provided professional development about shared decision-making and it increased scores on participants self-confidence post-test. Information included in the professional development to enhance pharmacists use of shared decision-making were active listening, using open questions, method to empower clients, developing a shared agenda, and encouraging clients to be accountable.*
- Use anticipatory guidance by proactively providing the client with information. (Refer to Impaired Emancipated **Decision-Making.**)
- Establish a purposeful provider–client relationship. EB: *Researchers examined the quality of the client–provider relationship and its effect on attachment and self-management of clients with multiple chronic diseases (N = 209). The study results demonstrated that client–provider relationships with attachment and communication provide that client with information and improve decisions about self-management (Brenk-Franz et al, 2017).* EB: *Stanley et al (2020) studied the effects of client–provider relationship on health care decisions of African American women. The researchers found that communication is key to improving client–provider trust. The focus groups discussed that the lack of commitment by the provider was a barrier to the client–provider relationship.*

▲ Include multiprofessional health care team members as needed to increase knowledge of chosen option. EB: *Wong et al (2017) studied the lived experience of emergency department (ED) staff (N = 31) members caring for agitated clients and found three themes from the focus groups: (1) ED staff provide high-quality care to marginalized clients, (2) teamwork is critical to safely managing clients and hierarchy and professional silos hinder care, and (3) environmental challenges increase threats to staff safety.* EB: *Labuschagne et al (2020) studied the spiritual needs of clients and their families (N = 254) admitted to the intensive care unit (ICU). Of all the clients and families seen for spiritual care by hospital Chaplains only 15% requested assistance in decision-making. The researchers suggest that Chaplains should be a more prominent part of the client's decision-making process, especially during times that include end-of-life care.*

- Provide decision-making support. (Refer to Impaired Emancipated **Decision-Making.**)
- Continue to provide a flexible environment for client to enact choice. EB: *Investigators studied shared decision-making about health care options with spinal cord injury (SCI) clients (N = 22) during the clients' first rehabilitation experience and found that decision-making capabilities were reduced in the first few days of hospitalizations because of physical, psychological, and environmental factors. Additionally, they stated that understandable, personalized information was necessary to participate in decision-making (Scheek-Sailer et al, 2017).* EB: *Li et al (2021) studied the Internet environment in relation to client decision-making. The researchers found that clients using the Internet had better follow-up outcomes and factors that assisted follow-up decisions included technical quality and interpersonal connectivity.*
- Encourage the client to use personal knowledge as part of the decision-making process to increase decisional satisfaction. EB: *Hultberg and Rudebeck (2017) explored client agency and resistance in decision-making about cardiovascular treatments in primary care settings. The study described client resistance as part of the decision-making process and it can be passive or aggressive. Health care providers need to allow client agency and open communication to establish a working relationship in shared decision-making.* EB: *Melzer et al (2020) qualitatively studied practitioners' (N = 24) views about shared decision-making for clients who are eligible for lung cancer screening. Interviews verified that practitioners agreed that screening should be congruent with clients' values and preferences.*

Pediatric

- Understand interventions that parents prefer when in the decision-making process. EBN: *Craske et al (2017) studied withdrawal syndrome in children and how nurses (N = 12) make decisions about treatment and qualitatively found each stage of decision-making described as noticing, interpreting, and responding.* EB: *Yamaji et al (2020) completed a meta-synthesis about children's decision-making related to palliative care, treatment, and family involvement. The four themes were (1) facing changes, (2) preparing for action, (3) asserting one's choice, and (4) internal and external influences. The results demonstrated that children's*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

preferences, values, and emotions are part of building a relationship with health care providers and this enhances their decision-making ability.

Multicultural

- Use open communication to assist clients to develop health care plans to which they can adhere. EBN: *Rodrigo, Caïs, and Monforte-Rovo (2017) used grounded theory to examine nurses' participation in decision-making in Spain and found that the health care system still functions mainly from a disease-focused view making it difficult for nurses to take responsibility for decision-making.*

Home Care/Nursing Home Care

- Optimize self-care personal knowledge for home care. EB: *Mariani et al (2017) studied shared decision-making in clients with dementia and found that team collaboration and communication skills assisted shared decision-making. Lack of funding and lack of family involvement hindered shared decision-making in nursing home care, but findings can be applicable to home care.* EBN: *Coburn (2018) used a grounded theory study to understand the reasons why women (N = 11) choose a home birth rather than a traditional hospital delivery. The study was based on the Emancipated Decision-Making Theory, and the women revealed the reasons for choosing a home birth fell into the following themes: (1) realizing an alternative, (2) deciding to call the shots, and (3) building a shelter.*
- Refer to care plan Impaired Emancipated **Decision-Making** for additional interventions for pediatric, critical care, geriatric, and multicultural care.

Risk for Impaired Emancipated Decision-Making

Domain 10 Life principles
Class 3 Value/belief/action congruence

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CNEcl, CHSE, ANEF, FAAN

NANDA-I

Definition

Susceptible to a process of choosing a health care decision that does not include personal knowledge and/or consideration of social norms, or does not occur in a flexible environment, resulting in decisional dissatisfaction.

Risk Factors

Decreased understanding of available health care options; difficulty adequately verbalizing perceptions about health care options; inadequate confidence to openly discuss health care options; inadequate information regarding health care options; inadequate privacy to openly discuss health care options; inadequate self-confidence in decision-making; insufficient time to discuss health care options

At-Risk Population

Individuals with limited decision making experience; women accessing health care from systems with patriarchal hierarchy; women living in families with patriarchal hierarchy

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Self-Confidence; Coping; Health Promotion Behavior; Stress Level; Communication; Self-Care; Participation in Health Care Decisions; Health-Seeking Behavior; Knowledge; Treatment Options; Psychosocial Adjustment

Example NOC Outcome with Indicators

Participation in Health Care Decisions as evidenced by the following indicator: Claims decision-making responsibility. (Rate the outcome and indicators of **Participation in Health Care Decisions:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize option outcomes freely before making a health care decision in a private setting with in which he or she feels comfortable
- Freely verbalize own opinion with health care providers before making a health care decision
- Discuss how options fit or hinder his or her lifestyle within an appropriate amount of time that allows enactment of the choice
- Discuss concerns about others' opinions before making the health care choice
- Decrease stress about others' opinions by placing options in perspective through informational resources
- Discuss the time frame in which the decision needs to be made

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Establish Rapport; Decision-Making Support

Example NIC Activities—Emancipated Decision-Making

Assist client to verbalize and discuss barriers that she or he perceives in making an emancipated decision about health care options; Acknowledge social norms about decision options; Provide a flexible environment that is safe and private for the discussions; Use empathy to understand the client's personal point of view about the options

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Nursing Interventions and *Rationales*

- Assess client's vulnerability for an impaired decision-making process. EBN: *Scheepmans et al (2017) studied the decision-making process of placing older adults* (N = *5) in restraints at home and found through a cross-sectional survey that the main decision-making variables were safety, keeping the client home longer, and to provide respite for the caregiver.* EB: *Hell and Nielsen (2020) did a literature review* (N = *6) about informed decisions related to alcohol-addicted clients and their choice of rehabilitation. The researchers examined four variables: (1) drinking outcome, (2) quality of life (QOL), (3) enrollment, and (4) adherence. The researchers found that involving clients in the choice of treatment improved QOL, increased enrollment, and promoted adherence.*
- Assess the client's experience with decision-making. EBN: *Smith et al (2017) studied cancer clients* (N = 21) *perceptions of their involvement in treatment decisions and found that most clients just consented to radiation because of oncologist recommendations. The study recommends that clients be provided with more opportunities to ask questions to be empowered in decisions about their uncertainties and concerns.* EBN: *Lippe et al (2020) completed a study to pilot a communication guide for clients with terminal cancer because they often needed to engage in prompt decision-making. The communication guide was developed by a multiprofessional team that included nurses. The research team found that clients wanted detailed information and welcomed different perspectives when making prompt decisions about their care.*
- Recognize the traditional hierarchical family and health care system. EBN: *Petrinec (2017) studied the effect of clients' long-term care experiences on the family decision maker* (N = *30) and found, using a qualitative descriptive study method, that family decision makers need support and often have post–intensive care syndrome caused by the stress.* EBN: *Virdun et al (2020) used an exploratory qualitative method with semi-structured interviews* (N = *21) to ascertain if palliative care clients perceived their needs were met and their decisions were respected by health care professionals. The important themes that emerged about decision-making were the need for effective communication and shared decision-making; the need for expert care; and family involvement, financial assistance, maintaining self-identity, decreasing burden, respect, compassion, and trust.*
- Provide privacy to discuss health care options. EBN: *Chang et al (2017) studied the decision-making of nurses who triage clients in an emergency department and what factors were considered in their decision-making. The study results indicated that the clients' privacy was an important consideration in choosing care options and prioritizing during a triage situation.* EBN: *Frey et al (2020) investigated palliative care services and found, through a cross-sectional survey* (N = *4778), that factors that increased client satisfaction with care included being treated with dignity and respect, adequate privacy, pain relief, and decisions in line with clients' wishes.*
- Allow the client time to choose. EB: *Simmons et al (2017) studied an online decision aid for youth* (N = *66) with depression and their ability to make decisions and found that it assisted clients to feel involved in their decision and providing them with time to make the decision and accessibility.* EBN: *Chan et al (2020) studied a hope intervention and its effect of decisional conflict with clients with stage 5 chronic kidney disease. The study is a randomized control trial in which a 4-week Brief Hope Intervention will be completed in the control group. Hope has been associated with decreasing depression and increasing positive expectations and this study will examine its effect on optimizing decision-making and attain better health.*
- ▲ Understand the primary health care providers' role in the decision-making process. EB: *Hyde et al (2017) did a systematic review about shared decision-making and prescribing analgesia by primary care practitioners for musculoskeletal pain and identified important factors in shared decision-making that mainly focus on client emotions and conditions that required analgesics.* EBN: *Asif et al (2020) completed a literature review* (N = *11) about the experiences of clients with hip fractures and their caregivers during the transitions in care. The results found that barriers to decision-making were lack of information, role confusion, and disorganized discharge planning. The study results encourage health care providers to collaborate with clients with hip fracture and caregivers on decision-making about plans after the acute care hospital stay.*
- Provide informational resources. EBN: *Asiodu et al (2017) completed a critical ethnographic research study to describe breastfeeding perceptions of African American mothers* (N = *21) and key themes that were identified about the high percentage of early weaning, which were expressed as guilt and shame for not breastfeeding, stressors, lack of breastfeeding role models, limited experiences, and changes to the family dynamics.* EBN: *Parker et al (2020) used the theory of planned behavior (attitudes, perceived control, and social norms) to qualitatively study mothers* (N = *23) of preterm infants experiences related to breastfeeding. The study found that mothers felt that breastfeeding was a way to bond, that breast milk was healthy and protective, and that breast milk alone was insufficient for a growing preterm infant. For perceived control, mothers felt*

empowered to breastfeed due to encouragement from hospital staff, friends, and family. Social norms were aligned with support for and against breastfeeding among providers, family, friends, and the media.

- Provide encouragement so clients increase their confidence in the decision-making process. EB: *Knox, Douglas, and Bigby (2017) studied how clients with traumatic brain injury (TBI) participated in decision-making and discovered that self-conceptualization was a theme and that TBI clients wanted a sense of autonomy.* EBN: *Şengün İnan et al (2020) investigated women's* (n = *12) perceptions about returning to work after being treated for breast cancer. The interviews revealed four themes: the decision-making process, difficulties in work life, sources of motivation, and benefits of working. The women's perspectives showed that support from family, colleagues, and employers was important in making the decision to successfully return to work.*

Pediatric

- Understand the parent/guardian's vulnerability when making health care decisions for their children. EB: *O'Hare et al (2016) studied a tool to evaluate children and young client's* (n = *151) participation in decision-making. The pilot demonstrated that the reliability and validity of the Child and Adolescent Participation in Decision-Making Questionnaire (CAP-DMQ) showed promise as a useful tool to evaluate decision-making participation, which can assist the family when decisions need to be made.* EBN: *Sedig et al (2020) surveyed parents* (n = *28) of children with cancer diagnoses about their decision-making, services, and communications. Parents reported a desire for shared decision-making, and shared decision-making was correlated positively with the parents' perception of how well the child's death was handled.*
- Understand the adolescent decision-making processes. EBN: *Lu et al (2020) retrospectively studied dialectical behavior therapy for adolescents (DBT-A) and if it was offered in a child and youth psychiatric outpatient clinic, and examined the variables of those who were and were not offered DBT-A. Forty-four healthcare records were reviewed for (1) initial mental health intake assessment, (2) age 13 to 16 years, and (3) active suicidal ideation. The decision to offer DBT-A increased with multiple suicide risks and youth who experienced significant childhood trauma. The study recommends that decision-making to use DBT-A be based on multiple factors, not just risk and adverse childhood experiences, since the treatment has been demonstrated to be effective.* EB: *Mosner et al (2017) investigated vicarious effort-based decision-making in adolescents* (N = *50) with autism spectrum disorders (ASDs) in a comparison study. Group comparisons demonstrated that adolescents with ASDs were better choosing for themselves than making choices that involved other people, indicating the participants had decreased sensitivity toward others.*
- Refer to care plan Impaired Emancipated **Decision-Making** for additional interventions for critical care, geriatric, multicultural care, and home care.

Readiness for Enhanced Exercise Engagement

Domain 1 Health promotion
Class 2 Health management

Stacey M. Carroll, PhD, APRN-BC

NANDA-I

Definition

A pattern of attention to physical activity characterized by planned, structured, repetitive body movements, which can be strengthened.

Defining Characteristics

Expresses desire to enhance autonomy for activities of daily living; expresses desire to enhance competence to interact with physical and social environments; expresses desire to enhance knowledge about environmental conditions for participation in physical activity; expresses desire to enhance knowledge about group opportunities for participation in physical activity; expresses desire to enhance knowledge about physical settings for participation in physical activity; expresses desire to enhance knowledge about the need for physical activity; expresses desire to enhance physical abilities; expresses desire to enhance physical appearance; expresses desire to enhance physical conditioning; expresses desire to maintain motivation to participate in a physical activity plan; expresses desire to maintain physical abilities; expresses desire to maintain physical well-being through physical activity; expresses desire to meet others' expectations about physical activity plans

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Exercise Participation; Physical Fitness; Exercise Promotion; Endurance

Example NOC Outcome with Indicators

Exercise Participation as evidenced by the following indicators: Plans appropriate exercise with health provider before starting exercise/Identifies barriers to exercise program/Balances life routine to include exercise/Participates in regular exercise. (Rate the outcome and indicators of: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated.)

Client Outcomes

Client Will (Specify Time Frame)

- Engage in purposeful moderate-intensity cardiorespiratory (aerobic) exercise for 30 to 60 minutes/day on 5 or more days per week for a total of 2 hours and 30 minutes (150 minutes) per week
- Increase pedometer step counts by 1000 steps per day every 2 weeks to reach a daily step count of at least 7000 steps per day, with a daily goal for most healthy adults of 10,000 steps per day
- Perform resistance exercises that involve all major muscle groups (legs, hips, back, chest, abdomen, shoulders, and arms) performed 2 to 3 days/week
- Perform flexibility exercise (stretching) for each of the major muscle-tendon groups 2 days/week for 10 to 60 seconds to improve joint range of motion; greatest gains occur with daily exercise

D

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Exercise Promotion; Exercise Promotion: Strength Training; Exercise Promotion: Stretching

Example NIC Activities—Exercise Promotion

Assist individuals to develop an appropriate exercise program to meet needs; Assist individual to set short-term and long-term goals for the exercise program; Assist individual to schedule regular periods for the exercise program into weekly routine

Nursing Interventions and *Rationales*

✱ Determine whether the client needs a physical examination, with a focus on cardiac health, before engaging in additional exercise. EB: *Per the American College of Sports Medicine, a physical examination is warranted if the client is sedentary; has a heart condition, diabetes, kidney disease, or lung disease; and/or plans to begin high-intensity exercise (Chokshi, 2017).*

▲ Highlight benefits of exercise on health outcomes to increase motivation. EB: *Benefits of physical activity were fou nd, via an overview of systematic reviews, to be decreased mortality and increased quality of life, with very few safety concerns (Posadzki et al, 2020).* EB: *Varying levels of intensity of exercise were all positively related to cognitive ability and health-related quality of life (Alsubaie et al, 2020).*

▲ Use theories to guide increasing motivation and engagement in physical activity. EB: *Self-determination theory was used to study dance and walking programs in older women; the programs were highly attended and participants expressed satisfaction and a desire to continue (Gray et al, 2018).* EB: *A health belief model–guided educational program on exercise and motivation resulted in a significantly higher physical activity level in middle-aged Iranian women (Shariati et al, 2021).*

● Support the client's autonomous (internal) motivation with regard to physical activity by discussing the value of positive health behaviors. EB: *Autonomous motivation was associated with physical activity engagements in clients with type 2 diabetes (Koponen et al, 2017).*

● Provide motivational support and encourage positive thinking to facilitate exercise engagement. EB: *Clients with heart failure who received motivational support felt more encouraged to be physically active (Klompstra et al, 2021).* EB: *Positive thinking regarding self-image as well as physical activity being a way to achieve goals resulted in increased motivation to continue with physical activity (Hall-McMaster et al, 2016).*

● Encourage activities the client finds enjoyable, to promote continued engagement. EB: *A qualitative analysis resulted in a proposal by the authors that joyful activities can result in a more positive body image (Alleva et al, 2019).*

● Develop exercise plans that allow for flexibility for the client. EB: *When clients with chronic illness had an activity plan with flexibility in its execution, they were more likely to enact the plan (Fleig et al, 2017).* EB: *Giving clients flexibility in choosing physical activity routines with regular follow-up resulted in increased motivation (Joelsson et al, 2020).*

▲ Provide resources for technology options, such as phone applications (which continue to be developed and tested), to increase exercise engagement. EB: *Use of a phone application while walking resulted in more steps walked by community adults (Samendinger et al, 2018).* EB: *Use of an electronic tracking device during physical activity resulted in increased health motivation (Bice et al, 2016).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Administer the Physical Self-Description Questionnaire short form (PSDQ-s) to assess physical self-concept. EB: *Sports competence scores on the PSDQ-s were associated with more frequent participation in a music exercise program (Aasa et al, 2017).*
- ▲ Consider sports programs to increase motivation regarding exercise. EB: *Teachers who participated in a team sport intervention reported increased motivation toward physical activity (Kim & Gurvitch, 2020).*
- Write a "prescription" for exercise for the client. EB: *Having a written prescription for physical activity served as a reminder and increased motivation (Joelsson et al, 2020).*
- ▲ Educate clients about modified or adaptive activities available. EB: *In clients who were status post–major trauma, facilitating access to modified activities such as clinical Pilates and hydrotherapy was appreciated (Ekegren et al, 2020).* EB: *Research supports aquatic therapy as helpful in neurorehabilitation (Becker, 2020). See https://www.moveunitedsport.org/ for resources on adaptive sports.*
- ▲ Incorporate genetically tailored physical activity interventions to individualize plan. EB: *Subjects in the group with genetically tailored physical activity interventions had greater physical activity energy expenditure than the standard program intervention group (Horne et al, 2020).*

Pediatric

- Assess the child's current activity status using the Pediatric Inactivity Triad (Faigenbaum et al, 2018). EB: *Components of the Pediatric Inactivity Triad include (1) exercise deficit disorder (less than 60 minutes of recommended physical activity daily), (2) pediatric dynapenia (decreased muscle strength and power), and (3) physical illiteracy (low competence and confidence). Addressing these components collectively will enhance effective change (Faigenbaum et al, 2018).*
- Assess parent's perceptions of children's screen time and active play. EB: *A study identified that parental perceptions of the benefits and risks of screen time and active play were not always consistent with current research (Hinkley & McCann, 2018).*
- Children and adolescents should participate in 60 minutes (1 hour) or more of physical activity daily.
  - ❍ Aerobic: Sixty or more minutes a day should be either moderate-intensity or vigorous-intensity aerobic physical activity, and should include vigorous-intensity physical activity at least 3 days a week.
  - ❍ Muscle-strengthening: As part of daily physical activity, children and adolescents should include muscle-strengthening physical activity at least 3 days of the week.
  - ❍ Bone-strengthening: As part of daily physical activity, children and adolescents should include bone-strengthening physical activity at least 3 days of the week.
  - ❍ Providing activities that are age appropriate, enjoyable, and varied will encourage young people to participate in physical activities (US Department of Health and Human Services, 2018).
- Assist families to develop family-based interventions to increase child physical activity. EB: *A meta-analysis of family-based interventions found a small effect on physical activity when interventions were tailored to the ethnicity, motivation, and time constraints of the family; combined goal-setting and reinforcement techniques were used; educational strategies were used to increase knowledge as needed; and consideration of the family psychosocial environment (Brown et al, 2016).*
- Encourage participation in youth sports. EB: *A systematic review found that participation in youth sport was positively associated with children's physical activity levels, and that youth participating in sports were more likely to persist in their physical activity (Lee, Pope, & Gao, 2018).*
- Encourage parents and caregivers to adhere to the following American Academy of Pediatrics guidelines for children's media use (Chassiakos et al, 2016):
  - ❍ For children younger than 18 months, avoid use of screen media other than video-chatting.
  - ❍ Parents of children 18 to 24 months of age who want to introduce digital media should choose high-quality programming and watch it with their children to help them understand what they are seeing.
  - ❍ For children ages 2 to 5 years, limit screen use to 1 hour/day of high-quality programs. Parents should co-view media with children to help them understand what they are seeing and apply it to the world around them.
  - ❍ For children ages 6 and older, place consistent limits on the time spent using media, and the types of media, and make sure media does not take the place of adequate sleep, physical activity, and other behaviors essential to health.
  - ❍ Designate media-free times together, such as dinner or driving, and media-free locations at home, such as bedrooms.
  - ❍ Have ongoing communication about online citizenship and safety, including treating others with respect online and off-line.

❍ Encourage parents and caregivers to create their personalized family media plan from the American Academy of Pediatrics (see https://www.healthychildren.org/English/media/Pages/default.aspx).

Geriatric

- Engage older adults in determining creative ways to exercise. EB: *Older adults co-developed strategies for staying active, including intergenerational purposeful activities (botanical walks) and activity companions (dog walking program) (Guell et al, 2018).*
- Explain that shorter periods of activity can still be beneficial, to increase engagement in exercise. EB: *Older adults who engaged in just 6 minutes of self-paced walking had an increase in motivation for more physical activity (Boolani et al, 2021).*

▲ Encourage participation in physical activity programs to increase motivation and engagement, even when living in a facility. EBN: *A physical activity program for older adults in a long-term care hospital resulted in improved physical outcomes and happiness (Ryu & Kim, 2020).*

▲ Educate older men about testosterone to increase physical activity. EB: *Testosterone treatment in men over 65 years of age resulted in a slight improvement in physical activity (Snyder et al, 2016).*

Multicultural

▲ Incorporate spirituality into physical activity plans to individualize them to the client's culture, to facilitate continued engagement. EB: *A pilot study combining Christian meditation with physical activity showed preliminary support for the intervention's effect on reducing stress (Knabb et al, 2020).*

Home Care

- The interventions described previously may be used in home care.

Client/Family Teaching and Discharge Planning

▲ Refer clients returning to sports after an injury for on-field physical therapy rehabilitation after gym rehabilitation is completed. EB: *On-field rehabilitation assists with transition back to a competitive team environment and includes restoring movement, physical conditioning, restoring specific skills, and increasing training load (Buckthorpe et al, 2019).*

▲ Encourage activity programs after the cardiac rehabilitation phase to increase physical activity. EB: *Interventions related to exercise shortly after cardiac rehabilitation ended overall showed that clients with cardiac issues maintained physical activity and had better physical activity outcomes than those receiving no specific interventions (Graham et al, 2020).*

Ineffective Denial

Domain 9 Coping/stress tolerance Class 2 Coping responses

Lorraine Chiappetta, MSN, RN, CNE and Julianne E. Doubet, BSN, RN, EMT-B

NANDA-I

Definition

Conscious or unconscious attempt to disavow the knowledge or meaning of an event to reduce anxiety and/or fear, leading to the detriment of health.

Defining Characteristics

Delayed search for health care; denies fear of death; denies fear of disability; displaced source of symptoms; does not admit impact of disease on life; does not perceive relevance of danger; does not perceive relevance of symptoms; fear displacement regarding impact of condition; inappropriate affect; minimizes symptoms; refuses health care; uses dismissive comments when speaking of distressing event; uses dismissive gestures when speaking of distressing event; uses treatment not advised

D

Related Factors

Anxiety; excessive stress; fear of death; fear of losing personal autonomy; fear of separation; inadequate emotional support; inadequate sense of control; ineffective coping strategies; perceived inadequacy in dealing with strong emotions; threat of unpleasant reality

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Acceptance: Health Status; Anxiety Self-Control; Health Beliefs: Perceived Threat; Symptom Control

Example NOC Outcome with Indicators

Anxiety Self-Control as evidenced by the following indicators: Eliminates precursors of anxiety/Monitors physical manifestations of anxiety/Controls anxiety response. (Rate the outcome and indicators of **Anxiety Self-Control:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Outcomes

Client Will (Specify Time Frame)

- Demonstrate understanding of a crisis event or change in health status
- Seek out appropriate health care attention when needed
- Demonstrate adherence to treatment regimen
- Display appropriate affect and verbalize fears
- Actively engage in treatment program related to substance misuse as needed
- Remain substance free
- Demonstrate alternate adaptive coping mechanism

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Anxiety Reduction

Example NIC—Activities Anxiety Reduction

Use a calm, reassuring approach; Stay with the patient to promote safety and reduce fear

Nursing Interventions and *Rationales*

- Establish a trusting nurse–client relationship. EBN: *Establishing a trusting relationship between nurses and clients improves outcomes and has been shown to increase clients' adaptation to the state of illness or disability (Polansky, 2019).*
- Assess the client's and family's understanding of the illness the person is experiencing and the feeling states evoked. EBN: *Clients may have complex feelings about their health, especially when living with chronic illnesses. Nursing assessments help nurses provide more individualized care (Polansky, 2019).*
- Express empathetic concern for the anxiety that can be evoked as a person considers the forced adjustments and potential limitations imposed due to the development of a chronic illness or stressful event that leads to a change in lifestyle. EB: *Health providers who offer empathy tend to be more effective in guiding clients and fostering behavior change and medication adherence. Clients are more likely to reveal nonadherence when they believe their provider cares about them (Kourakos et al, 2018).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Function as a knowledgeable resource for clients who rely on home remedies or complementary and alternative medicine. EB: *Alternative therapies are not free from risks and contraindications. Without guidance from a care provider, clients are left to self-educate, leading to a potential risk to the client's health (Wojciechowski, 2020).*

▲ Support referral to a medical or mental health professional when the use of denial or extreme levels of anxiety significantly interfere with health care needs; the use of motivational interviewing is one counseling method to facilitate change. EB: *Implementing motivational interviewing has been shown to facilitate the establishment of rapport and potentially improve long-term health outcomes for individuals with chronic illness (Schaefer & Kavookjian, 2017).*

- Aid the client in making choices regarding treatment and actively involve him or her in the decision-making process. EBN: *Nurses must encourage a client's participation in shared decision-making by providing the client with balanced, evidence-based treatment alternatives and endeavor to identify what is most important to the client and then support their choices (Dawn & Légaré, 2015).*
- Allow the client to express and use denial as a coping mechanism if appropriate to treatment. EB: *According to Werner and Steihaug (2017), it is important for the health care provider to respect the client's autonomy and realize that the client has the right to refuse information regarding his or her condition.*
- Assist the client in using existing and additional sources of support. EBN: *In their study of men with brain tumors who did not access social services, Longbecker, Eckberg, and Yates (2017) opined that there is a divide between clients' needs and utilization of services; this may be a result of the client's expectancy of what the medical system would offer, alternations in standards for well-being, changes in cognition, and difficulties accessing services.*
- Refer to care plans for Defensive **Coping** and Dysfunctional **Family** Processes.

Geriatric

- Engage the person in any decision making about health care issues. EB: *A pilot study found that a communication guide can bridge the gap of understanding between provider and client, allowing the client a more informed decision-making process (Lippe et al, 2020).*
- Enlist the family and significant others to help support the individual. EB: *Family and friends have significant potential to influence clients' chronic illness self-management (Lee et al, 2017).*
- Allow the client to explain his or her concepts of health care needs, and then use reality-focused techniques whenever possible to provide feedback. EB: *Clients should be made aware that primary medical treatment, even when associated with a positive prognosis, does not predict how well clients will fare during their lifetime (Linden et al, 2015).*
- Encourage communication among family members. EB: *According to Hays, Maliski, and Warner (2017), family can be the most important means of support for those diagnosed with health problems, if they are made aware of the client's medical issues.*

Multicultural

- Discuss with the client those aspects of his or her health behavior/lifestyle that will remain unchanged by health status and those aspects of health behavior that need to be modified to improve health status. EBN: *"Culturally sensitive interventions are required to ensure people of culturally and linguistically diverse backgrounds have the appropriate skills to self-manage their complex medical conditions" (Williams et al, 2015).*
- Establish a trusting relationship. Recognize the role that *medical mistrust* plays in the client's and family's ability to acknowledge health status. Groups who have faced exploitation and discrimination at the hands of the medical/health care community are at greater risk of struggling with this potential barrier. EB: *Trust in one's health care providers is vital to optimal client outcomes. In establishing trust the responsibility lies with providers, and the answer requires recognizing and attending to the mistrust (Sullivan, 2020).*
- Support the client's spiritual coping. EB: *The aim of spiritual care is to facilitate meaning making, providing clients guidance to adequately deal with difficult situations (Kruizinga et al, 2018).*

Home Care

- Previously mentioned interventions may be adapted for home care utilization.
- Provide family with education about the individual's disease process, the grief process, and how to support a loved one through a difficult situation to encourage meaningful family support. EB: *People with chronic conditions who have more support from family and friends are more successful in managing their health (Lee et al, 2017).*

- Observe family interaction and roles. Encourage effective communication between family members. EB: *Family can be a key site of support for individuals who are diagnosed with a health issue, as long as the health condition is known within the family unit (Hays et al, 2017).*

✱ Support the use of peer support networks, including formal support groups, community group-based programs, and online social media platforms. EB: *Peer support is especially effective at engaging people into needed services and empowering them to play an active role in their own recovery (Davidson et al, 2018).*

▲ Observe family interaction and roles. Refer the client/family for follow-up if prolonged denial is a risk. EBN: *Nurses are mentors and guides who can support caregivers of dying family members with coordination of care, symptom management education, and making referrals to other agencies as needed (Hartnett, Thom, & Kline, 2016).*

Client/Family Teaching and Discharge Planning

- Instruct client and family to recognize the signs and symptoms of recurring illness and the appropriate responses to alterations in client's health status. EB: *Giving necessary client education can boost chronic disease management, gives clients knowledge and skills regarding their chronic disease, and improves client–provider communication (Stoner et al, 2018).*

▲ Inform family of available community support resources. EBN: *According to study findings by Mendes and Palmer (2016), nurses, especially those involved with the community, can play a pivotal part in aiding caregivers by furnishing useful information, connecting caregivers to community resources, and contributing essential emotional support.*

Impaired Dentition Domain 11 Safety/protection Class 2 Physical injury

Morgan Nestingen, MSN, APRN, AGCNS-BC, OCN, ONN-CG

NANDA-I

Definition

Disruption in tooth development/eruption pattern or structural integrity of individual teeth.

Defining Characteristics

Abraded teeth; absence of teeth; dental caries; enamel discoloration; eroded enamel; excessive oral calculus; excessive oral plaque; facial asymmetry; halitosis; incomplete tooth eruption for age; loose tooth; malocclusion; premature loss of primary teeth; root caries; tooth fracture; tooth misalignment; toothache

Related Factors

Difficulty accessing dental care; difficulty performing oral self-care; excessive intake of fluoride; excessive use of abrasive oral cleaning agents; habitual use of staining substance; inadequate dietary habits; inadequate knowledge of dental health; inadequate oral hygiene habits; malnutrition

At-Risk Population

Economically disadvantaged individuals; individuals with genetic predisposition to dental disorders

Associated Conditions

Bruxism; chronic vomiting; oral temperature sensitivity; pharmaceutical preparations

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Oral Health

Example NOC Outcome with Indicators

Oral Health as evidenced by the following indicators: Cleanliness of teeth/Cleanliness of gums/Cleanliness of dentures/Tongue integrity/Gum integrity. (Rate the outcome and indicators of **Oral Health:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Have clean teeth, healthy pink gums
- Be free of halitosis
- Explain and demonstrate how to perform oral care
- Demonstrate ability to masticate foods without difficulty
- State absence of pain in mouth

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Oral Health Maintenance; Oral Health Promotion; Oral Health Restoration

Example NIC Activities—Oral Health Maintenance

Establish a mouth care routine; Arrange for dental care and check-ups as needed

Nursing Interventions and *Rationales*

▲ Inspect oral cavity/teeth/gingiva at least once daily and note any discoloration, presence of debris, amount of plaque buildup, presence of lesions such as white lesions or patches, edema, or bleeding, and intactness of teeth. Refer to a dentist or periodontist as appropriate. EB: *Inspection is a critical diagnostic tool; observations can identify impending problems. Leukoplakia is the presence of uncharacterized white lesions, which can be a precursor to squamous cell carcinoma. If leukoplakia is observed, prompt referral for diagnosis and potential biopsy is indicated (Lingen et al, 2017; Abadeh et al, 2019).*

- If the client is free of bleeding disorders and able to swallow, encourage toothbrushing with a soft toothbrush using fluoride-containing toothpaste at least two times per day. Do not use foam swabs or lemon glycerin swabs to clean the teeth. EB: *Oral bacteria cause caries and periodontal disease. Plaque is a biofilm of bacteria, which often becomes contaminated with antibiotic-resistant bacteria in the hospitalized client (Featherstone & Chaffee, 2018; Kearney et al, 2020). Lemon glycerin swabs are no longer recommended for use in tooth cleaning, prevention of ventilator-associated pneumonia, or treating xerostomia as they may cause disturbances in the pH and microbial balance within the oral cavity, may cause decalcification, and may worsen xerostomia (Lavigne & Lavigne, 2019).*
- The toothbrush is the most important tool for oral care. Twice daily mechanical toothbrushing is the most effective method of reducing plaque and controlling periodontal disease (Pitchika et al, 2019). EB: *A recent systematic review found no difference in oral health outcomes including cleanliness, gingival health, and ventilator-assisted pneumonia when toothbrushes were used versus oral swabs; limited evidence suggests a soft toothbrush may be preferred in mechanically ventilated children and should be used unless toothbrushing causes pain (Narain & Felipe, 2017; Gadepalli & Hirschl, 2020).*
- Normal gums should be pink and firm. *Gingivitis is characterized by changes in gingival tissue, including redness, sponginess, bleeding, and changes in contour, and weakening of dental attachment (Trombelli et al, 2018).*
- Encourage the client to perform interdental hygiene by flossing or cleaning between teeth with interdental brushes, woodsticks, or oral irrigation at least once per day if free of a bleeding disorder. If the client is unable to floss, assist with flossing or encourage the use of an oral irrigator (i.e., "water flossing"). EB: *A Cochrane review determined that all forms of interdental cleaning performed in addition to toothbrushing are associated with decreased gingivitis; no specific method of interdental cleaning was found to be superior (Worthington et al, 2019). Some interdental cleaning techniques may also assist with interdental plaque removal, but current findings are inconsistent (Ng & Lim, 2019; Slot, Valkenburg, & Van der Weijden, 2020).*
- Use a rotation-oscillation power toothbrush for removal of dental plaque. If the client has a fixed orthodontic appliance, particularly any appliance that limits access or toothbrushing motion, a manual toothbrush may be used. EB: *Use of a rotation-oscillation power toothbrush more effectively removes plaque and reduces gingivitis versus manual toothbrushing (Elkerbout et al, 2020; Grender, Adam, & Erb, 2020). A systematic review and meta-analysis found strong, consistent evidence that rotation-oscillation power toothbrushes are more effective at reducing plaque and gingivitis than ultrasonic and other power toothbrushes (Clark-Perry & Levin, 2020). Recent systematic reviews and meta-analyses fail to show a significant difference between manual toothbrushing use of a powered toothbrush when the client has a fixed orthodontic appliance (Tilliss & Carey, 2018; ElShehaby et al, 2020).*
- Determine the client's mental status and manual dexterity; if the client is unable to care for self, nursing personnel must provide dental hygiene. The nursing diagnosis **Bathing Self-Care Deficit** is then applicable.
- If the client is unable to brush his or her own teeth, follow this procedure:
  - ❍ Position the client sitting upright or on side.
  - ❍ Use a soft bristle toothbrush.
  - ❍ Use fluoride toothpaste and tap water or saline as a solution.
  - ❍ Brush teeth with a manual toothbrush by positioning the brush at a 45-degree angle and directing the bristle tips just below the gingival margin.
  - ❍ Brush teeth with an oscillating toothbrush by positioning the brush over the teeth and directing the edge of the oscillating bristle head just below the gingival margin.
  - ❍ Suction as needed.

EB: *Each client must receive oral care including toothbrushing twice daily to maintain healthy teeth and oral tissues and to prevent complications associated with periodontitis (the advanced form of gum disease that can cause tooth loss), which is associated with health problems such as cardiovascular disease, stroke, and bacterial pneumonia (Zimmermann et al, 2015; Kumar, Tadakamadla, & Johnson, 2016).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Monitor the client's nutritional and fluid status to determine if adequate. Recommend the client eat a balanced diet and limit between-meal snacks. EB: *Poor nutrition and frequent snacking predispose clients to dental disease (Hujoel & Lingström, 2017; Blostein et al, 2020).*
- Recommend that the client maintain a healthy diet with limited sugar intake; in particular, the client should limit sugary beverages and snacks. EB: *Diets high in sugar are strongly associated with formation of caries in adults and children (Laniado et al, 2020).*
- Instruct the client with halitosis to clean the tongue when performing oral hygiene. Brush tongue with a tongue scraper or toothbrush and follow with a mouth rinse. EB: *A Cochrane review found limited evidence that tongue cleaning, chewing gum, systemic deodorizing agents, topical agents, or specialized toothpastes/mouth rinses were effective in controlling halitosis; toothbrushing combined with tongue cleaning and mouthwash has been identified as the most effective method of control (Van der Sluijs et al, 2018; Nagraj et al, 2019).*
- Determine the client's usual method of oral care. Whenever possible, build on the client's existing knowledge base and current practices to develop an individualized plan of care, including strategies to support oral hygiene as a routine habit. EB: *Teaching oral hygiene during childhood is associated with long-term benefits in plaque score, periodontal health, and caries formation (Lai et al, 2016). Habits play a key role in sustaining twice daily oral hygiene (Raison et al, 2020).*
- Instruct the client on effective toothbrushing technique. A manual toothbrush should be held at a 45-degree angle to the gums; clients should brush using short lateral strokes, gently directing the bristle tips just below the gingival margin, brushing all surfaces of each tooth. An oscillating toothbrush should be placed directly over each tooth with the bristled head just below the gingival margin; the client should brush all surfaces of each tooth. EB: *Several toothbrushing methods have been evaluated for impact on oral health outcomes; there is little evidence to suggest one method is clearly superior, but angled brushing and gentle agitation at the gingival margin have been associated with disruption of biofilm and prevention of gingival pockets. Oscillating toothbrushes provide sufficient action without specialized toothbrushing techniques (American Dental Association, 2019a; Perry, Takei, & Do, 2019).*
- Instruct the client to use a soft-bristled toothbrush, which should be replaced every 3 to 4 months or sooner if bristles begin to appear splayed or worn. EB: *Worn toothbrushes are less effective at removing plaque (American Dental Association, 2019a; Van Leeuwen et al, 2019).*
- Recommend appropriate therapeutic mouthwashes to prevent or reduce symptoms of periodontal disease, including plaque, gingivitis, caries, and halitosis. Over-the-counter mouthwashes containing mint or essential oils may be used in combination with toothbrushing and interdental cleaning to maintain oral health. Avoid routine use of hydrogen peroxide, chlorhexidine, or alcohol-based mouthwashes. EB: *Mint and essential oil mouthwashes have been shown to exert an antimicrobial effect on biofilm, reduce loss of mineralization, and improve halitosis when used with toothbrushing and interdental cleaning with minimal discomfort and other adverse effects (Alaee et al, 2017; Albuquerque et al, 2018; Kulaksiz et al, 2018). Although hydrogen peroxide in mouthwash has been linked with chemical gastritis and colitis, it has been shown to be an effective preprocedural virucidal during the SARS-CoV-2 pandemic (Sabau et al, 2017; Zanelli, Ragazzi, & De Marco, 2017; Kulaksiz et al, 2018; Bidra et al, 2020). Chlorhexidine may be beneficial in reducing plaque, gingivitis, and bacterial aerosolization; however, its use is associated with tooth staining, microbial resistance, and anaphylaxis (Rashed, 2016; Brookes et al, 2020). Routine use of alcohol-based mouthwashes may be associated with oral cancers (Argemí et al, 2020; Ustrell-Borràs, Traboulsi-Garet, & Gay-Escoda, 2020).*
- Recommend client see a dentist at prescribed intervals, generally two times per year (recommended frequency depends on overall oral health and potential comorbidities). EB: *Twice yearly dental visits for assessment of dental health and preventive and restorative treatment are associated with a lower incidence of tooth loss (Hahn, Kraus, & Hooper-Lane, 2017).*
- If there are any signs of bleeding when the teeth are brushed, refer the client to a dentist. If bleeding accompanies apparently inflamed gums, refer client to a periodontist. EB: *Early gingivitis can often be reversed with good oral hygiene; advanced cases may require treatment by a periodontist (Trombelli et al, 2018).*
- If platelets are low, use a soft-bristled toothbrush with a fluoride-containing toothpaste to maintain oral hygiene. Flossing should be avoided if it stimulates gingival bleeding. Moistened toothettes and mild cleaning fluids (e.g., saline rinse) may be used if thrombocytopenia is severe. EB: *Use of toothettes is not an adequate substitute for toothbrushing but may be used to improve oral cleanliness and appearance (Onubogu et al, 2019). Adequate cleaning with toothbrush and fluoride toothpaste helps to reduce biofilm and prevent*

secondary infection of mucosal ulcers; if thrombocytopenia is severe, toothettes with saline may reduce mucosal trauma to damaged tissues (Madeswaran et al, 2019).

- Provide meticulous dental care/oral care to prevent hospital-acquired (or extended care–acquired) pneumonia. EB: *Numerous references have found oral care effective in preventing new-onset pneumonia, although heterogeneity in interventions weakens the level and consistency of evidence (Mitchell et al, 2019; Quinn, Giuliano, & Baker, 2020; Satheeshkumar, Papatheodorou, & Sonis, 2020).*
- Provide scrupulous dental care to critically ill clients, including ventilated clients to prevent ventilator-associated pneumonia. EB/EBN: *Numerous studies have demonstrated decreased incidence of ventilator-associated pneumonia with good oral care. Germicides (i.e., chlorhexidine gluconate) may further reduce risk of ventilator-associated pneumonia in addition to toothbrushing (de Camargo, da Silva, & Chambrone, 2019; Kocaçal Güler & Türk, 2019; Kusumasari & Achadi, 2019; Pechilis, 2019).*
- If teeth are nonfunctional for chewing, modification of oral intake (e.g., edentulous diet, soft diet) may be necessary. The nursing diagnosis Imbalanced **Nutrition:** Less Than Body Requirements may apply.
- If the client is unable to swallow, keep suction nearby when providing oral care.
- See care plan for Impaired **Oral Mucous Membrane** Integrity.

Pregnant Client

- Encourage the expectant mother to eat a healthy, balanced diet that is rich in calcium and abstain from alcohol during pregnancy. The teeth usually start to form in the gums during the second trimester of pregnancy. EB: *Maternal dietary imbalance leading to malnutrition or obesity may be associated with changes in the health of infants' deciduous teeth and subsequent caries in children (Badruddin et al, 2017; Behie & Miszkiewicz, 2019; Wu et al, 2019; Yenen & Ataçağ, 2019).*
- Instruct the pregnant mother to perform twice-daily meticulous oral care. EB: *Pregnancy is associated with hormonal changes, emesis, changes in dietary patterns, and altered metabolism of nutrients, which may lead to poor periodontal maternal outcomes during pregnancy, including gingivitis, caries, erosion, and granulomas. Meticulous, twice-daily oral care is critical to maternal health and pregnancy outcomes (Yenen & Ataçağ, 2019).*
- Advise the pregnant mother not to smoke. EB: *Maternal smoking during pregnancy has been associated with caries formation and tooth loss in the child (Kellesarian et al, 2017; Nakagawa Kang et al, 2019).*

Infant Oral Hygiene

- Gently wipe the infant's gums with a clean washcloth or sterile gauze at least once a day. EB: *Wiping infant gums is recommended by the American Dental Association as part of routine infant oral care (American Dental Association, 2020a).*
- Never allow the infant to fall asleep with a bottle containing milk, formula, fruit juice, or sweetened liquids. Instead, parents may give the infant a bottle filled with cool water or provide a clean pacifier recommended by the dentist or health care provider. Do not dip pacifiers in sweet liquids. Avoid filling the infant's bottle with liquids such as sugar water and soft drinks. EB: *Decay occurs when sweetened liquids such as milk, formula, and fruit juice are left to pool in the infant's mouth during sleep. Cariogenic bacteria in the mouth feed on these sugars and promote early childhood caries (Brecher & Lewis, 2018).*
- Maintain meticulous parental and infant oral hygiene and avoid use of shared utensils or prechewing food when feeding the infant. EB: *Certain feeding habits including use of shared utensils are associated with transfer of Streptococcus mutans from mother to infant (Esra et al, 2020).*
- Instruct parents to begin toothbrushing at first tooth eruption, twice daily using a small, soft toothbrush with a rice grain–sized amount of fluoride-containing toothpaste (a pea-sized amount should be used in children older than 3 years of age). EB: *Parental toothbrushing and use of fluoride have been shown to be effective in reducing the formation of early childhood caries (Brecher & Lewis, 2018).*
- Advise parents to begin regular dental visits at 12 months; parents should establish a "dental home" for routine care, including early application of dental fluoride. EB: *Dental care should be established early to support routine preventive care, evaluate infant anatomic concerns (e.g., frenum attachments), and effective approaches to feeding, sucking, and weaning (American Academy of Pediatric Dentistry, 2017; Brecher & Lewis, 2018).*

Older Children

▲ Encourage the family to talk with the dentist about dental sealants or fluoride varnishes, which can help reduce biofilm and prevent cavities in permanent teeth. EB: *A Cochrane review found that dental sealants and fluoride varnishes are both effective in preventing caries (Kashbour et al, 2020).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Teach children to brush teeth twice a day and begin flossing when directed by their dentist; instruct parents to provide support and guidance as needed until children are independent in the task. EB: *The American Dental Association recommends brushing twice daily beginning in early childhood and flossing between ages 7 and 12 (American Dental Association, 2020a).*
- Recommend that parents should not allow the child to smoke or chew tobacco, and stress the importance of setting a good example by not using tobacco products themselves. EB: *Smoking is associated with dental caries (Jiang et al, 2019). Secondary exposure to tobacco is associated with increased risk for dental caries in children (Drummond et al, 2017).*
- Recommend the child drink fluoridated water when possible and use fluoride-containing toothpaste. EB: *The American Dental Association strongly endorses use of fluoridated water as an effective, low-risk public health strategy to reduce tooth decay. Other sources of fluoride including fluoride-containing toothpastes and topical fluoride applications are safe methods of preventing tooth decay (American Dental Association, 2019c).*

Geriatric

- Provide dentists with accurate medication history to avoid drug interactions and client harm. If the client is taking anticoagulants, laboratory values should be reviewed before providing dental care. EB: *Older adults are at higher risk for medication errors, drug interactions, and sensitivity to medications used in dentistry (e.g., anesthetics) (American Dental Association, 2019b).*
- Help clients brush their own teeth twice daily; if clients lack dexterity, provide assistance or modified equipment to support self-care.
- If the client has dementia or delirium and exhibits care-resistant behavior such as fighting, biting, or refusing care, use the following method:
  - ❍ Ensure client is in a quiet environment, such as his or her own bathroom, and sitting or standing at the sink to prime memory for appropriate actions.
  - ❍ Approach the client at eye level within his or her range of vision.
  - ❍ Approach with a smile, and begin conversation with a touch of the hand and gradually move up.
  - ❍ Use mirror–mirror technique, standing behind the client, and brush and floss teeth.
  - ❍ Use respectful adult speech. Avoid "elderspeak," a style of speech characterized by short phrases and questions uttered in a sing-song voice and use of collective pronouns and intimate terms (e.g., first name, nicknames, "deary" or "honey"). *Elderspeak is perceived as demeaning and is a documented trigger for care-resistant behavior (Schnabel et al, 2020; Zhang, Zhao, & Meng, 2020).*
  - ❍ Promote self-care when client brushes own teeth if possible.
  - ❍ Use distractors when needed: talking, reminiscing, singing.

  EB: Use of specific techniques can decrease resistance to nursing care and increase the effectiveness of nurses providing oral care to older clients. (National Institute for Health and Care Excellence [NICE], 2016).
- ▲ Ensure that dentures are removed and cleaned regularly, after each meal and before bedtime. Brush and rinse dentures to remove debris and soak overnight in a peroxide-based cleaning solution. Dentures left in the mouth at night impede circulation to the palate and predispose the client to oral lesions. EB: *Brushing combined with immersion in a peroxide-based cleaning solution reduces the number of microorganisms surviving on the surface of dentures (Shastri et al, 2018).*
- ▲ Support other caregivers by providing oral hygiene. Physical and cognitive impairment in older adults can interfere with the client's ability to perform oral hygiene, and oral hygiene should be provided by a caregiver. If no caregiver is available, the client is prone to dental problems such as dental caries, tooth abscess, tooth fracture, and gingival and periodontal disease.

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's understanding of dental care. EBN: *What the client considers normal and abnormal dental health and appropriate care may be based on cultural perceptions (Attanasi, 2017; Updegraff et al, 2017).*
- Assess for barriers to access to dental care, such as lack of insurance. EB: *Social determinants of health including ethnic minority, low socioeconomic status, impaired family structure, and low health literacy are associated with limited access to care and poor oral health outcomes, including caries and tooth loss (Zhou, Elyasi, & Amin, 2017).*

D

Home Care

- Assess client patterns for daily and professional dental care and related patterns (e.g., smoking, nail biting). Assess for environmental influences on dental status (e.g., fluoride).
- Assess client facilities and financial resources for providing dental care. *Lack of appropriate facilities or financial resources is a barrier to positive dental care patterns. Provision for dental care may be missing from health care plans or unavailable to the uninsured.*
- Request dietary log from the client, adding column for type of food (i.e., soft, pureed, regular).
- Observe a typical meal to assess first-hand the effect of impaired dentition on nutrition. *Clients, especially older adults, are often hesitant to admit nutritional changes that may be embarrassing because of poor dentition.*
- Assist the client with accessing financial or other resources *to support optimum dental and nutritional status.*

Client/Family Teaching and Discharge Planning

- Teach how to inspect the oral cavity and monitor for problems with the teeth and gums. EB: *Education is key to supporting clients' understanding of their oral health and thus their self-care behaviors (Albano et al, 2019).*
- Teach clients to implement a personal plan of dental hygiene, including appropriate toothbrushing and interdental cleaning. Consider motivational interviewing sessions to promote self-care. EB: *Recent systematic reviews have demonstrated an association between motivational interviewing with improved adherence to oral hygiene self-care and may decrease gingival bleeding times and plaque scores; results are more significant among high-risk groups (Carra et al, 2020; Colvara et al, 2020). See Appendix C, Motivational Interviewing, on Evolve.*
- Educate clients to change their toothbrush every 3 to 4 months to ensure effective plaque removal. EB: *Worn toothbrushes are less effective at removing plaque (American Dental Association, 2019a; Van Leeuwen et al, 2019).*
- Teach the client the value of having an optimal fluoride concentration in drinking water and to brush teeth twice daily with toothpaste containing fluoride.
- Teach clients of all ages about the need to decrease intake of sugary foods and to brush teeth regularly. EB: *The World Health Organization recommends limiting sugar to no more than 5% of energy intake to preserve oral health; client education plays a key role in client adherence (Moynihan et al, 2018).*
- Inform individuals who are considering oral piercing or body modification of the potential complications such as infection, development of oral "tic" behaviors, tooth chipping, or gingival recession. If client undergoes oral body modification, teach the client how to care for the wound and prevent complications. EB: *Oral piercings and modifications are associated with infection and oral trauma, including increased risk of gingival recession and tooth injuries (American Dental Association, 2020b; Magno et al, 2020).*
- Advise clients to avoid smoking. EB: *A PRISMA systematic review and meta-analysis found a positive and consistent association between smoking and dental caries (Jiang et al, 2019).*

Delayed Child Development

Domain 13 Growth/development Class 2 Development

Daniela Moscarella, DNP, APN, CPNP-PC, CCRN-K

NANDA-I

Definition

Child who continually fails to achieve developmental milestones within the expected timeframe.

Defining Characteristics

Consistent difficulty performing cognitive skills typical of age group; consistent difficulty performing language skills typical of age group; consistent difficulty performing motor skills typical of age group; consistent difficulty performing psychosocial skills typical of age group

Related Factors

Infant or Child Factors

Inadequate access to health care provider; inadequate attachment behavior; inadequate stimulation; unaddressed abuse; unaddressed psychological neglect

Caregiver Factors

Anxiety; decreased emotional support availability; depressive symptoms; excessive stress; unaddressed domestic violence

At-Risk Population

Children aged 0-9 years; children born to economically disadvantaged families; children exposed to community violence; children exposed to environmental pollutants; children whose caregivers have developmental disabilities; children whose mothers had inadequate prenatal care; children with below normal growth standards for age and gender; institutionalized children; low birth weight infants; premature infants

Associated Conditions

Antenatal pharmaceutical preparations; congenital disorders; depression; inborn genetic diseases; maternal mental disorders; maternal physical illnesses; prenatal substance misuse; sensation disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Recovery; Child Development: 1 Month, 2 Months, 4 Months, 6 Months, 12 Months, 2 Years, 3 Years, 4 Years, 5 Years, Middle Childhood, Adolescence; Development: Late Adulthood, Middle Adulthood, Young Adulthood; Knowledge: Parenting, Neglect Recovery

Example NOC Outcome with Indicators

Child Development as evidenced by the following indicators: Appropriate milestones of physical, cognitive, and psychosocial age-appropriate progression. (Rate the outcome and indicators of **Child Development:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client/Parents/Primary Caregiver Will (Specify Time Frame)

- Child will achieve expected milestones in all areas of development (physical, cognitive, academic, and psychosocial)
- Parent/caregiver will verbalize understanding of potential impediments to normal development and demonstrate actions or environmental/lifestyle changes necessary to provide appropriate care in a safe, nurturing environment

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Abuse Protection Support: Child; Caregiver Support; Developmental Enhancement: Child/Adolescent; Home Maintenance Assistance; Immunization/Vaccination Management; Infant Care; Kangaroo Care; Lactation Counseling; Learning Facilitation; Newborn Care; Newborn Monitoring; Nonnutritive Sucking; Normalization Promotion; Nutrition Management; Parent Education: Infant/Adolescent/Childbearing Family; Parenting Promotion; Referral; Risk Identification: Childbearing Family; Teaching: (Infant) Nutrition/Safety/Stimulation; (Toddler) Nutrition/Safety; Temperature Regulation (Infant); Therapeutic Play

Example NIC Activities—Parent Education

Instruct parent on normal physiological, emotional, and behavioral characteristics of child

Nursing Interventions and *Rationales*

Preconception/Pregnancy

- Assess for nutritional status during pregnancy. Review the importance of iron, folate, iodine, choline, and essential fatty acids. EB: *Maternal nutrition during pregnancy is essential for the health of an infant. Deficiencies in iron, folate, iodine, choline, and essential fatty acids can lead to neural tube defects, abnormal brain development, and preventable developmental delays (Black et al, 2020).*
- Assess for alcohol/drug use during pregnancy. Expectant mothers should be instructed that no amount of alcohol consumption is safe during pregnancy. EBN: *Alcohol is a well-established teratogen that can cause variable physical and behavioral effects on the fetus. Increased fetal exposure to alcohol and sustained alcohol intake during any trimester of pregnancy are associated with an increased risk of fetal alcohol syndrome (FAS) (Gupta, Gupta, & Shirasaka, 2016).*
- Assess and educate about consumption of marijuana use in pregnancy. EB: *Marijuana crosses the placenta and has been found to affect fetal neurodevelopment, which may cause problems with neurological development resulting in hyperactivity and poor cognitive function (Metz & Stickrath, 2015).*
- Educate expectant mothers to stop smoking and assist with methods of smoking cessation. Smoking is an avoidable risk factor for low birth weight and other significant prenatal issues. EB: *Reese et al (2017) noted that pregnant women disproportionately underreport smoking and smokers tend to have lower follow-up rates to repeat questionnaires.*
- Educate that it is recommended that women of childbearing age take 400 mcg of folic acid daily, along with a healthy, well-balanced diet, to reduce the risk of neural tube and other birth defects. EB: *The recommended supplementation of folic acid is 0.4 mg/400 mcg taken once per day, before attempting conception and continuing throughout pregnancy (Atrash & Jack, 2020).* EB: *The benefits of using folic acid supplements during the periconception period are to prevent neural tube defects and to ensure normal brain development (Valera-Gran et al, 2017).* EB: *Additionally, a comprehensive meta-analysis suggested that maternal use of folic acid supplements during pregnancy could significantly reduce the risk of autism spectrum disorders in children regardless of ethnicity compared with those women who did not supplement with folic acid (Wang et al, 2017).*

Neonate/Infant

- Educate new mothers about the importance of breastfeeding. EB: *Breast milk and the act of breastfeeding may benefit children's cognitive development (Black et al, 2020).*
- Assess the neonate/infant for age-appropriate milestones. EB: *Early identification of developmental delays expedites a referral for therapeutic services such as early intervention, which encourages gains in developmental milestones (Scharf et al, 2016).*
- Assess for maternal depression when caring for a newborn infant. EB: *It is essential to address maternal mental health and promote parenting strategies that encourage play-based interactions, which would reduce the risk of behavior and social-emotional problems in childhood (McDonald et al, 2018).*
- Provide information to parents about the importance of health supervision visits at the following intervals: first week of life, 1 month, 2 months, 4 months, 6 months, 9 months, and 12 months, with standardized developmental screen at 9 months old. EB: *Early identification of and intervention for developmental disorders are critical to the well-being of childhood development (Lipkin & Macias, 2020).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Teach parents about the necessity of daily tummy time for infants less than 6 months old. EB: *Tummy time has a positive effect related to infant development with an emphasis on motor development (Hewitt et al, 2017).*
- Explain the use of developmentally appropriate toys for play. EB: *Toys that match a child's developmental skills and abilities will further encourage the development of new skills. That is important in early childhood to facilitate cognitive development, language interactions, symbolic and pretend play, problem-solving, social interactions, and physical activity (Healey & Mendelsohn, 2019).*
- Monitor mother–baby interactions when caring for premature infants. EBN: *Posttraumatic stress disorder (PTSD) induced by preterm delivery has a significant impact on the infant–mother attachment dyad. Mothers often have attachment issues, and the infant may be affected, resulting in delayed development (Anderson & Cacola, 2017).*

Toddler/Preschooler/School-Age

- Assess for the effects of social disruption on cognitive abilities. EB: *A study found delayed negative effects on the academic achievement of children living in postdisaster communities (Gibbs et al, 2019).*
- Educate about the importance of eating a well-balanced diet in early childhood. EB: *Brain development is rapid in the early years of childhood and therefore adequate nutrition has a significant impact on neurodevelopment (Black et al, 2020).*
- Assess for age-appropriate milestones and developmental history at every visit.
- Autism spectrum disorder (ASD) screening should be conducted at the 18-month and 24-month visits. EB: *A developmental screen is recommended at the 18-month visit because delays in fine motor, communication, and language development are often evident by 18 months of age and may be indicative of ASD (Lipkin & Macias, 2020).*
- Educate parents about the importance of health supervision visits yearly with standardized developmental screening at 30 months' old and then again at the 4- to 5-year-old visit. EB: *Close attention to developmental skills necessary for school readiness should be performed at the 4- or 5-year visit. This is the opportunity to capture mild delays that may have been previously missed (Lipkin & Macias, 2020).*
- Monitor preterm infants more closely for developmental delays. EBN: *Children born prematurely have a higher risk of chronic health conditions, including attention deficit disorder and attention deficit hyperactivity disorder, speech problems, learning disability, anxiety, asthma, and developmental delays (Kelly, 2018).*
- Provide support and education to parents of toddlers with developmental disabilities (e.g., Down's syndrome [DS], cerebral palsy). EB: *A recent study of infants with DS affirmed previous findings showing that the rate of attainment of motor skills is delayed in children with DS compared with children with typical development; however, the developmental sequence is the same. The delayed development is more prominent in more complex skills (Beqaj, Jusaj, & Živković, 2017).*
- Provide parents and caregivers with information about speech-language development, play development, and speech-language stimulation strategies for children with language delay. Refer to speech and language specialists as needed. EB: *A study that implemented a low-intensity training program for parents, supported by a manual focusing on developmentally appropriate play and speech-language stimulation, found increased verbal interaction and changes in language input to children with language delay (Rajesh & Vankatesh, 2019).*
- Monitor for maternal eating disorders because they have a direct effect on childhood development. EB: *Sadeh-Sharvit, Levy-Shiff, and Lock (2016) found that children of mothers with eating disorders showed delayed mental and psychomotor development. Severity of maternal eating disorder symptoms emerged as a significant predictor of child development, but other maternal psychopathology did not. Findings suggest that maternal eating disorder history may play a unique role in the development of neurodevelopmental functions in their children.*
- Educate parents about the importance of avoiding lead-based paints in the home and other sources of lead in the environment. EB: *Low-level lead exposure has been shown to significantly increase the risk for learning disabilities, behavioral problems, and developmental delay (Hamp et al, 2018).*

▲ Refer parents and caregivers of children with language delays to Enhanced Milieu Teaching (EMT). EB: *EMT is an evidence-based, conversation-based intervention that uses child interests and initiations as opportunities to model and prompt language in everyday contexts. A study of EMT with language-delayed young children found gains in expressive language (Hatcher & Page, 2020).* EB: *Another study found that 12 months after the EMT intervention ended, children in the EMT intervention group displayed lower rates of parent-reported problem behaviors (Curtis et al, 2019).*

NANDA-I

Definition

Child who is susceptible to failure to achieve developmental milestones within the expected timeframe.

Risk Factors

Infant or Child Factors

Inadequate access to health care provider; inadequate attachment behavior; inadequate stimulation; unaddressed abuse; unaddressed psychological neglect

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Caregiver Factors

Anxiety; decreased emotional support availability; depressive symptoms; excessive stress; unaddressed domestic violence

At-Risk Population

Children aged 0-9 years; children born to economically disadvantaged families; children exposed to community violence; children exposed to environmental pollutants; children whose caregivers have developmental disabilities; children whose mothers had inadequate prenatal care; children with below normal growth standards for age and gender; institutionalized children; low birth weight infants; premature infants

Associated Conditions

Antenatal pharmaceutical preparations; congenital disorders; depression; inborn genetic diseases; maternal mental disorders; maternal physical illnesses; prenatal substance misuse; sensation disorders

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching, and References

Refer to care plan for Delayed Child **Development**.

Delayed Infant Motor Development

Domain 13 Growth/development Class 2 Development

Daniela Moscarella, DNP, APN, CPNP-PC, CCRN-K

NANDA-I

Definition

Individual who consistently fails to achieve developmental milestones related to the normal strengthening of bones, muscles and ability to move and touch one's surroundings.

Defining Characteristics

Difficulty lifting head; difficulty maintaining head position; difficulty picking up blocks; difficulty pulling self to stand; difficulty rolling over; difficulty sitting with support; difficulty sitting without support; difficulty standing with assistance; difficulty transferring objects; difficulty with hand-and-knee crawling; does not engage in activities; does not initiate activities

Related Factors

Infant Factors

Difficulty with sensory processing; insufficient curiosity; insufficient initiative; insufficient persistence

Caregiver Factors

Anxiety about infant care; carries infant in arms for excessive time; does not allow infant to choose physical activities; does not allow infant to choose toys; does not encourage infant to grasp; does not encourage infant to reach; does not encourage sufficient infant play with other children; does not engage infant in games about body parts; does not teach movement words; insufficient fine motor toys for infant; insufficient gross motor toys for infant; insufficient time between periods of infant stimulation; limits infant experiences in the prone position; maternal postpartum depressive symptoms; negative perception of infant temperament; overstimulation of infant; perceived infant care incompetence

At-Risk Population

Boys; infants aged 0-12 months; infants born to economically disadvantaged families; infants born to large families; infants born to parents with low educational levels; infants in intensive care units; infants living in home with inadequate physical space; infants whose mothers had inadequate antenatal diet; infants with below normal growth standards for age and gender; low birth weight infants; premature infants; premature infants who do not receive physiotherapy during hospitalization

Associated Conditions

5 Minute Appearance, Pulse, Grimace, Activity, & Respiration (APGAR) score < 7; antenatal pharmaceutical preparations; complex medical conditions; failure to thrive; maternal anemia in late pregnancy; maternal mental health disorders in early pregnancy; maternal prepregnancy obesity; neonatal abstinence syndrome; neurodevelopmental disorders; postnatal infection of preterm infant; sensation disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Recovery; Child Development: 1 Month, 2 Months, 4 Months, 6 Months, 12 Months; Knowledge: Infant Care, Pre-term Infant Care, Parenting; Neglect Cessation; Neglect Recovery

Example NOC Outcome with Indicators

Child Development as evidenced by the following indicators: Appropriate milestones of physical, cognitive, and psychosocial age-appropriate progression. (Rate the outcome and indicators of **Child Development:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client/Parents/Primary Caregiver Will (Specify Time Frame)

- Infant will achieve expected milestones in all areas of physical and motor development
- Parent/caregiver will verbalize understanding of potential impediments to normal development and demonstrate actions or environmental/lifestyle changes necessary to provide appropriate care in a safe, nurturing environment

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Abuse Protection Support; Caregiver Support; Developmental Enhancement: Infant; Immunization/Vaccination Management; Infant Care: Newborn/Pre-term; Kangaroo Care; Lactation Counseling; Learning Facilitation; Nonnutritive Sucking; Normalization Promotion; Nutrition Management; Parent Education: Infant/Childbearing Family; Parenting Promotion; Referral; Risk Identification: Childbearing Family; Teaching: (Infant) Nutrition/Safety/Stimulation; Temperature Regulation (Infant); Therapeutic Play

Example NIC Activities—Parent Education

Instruct parent on normal physiological, emotional, and behavioral characteristics of infant

Nursing Interventions and *Rationales*

Preconception/Pregnancy

- Assess for nutritional status during pregnancy. Review the importance of iron, folate, iodine, choline, and essential fatty acids. EB: *Maternal nutrition during pregnancy is essential for the health of an infant. Deficiencies in iron, folate, iodine, choline, and essential fatty acids can lead to neural tube defects, abnormal brain development, and preventable developmental delays (Black et al, 2020).*
- Assess for alcohol/drug use during pregnancy. Expectant mothers should be instructed that no amount of alcohol consumption is safe during pregnancy. EBN: *Alcohol is a well-established teratogen that can cause variable physical and behavioral effects on the fetus. Increased fetal exposure to alcohol and sustained alcohol intake during any trimester of pregnancy are associated with an increased risk of fetal alcohol syndrome (FAS) (Gupta, Gupta, & Shirasaka, 2016).*
- Assess and educate about consumption of marijuana use in pregnancy. EB: *Marijuana crosses the placenta and has been found to affect fetal neurodevelopment, which may cause problems with neurological development resulting in hyperactivity and poor cognitive function (Metz & Stickrath, 2015).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Educate expectant mothers to stop smoking and assist with methods of smoking cessation. Smoking is an avoidable risk factor for low birth weight and other significant prenatal issues. EB: *Reese et al (2017) noted that pregnant women disproportionately underreport smoking and smokers tend to have lower follow-up rates to repeat questionnaires.*
- Educate that it is recommended that women of childbearing age take 400 mcg of folic acid daily, along with a healthy, well-balanced diet, to reduce the risk of neural tube and other birth defects. EB: *The recommended supplementation of folic acid is 0.4 mg/400 mcg taken once per day, beginning at least 1 month before attempting conception and continuing throughout pregnancy (Kerr et al, 2017).* EB: *The benefits of using folic acid supplements during the periconception period are to prevent neural tube defects and to ensure normal brain development (Valera-Gran et al, 2017).*

Neonate/Infant

- Educate new mothers about the importance of breastfeeding. EB: *Breast milk and the act of breastfeeding may benefit children's cognitive development (Black et al, 2020).*
- Assess the neonate/infant for age-appropriate milestones. EB: *Early identification of developmental delays expedites a referral for therapeutic services such as early intervention, which encourages gains in developmental milestones (Scharf et al, 2016).*
- Assess for maternal depression. EB: *It is essential to address maternal mental health and promote parenting strategies that encourage play-based interactions, which would reduce the risk of behavior and social-emotional problems in childhood (McDonald et al, 2018).*
- Provide information to parents about the importance of health supervision visits at the following intervals: first week of life, 1 month, 2 months, 4 months, 6 months, 9 months, and 12 months, with standardized developmental screen at 9 months old. EB: *Early identification of and intervention for developmental disorders are critical to the well-being of childhood development (Lipkin & Macias, 2020).*
- Teach parents about the necessity of daily tummy time for infants less than 6 months old. EB: *Tummy time has a positive effect related to infant development with an emphasis on motor development (Hewitt et al, 2017).*
- Explain the use of developmentally appropriate toys for play. EB: *Toys that match a child's developmental skills and abilities will further encourage the development of new skills. That is important in early childhood to facilitate cognitive development, language interactions, symbolic and pretend play, problem-solving, social interactions, and physical activity (Healey & Mendelsohn, 2019).*
- Monitor mother–baby interactions when caring for premature infants. EBN: *Posttraumatic stress disorder (PTSD) induced by preterm delivery has a significant impact on the infant–mother attachment dyad. Mothers often have attachment issues, and the infant may be affected, resulting in delayed development (Anderson & Cacola, 2017).*
- Educate about the importance of eating a well-balanced diet in early childhood. EB: *Brain development is rapid in the early years of childhood and therefore adequate nutrition has a significant impact on neurodevelopment (Black et al, 2020).*
- Monitor preterm infants more closely for developmental delays. EBN: *Children born prematurely have a higher risk of chronic health conditions, including attention deficit disorder and attention deficit hyperactivity disorder, speech problems, learning disability, anxiety, asthma, and developmental delays (Kelly, 2018).*
- Provide parents or caregiver with teaching to provide postural support and opportunities for movement with support during parent–infant interactions with the goal of increasing infant movement quality and quantity. EB: *A study found that parent-delivered motor interventions (PDMI) were more effective in improving motor and cognitive outcomes than other interventions (Kharuna et al, 2020).*
- Provide support and education to parents of infants with developmental disabilities (e.g., Down syndrome [DS], cerebral palsy). EB: *A recent study of infants with DS affirmed previous findings showing that the rate of attainment of motor skills is delayed in children with DS compared with children with typical development; however, the developmental sequence is the same. The delayed development is more prominent in more complex skills (Beqaj, Jusaj, & Živković, 2017).*
- Provide education and support for parents of infants with tracheostomy to promote early motor development. EB: *A study found that infants with tracheostomy showed delayed gross motor milestones in head control in a supine position and rolling from a prone to a supine position compared with nontracheostomized infants. Parents should be instructed on the importance of time spent in the prone position (using a wedge or other support as needed) and exercises that strengthen the neck flexor muscle (Shin & Shin, 2020).*
- Monitor for maternal eating disorders because they have a direct effect on childhood development. EB: *Sadeh-Sharvit, Levy-Shiff, and Lock (2016) found that children of mothers with eating disorders showed*

delayed mental and psychomotor development. Severity of maternal eating disorder symptoms emerged as a significant predictor of child development, but other maternal psychopathology did not. Findings suggest that maternal eating disorder history may play a unique role in the development of neurodevelopmental functions in their children.

- Educate parents about the importance of avoiding lead-based paints in the home and other sources of lead in the environment. EB: *Low-level lead exposure has been shown to significantly increase the risk for learning disabilities, behavioral problems, and developmental delay (Hamp et al, 2018).*

Risk for Delayed Infant Motor Development

Domain 13 Growth/development
Class 2 Development

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Individual susceptible to fails to achieve developmental milestones related to the normal strengthening of bones, muscles and ability to move and touch one's surroundings.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Risk Factors

Infant Factors

Difficulty with sensory processing; insufficient curiosity; insufficient initiative; insufficient persistence

Caregiver Factors

Anxiety about infant care; carries infant in arms for excessive time; does not allow infant to choose physical activities; does not allow infant to choose toys; does not encourage infant to grasp; does not encourage infant to reach; does not encourage sufficient infant play with other children; does not engage infant in games about body parts; does not teach movement words; insufficient fine motor toys for infant; insufficient gross motor toys for infant; insufficient time between periods of infant stimulation; limits infant experiences in the prone position; maternal postpartum depressive symptoms; negative perception of infant temperament; overstimulation of infant; perceived infant care incompetence

At-Risk Population

Boys; infants aged 0-12 months; infants born to economically disadvantaged families; infants born to large families; infants born to parents with low educational levels; infants in intensive care units; infants living in home with inadequate physical space; infants whose mothers had inadequate antenatal diet; infants with below normal growth standards for age and gender; low birth weight infants; premature infants; premature infants who do not receive physiotherapy during hospitalization

Associated Conditions

5 Minute Appearance, Pulse, Grimace, Activity, & Respiration (APGAR) score < 7; antenatal pharmaceutical preparations; complex medical conditions; failure to thrive; maternal anemia in late pregnancy; maternal mental health disorders in early pregnancy; maternal prepregnancy obesity; neonatal abstinence syndrome; neurodevelopmental disorders; postnatal infection of preterm infant; sensation disorders

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching, and References

Refer to care plan for Delayed Infant Motor **Development.**

Diarrhea Domain 3 Elimination and exchange Class 2 Gastrointestinal function

Rosemary Timmerman, DNP, APRN, CCNS, CCRN-CSC-CMC

NANDA-I

Definition

Passage of three or more loose or liquid stools per day.

Defining Characteristics

Abdominal cramping; abdominal pain; bowel urgency; dehydration; hyperactive bowel sounds

Related Factors

Anxiety; early formula feeding; inadequate access to safe drinking water; inadequate access to safe food; inadequate knowledge about rotavirus vaccine; inadequate knowledge about sanitary food preparation; inadequate knowledge about sanitary food storage; inadequate personal hygiene practices; increased stress level; laxative misuse; malnutrition; substance misuse

At-Risk Population

Frequent travelers; individuals at extremes of age; individuals exposed to toxins

Associated Conditions

Critical illness; endocrine system diseases; enteral nutrition; gastrointestinal diseases; immunosuppression; infections; pharmaceutical preparations; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Bowel Elimination; Electrolyte and Acid-Base Balance; Fluid Balance; Hydration; Risk Control: Environmental Hazards; Community Risk Control: Communicable Disease

Example NOC Outcome with Indicators

Bowel Elimination as evidenced by the following indicators: Elimination pattern/Stool soft and formed/Bowel sounds/Liquid stool. (Rate each indicator of **Bowel Elimination:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Defecate formed, soft stool every 1 to 3 days
- Maintain the perirectal area free of irritation
- State relief from cramping and less or no diarrhea
- Explain cause of diarrhea and rationale for treatment
- Maintain good skin turgor and weight at usual level
- Have negative stool cultures

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Diarrhea Management

Example NIC Activities—Diarrhea Management

Evaluate medication profile for gastrointestinal side effects; Suggest trial elimination of foods containing lactose

Nursing Interventions and *Rationales*

- Recognize that diarrhea is defined as the passage of three or more loose or liquid stools in a 24-hour period (Shane et al, 2017).
- Assess pattern of defecation or have the client keep a diary that includes the following: time of day defecation occurs; usual stimulus for defecation; consistency, amount, and frequency of stool; type of, amount of, and time food consumed; fluid intake; history of bowel habits and laxative use; diet; exercise patterns; obstetrical/gynecological, medical, and surgical histories; medications; alterations in perianal sensations; and present bowel regimen. EB: *Assessment of defecation pattern and factors surrounding diarrhea episode, including changes in diet, medications, exercise, and health history, will help direct interventions and treatment (Gale & Wilson, 2016; Shane et al, 2017).*
- Recommend use of standardized tool to consistently assess, quantify, and then treat diarrhea. EB: *Stool classification systems include the Hart and Dobb Diarrhea Scale, the Guenther and Sweed Stool Output Assessment Tool, the Bristol Stool Scale, and the Diarrhea Grading Scale (Dag et al, 2015; Ford & Talley, 2016).*
- Although the abdominal examination has been historically performed in the order of inspection, auscultation, palpation, and percussion, recent scientific investigations have found that palpation and percussion do not affect the number of bowel sounds (Calis et al, 2019; Vizioli et al, 2020). EB: *Expect increased frequency of bowel sounds with diarrhea (Lattimer, Chandler, & Borum, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ Use an evidence-based bowel management protocol that includes identifying and treating the cause of the diarrhea, obtaining a stool specimen if infectious etiology is suspected, evaluating current medications and osmolality of enteral feedings, assessing and treating hydration status of client, reviewing and stopping ordered and/or over-the-counter (OTC) laxatives, assessing food preparation practices, assessing home environment, providing good skin care and applying barrier creams to prevent skin irritation from diarrhea, and evaluating the need for antidiarrheal agents and possible fecal containment device with provider. EB: *The possible cause of the diarrhea needs to be assessed and client hydration and skin protective interventions put into place rapidly to prevent secondary complications associated with the client's diarrhea episodes (Gale & Wilson, 2016; Shane et al, 2017).*

● Identify the cause of diarrhea if possible based on history (e.g., infection, gastrointestinal inflammation, medication effect, malnutrition or malabsorption, laxative abuse, osmotic enteral feedings, anxiety, stress).

● Identification of the underlying cause is important because the treatment is determined based on the cause of diarrhea.

▲ Testing for diarrhea may consist of laboratory work such as a complete blood count with differential and blood cultures if the client is febrile. Also obtain stool specimens as ordered to either rule out or diagnose an infectious process (e.g., ova and parasites, *Clostridioides [Clostridium] difficile* infection [CDI], bacterial cultures for food poisoning). EB: *Assessing for signs of systemic infection and inflammatory response and evaluation of the stool for infection are important first steps in identifying the cause of diarrhea (Shane et al, 2017).*

● Consider the possibility of CDI if the client over the age of 2 years has any of the following: watery diarrhea, low-grade fever, abdominal cramps, history of antibiotic therapy, history of gastrointestinal tract surgery, and if the client is taking medications that reduce gastric acid, including proton-pump inhibitors (PPIs), or if diarrhea occurs in the hospital setting. Any antibiotic can cause CDI, but clindamycin, cephalosporins, β-lactam/β-lactamase inhibitors, and fluoroquinolones pose the greatest risk, as do multiple antibiotics and longer duration of antibiotics (Shane et al, 2017; McDonald et al, 2018). EB: *CDIs have become increasingly common because of the frequent use of broad-spectrum antibiotics. Antibiotics and gastric acid–reducing medications can change normal gut flora, increasing the risk for development of CDI, diarrhea, and colitis (Shane et al, 2017; McDonald et al, 2018).*

● Use standard precautions when caring for clients with diarrhea to prevent spread of infectious diarrhea; for individuals with a CDI, employ contact precautions until 48 hours after diarrhea has resolved; use gloves, gowns, and, when able, disposable equipment; perform handwashing with soap and water; perform routine room and equipment decontamination with a *C. difficile* sporicidal agent; provide a private room or cohort with other clients with a CDI; and provide a dedicated toilet to reduce transmission. *C. difficile* and viruses causing diarrhea have been shown to be highly contagious. *C. difficile* is difficult to eradicate because of spore formation (Shane et al, 2017; McDonald et al, 2018). EB: *Alcohol rubs are not effective in killing* C. difficile *spores (Shane et al, 2017; Centers for Disease Control and Prevention [CDC], 2018).* C. difficile *can survive for at least 24 hours on inanimate surfaces, and spores can survive for months on objects such as toilets, sinks, and bed rails (CDC, 2018).*

▲ Antibiotic stewardship is an important aspect in the prevention of *C. difficile* infections. *Antibiotics should be used judiciously (CDC, 2018; McDonald et al, 2018).* If the client has diarrhea associated with antibiotic therapy, consult with the health care provider regarding the use of probiotics, such as yogurt with active cultures, to treat diarrhea, or probiotic dietary supplements, or preferably use probiotics to prevent diarrhea when first beginning antibiotic therapy. EB: *Although conclusive evidence on the effectiveness of probiotic in treating and preventing CDI and diarrhea is lacking, evidence suggests that probiotics may be helpful for reducing the severity and duration of infectious diarrhea in immunocompetent adults and children; probiotics may be used in an attempt to balance intestinal flora and restrict the colonization of* C. difficile, *but the efficacy is influenced by the strain composition of the probiotic as well as the type and duration of antibiotic therapy (Agamennone et al, 2018; McDonald et al, 2018).*

▲ Probiotics may also be ordered for immunocompetent clients to prevent a CDI when high-risk antibiotics are prescribed; if a probiotic is ordered, administer it with food. Recommend that it should be taken through the antibiotic course and 10 to 14 days afterward. EB: *Food tends to buffer the stomach acids, allowing more of the probiotic ingredients to pass through the stomach for absorption in the intestines. Beginning this therapy early helps prevent antibiotic-associated diarrhea (McDonald et al, 2018).*

▲ Recognize that a CDI can commonly recur and that reculturing of stool is often required before initiating retreatment. EB: *High reinfection rates have been reported within the first 2 months of initial diagnosis. Repeat courses of antibiotics, usually metronidazole or vancomycin, are necessary to treat repeat CDIs. Fecal*

microbiota transplantation may be used for clients with severe recurrent or refractory CDIs who have failed antibiotic treatments (Eliakim-Raz & Bishara, 2019; Hui et al, 2019).

- Have the client complete a diet diary for 7 days and monitor the intake of high-fructose corn syrup and fructose sweeteners in relation to onset of diarrhea symptoms. If diarrhea is associated with fructose ingestion, intake should be limited or eliminated. EB: *High-fructose corn syrup or fructose sweeteners from fruit juices can cause gastrointestinal symptoms of bloating, rumbling, flatulence, and diarrhea (Pitta et al, 2019).*

▲ If the client has infectious diarrhea, consider avoiding use of medications that slow peristalsis. EB: *If an infectious process is occurring, such as a CDI or food poisoning, medication to slow peristalsis should generally not be given. The increase in gut motility helps eliminate the causative factor, and use of antidiarrheal medication could result in a toxic megacolon (Shane et al, 2017; McDonald et al, 2018).*

- Assess for dehydration by observing skin turgor over sternum or delayed capillary refill and inspecting for longitudinal furrows of the tongue. Watch for excessive thirst, fever, dizziness, lightheadedness, palpitations, excessive cramping, bloody stools, hypotension, and symptoms of shock. EB: *Severe diarrhea can cause deficient fluid volume, electrolyte imbalance, extreme weakness, and a possible shock state (Gale & Wilson, 2016; Shane et al, 2017).*

▲ Administer oral rehydration solution, consisting of a balanced sodium, potassium, and glucose solution, for individuals with mild to moderate dehydration or in individuals with mild dehydration associated with vomiting or severe diarrhea; provide isotonic intravenous solutions for severe dehydration, shock, or altered mental states (Shane et al, 2017; Ofei & Fuchs, 2019).

- Refer to care plans for Deficient **Fluid** Volume and Risk for Imbalanced **Fluid** Volume if appropriate.

▲ If the client has frequent or chronic diarrhea, consider suggesting use of dietary fiber after consultation with a nutritionist and/or provider. EB: *Use of a fiber supplement decreases the number of incontinent stools and improves stool consistency (Pitta et al, 2019).*

▲ If diarrhea is chronic and there is evidence of malnutrition, consult with the provider for a dietary consultation and possible nutrition supplementation to maintain nutrition while the gastrointestinal system heals (Pitta et al, 2019).

- Encourage the client to eat small, frequent meals, eating foods that are easy to digest at first (e.g., bananas, crackers, pretzels, rice, potatoes, clear soups, applesauce), but switch to a regular diet as soon as tolerated. Also recommend avoiding milk products, foods high in fiber, and caffeine (dark sodas, tea, coffee, chocolate). EB: *The bananas, rice, applesauce, and toast (BRAT) diet has been traditionally recommended but may be nutritionally incomplete (Schiller, Pardi, & Sellin, 2017; Bonci, & Almario, 2020).*
- Provide a readily available bathroom, commode, or bedpan; provide individuals with a CDI with a dedicated toilet to reduce transmission to other clients (McDonald et al, 2018).
- Thoroughly cleanse and dry the perianal and perineal skin daily as needed using a cleanser capable of stool removal. Apply skin moisture barrier cream as needed. Refer to perirectal skin care in the care plan for Bowel **Incontinence.**

▲ If the client has enteral tube feedings and diarrhea, consider infusion rate; position of feeding tube; tonicity of formula; fiber content in the formula; possible formula contamination; and excessive intake of hyperosmolar medications, such as sorbitol commonly found in the liquid version of medications; administer antidiarrheal medications such as loperamide as prescribed (Tatsumi, 2019; Pitta et al, 2019). Consider changing the formula to a lower osmolarity, lactose-free, or high-fiber feeding. *Determination of the cause of diarrhea should include an abdominal examination, fecal leukocytes, quantification of stool, stool culture for* C. difficile *(and/or toxin assay), serum electrolyte panel, and review of medications (Pitta et al, 2019; Tatsumi, 2019).*

- Avoid administering bolus enteral feedings or hyperosmolar formulas directly into the small bowel. EB: *The stomach has a larger capacity for large fluid volumes, whereas the small bowel can usually only tolerate up to 150 mL/h (Tatsumi, 2019; Pitta et al, 2019).*

▲ Dilute liquid medications before administration through the enteral tube and flush the enteral feeding tube with sufficient water before and after medication administration. *Because many liquid medications contain sorbitol or are hyperosmotic, diluting the medication may help decrease occurrence of diarrhea (Pitta et al, 2019).*

- Teach clients with cancer the types of diarrhea they may encounter, emphasizing not only chemotherapy- and radiation-induced diarrhea but also *C. difficile,* along with associated signs and symptoms and treatments. EB: *Diarrhea in cancer clients is a common complication that causes dehydration, electrolyte imbalances, nutritional deficits, and hospitalization for treatment. Providing the client education focusing on early*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

recognition of diarrhea necessitating early interventions is important in preventing adverse client outcomes (Escalante et al, 2017; Schiller, Pardi, & Sellin, 2017).

▲ For chemotherapy-induced diarrhea (CID) and radiation-induced diarrhea (RID), review rationale for pharmacological interventions, along with soluble fiber and probiotic supplements. Consult a registered dietitian to assist with recommendations to alleviate diarrhea, decrease dehydration, and maintain nutritional status. EBN: *Both CID and RID can occur as often as or more than 50% of the time, depending on the chemotherapy regimen or combination with radiation (Escalante et al, 2017; Schiller, Pardi, & Sellin, 2017).*

▲ Acute traveler's diarrhea is the most common illness affecting individuals traveling to, usually, low-income regions of the world. EB: *Improved hygiene, avoidance of foods for which preparation methods are unknown (e.g., street food) as well as raw fruits or vegetables, water, drinks with ice, and use of bismuth salicylates can mitigate the severity of gastric distress. Clients should be counseled about precautions they can take while traveling to reduce the severity of the diarrhea, and a self-treatment antibiotic series may be prescribed by the health care provider for at-risk clients (Porter et al, 2017; Shane et al, 2017).*

Pediatric

▲ Assess for mild or moderate signs of dehydration with both acute and persistent diarrhea: mild (increased thirst and dry mouth or tongue) and moderate (decreased urination; no wet diapers for 3+ hours; feeling of weakness/lightheadedness, irritability, or listlessness; few or no tears when crying) (Gupta, 2016). Refer to primary care provider for treatment.

▲ Recommend that parents give the child oral rehydration fluids to drink in the amounts specified by the health care provider, especially during the first 4 to 6 hours to replace lost fluid; avoid sodas, fruit juices, and clear liquids such as water and chicken broth. Once the child is rehydrated, an orally administered maintenance solution should be used along with food. Continue even if child vomits. EB: *Treatment with oral rehydration fluids for children is generally as effective as intravenous fluids (Shane et al, 2017; Ofei & Fuchs, 2019). Oral rehydration therapy (ORT) is an iso-osmolar, glucose-electrolyte solution that has been recognized for more than 40 years to be effective in treating children with dehydration caused by acute infectious diarrhea. Vomiting is not a contraindication to ORT but antinausea and antiemetic agents may be given to children older than 4 years to facilitate tolerance of oral rehydration. Adequate ORT is absorbed by most clients during vomiting (Shane et al, 2017; Rehydration Project, 2019).*

● Recommend that the mother resume breastfeeding as soon as possible.

● Recommend that parents avoid giving the child flat soda, fruit juices, sports drinks, gelatin dessert, broth, or instant fruit drink. EB: *These fluids have a high osmolality from carbohydrate contents and can exacerbate diarrhea. In addition, they have low sodium concentrations that can aggravate existing hyponatremia (Ofei & Fuchs, 2019; Rehydration Project, 2019).*

● Recommend that parents give children foods with complex carbohydrates, such as potatoes, rice, bread, cereal, yogurt, fruits, and vegetables. Avoid fatty foods, foods high in simple sugars, and milk products.

● Advise parents to return for assistance if fever, bloody diarrhea, or signs of severe dehydration such as decreased urine output, lightheadedness, or lethargy occur.

● Recommend CDC principles of safe food preparation, which include clean, separate, cook, chill, and report, particularly for children under the age of 5 years (US Department of Health and Human Services, 2019).

▲ Recommend rotavirus vaccine within the child's vaccination schedule. EB: *Two vaccines, Rotarix and RotaTeq, have undergone comprehensive studies with findings that they can significantly prevent severe rotavirus diarrhea and death caused by dehydration in children (Mwenda et al, 2017; Shane et al, 2017).*

Geriatric

▲ Evaluate medications the client is taking. Recognize that many medications can result in diarrhea, including digitalis, propranolol, angiotensin-converting enzyme inhibitors, histamine-receptor antagonists, nonsteroidal antiinflammatory drugs, anticholinergic agents, oral hypoglycemia agents, antibiotics, and so forth. EB: *Numerous medications can cause diarrhea. Evaluate changes in the client's medications as a possible cause of the diarrhea (DuPont, 2016; Schiller, Pardi, & Sellin, 2017).*

▲ Monitor the client closely to detect whether an impaction is causing diarrhea; remove impaction as ordered. Clients with fecal impaction commonly experience leakage of mucus or liquid stool from the rectum, rectal irritation, distention, and impaired anal sensation (Schiller, Pardi, & Sellin, 2017; Pitta et al, 2019).

▲ Seek medical attention if diarrhea is severe or persists for more than 24 hours, or if the client has a history of dehydration or electrolyte disturbances, such as lassitude, weakness, or prostration. EB: *Older adult*

clients can dehydrate rapidly; especially serious is the development of hypokalemia with dysrhythmias. C. difficile *is a common cause of diarrhea in older clients when they have been subjected to long-term antibiotic therapy (Gale & Wilson, 2016; Shane et al, 2017).*

- Provide emotional support for clients who are having trouble controlling unpredictable episodes of diarrhea. *Diarrhea can be a great source of embarrassment to older clients and can lead to social isolation and a feeling of powerlessness.*

Home Care

- Previously mentioned interventions may be adapted for home care use to keep the client well hydrated.
- Assess the home for general sanitation and methods of food preparation. Reinforce principles of sanitation for food handling. *Poor sanitation or mishandling of food may cause bacterial infection or transmission of dangerous organisms from utensils to food.*
- Assess for methods of handling soiled laundry if the client is bed bound or has been incontinent. Instruct or reinforce universal precautions with family and bloodborne pathogen precautions with agency caregivers. *The Bloodborne Pathogen Regulations of the Occupational Safety and Health Administration (OSHA) identify legal guidelines for caregivers.*
- When assessing medication history, include OTC drugs, both general and those currently being used to treat the diarrhea. Instruct clients not to mix OTC medications when self-treating. *Mixing OTC medications can further irritate the gastrointestinal system, intensifying the diarrhea or causing nausea and vomiting.*
- Evaluate current medications for indications that specific interventions are warranted. Blood levels of medications may increase during prolonged episodes of diarrhea, indicating the need for close monitoring of the client or direct intervention.
- Teach client importance of food safety practices and hand hygiene after using the toilet, changing a diaper, handling garbage or soiled laundry, and touching animals or their feces or their environment (Shane et al, 2017).
- Teach the client experiencing diarrhea to avoid swimming, water-related activities, and sex with other people while symptomatic (Shane et al, 2017).

▲ Evaluate the need for a home health aide or homemaker service referral. Caregiver may need support for maintaining client cleanliness to prevent skin breakdown.

- Evaluate the need for durable medical equipment in the home. The client may need a bedside commode, call bell, or raised toilet seat to facilitate prompt toileting.

Client/Family Teaching and Discharge Planning

- Encourage avoidance of coffee, spices, milk products, and foods that irritate or stimulate the gastrointestinal tract.
- Teach the appropriate method of taking ordered antidiarrheal medications; explain side effects.
- Explain how to prevent the spread of infectious diarrhea (e.g., careful handwashing, appropriate handling and storage of food, and thoroughly cleaning the bathroom and kitchen). EB: *Good hand hygiene has repeatedly been found to be the first step in preventing the spread of infectious diarrhea (CDC, 2018).*
- Help the client to determine stressors and set up an appropriate stress reduction plan, if stress is the cause of diarrhea.
- Teach signs and symptoms of dehydration and electrolyte imbalance.
- Teach perirectal skin care.

▲ Consider teaching clients about complementary therapies, such as probiotics, after consultation with primary care provider.

Risk for Disuse Syndrome

Domain 4 Activity/rest Class 2 Activity/exercise

Darcy O'Banion, RN, MS, ACCNS-AG

NANDA-I

Definition

Susceptible to deterioration of body systems as the result of prescribed or unavoidable musculoskeletal inactivity, which may compromise health.

Risk Factors

Pain

Associated Conditions

Decreased level of consciousness; immobilization; paralysis; prescribed movement restrictions

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Pain Level; Endurance; Immobility Consequences: Physiological; Mobility; Neurological Status: Consciousness; Progressive Mobility

Example NOC Outcome with Indicators

Immobility Consequences: Physiological as evidenced by the following indicators: Pressure injury/Constipation/Compromised nutrition status/Urinary calculi/Compromised muscle strength. (Rate the outcome and indicators of **Immobility Consequences: Physiological:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

D

Client Outcomes

Client Will (Specify Time Frame)

- Express pain level that is tolerable to allow for desired mobility
- Maintain full range of motion in joints
- Maintain intact skin, good peripheral blood flow, and normal pulmonary function
- Maintain normal bowel and bladder function
- Express feelings about imposed immobility
- Explain methods to prevent complications of immobility

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Energy Management; Exercise Therapy: Joint Mobility; Muscle Control; Positioning; Pain Management

Example NIC Activities—Energy Management

Determine the client's significant other's perception of causes of fatigue; Use valid instruments to measure fatigue, as indicated

Nursing Interventions and *Rationales*

- Screen for mobility skills in the following order: (1) bed mobility; (2) supported and unsupported sitting; (3) transitional movements such as sit to stand, stand to sit, and transfers to chair from bed, from chair to bed, and so forth; and (4) standing and walking activities. Use a mobility assessment tool such as the Banner Mobility Assessment Tool (Boynton et al, 2014) or the ICU Mobility Scale (Hodgson et al, 2014). EB: *A systematic review showed that early mobilization led to a greater probability of walking without assistance at time of discharge and more days alive and out of hospital (Tipping et al, 2017).* EB: *Early mobilization is associated with decrease in intensive care unit (ICU) length of stay and hospital length of stay (Laurent et al, 2016).*
- Assess the level of assistance needed by the client and express in terms of amount of effort expended by the person assisting the client. The range is as follows: total assist, meaning client performs 0% to 25% of task and, if client requires the help of more than one caregiver, it is referred to as a dependent transfer; maximum assist, meaning client gives 25% of effort while the caregiver performs the majority of the work; moderate assist, meaning client gives 50% of effort; minimal assist, meaning client gives 75% of effort; contact guard assist, meaning no physical assist is given but caregiver is physically touching client for steadying, guiding, or in case of loss of balance; standby assist, meaning caregiver's hands are up and ready in case needed; supervision, meaning supervision of task is needed even if at a distance; modified independent, meaning client needs assistive device or extra time to accomplish task; and independent, meaning client is able to complete task safely without instruction or assistance. EB: *Functional status is often based on rating from the Functional Independence Measure. It is an 18-item instrument that measures care burden associated with physical and cognitive functioning on a scale from 1 (total assistance) to 7 (complete independence) based on assessments of memory, comprehension, self-care, transfers, and locomotion (Pretz et al, 2016).*
- ▲ Request a referral to a physical therapist (PT) as needed so that client's range of motion, muscle strength, balance, coordination, endurance, and early mobilization can be part of the initial evaluation. The PT may provide the client with bed exercises, including stretching, flexing/extending muscle groups, or using bands to maintain muscle strength and tone. Collaboration with nursing staff, therapy, and respiratory therapy as needed to mobilize clients as early and as safely possible. EB: *Muscle atrophy from disuse is associated with disability, functional decline, metabolic derangements, and early mortality (Atherton et al, 2016).*
- Passive range of motion can be done as the client tolerates. EBN: *Although there is evidence to support early mobility in reducing complications, recent literature shows that passive range of motion and stretching does not improve joint mobility (Harvey et al, 2017).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Use specialized boots to prevent pressure injury on the heels and foot drop; remove boots twice daily to assess the skin and to provide foot care as needed. Elevate heels off the bed as the client tolerates when boots are not in place. EB: *Boots help keep the foot in normal anatomical alignment to prevent foot drop and off-loading prevents pressure injury formation on the heel. Although no single support surface has been shown to be more effective than another, off-loading the heel will prevent heel pressure injuries (EPUAP/NPUAP, 2019; McNichol et al, 2020; Rivolo et al, 2020).*
- When positioning a client on the side, tilt client 30 degrees or less while lying on the side. EB: *There is insufficient evidence to support which particular positions or repositioning frequencies are most effective in reducing pressure injuries (Gillespie et al, 2020).*
- Assess skin condition every shift and more frequently if needed. Use a risk assessment tool such as the Braden Scale or Waterlow scale to predict the risk of developing pressure ulcers (now referred to as pressure injury). EBN: *There is insufficient evidence to support the effect of risk assessment on pressure ulcer incidence (such as the Braden Scale or Waterlow tool) when compared with training and risk assessment using clinical judgment (Moore & Patton, 2019). Refer to care plan for Risk for Impaired* ***Skin*** *Integrity.*
- Discuss with staff and management a "safe patient handling" policy that may include a "no lift" policy to prevent staff injury. EB: *Safe patient handling and mobilization programs are effective in reducing injuries; however, evidence is insufficient to identify the most effective interventions for the various levels of client care (Teeple et al, 2017).*
- Turn clients at high risk for pressure/shear/friction frequently and apply pressure-relieving devices when able. EB: *Although there are varying results around the most appropriate turning frequency and positions, the combination of frequent repositioning with the use of pressure-relieving devices is most effective in reducing pressure ulcers/injury in hospitalized clients (Chew et al, 2018; Gillespie et al, 2020).*
- Provide the client with appropriate pressure-relieving devices. For further interventions on skin care, refer to the care plan for Impaired **Skin** Integrity.
- Help the client out of bed as soon as able. EB: *Prolonged immobilization leads to harmful consequences in musculoskeletal, cardiovascular, respiratory, and integumentary systems, as well as cognition (Parry & Puthucheary, 2015; Atherton et al, 2016). However, there is insufficient evidence on the effect of early mobilization on functional outcome, adverse events, muscle strength, and quality of life (Doiron et al, 2018).*
- When getting the client up after bed rest, do so slowly and watch for signs and symptoms of postural (orthostatic) hypotension, including dizziness, tachycardia, nausea, diaphoresis, or syncope. EB: *To assess orthostatic vital signs, take the first blood pressure and heart rate measurements once the client has been lying supine for 5 minutes. Then have the client stand and check blood pressure and heart rate 1 and 3 minutes after standing. A decrease in systolic blood pressure by 20 mm Hg, a decrease in diastolic pressure of 10 mm Hg or more, or an increase in heart rate by 20 beats per minute or more is indicative of intravascular volume loss (Whelton et al, 2017). Compression wraps to abdomen and/or lower limbs can facilitate venous return if hypotension is an issue (Logan et al, 2017).*
- Obtain assistive devices such as braces, crutches, or canes to help the client reach and maintain as much mobility as possible. *Assistive devices can help increase mobility (Boynton et al, 2014).*

▲ Apply graduated compression stockings as ordered, if indicated for orthostatic hypotension. Ensure proper fit by measuring accurately. Remove the stockings at least twice a day, in the morning with the bath and in the evening to assess the condition of the extremity and skin, then reapply. Knee length is preferred rather than thigh length. EB: *The American College of Chest Physicians (Stevens et al, 2021) does not recommend graduated compression stockings to prevent deep vein thrombosis (DVT). Intermittent pneumatic compression devices alone are insufficient in preventing venous thromboembolism (VTE) compared with chemoprophylaxis or a combination of the two in high-risk surgical clients or medical inpatients who are not high bleeding risk (O'Connell et al, 2016; Schünemann et al, 2018). Refer to the CHEST guidelines for use of mechanical prophylaxis for specific client situations (Stevens et al, 2021).*

- Observe for signs of DVT, including pain, tenderness, redness, and swelling in the calf and thigh. Also observe for signs and symptoms of pulmonary embolism, including sudden onset of dyspnea, chest pain, syncope, dizziness, tachycardia, or tachypnea. EB: *Because of poor specificity of signs and symptoms of VTE, the diagnosis based on clinical manifestation alone is unreliable (Di Nisio, van Es, & Büller, 2016).*
- Have the client cough and deep breathe or use incentive spirometry every 2 hours while awake. EB: *Bed rest compromises breathing and can lead to atelectasis and pneumonia because of decreased chest expansion, decreased cilia activity, pooling of mucus, and the effects of organ shift (such as the diaphragm and heart and pressure on the esophagus when in the supine position) and leads to partial or complete atelectasis usually of the left lower lobe (Parry & Puthucheary, 2015).*

- Monitor respiratory functions, noting breath sounds, work of breathing, and respiratory rate. Percuss for new onset of dullness in lungs.
- Note bowel function daily. Provide fluids, fiber, and natural laxatives such as prune juice as needed. *Constipation is common in immobilized clients because of decreased activity and reduced fluid and food intake. Refer to care plan for* ***Constipation.***
- Increase fluid intake to 2000 mL/day within the client's cardiac and renal reserve. *Adequate fluids help prevent kidney stones and constipation, both of which are associated with bed rest.*
- Encourage intake of a balanced diet with adequate amounts of fiber and protein. Consider recommending Practical Interventions to Achieve Therapeutic Lifestyle Changes (TLC), which includes monounsaturated and polyunsaturated fats, oils, margarines, beans, peas, lentils, soy, skinless poultry, lean fish, trimmed cuts of meat, fat-free and low-fat dairy foods, omega-3 polyunsaturated fat sources, and whole grains, including soluble fiber sources such as oats, oat bran, and barley (Osborne et al, 2013).

Critical Care

▲ Recognize that the client who has been in an intensive care environment may develop a neuromuscular dysfunction acquired in the absence of causative factors other than the underlying critical illness and its treatment, resulting in ICU-acquired weakness, with an approximate incidence of 40% requiring more than 1 week of mechanical ventilation (Appleton, Kinsella, & Quasim, 2015). The client may need a workup to determine the cause before satisfactory ambulation can begin. EB: *Critical care clients can develop neuromuscular weakness, polyneuropathy, and delirium (Appleton, Kinsella, & Quasim, 2015; Wintermann et al, 2015).*

▲ Consider the use of a continuous lateral rotation therapy bed. EB: *A systematic review demonstrated limited evidence of the effects of routine lateral repositioning for critically ill clients, although mostly because of poor-quality studies (Hewitt, Bucknall, & Faraone, 2016).*

▲ For the stable client in the ICU, consider mobilizing the client in a four-phase method from dangling at the side of the bed to walking if there is sufficient knowledgeable staff available to protect the client from harm. Even ICU clients receiving mechanical ventilation can be mobilized safely if a multiprofessional team is present to support, protect, and monitor the client for intolerance to activity (Green et al, 2016; Agency for Healthcare Research and Quality, 2017). EBN: *Critical care clients are at high risk for complications related to immobility such as ventilator-associated pneumonia (VAP), atelectasis, and long-lasting functional limitations. Early mobility may reduce length of stay and improve functional outcomes but there is low quality of evidence in the current studies and many barriers to early mobility (Doiron, Hoffmann & Beller, 2018; Hodgson, Capell & Tipping, 2018).*

Geriatric

- Get the client out of bed as early as possible and ambulate frequently after consultation with the health care provider. EB: *Immobility is a risk factor for VTE; immobilization is a major risk factor for VTE, especially in people over 70 years old (Stevens et al, 2021; Talec, Gaujoux, & Samama, 2016). Functional decline from hospital-associated deconditioning is common in older adults, particularly because they are already more deconditioned with less muscle mass, and early rehabilitation can be effective in preventing this condition in addition to other comorbidities (Heldmann et al, 2019; Wald et al, 2019).*
- Consider physical and occupational therapy referrals to guide with environmental safety assessment and home exercise programs.
- Monitor nutrition status in the elderly to prevent malnutrition. EB: *Malnutrition is common in the elderly and can interfere with functional recovery (Agarwalla, Saikia, & Baruah, 2015; Engelheart & Brummer, 2018).*
- Monitor for signs of depression: flat affect, poor appetite, insomnia, and many somatic complaints. EB: *Depression can commonly accompany decreased mobility and function in older adults, and mobilization has a positive effect on depressive mood and enhances quality of life (López-Torres Hidalgo & DEP-EXERCISE Group, 2019).*
- Keep careful track of bowel function in older adults; do not allow the client to become constipated. EB: *Older adults can easily develop impactions as a result of immobility. Refer to* ***Constipation*** *care plan.*

Home Care

- Some of the previous interventions may be adapted for home care use.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ Begin discharge planning at time of admission with case manager or social worker and input from physical and occupational therapy as appropriate to assess need for home support systems and community or home health services.
▲ Become oriented to all programs of care for the client before discharge from institutional care.
▲ Confirm the immediate availability of all necessary assistive devices for home.
● Perform complete physical assessment and recent history at initial home visit.
▲ Refer to physical and occupational therapies for immediate evaluations of the client's potential for independence and functioning in the home setting and for follow-up care.
● Allow the client to have as much input and control of the plan of care as possible. *Client perception of control increases self-esteem and motivation to follow medical plan of care.*
● Assess knowledge of all care with caregivers. Review as necessary. *Having the necessary knowledge and skills to perform care decreases caregiver role strain and supports safety of the client.*
▲ Support the family of the client in the assumption of caregiver activities. Refer for home health aide services for assistance and respite as appropriate. Refer to medical social services as appropriate.
▲ Institute case management of frail elderly to support continued independent living, if possible in the home environment.

Client/Family Teaching and Discharge Planning

● Teach client/family how to perform range-of-motion exercises in bed if not contraindicated; this is referred to as a home exercise program.
● Teach the family how to turn and position the client and provide all care necessary.

Note: Nursing diagnoses that are commonly relevant when the client is on bed rest include **Constipation,** Risk for Impaired **Skin** Integrity, Disturbed **Sleep** Pattern**, Frail Elderly** Syndrome**,** and **Powerlessness.**

Decreased Diversional Activity Engagement

Domain 1 Health promotion Class 1 Health awareness

Nadia Ali Muhammad Ali Charania, PhD, RN

NANDA-I

Definition

Reduced stimulation, interest, or participation in recreational or leisure activities.

Defining Characteristics

Alteration in mood; boredom; expresses discontentment with situation; flat affect; frequent naps; physical deconditioning

Related Factors

Current setting does not allow engagement in activities; environmental constraints; impaired physical mobility; inadequate available activities; inadequate motivation; insufficient physical endurance; physical discomfort; psychological distress

At-Risk Population

Individuals at extremes of age; individuals experiencing prolonged hospitalization; individuals experiencing prolonged institutionalization

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Associated Conditions

Prescribed movement restrictions; therapeutic isolation

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Leisure Participation; Play Participation; Social Involvement

Example NOC Outcome with Indicators

Leisure Participation as evidenced by the following indicators: Expresses satisfaction with leisure activities/Feels relaxed from leisure activities/Enjoys leisure activities. (Rate the outcome and indicators of **Leisure Participation:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Engage in personally satisfying diversional activities

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Recreation Therapy; Self-Responsibility Facilitation

Example NIC Activities—Recreation Therapy

Assist the client to identify meaningful recreational activities; Provide safe recreational equipment

Nursing Interventions and *Rationales*

- Assess the client's needs through mapping to assess existing networks, current activities, and the impact on well-being. EB: *Mapping allows nurse and client to examine the quality of existing relationships and activities to identify where intervention is needed (Mann et al, 2017).*
- ▲ Encourage the client to share feelings of boredom. EB: *A better understanding of boredom will allow the development and implementation of interventions to address the client's needs (Kenah et al, 2018).*
- Encourage the client to participate in any available social or recreational opportunities in the health care environment. EB: *Client interviews revealed that participation in occupational therapy activity-based groups was associated with the themes of therapeutic relationship, connection with others, and the opportunity to engage (Ngooi et al, 2021).*
- Promote relaxation through guided imagery, visual imagery, and music interventions. EB: *Qualitative interviews on the effects of hospitalized bed rest on well-being found that relaxation interventions improved physical well-being and sleep (Yeager, 2019).*
- Use art making and music listening. EBN: *A randomized trial did not show a significant difference among the control, art making, and diversional music groups in reducing symptoms related to blood and marrow transplantation. It was asserted that art making and music listening are safe and desirable diversional activities for clients undergoing blood and marrow transplant in an outpatient clinic (Lawson et al, 2016).*
- Be creative, for example, use of the activity pillowcases with soft fabric pieces, plastic zipper, and a pouch to hold a picture as a diversional intervention that could be used in inpatient and hospice care settings. EBN: *Considered to be a helpful aid for adult clients who have intellectual and developmental disabilities and need a distraction and sensory input or modulation (Bahle et al, 2016).*
- Engage clients in physical activity or exercise programs as an adjunct treatment modality for a variety of mental illnesses; for example, depression, schizophrenia, anxiety, disorders, posttraumatic stress disorders, and substance abuse. EB: *The narrative synthesis of systematic reviews and clinical trials endorsed the integration of physical activity programs as part of the mental health treatment plan (Rosenbaum et al, 2016).*
- Engage clients in leisure activities such as art and coloring; puzzles, games, and reading; meditation, deep breathing, and relaxation techniques; and music as ways to reduce screen time during hospitalization.

EBN: *Decreasing screen time and engaging in leisure activities could contribute to short-term benefits during hospitalization and long-term health benefits after hospitalization if they continue to be used (Nelson, 2018).*

- Engage antepartum women and families in diversional fun promoting activities including scrapbooking, game night, book clubs, movie night, and prayer services during hospitalization. EB: *Integration of diversional activities programs to promote socialization and family support can contribute to improving clients' satisfaction and promote nurses' engagement and empowerment (Lankford, 2017).*

▲ Hospitalized clients, particularly quarantined clients, are at risk for isolation and boredom and must be engaged in meaningful activities including technology-based (iPad with games or reactional-based applications) and non–technology-based (e.g., books, magazines, crafts, puzzles, games, adult coloring books, mind-stimulating activity books) activities. EB: *Availability of resources to engage clients in meaningful activities contributes to a decrease in clients' complaints of isolation and boredom (Knowles et al, 2020).*

▲ Refer to recreational, occupational, or art therapist to assist with activities. EB: *An evaluation of an art therapy program found overwhelming support for art therapy as one element within multiprofessional services available to clients in the acute psychiatry setting. The qualitative feedback associated art therapy with improvements in quality of life, individual support, and a nonverbal intervention for those who find talking therapy difficult (Brady, Moss, & Kelly, 2017).*

Pediatric

- Assess for the child's interests, preferences, and hobbies. EBN: *A phenomenological study of nurses who care for children with cancer found that understanding the client helps the nurse identify ways to meet the child's needs (Nukpezah et al, 2020).*
- Engage preschool children in play therapy. EBN: *The result of a prospective randomized controlled study supported the role of play therapy among preschoolers in promoting their social, emotional, and behavioral skills. Moreover, play therapy might be beneficial in reducing fear and anxiety and promoting communication, coping skills, and self-esteem (Sezici, Ocakci, & Kadioglu, 2017).*
- Engage school-age children in origami during hospitalization. EB: *Origami as a play therapy was reported to be effective in reducing the level of hospitalization-associated anxiety among school-age children (Mathew & Daly, 2018) and assist them in better adapting to unpleasant situations during hospitalization (Varghese et al, 2018).*

▲ Refer to a music therapist. EBN: *A review of evidence found a beneficial effect of music medicine, music therapy, and other music-based interventions (Stegemann et al, 2019).*

- Provide technology access for children to connect with family and friends, play computer games, and engage in virtual reality experiences for children. EBN: *A qualitative study of computer use in hospitalized children found benefits that included distraction from unpleasant treatments, social support, and normalization of experience (Nicholas & Chahauver, 2017).*
- Provide animal-assisted therapy for hospitalized children. EB: *A study of an animal-assisted therapy program on physiological and psychosocial variables of pediatric oncology clients found a decrease in pain, irritation, and stress and an improvement in depression scores (Silva & Osório, 2018).*

▲ Refer to a child life specialist, play therapist, recreational therapist, or occupational therapist. EBN: *Child life therapists provide opportunities for self-expression and play for hospitalized children and may help to normalize the environment. Qualitative study of pediatric nurses found that nurses often do not have enough time to develop any playful activity and stressed the importance of having an adequate number of professionals to address the needs of the child (Ribeiro et al, 2020).*

Geriatric

- Many of the previously listed interventions may be used with geriatric clients.
- If the client is able, arrange for participation in group community activities. EB: *Research found that geriatric participation in group activities was important in offering social support as a platform to develop friendships, as well as create a sense of belonging and connectedness (Dare et al, 2018).*
- Promote activity for older adults through the use of emerging information and communication technologies. EB: *Emerging information and communication technologies can be combined with high-intensity interval exercise regimens to make rehabilitation for impaired older adults more effective and enjoyable (McCaskey et al, 2018).*
- Engage nursing home residents with dementia in music therapy. EB: *Evidence suggests that music therapy significantly contributes to decreasing depressive symptoms among nursing home residents with dementia and particularly improves the well-being of residents with moderate to severe dementia (Ray & Götell, 2018).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Engage hospitalized clients with dementia/delirium in a person-centered activity program including (1) the use of "Pleasant Events Schedule," (2) implementation of "Identity Cards," and (3) engaging in "Occupational Workstations and Programs." EB: *A person-centered activity program has been reported to reduce the behavioral and psychological symptoms of dementia. Moreover, the use of "Identify Cards" promoted client/family connections in the subacute inpatient unit setting (Goonan et al, 2019).*

Home Care

- Many of the previously listed interventions may be administered in the home setting.

Client/Family Teaching and Discharge Planning

- Offer group-based educational workshops such as the "Creative Ways to Care" for family and friends to learn strategies to engage their family or friends with dementia in diversional activities. "Creative Ways to Care" is a series of a total of seven workshops: (1) Introduction Session, (2)Dementia Behavior and Activities, (3) Reminiscence, (4) Stimulating and Soothing the Senses, (5) Music, (6) Creative Activities, and (7) Review Session. EB: *The program "Creative Ways to Care" contributes to carers' confidence in responding to changed behavior, decreases the occurrence of changed behaviors, improves the relationship between carers and the person with dementia, and improves carers' quality of life (Allen, 2017).*
- If the client is in isolation, give the client complete information on why isolation is needed and how it should be accomplished, especially guidelines for visitors; provide diversional activities and encourage visitation. EBN: *Most reviewed studies reported negative psychological effects of isolation, including posttraumatic stress symptoms, confusion, and anger. Stressors included longer quarantine duration, infection fears, frustration, boredom, inadequate supplies, inadequate information, financial loss, and stigma (Brooks et al, 2020).*

Ineffective Adolescent Eating Dynamics

Domain 2 Nutrition Class 1 Ingestion

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Altered eating attitudes and behaviors resulting in over or under eating patterns that compromise nutritional health.

Defining Characteristics

Avoids participation in regular mealtimes; complains of hunger between meals; depressive symptoms; food refusal; frequent snacking; frequently consumes fast food; frequently eating processed food; frequently eats low quality food; inadequate appetite; overeating; undereating

Related Factors

Altered family relations; anxiety; changes to self-esteem upon entering puberty; eating disorder; eating in isolation; excessive family mealtime control; excessive stress; inadequate dietary habits; irregular mealtime; media influence on eating behaviors of high caloric unhealthy foods; media influence on knowledge of high caloric unhealthy foods; negative parental influences on eating behaviors; psychological neglect; stressful mealtimes; unaddressed abuse

Associated Conditions

Depression; parental psychiatric disorder; physical challenge with eating; physical challenge with feeding; physical health issue of parent; psychological health issue of parent

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Nutritional Status; Nutritional Status: Food and Fluid Intake; Nutrient Intake; Weight Control; Knowledge: Healthy Diet; Knowledge: Weight Management; Eating Disorder Self-Control; Body Image

Example NOC Outcome with Indicators

Knowledge: Healthy Diet as evidenced by the following indicators: Caloric intake appropriate for metabolic needs/Nutrient intake appropriate for individual needs/Guidelines for food portions/Importance of eating breakfast/Strategies to avoid foods with high caloric value. (Rate the outcome and indicators of **Nutritional Status:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

● = Independent; ▲ = Collaborative; EBN = Evidence-Based Nursing; EB = Evidence-Based; ✱ = QSEN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Client Outcomes

Client Will (Specify Time Frame)

- Maintain weight within normal range for height and age
- Eat breakfast daily
- Participate in meal planning and preparation
- Consume healthy and nutritious foods

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Nutrition Counseling; Nutrition Monitoring; Family Involvement Promotion; Parenting Promotion

Example NIC Activities—Nutritional Counseling

Establish a therapeutic relationship based on trust and respect; Facilitate identification of eating behaviors to be changed; Discuss the meaning of food to client

Nursing Interventions and *Rationales*

- Assess for goals and motives related to eating behaviors. EB: *A study found that appearance-focused goals and controlled eating regulation were positively related to disordered eating symptoms (Verstuyf et al, 2016)*
- ▲ Assess the adolescent client for comorbid psychological disorders and make appropriate referrals for treatment. EB: *A long-term evolution study's findings suggested a reciprocal relationship between depressive symptoms and unhealthy eating behaviors (Wu et al, 2016). A cross-sectional study found that binge eating was associated with trait anxiety in Korean adolescent girls (Jung et al, 2017).*
- Assess the adolescent for experiences of cyberbullying and the strength of friendship dynamics. EB: *A study found that adolescents who were cyberbullied were almost twice as likely to consider themselves too fat. Stronger friendship dynamics were associated with decreased levels of body dissatisfaction, with friendship dynamics partially mediating the relationship between cyberbullying and body dissatisfaction (Kenny et al, 2018).*
- Offer obese or overweight adolescents healthy methods for weight loss. EB: *A study showed statistically significant health behavior improvements after implementing a developmentally informed intervention to increase positive health diet and exercise behaviors (Issner et al, 2017).*
- Offer families of obese or overweight adolescents bias-free, individually accepting, and supportive interventions to address weight loss. EBN: *Optimal weight loss practices that encourage healthy eating and exercise must be mindful of the possible negative implications of inducing overweight or obesity perceptions (Lucibello et al, 2020).*
- Recommend that families eat together for at least one meal per day. EB: *Research findings show a significant relationship between frequent family meals and better nutritional health in younger and older children (Dallacker, Hertwig, & Mata, 2018).*
- Recommend involving the adolescents in planning family meals and food preparation. EB: *Results suggested that involving adolescents in food preparation for the family is related to better adolescent dietary quality and eating patterns (Berge et al, 2016).*
- Assist parents at being good role models of healthy eating. EB: *The Healthy Home Offerings via the Mealtime Environment Plus program showed significantly improved parental self-efficacy for identifying appropriate portion sizes (Fulkerson et al, 2014).*
- Recommend that the family try new foods, such as either a new food or recipe every week. EB: *The Healthy Home Offerings via the Mealtime Environment Plus program showed decreasing child neophobia scores over time that were developmentally appropriate (Fulkerson et al, 2014).*
- Frame healthy eating as consistent with the adolescent values of autonomy from adult control and the pursuit of social justice. EB: *A study with eighth-graders framed healthy eating as a way to take a stand against manipulative practices of the food industry, such as engineering addictive junk food and marketing to young children. These youth would forgo unhealthy foods for healthier options after associating healthy eating with autonomy-assertive and social justice–oriented behavior (Bryan et al, 2016).*

- Explore the adolescent's friendship dynamics. EB: *Findings from a recent study indicated that adolescent friendships play an integral role in the development of unhealthy weight control and are a useful method to identify adolescents at risk (Simone, Long, & Lockhart, 2018).*

Multicultural

- Assess racial-ethnic minority overweight adolescents for disordered eating behaviors. EB: *A study found that across diverse cultural groups, overweight adolescents are at risk for disordered eating (Rodgers et al, 2017).*
- Encourage racial-ethnic minority families to refrain from weight-based teasing. EB: *A study found that family weight-based teasing was common and was associated with negative well-being among youth from all ethnic groups studied (Eisenberg et al, 2019).*

Home Care

- The interventions previously described may be adapted for home care use.

Client/Family Teaching and Discharge Planning

▲ Refer the adolescent and family to family treatment-behavior (FT-B) for treatment of eating disorders. EB: *A review found that FT-B is the only well-established treatment for adolescent eating disorders (Lock, 2015).*

▲ Teach the family that hospitalization of the adolescent may be indicated for medical stabilization of serious physical complications and refer as needed. EB: *A study found that inpatient medical stabilization for adolescent eating disorders addresses acute medical complications and also appears to activate the client and family regarding the need for ongoing treatment (Bravender, Elkus, & Lange, 2017).*

Ineffective Child Eating Dynamics

Domain 2 Nutrition Class 1 Ingestion

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Altered attitudes, behaviors, and influences on child eating patterns resulting in compromised nutritional health.

Defining Characteristics

Avoids participation in regular mealtimes; complains of hunger between meals, food refusal, frequent snacking; frequently consumes fast food; frequently eating processed food; frequently eats low quality food; inadequate appetite; overeating; undereating

Related Factors

Eating Habit

Abnormal eating habit patterns; bribing child to eat; consumption of large volumes of food in a short period of time; eating in isolation; excessive parental control over child's eating experience; excessive parental control over family mealtime; forcing child to eat; inadequate dietary habits; lack of regular mealtimes; limiting child's eating; rewarding child to eat; stressful mealtimes; unpredictable eating patterns; unstructured eating of snacks between meals

Family Process

Abusive interpersonal relations; anxious parent-child relations; disengaged parenting; hostile parent-child relations; insecure parent-child relations; intrusive parenting; tense parent-child relations; uninvolved parenting

Parental

Anorexia; inability to divide eating responsibility between parent and child; inability to divide feeding responsibility between parent and child; inability to support healthy eating patterns; ineffective coping strategies; lack of confidence in child to develop healthy eating habits; lack of confidence in child to grow appropriately; substance misuse

Unmodified Environmental Factors

Media influence on eating behaviors of high caloric unhealthy foods; media influence on knowledge of high caloric unhealthy foods

At-Risk Population

Children born to economically disadvantaged families; children experiencing homelessness; children experiencing life transition; children living in foster care; children whose parents are obese

Associated Conditions

Depression; parental psychiatric disorder; physical challenge with eating; physical challenge with feeding; physical health issue of parent; psychological health issue of parent

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Appetite; Parenting Performance; Knowledge: Healthy Diet; Health Beliefs; Nutritional Status

Example NOC Outcome with Indicators

Appetite as evidenced by the following indicators: Desire to eat/Food intake/Nutrient intake/Fluid intake/Stimulus to eat. (Rate the outcome and indicators of **Appetite:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify hunger and satiety cues
- Consume healthy and nutritious foods
- Consume adequate calories to support growth and development
- Engage in positive interactions with caregiver during meals

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Nutrition management; Nutrition Counseling; Nutritional Monitoring

Example NIC Activities—Nutritional Counseling

Establish a therapeutic relationship based on trust and respect; Determine attitudes and beliefs of significant others about food, eating, and the client's needed nutritional change

Nursing Interventions and *Rationales*

▲ Use a nutritional screening tool designed for nurses, such as Subjective Global Nutrition Assessment (SGNA), and refer to a dietitian for scores of moderate or severe. EB: *A study found that SGNA can be a reliable tool for assessing nutritional status in children (Minocha et al, 2018).*

- Assess parents for food or eating concerns, aberrant feeding behavior, or inappropriate feeding practices. EB: *Caregiver concerns about food or child eating warrant additional assessment (Kerzner et al, 2015).*
- Assess child for type of eating difficulty. Children can present with limited appetite, food selectivity, and fear of feeding. EB: *Identifying the eating issue will enable appropriate intervention (Kerzner et al, 2015).*
- Assess the caregiver's feeding style by asking three questions: How anxious are you about your child's eating? How would you describe what happens during mealtime? What do you do when your child will not eat? EB: *Kerzner et al (2015) identify three feeding styles that have negative consequences: neglectful, controlling, and indulgent. Responses from neglectful parents will be vague, and controlling parents will describe pressuring/forcing their child to eat. Indulgent parents will describe pleading, begging, and preparing special foods.*
- Assess the child for persistent picky eating with three questions/answers: Is your child a picky eater? (yes). Does she or he have strong likes with regard to food? (yes). Does your child accept new foods readily? (no). EB: *A study found that 3 of 18 feeding behavior questions were significantly associated with persistent picky eaters (Toyama & Agras, 2016). Early identification of picky eating will allow early intervention.*
- Assess child for symptoms of malnutrition, including short stature, thin arms and legs, poor condition of skin and hair, visible vertebrae and rib cage, wasted buttocks, wasted facial appearance, lethargy, and, in extreme cases, edema.
- Assess weight and height of the child and use a growth chart to help determine growth pattern, which reflects nutrition. Age-related growth charts are available from www.cdc.gov/growthcharts/ (Centers for Disease Control and Prevention, 2016).
- Recommend that families turn off the television during meal times. EB: *A study found that the presence of television during meals was negatively associated with the dietary healthfulness and emotional atmosphere of the meal and the child's overall dietary quality. Television was also positively associated with serving fast food for family meals (Trofholz et al, 2017).*
- Recommend that families eat together for at least one meal per day. EB: *A family meals intervention led to improvements in children's weight status, food preparation skills, and TV viewing during meals (Gunther et al, 2019).*
- Encourage parent–child interactions that promote attachment. EB: *A study found that insecure attachment was significantly associated with higher body mass index (Maras et al, 2016).*
- Recommend that the child eats breakfast daily. EB: *A systemic review of children and adolescents found that breakfast eaters had higher energy intake, higher fiber intake, and higher consumption of fruits and vegetables and lower consumption of soft drinks than breakfast skippers (Giménez-Legare et al, 2020).*
- Recommend involving the family in planning meals and food preparation. Children can learn about nutrition as they help plan and make meals. EB: *The Healthy Home Offerings via the Mealtime Environment Plus program showed increased cooking skills among the children participating (Fulkerson et al, 2018).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Assist parents at being good role models of healthy eating. EB: *The Healthy Home Offerings via the Mealtime Environment Plus program showed significantly improved parental self-efficacy for identifying appropriate portion sizes (Fulkerson et al, 2018).*
- Recommend that the family try new foods, either a new food or recipe every week. EB: *The Healthy Home Offerings via the Mealtime Environment Plus program showed decreasing child neophobia scores over time that were developmentally appropriate (Fulkerson et al, 2018).*

▲ Refer children with highly selective food behaviors and sensory food aversion to a nutritional specialist. EB: *Refusal to eat entire categories of foods related to their taste, texture, smell, temperature, and/or appearance can interrupt normal development and have negative health consequences (Kerzner et al, 2015).*

▲ Refer children with feeding difficulties caused by a medical condition to the appropriate specialist. EB: *Organic conditions may contribute to feeding difficulties and express as food aversions, fear of feeding, and selective eating (Kerzner et al, 2015).*

E

Multicultural

- Assess for the meanings, attitudes, and behaviors related to feeding practices in culturally diverse families. EB: *A qualitative study of Hispanic mothers found that feeding attitudes were central to the maternal responsibility of having well-fed children, and feeding practices included the use of coercive/negative reinforcement strategies (Martinez et al, 2015).*
- Assess the feeding styles of Hispanic and African American mothers for congruence with current child feeding recommendations. EB: *A study showed that Hispanic and African American mothers seldom spoke to their children about food characteristics, rarely referred to feelings of hunger and fullness, encouraged more eating, and made more attempts to enforce table manners than to teach eating skills (Power et al, 2015).*

Home Care

- The interventions previously described may be adapted for home care use.

Client/Family Teaching and Discharge Planning

- Provide parents with the following guidelines: avoid distractions during mealtimes (e.g., television, cell phones), maintain a pleasant neutral attitude throughout meal, feed to encourage appetite, limit meal duration (20–30 minutes), limit to 4 to 6 meals/snacks a day with only water in between, serve age-appropriate foods, systematically introduce new foods (up to 8–15 times), encourage self-feeding, and tolerate age-appropriate mess. EB: *Guidelines will prevent and/or resolve feeding difficulties, whether mild or severe (Kerzner et al, 2015).*
- Teach families to provide a feeding environment that sets boundaries around food, through meal timing and the types of foods offered. EB: *Evidence suggests that children's eating self-regulation is best supported when caregivers provide a structured feeding environment (Wood et al, 2020).*
- Teach parents to recognize the difference between hunger and satiety in their children. EB: *Parents may misperceive the child's appetite despite normal growth and need encouragement to accept the child's interpretation of their hunger and satiety (Kerzner et al, 2015).*
- Teach parents of children with limited appetites to establish a feeding schedule with a maximum of five meals per day and nothing but water in between. Parents must be taught to model healthy eating, adhere to the established feeding schedule, and set limits/consequences for mealtime behavior. EB: *A feeding schedule will provide adequate nutrition and assist the child with recognizing and responding appropriately to hunger and satiety (Kerzner et al, 2015).*
- Teach parents of children with food selectivity to refrain from coercive and indulgent feeding practices. EB: *Coercive and indulgent feeding practices may create family discord and subsequent child behavioral problems (Kerzner et al, 2015).*
- Teach parents to use nondirective feeding strategies such as repeatedly offering foods, offering a familiar and accepted food (e.g., ketchup) alongside novel or refused foods, and having family and/or peers model eating the food with enjoyment. EB: *Nondirective feeding strategies have been demonstrated to increase the consumption of a given food and maintain responsivity in the feeding environment (Wood et al, 2020).*
- Teach parents to avoid restrictive feeding practices such as limiting intakes of certain foods. EB: *Restrictive feeding practices have been associated with eating when not hungry (Bauer et al, 2017).*
- Teach parents the concept of being a responsive feeder, in which the parent determines where, when, and what the child is fed and the child determines how much to eat. Responsive feeders guide the child's eating, set limits, model appropriate eating, talk positively about food, and respond appropriately to the

child's feeding cues. EB: *Research has reported that a responsive feeding style has resulted in children developing a lower risk of being overweight through consumption of more fruits, vegetables, and dairy products and less unhealthy foods (Kerzner et al, 2015).*

Risk for Electrolyte Imbalance

Domain 2 Nutrition Class 5 Hydration

Dina M. Hewett, PhD, RN, NEA-BC

NANDA-I

Definition

Susceptible to changes in serum electrolyte levels, which may compromise health.

Risk Factors

Diarrhea; excessive fluid volume; inadequate knowledge of modifiable factors; insufficient fluid volume; vomiting

Associated Conditions

Compromised regulatory mechanism; endocrine regulatory dysfunction; renal dysfunction; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Electrolyte and Acid-Base Balance; Fluid Balance; Hydration; Nutritional Status: Biochemical Measures; Nutritional Status: Food and Fluid Intake; Nutritional Status: Nutrient Intake; Kidney Function

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NOC Outcome with Indicators

Electrolyte and Acid-Base Balance as evidenced by the following indicators: Apical heart rate/Apical heart rhythm/Serum potassium/Serum sodium/Serum calcium, serum magnesium, serum phosphorus. (Rate the outcome and indicators of **Electrolyte and Acid-Base Balance:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain a normal sinus heart rhythm with a regular rate
- Have a decrease in edema
- Maintain an absence of muscle cramping
- Maintain normal serum potassium, sodium, calcium, magnesium and phosphorus
- Maintain normal serum pH

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Electrolyte Monitoring; Electrolyte Management: Hypokalemia, Hyperkalemia, Hypocalcemia, Hypercalcemia, Hyponatremia, Hypernatremia, Hypomagnesemia, Hypermagnesemia, Hypophosphatemia, and Hyperphosphatemia; Electrolyte Management: Hyponatremia; Fluid/Electrolyte Management; Laboratory Data Interpretation

Example NIC Activities—Electrolyte Monitoring

Identify possible causes of electrolyte imbalances; Monitor the serum level of electrolytes

Nursing Interventions and *Rationales*

▲ Monitor vital signs at least three times a day, or more frequently as needed. Notify health care provider of significant deviation from baseline. EB: *Electrolyte imbalance can lead to clinical manifestations such as respiratory failure, arrhythmias, edema, muscle weakness, and altered mental status (Shrimanker & Bhattarai, 2020)*

▲ Monitor cardiac rate and rhythm. Report changes to provider. Hypokalemia and hyperkalemia can result in electrocardiogram (ECG) changes that can lead to cardiac arrest and ventricular dysrhythmias. EB: *Hypophosphatemia can cause ventricular arrhythmias, derangements of cardiac and respiratory function, and death. It can also cause cardiomyopathy (Ariyoshi et al, 2016; Christopoulou et al, 2017). Magnesium and calcium imbalances also can cause cardiac arrhythmias. Low serum magnesium (≤2 mEq/L) is associated with hypokalemia and ECG changes, and high phosphate may indicate kidney injury (Shrimanker & Bhattarai, 2020). Low magnesium also may impair respiratory function. It has been associated with higher mortality, the need for mechanical ventilation, and increased length of stay (Upala et al, 2016). Low magnesium also is common in clients with heart failure (Shrimanker & Bhattarai, 2020).*

- Monitor intake and output and daily weights using a consistent scale. EB: *Weight gain is a sensitive and consistent sign of fluid volume excess (Shrimanker & Bhattarai, 2020).*
- Monitor for abdominal distention and discomfort. A focused assessment should be done on any client presenting with hepatic, gastrointestinal, or pancreatic dysfunction (Shrimanker & Bhattarai, 2020). EB: *Abdominal distention and intraabdominal swelling can lead to compression of the abdominal contents and acute kidney injury, especially in the postoperative period (Raghavendra Prasad et al, 2017).*
- Monitor the client's respiratory status and muscle strength. Phosphorus is an essential element in cell structure, metabolism, and maintenance of acid-base processes. EB: *Consequences of hypophosphatemia include cardiac failure, respiratory failure, and alterations in sensorium (Diringer, 2017).*
- Assess cardiac status and neurological alterations. EB: *Hypophosphatemia can cause myocardial dysfunction, hematological dysfunction, respiratory depression, and neurological changes (Diringer, 2017).*
- Imbalances of sodium, potassium, calcium, and magnesium all can cause neurological disturbances (Kear, 2017). EB: *Hyperphosphatemia is associated with hypocalcemia (because it is inversely related to calcium), causing tetany, muscle spasms, and cardiac arrhythmias, as well as vascular mineralization (Marcuccilini, Chonchol, & Jovanovich, 2017).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

▲ Review laboratory data as ordered and report deviations to provider. Laboratory studies may include serum electrolytes potassium, chloride, sodium, bicarbonate, magnesium, phosphate, and calcium; serum pH; comprehensive metabolic panel; and arterial blood gases.

● Review the client's medical and surgical history for possible causes of altered electrolytes. EB: *Periods of excess fluid loss can lead to dehydration and resulting loss of electrolytes; fluid can be lost through gastrointestinal illness, renal failure, hyperthermia, blood loss, and perspiration caused by strenuous exercise (Hew-Butler et al, 2017; Kear, 2017). Additional causes of electrolyte imbalances include excessive use of antacids, burns, trauma, sepsis, diabetic ketoacidosis, extensive surgeries, and changes in acid-base balance (Shrimanker & Bhattarai, 2020).*

▲ Complete pain assessment. Assess and document the onset, intensity, character, location, duration, aggravating factors, and relieving factors. Notify the provider of any increase in pain or discomfort or if comfort measures are not effective. EB: *Symptoms of electrolyte imbalance and dehydration can include muscle cramps, paresthesias, abdominal cramps, skin manifestations, cardiac arrhythmias, and tetany (Shrimanker & Bhattarai, 2020).*

▲ Monitor the effects of ordered medications such as diuretics and heart medications. EB: *Medications can have adverse effects on kidney function and electrolyte balance, particularly contrast agents, chemotherapeutic agents, amphotericin B, aminoglycosides, phosphate ingestion, loop diuretics, and vitamin D (Kear, 2017; Alfarouk et al, 2020).*

▲ Administer parenteral fluids as ordered and monitor their effects. EB: *Rapid resuscitation with fluids can cause adverse effects such as electrolyte imbalance, increased bleeding, and coagulopathies (Shrimanker & Bhattarai, 2020). Administration of fluids should be done to improve the plasma electrolytes and pH and hemodynamic improvement (Bedreag et al, 2016).*

Geriatric

● Monitor electrolyte levels carefully, including sodium levels and potassium levels, with both increased and decreased levels possible. EB: *Older adults are prone to electrolyte abnormalities because of failure of regulatory mechanisms associated with heart and kidney disease, a decrease in the ability to reabsorb sodium, and a loss of diluting capacity in the kidneys (Kear, 2017). Dehydration in the elderly is attributable to inadequate water intake caused by dysfunction of the central nervous system controlling thirst. Data also suggest that sodium appetite is reduced in aged rats and therefore also in the elderly (Begg, 2017). Many older clients receive selective serotonin reuptake inhibitors for treatment of depression, which can result in hyponatremia (Varela-Piñón & Adán-Manes, 2017).*

Client/Family Teaching and Discharge Planning

● Teach client/family the signs of low potassium and the risk factors. EB: *Signs and symptoms of low potassium include muscle weakness, nausea, vomiting, constipation, and irregular pulse (Shrimanker & Bhattarai, 2020).*

● Teach client/family the signs of high potassium and the risk factors. EB: *Signs and symptoms of high potassium include restlessness, muscle weakness, slow heart rate, diarrhea, and cramping (Shrimanker & Bhattarai, 2020).*

● Teach client/family the signs of low sodium and the risk factors. EB: *Early signs of low sodium include nausea, muscle cramps, disorientation, and mental status changes (Shrimanker & Bhattarai, 2020).*

● Teach client/family the signs of high sodium and the risk factors. EB: *Signs of high sodium include thirst, dry mucous membranes, rapid heartbeat, low blood pressure, and mental status changes; symptoms can progress to confusion, delirium, and seizures (Shrimanker & Bhattarai, 2020).*

● Teach client/family the importance of hydration during exercise. Dehydration occurs when the amount of water leaving the body is greater than the amount consumed. EB: *The body can lose large amounts of fluid when it tries to cool itself by sweating (Begg, 2017).*

● Teach client/family the warning signs of dehydration. Early signs of dehydration include thirst and decreased urine output. As dehydration increases, symptoms may include dry mouth, muscle cramps, nausea and vomiting, lightheadedness, and orthostatic hypotension. EB: *Severe dehydration can cause confusion, weakness, coma, and organ failure (Shrimanker & Bhattarai, 2020).*

● Teach client about any medications prescribed. Medication teaching includes the drug name, its purpose, administration instructions such as taking it with or without food, and any side effects. EB: *Studies have shown that insufficient and ineffective client education, leading to poor treatment adherence, and suboptimal*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

use of guideline-recommended drug regimens have been identified as contributing factors to client nonadherence to antiplatelet therapy and high hospital acute coronary syndrome (ACS) readmission rates (Larkin et al, 2017). Clients on a diuretic should understand side effects such as those for low potassium. Diuretic use remains a primary cause of low serum potassium levels (Kear, 2017). Clients on warfarin should also be educated on dietary interactions to improve medication efficacy (Jenner et al, 2015).

▲ Instruct the client to report any adverse medication side effects to his or her health care provider. Assessing and instructing clients about medications and focusing on important details can help prevent client medication errors. EB: *Pharmacist involvement with client education can improve medication efficacy and decrease hospital readmissions (Phatak et al, 2016).*

Labile Emotional Control

Domain 5 Perception/cognition Class 4 Cognition

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Uncontrollable outbursts of exaggerated and involuntary emotional expression.

Defining Characteristics

Absence of eye contact; crying; excessive crying without feeling sadness; excessive laughing without feeling happiness; expresses embarrassment regarding emotional expression; expression of emotion incongruent with triggering factor; impaired nonverbal communication; involuntary crying; involuntary laughing; social alienation; uncontrollable crying; uncontrollable laughing; withdrawal from occupational situation

Related Factors

Altered self-esteem; excessive emotional disturbance; fatigue; inadequate knowledge about symptom control; inadequate knowledge of disease; insufficient muscle strength; social distress; stressors; substance misuse

Associated Conditions

Brain injuries; functional impairment; mental disorders; mood disorders; musculoskeletal impairment; pharmaceutical preparations; physical disability

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Knowledge: Disease Process; Impulse; Self-Control; Self-Esteem; Quality of Life; Personal Well-Being; Stress Level

Example NOC Outcome with Indicators

Knowledge: Disease Process as evidenced by the following indicator: Specific disease process. (Rate the outcome and indicators of **Knowledge: Disease Process:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Improve coping strategies
- Improve knowledge about disease process, signs and symptoms, triggers, symptom control
- Use mechanisms to control impulses and ask for help when feeling impulses
- Improve feelings of dignity
- Enhance and improve response to social and environmental stimuli

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Teaching: Disease Process; Enhance Self-Esteem; Improved Quality of Life; Improved Well-Being

Example NIC Activities—Labile Emotional Control

Coping Enhancement: Assist the patient to solve problems in a constructive manner; Instruct the patient on the use of relaxation techniques, as needed; Assist the patient to identify positive strategies to deal with limitations and manage needed lifestyle or role changes

Nursing Interventions and *Rationales*

- Identify clients at risk of having labile emotional control. EB: *Clients with traumatic brain injury (TBI), Parkinson's disease (PD), multiple sclerosis (MS), amyotrophic lateral sclerosis (ALS), stroke, and schizophrenia (including schizoaffective and schizophreniform disorders) were most closely associated with pseudobulbar affect (PBA) diagnosis, which is associated with emotional lability (Allen et al, 2018).*
- Assess clients with an appropriate screening tool such as the Pathological Laughter and Crying Scale (PLACS), Center for Neurologic Study-Lability Scale (CNS-LS), or the Emotional Lability Questionnaire (ELQ). EB: *A review found that these tools have been used with success in both academic research and clinical trials (Finegan et al, 2019).*
- Offer client the choice of email and/or videoconferencing for delivery of therapy. EBN: *A cross-sectional study found that virtually delivered therapy can be a beneficial alternative to face-to-face meetings for people with PBA (Bentley, O'Connor, & Breen, 2017).*
- Assess clients for use of experiential avoidance, which is the process of negatively evaluating, escaping, or avoiding unwanted thoughts, emotions, or sensations. EB: *A recent study found experiential avoidance was*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

associated with both higher levels of negative affect (P < .001) *and increased emotional lability* (P = .021) *(Gerhart et al, 2018).*

- Offer the client choices when possible in emotional situations. EB: *A study found that choice appears to be a powerful tool that permits regulation of negative emotions in an adaptive fashion (Thuillard & Dan-Glauser, 2017).*
- Encourage clients to verbalize their emotional reactions and lability. EB: *Encouraging clients to talk about their emotional reactions could help normalize their experiences and may prevent the development of responses that could delay or negatively affect their recovery (Gillespie et al, 2020).*
- Encourage clients to talk about their emotional reactions and acknowledge that the unpredictable and uncontrollable nature of emotional lability can be embarrassing and cause distress. EB: *A qualitative study found that embarrassment and social withdrawal were commonly reported and had a detrimental effect on participant's mood and quality of life (McAleese et al, 2021).*
- Encourage the client to use distraction, humor, optimism, and social support as a way to manage the episodes. EB: *A qualitative study found that positive experiences were shaped by a better understanding of the condition, an increased sense of control, social support, and optimism (McAleese et al, 2021).*
- Consider using motive-oriented therapeutic relationship (MOTR). EB: *A randomized controlled study using MOTR found that early expressions of distress were shown to significantly decrease with adaptive emotions emerging in clients diagnosed with borderline personality disorder (Berthoud et al, 2017).*
- Provide progressive muscle relaxation (PMR) exercise and guided imagery (GI) techniques. EB: *A nursing study found that PMR and GI were effective in reducing anxiety and improving mood states in parents of children with malignancy (Tsitsi et al, 2017).*
- Consider using cognitive-behavioral therapy (CBT). EB: *A current study of youth with anxiety disorders found that CBT resulted in decreased sadness and anger dysregulation and increases in adaptive coping with anger (Suveg et al, 2018).*

Pediatric

- Assess adolescents with high emotional dysregulation for substance use disorders. EB: *Study results indicated that adolescents scoring high on emotional dysregulation are at risk for substance dependence because of more externalizing and internalizing symptomatology (Wills et al, 2016).*
- Teach parents that their reactions to their children's emotions play a critical role in teaching children effective emotion regulation. EB: *A recent study suggested that supportive parent emotion socialization practices are associated with parent-rated emotion regulation skills (Breaux et al, 2018).*
- Provide parents with emotion coaching strategies to manage their children's emotional outbursts. Emotion coaching includes fostering parental awareness and acceptance of their children's emotions with behaviors that acknowledge their children's emotions and teaches understanding, coping with, and appropriately expressing emotion. EB: *Study results suggested that when children with oppositional defiant disorder (ODD) experience more frequent, intense, and unstable emotions, families are better able to benefit from treatment and reduce children's behavior problems when mothers begin treatment or are already engaging in emotion coaching (Dunsmore et al, 2016).*

▲ Refer adolescent clients to a dialectical behavior therapy (DBT) group. EB: *Research shows that DBT is an effective means of assisting adolescents in learning to enhance their emotion-regulation skills (Gill et al, 2018).*

Geriatric

- Many of the previous interventions may be adapted for geriatric use.
- Evaluate geriatric clients suspected of PBA with the following three-step model: (1) crying inconsistent with environment/stimuli; (2) diagnosis of any of the following neurological disorders: TBI, PD, MS, ALS; or (3) at least two of the following disorders: stroke, schizophrenia (including schizoaffective and schizophreniform disorders), or documentation of spinal cord injury (SCI) as most closely associated with the PBA diagnosis. EB: *Based on analysis, this three-item checklist to facilitate PBA risk assessment in the nursing home setting was developed (Allen et al, 2018).*

Multicultural and Home Care

- The previous interventions may be adapted for multicultural and home care.

Client/Family Teaching and Discharge Planning

- Instruct client and family to monitor for cutaneous adverse effects of the neurological medications used to treat PBA and report occurrence to their health care provider. EB: *A review of the literature found that cutaneous reactions were associated with medications approved by the US Food and Drug Administration (FDA) to treat PBA (Bahrani et al, 2016).*
- Inform client and family about the emotional lability and talk with them about how to cope with the situation. EBN: *Clients and families need more information about this syndrome so they can recognize the signs and symptoms, get a diagnosis, and obtain treatment (Schneider & Schneider, 2017).*
- For clients with neurological disorders, provide teaching that emotionalism is a neurological condition and not a clinical mood disorder to promote better understanding for clients, their families, and significant others. EB: *For poststroke clients, positive experiences were shaped by a better understanding of the condition (McAleese et al, 2021).*
- Use verbal and nonverbal therapeutic communication approaches including empathy, active listening, and confrontation to encourage the client and family to express emotions such as sadness, guilt, and anger (within appropriate limits); verbalize fears and concerns; and set goals. *Solution-focused communication with clients helps focus on goals and helps find solutions.*
- Offer instruction to the client and family to wait for emotional episodes to pass. EB: *A qualitative study found that positive experiences were shaped by an increased sense of control (McAleese et al, 2021).*

Imbalanced Energy Field Domain 4 Activity/rest Class 3 Energy balance

Gail B. Ladwig, MSN, RN and Julianne E. Doubet, BSN, RN, EMT-B

NANDA-I

Definition

A disruption in the vital flow of human energy that is normally a continuous whole and is unique, dynamic, creative and nonlinear.

Defining Characteristics

Arrhythmic energy field patterns; blockage of the energy flow; congested energy field patterns; congestion of the energy flow; dissonant rhythms of the energy field patterns; energy deficit of the energy flow; expression of the need to regain the experience of the whole; hyperactivity of the energy flow; irregular energy field patterns; magnetic pull to an area of the energy field; pulsating to pounding frequency of the energy field patterns; pulsations sensed in the energy flow; random energy field patterns; rapid energy field patterns; slow energy field patterns; strong energy field patterns; temperature differentials of cold in the energy flow; temperature differentials of heat in the energy flow; tingling sensed in the energy flow; tumultuous energy field patterns; unsynchronized rhythms sensed in the energy flow; weak energy field patterns

Related Factors

Anxiety; discomfort; excessive stress; interventions that disrupt the energetic pattern or flow; pain

At-Risk Population

Individuals experiencing life transition; individuals experiencing personal crisis

Associated Conditions

Impaired health status; injury

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Well-Being, Personal Health Status; Psychomotor Energy; Quality of Life

Example NOC Outcome with Indicators

Personal Well-Being as evidenced by the following indicators: Psychological health/Spiritual life/Ability to relax/Level of happiness. (Rate the outcome and indicators of **Personal Well-Being:** 1 = not all satisfied, 2 = somewhat satisfied, 3 = moderately satisfied, 4 = very satisfied, 5 = completely satisfied [see Section I].)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Therapeutic Touch (TT); Hope Inspiration; Reiki

Nursing Interventions and *Rationales*

- Consider using complementary health approaches (CHAs), such as energy medicine (TT/healing touch, hope inspiration, and reiki), for clients with anxiety, tension, pain, or other conditions that indicate a disruption in the flow of energy. EBN: *Developing evidence suggests that there is biological support for the lessening of pain and anxiety for clients who receive CHAs in acute care settings (Kramlich, 2017).*
- Refer to care plans for **Anxiety,** Acute **Pain,** and Chronic **Pain.**

Guidelines for Complementary Health Approaches

- CHAs may be practiced by anyone with the requisite preparation, desire, and commitment. EBN: *Acute and critical care nurses who are certified to practice CHAs in the acute care setting must adhere to their scope of practice, be conscious of their role, and recognize their professional boundaries (Kramlich, 2017).*

- Volunteers who are not licensed health care professionals may practice in the home, but not in the health care setting unless they undertake a rigorous training program. EBN: *Because client safety is of utmost concern in the acute and critical care settings, volunteer complementary health professionals (CHPs) must support infection control, client privacy, and client security (Kramlich, 2017).*

Pediatric

- Consider using CHAs for pediatric clients with adjunct therapies to decrease stress, anxiety, and pain. EB: *McClafferty et al (2017) encouraged health care providers who care for children to foster the utilization of "relevant, safe, effective, and age-appropriate health services and therapies," whether conventional or complementary (McClafferty et al, 2017).*

Geriatric

- Consider CHAs for elderly with pain. EBN: *Bruckenthal et al (2016) found that comorbidities in older adults cause difficulties with relief of chronic pain due to polypharmacy, the number of painful conditions, and age-related disparities and especially in the use of opioids. The addition of complementary and alternative medicine (CAM) alternatives was recognized as effective in support of chronic pain respite for older adults (Bruckenthal et al, 2016).*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's use of CAM. EBN: *The popularity of CAM fluctuates from country to country depending on economic, cultural, and social influences (Walker & Tangkiakumjat, 2018).*

Home Care

- Help the client and family accept CAM therapies as natural healing interventions. EBN: *Kramlich (2016) found, in her study of nurses employing CAM therapies in the treatment of acute illness, that these interventions adhere to the nursing standards of person- and family-centered care and in shared decision-making.*

▲ In the presence of a psychiatric disorder, refer for psychiatric home health care services for client reassurance and implementation of therapeutic regimens. EB: *It has been shown that a home visit intervention (HoVI) of psychiatric clients generates positive outcomes shown by the documented decrease in rehospitalization rates and number of days hospitalized, leading to health care cost savings (Chang & Chou, 2015).*

Client/Family Teaching and Discharge Planning

- Teach the client how to use guided imagery. EBN: *Assisting the client in the use of guided imagery may lead to progression in their comfort (Coelho et al, 2018).*
- Consider the use of progressive muscle relaxation, autogenic training, relaxation response, biofeedback, emotional freedom technique, guided imagery, diaphragmatic breathing, transcendental meditation, cognitive behavioral therapy, mindfulness-based stress reduction, and emotional freedom technique. EBN: *Family caregivers of the elderly who have received training in the practice of reflexology found that this technique had a substantial and affirmative effect on the health management of their elderly family member (Ali et al, 2017).*
- The practice of CAM therapies, both giving and receiving, can improve well-being. EBN: *In her honors thesis concerning the use of healing touch by nurses, Nunez (2017) found that nurses felt a genuine connection with their clients as they provided a holistic component in client care and helped to improve the clients' feeling of well-being.*

Nurses/Staff

- See the Evolve website for weblinks for client education resources.

Ineffective Dry Eye Self-Management

Domain 11 Safety/protection Class 2 Physical injury

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Unsatisfactory management of symptoms, treatment regimen, physical, psychosocial, and spiritual consequences and lifestyle changes inherent in living with inadequate tear film.

Defining Characteristics

Dry Eye Signs

Chemosis; conjunctival hyperemia; epiphora; filamentary keratitis; keratoconjunctival staining with fluorescein; low aqueous tear production according to Schirmer I Test; mucous plaques

Dry Eye Symptoms

Expresses dissatisfaction with quality of life; reports blurred vision; reports eye fatigue; reports feeling of burning eyes; reports feeling of ocular dryness; reports feeling of ocular foreign body; reports feeling of ocular itching; reports feeling of sand in eye

Behaviors

Difficulty performing eyelid care; difficulty reducing caffeine consumption; inadequate maintenance of air humidity; inadequate use of eyelid closure device; inadequate use of prescribed medication; inappropriate use of contact lenses; inappropriate use of fans; inappropriate use of hairdryer; inappropriate use of moisture chamber goggles; inattentive to dry eye signs; inattentive to dry eye symptoms; inattentive to second-hand smoke; insufficient dietary intake of omega-3 fatty acids; insufficient dietary intake of vitamin A; insufficient fluid intake; nonadherence to recommended blinking exercises; nonadherence to recommended eye breaks; use of products with benzalkonium chloride preservatives

Risk Factors

Competing demands; competing lifestyle preferences; conflict between health behaviors and social norms; decreased perceived quality of life; difficulty accessing community resources; difficulty managing complex treatment regimen; difficulty navigating complex health care systems; difficulty with decision-making; inadequate commitment to a plan of action; inadequate health literacy; inadequate knowledge of treatment regimen; inadequate number of cues to action; inadequate role models; inadequate social support; limited ability to perform aspects of treatment regimen; low self efficacy; negative feelings toward treatment regimen; nonacceptance of condition; perceived barrier to treatment regimen; perceived social stigma associated with condition; unrealistic perception of seriousness of condition; unrealistic perception of susceptibility to sequelae; unrealistic perception of treatment benefit

At-Risk Population

Children; economically disadvantaged individuals; individuals experiencing prolonged hospitalization; individuals with history of ineffective health self-management; individuals with limited decision-making experience; individuals with low educational level; older adults; women experiencing menopause

Associated Conditions

Allergies; autoimmune diseases; chemotherapy; developmental disabilities; graft versus host disease; incomplete eyelid closure; leukocytosis; metabolic diseases; neurological injury with motor reflex loss; neurological injury with sensory reflex loss; oxygen therapy; pharmaceutical preparations; proptosis; radiotherapy; reduced tear volume; surgical procedures

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes (Visual)

Dry Eye Severity; Sensory Function: Vision; Vision Compensation Behavior

Example NOC Outcome with Indicators

Dry Eye Severity as evidenced by the following indicators: Decreased tear production/Redness of conjunctiva/Burning eye sensation/Itchy eye sensation/Eye pain/Excessive watering/Blurred vision. (Rate each indicator of **Dry Eye Severity:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State eyes are comfortable with no itching, burning, or dryness
- Have corneal surface that is intact and without injury
- Demonstrate self-administration of eye drops if ordered
- State vision is clear

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Communication Enhancement: Visual Deficit; Environmental Management

Example NIC Activities—Communication Enhancement: Visual Deficit

Identify yourself when you enter the client's space; Provide adequate room lighting

Nursing Interventions and *Rationales*

▲ Assess for symptoms of dry eyes, such as "irritation, tearing, burning, stinging, dry or foreign body sensation, mild itching, photophobia, blurry vision, contact lens intolerance, redness, mucus discharge, increased frequency of blinking, eye fatigue, diurnal fluctuation, symptoms that worsen later in the day" (Boyd, 2018; Mukamal, 2020).

▲ If symptoms are present, refer client to an ophthalmologist for diagnosis and treatment. EB: *Clients with dry eye who are evaluated by nonophthalmologist health care providers should be referred promptly to the ophthalmologist if moderate or severe pain, lack of response to therapy, corneal infiltration or ulceration, or vision loss occurs (Churchill & Gudgel, 2021).*

▲ Administer ordered eye drops. EB: *As the severity of the dry eye increases, aqueous enhancement of the eye using topical agents is appropriate. Emulsions, gels, and ointments can be used (Boyd, 2018).*

● Consider use of eyeglass side shields or moisture chambers. EB: *Eyeglass side shields can protect the eyes from drafts. Moisture chambers are a type of eyeglasses that are frequently worn by motorcyclists and mountain climbers and can be purchased at stores or online (Boyd, 2018; Mukamal, 2020).*

▲ Watch for symptoms of blepharitis including crusting and irritation at the base of the lashes and adjacent redness of the eyelid, which may accompany dry eye; refer for treatment as needed. EB: *Contributing ocular factors such as blepharitis should be treated. Particularly effective treatments for evaporative tear deficiency include eyelid therapy for conditions such as blepharitis (Boyd, 2018; O'Neil et al, 2019).*

▲ Discuss use of caffeine with client's health care provider. EB: *Seltman (2020) and Wang et al (2021) found that caffeine consumption may be a protective factor with dry eye disease, increasing tear volume or eye moisture.*

● Provide education to the client about how limiting screen time, computers, smart devices, and television can assist with reducing eyestrain and dry eyes. EB: *Eye discomfort is associated with screen time and "digital eyestrain" because most people blink less when looking at screens, causing eyestrain and dryness (Vimont, 2021;*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Wang et al, 2021). For clients who engage in a lot of screen time, glasses that filter blue light may reduce eyestrain (Palavets & Rosenfield, 2019). Encourage the client to use natural tears if prolonged or frequent digital eyestrain is anticipated.

Critical Care

▲ Provide regular cleaning of the eyes, lubricating eye drops and ointments, and consultation with an ophthalmologist if infection is suspected in clients in the intensive care unit (ICU). ICU staff may miss ocular complications while caring for life-threatening conditions. Ocular complications can seriously impair vision and quality of life. EBN: *A nursing study that randomized clients (n = 70 in each group) to either liquid artificial tears or gel artificial tears found that gel tears resulted in less symptoms of dry eye (Dias de Araujo et al, 2019).*

● Avoid using adhesive tape to keep eyes closed in sedated clients. EBN: *In an audit of eye dryness and corneal abrasions of clients in four ICUs in Iran, clients receiving adhesive tape as an eye care method were twice as likely to develop corneal abrasion (Masoudi et al, 2014).* EB: *Apply lubricant and ophthalmology-approved eye covers to protect the eyes of high-risk critically ill clients who lack natural mechanism to blink or keep eye lids fully closed (Alansari et al, 2015; Marsden & Davies, 2016).*

Geriatric

● Recognize that symptoms of dry eye are more common in menopausal women and geriatric clients. EB: *Hormonal changes after menopause can disrupt tear production. It is estimated that one in three individuals older than 65 years experiences dry eyes (National Health Service [NHS], 2018).*

● Many clients as they age develop comorbidities in which the treatments can cause dry eyes. EB: *Medications used to manage cardiovascular diseases, type 2 diabetes, or depression can have secondary effects, causing dry eyes (de Paiva, 2017).*

Client/Family Teaching and Discharge Planning

● Teach client conditions that can exacerbate dry eye symptoms. EB: *Exacerbating conditions include wind, air travel, decreased humidity, air conditioning or heating, and prolonged activities that reduce blink rate such as reading and computer use (Marshall & Roach, 2016; Boyd, 2018).*

● Teach client good eye hygiene:
  ❍ Apply warm compresses for 10-minute intervals using a clean cloth and water that has been boiled and cooled (or sterile water).
  ❍ Gently massage around eyelids.
  ❍ Gently clean eyelids to remove excess oil, crusts, and bacteria. Use a few drops of baby shampoo in water that has been boiled and cooled, or in sterile water.
  ❍ Good hygiene can help improve dry eyes, especially dry eye associated with blepharitis (NHS, 2018).

● Teach clients methods to decrease problems with dry eye, including the following:
  ❍ Avoid drafty (e.g., ceiling fans) and low-humidity environments.
  ❍ Avoid smoking and exposure to secondhand smoke.

▲ Discuss avoidance of offending medications with health care provider.

● Drink plenty of water to keep well hydrated. EB: *For clients with a clinical diagnosis of mild dry eye, potentially exacerbating exogenous factors such as antihistamine or diuretic use, cigarette smoking or exposure to secondhand smoke, and environmental factors such as air drafts and low-humidity environments should be addressed (Boyd, 2018; Mukamal, 2020). Symptoms of dry eye may be exacerbated by the use of medications such as diuretics, antihistamines, anticholinergics, antidepressants, and systemic retinoids (Boyd, 2018; Mukamal, 2020). Self-care includes drinking plenty of water to stay hydrated (Boyd, 2018; Mukamal, 2020).*

● Teach client to lower the computer screen to below eye level and to blink more frequently. EB: *Measures such as lowering the computer screen to below eye level to decrease lid aperture, scheduling regular breaks, and increasing blink frequency may decrease the discomfort associated with computer and reading activities (Boyd, 2018; Mukamal, 2020).*

▲ Teach client to consult with the health care provider regarding use of omega-3 supplements to decrease dry eye. EB: *Omega-3 fatty acid products without ethyl esters may be beneficial in the treatment of dry eye, although they may increase the risk of prostate cancer (Boyd, 2018; Mukamal, 2020; Wang et al, 2020).*

● Teach client how to self-administer eye drops.

● Warn clients with dry eyes that driving at night can be dangerous. Clients with dry eyes have light sensitivity and decreased refraction.

Risk for Dry Eye

Domain 11 Safety/protection Class 2 Physical injury

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to inadequate tear film, which may cause eye discomfort and/or damage ocular surface, which may compromise health.

Risk Factors

Air conditioning; air pollution; caffeine consumption; decreased blinking frequency; excessive wind; inadequate knowledge of modifiable factors; inappropriate use of contact lenses; inappropriate use of fans; inappropriate use of hairdryer; inattentive to second-hand smoke; insufficient fluid intake; low air humidity; omega-3 fatty acids deficiency; smoking; sunlight exposure; use of products with benzalkonium chloride preservatives; vitamin A deficiency

At-Risk Population

Contact lens wearer; individuals experiencing prolonged intensive care unit stay; individuals with history of allergy; older adults; women

Associated Conditions

Artificial respiration; autoimmune disease; chemotherapy; decreased blinking; decreased level of consciousness; hormonal change; incomplete eyelid closure; leukocytosis; metabolic diseases; neurological injury with sensory or motor reflex loss; neuromuscular blockade; oxygen therapy; pharmaceutical preparations; proptosis; radiotherapy; reduced tear volume; surgical procedures

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Ineffective Dry **Eye** Self-Management.

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

Risk for Adult Falls

Domain 11 Safety/protection Class 2 Physical injury

Sherry A. Greenberg, PhD, RN, GNP-BC, FGSA, FAANP, FAAN

NANDA-I

Definition

Adult susceptible to experiencing an event resulting in coming to rest inadvertently on the ground, floor, or other lower level, which may compromise health.

Risk Factors

Physiological Factors

Chronic musculoskeletal pain; decreased lower extremity strength; dehydration; diarrhea; faintness when extending neck; faintness when turning neck; hypoglycemia; impaired physical mobility; impaired postural balance; incontinence; obesity; sleep disturbances; vitamin D deficiency

Psychoneurological Factors

Agitated confusion; anxiety; depressive symptoms; fear of falling; persistent wandering; substance misuse

Unmodified Environmental Factors

Cluttered environment; elevated bed surface; exposure to unsafe weather-related condition; inadequate anti-slip material in bathroom; inadequate anti-slip material on floors; inadequate lighting; inappropriate toilet seat height; inattentive to pets; lack of safety rails; objects out of reach; seats without arms; seats without backs; uneven floor; unfamiliar setting; use of throw rugs

Other Factors

Factors identified by standardized, validated screening tool; getting up at night without help; inadequate knowledge of modifiable factors; inappropriate clothing for walking; inappropriate footwear

At-Risk Population

Economically disadvantaged individuals; individuals aged ≥60 years; individuals dependent for activities of daily living; individuals dependent for instrumental activities of daily living; individuals experiencing prolonged hospitalization; individuals in aged care settings; individuals in palliative care settings; individuals in rehabilitation settings; individuals in the early postoperative period; individuals living alone; individuals receiving home-based care; individuals with history of falls; individuals with low educational level; individuals with restraints

Associated Conditions

Anemia; assistive devices for walking; depression; endocrine system diseases; lower limb prosthesis; major injury; mental disorders; musculoskeletal diseases; neurocognitive disorders; orthostatic hypotension; pharmaceutical preparations; sensation disorders; vascular disease

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Fall Prevention Behavior; Knowledge: Fall Prevention; Risk Control: Falls

Example NOC Outcome with Indicators

Fall Prevention Behavior as evidenced by the following indicators: Uses assistive devices correctly/ Eliminates clutter, spills, glare from floors/Uses safe transfer procedures. (Rate each indicator of **Fall Prevention Behavior:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of falls
- Have a decreased risk of injury if sustains a fall
- Adapt environment to minimize the incidence of falls
- Explain methods to prevent injury

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Dementia Management; Fall Prevention; Post-Fall Assessment; Surveillance: Safety

Example NIC Activities—Fall Prevention

Assist unsteady individual with ambulation; Monitor gait, balance, and fatigue level with ambulation

Nursing Interventions and *Rationales*

- Safety guidelines suggest a fall-risk assessment be completed for older adults in any health care setting with national guidelines and action plans such as the Falls Free Initiative (National Council on Aging, 2021).
- Use a valid and reliable fall risk assessment tool to assess the client's risk for falling; for example, in the acute care setting use the Hendrich II Model (Hendrich, 2013). Recognize that risk factors for falling include recent history of falls, fear of falling, confusion, depression, altered elimination patterns, cardiovascular/respiratory disease impairing perfusion or oxygenation, postural hypotension, dizziness or vertigo, primary cancer diagnosis, and altered mobility (National Council on Aging, 2021; Gray-Miceli & Quigley, 2021). **CEB:** *The Hendrich II Fall Risk Model is quick to administer and provides a determination of risk for falling based on gender, mental and emotional status, symptoms of dizziness, and known categories of medications increasing risk (Hendrich, 2013). This tool screens for primary prevention of falls and is integral in a postfall assessment for the secondary prevention of falls (Hendrich, 2013).*
- Screen all clients for balance and mobility skills (i.e., supine to sit, sitting supported and unsupported, sit to stand, standing, walking and turning around, transferring, stooping to floor and recovering, and sitting down). Use tools such as the Balance Scale by Tinetti, the Performance-Oriented Mobility Assessment (POMA), or the Timed Up & Go Test. **CEB/EB:** *It is helpful to determine the client's functional abilities and then plan for ways to improve problem areas or determine methods to ensure safety (Podsiadlo & Richardson, 1991; Resnick, 2019; National Council on Aging, 2021; Gray-Miceli & Quigley, 2021).*
- Identify client mobility function deficits and consider appropriate equipment needed to safely mobilize clients while promoting self-care. The Bedside Mobility Assessment Tool 2.0 (BMAT 2.0) helps nurses assess client mobility status and standardize safe client handling and mobility equipment use. **EB:** *The BMAT 2.0 is used mainly in the inpatient setting; takes only a few minutes to complete; and is conducted on admission, once per shift, and at a change in client status. Four levels of mobility are assessed: strength, coordination, balance, and tolerance. These are assessed at different levels depending on the client's function and overall safety depending on the health condition(s) and client ability. Nurses may work with multiprofessional team members to help clients progress in terms of mobility, strength, and type and safe use of mobility aids (Boynton, Kumpar, & VanGilder, 2020).*
- Older adults and others who may have been immobile due to acute illnesses and changing medications may be at risk for orthostatic hypotension. This is a drop in systolic blood pressure of 20 mm Hg or more or a drop in diastolic blood pressure of 10 mm Hg or more when changing from lying to sitting or sitting to standing. A concurrent rise in heart rate may occur as well. The client may or may not experience lightheadedness or dizziness. **EB:** *Encourage clients to change positions slowly. Take a client's blood pressure and pulse after standing 1 and 3 minutes to assess for orthostatic hypotension (Centers for Disease Control and Prevention, 2017).*
- Carefully assist a mostly immobile client up. Be sure to lock the bed and wheelchair and have sufficient personnel to protect the client from falls. When rising from a lying position, have the client change positions slowly, dangle legs, and stand next to the bed before walking to prevent orthostatic hypotension. **EB:** *Encourage client engagement in a monitored exercise program that will strengthen core and lower extremities to reduce fall risk (Grabiner, 2014; Hirase et al, 2014; National Institute of Neurological Disorders and Stroke [NINDS], 2019).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Use a "high-risk fall" armband/bracelet and fall risk room sign to alert staff for increased vigilance and mobility assistance. **EB:** *These steps alert the nursing staff of the increased risk of falls (Goodwin et al, 2014).*

▲ Evaluate the client's medications to determine whether medications increase the risk of falling. Consult with health care provider regarding the client's need for medication if appropriate. **EB:** *Polypharmacy, or taking more than four medications, has been associated with increased falls. Medications such as benzodiazepines, as well as psychotropic, antipsychotic, and antidepressant medications given to promote sleep, actually increase the rate of falls (Goodwin et al, 2014; The 2019 American Geriatrics Society Beers Criteria Update Expert Panel, 2019; Greenberg 2019b; National Council on Aging, 2020).* **EB:** *Short- to intermediate-acting benzodiazepine and tricyclic antidepressants may produce ataxia, impaired psychomotor function, syncope, and additional falls (Greenberg et al, 2016; Resnick, 2019; The 2019 American Geriatrics Society Beers Criteria Update Expert Panel, 2019).*

- Orient the client to the environment. Place the call light within reach and show how to call for assistance; answer call light promptly.
- Use one-fourth to one-half length side rails only, and maintain bed in a low position. Ensure that wheels are locked on the bed and commode. Keep dim light in the room at night. **CEB/EB:** *Use of full side rails can result in the client climbing over the rails, leading with the head, and sustaining a head injury. Side rails with widely spaced vertical bars and side rails not situated flush with the mattress have been associated with asphyxiation deaths because of rail and in-bed entrapment and should not be used (Capezuti, 2004; Goodwin et al, 2014).*
- Routinely assist the client with toileting on his or her own schedule. Take the client to the bathroom on awakening and before bedtime (Goodwin et al, 2014).
- Keep the path to the bathroom clear, label the bathroom, and leave the door open.

▲ Avoid use of restraints if possible. Obtain health care provider's order if restraints are deemed necessary, and use the least restrictive device. **EB:** *The use of restraints has been associated with serious injuries, including rhabdomyolysis, brachial plexus injury, neuropathy, and dysrhythmias, as well as strangulation, asphyxiation, traumatic brain injuries, and all the consequences of immobility (Cotter & Evans, 2018).* **CEB:** *A study demonstrated that there was no increase in falls or injuries in a group of clients who were not restrained versus a similar group that was restrained in a nursing home (Capezuti, 2004). A study in two acute care hospitals demonstrated that when restraints were not used, there was no increase in client falls, injuries, or therapy disruptions (Mion et al, 2001).*

- In place of restraints, use the following:
  - Well-staffed and educated nursing personnel with frequent client contact with careful consideration during shift changes
  - Nursing units designed to care for clients with cognitive and/or functional impairments
  - Nonskid footwear, sneakers preferable
  - Glasses and/or hearing aids, as needed
  - Adequate lighting, night-light in bathroom
  - Frequent toileting
  - Frequently assess need for invasive devices, tubes, intravenous (IV) access
  - Hide tubes with bandages to prevent pulling of tubes
  - Consider alternative IV placement site to prevent pulling out IV line
  - Alarm systems with ankle, above-the-knee, or wrist sensors
  - Bed or wheelchair alarms
  - Wedge cushions on chairs to prevent slipping
  - Increased observation of the client
  - Locked doors to unit
  - Low Low- or very-low-height beds
  - Border-defining pillow/mattress to cue the client to stay in bed

  EB: *These alternatives to restraints can be helpful to prevent falls (Grabiner, 2014; Cotter & Evans, 2018).*
- If the client has an acute change in mental status (delirium), recognize that the cause is usually physiological and is a medical emergency. Consider possible causes for delirium. Consult with the health care provider immediately. See interventions for Acute **Confusion.**
- If the client has chronic confusion caused by dementia, implement individualized strategies to enhance communication. Assessment of specific receptive and expressive language abilities is needed to understand the client's communication difficulties and facilitate communication. See interventions for Chronic **Confusion.**

- Ask family to stay with the client to assist with activities of daily living and prevent the client from accidentally falling or pulling out tubes.

▲ If the client is unsteady on his or her feet, have two nursing staff members alongside when walking the client. Use facility-approved mobility devices to assist with client ambulation (e.g., gait belts, walkers). Consider referral to physical therapy for gait training and strengthening. **EB:** *The client can walk independently, but the nurse can rapidly ensure safety if the client becomes weak or unsteady. Multiprofessional care is most comprehensive and beneficial to the client (Grabiner, 2014).*

- Place a fall-prone client in a room that is near the nurses' station. Such placement allows more frequent observation of the client.
- Help clients sit in a stable chair with armrests. Avoid use of wheelchairs except for transportation as needed. Clients are likely to fall when left in a wheelchair because they may stand up without locking the wheels or removing the footrests.

▲ Refer to physical therapy or other programs for exercise programs that target strength, balance, flexibility, or endurance. **EB:** *Programs with at least two of these components have been shown to decrease the rate of falling and number of people falling (National Council on Aging, 2021).*

Geriatric

- Assess mobility and gait speed using the Timed Up & Go Test. Ask the client to stand up from a standard arm chair, walk 10 feet (or 3 meters), turn around, walk back to the chair, and sit down (Podsiadlo & Richardson, 1991). This should be done with the client wearing usual footwear. **EB:** *Performance on this screening examination demonstrates the client's mobility. If the client completes the test in less than 10 seconds, he or she is considered freely mobile. If completing the test takes 10 to 19 seconds, the client is considered to be mostly independent in mobility. If the client takes 20 to 29 seconds, the client is considered to have variable mobility. If the client takes 30 or more seconds, he or she is considered to have impaired mobility and is more likely to be dependent on others and more likely to sustain a fall (Podsiadlo & Richardson, 1991; Centers for Disease Control and Prevention, National Center for Injury Prevention and Control, 2020).*
- Mobility assessment and acting on findings are crucial in care of older adults. This is embedded in the Age-Friendly Health System's Model of Care, an initiative of the John A. Hartford Foundation and the Institute of Healthcare Improvement (IHI) in partnership with the American Hospital Association and the Catholic Health Association of the United States that began in 2017. The Age-Friendly Health System model promotes the evidence-based 4Ms framework: (1) **What Matters** to the older adult, considering what is most important to the older adult, family, and caregivers, in terms of goals and preferences; (2) **Medication**, making sure all medications have a clear indication, prescribed at the lowest effective dosage and frequency; (3) **Mentation**, assessing and managing dementia, delirium, and/or depression; and (4) **Mobility**, maintaining or improving mobility and function (Institute for Healthcare Improvement, 2019). **EB:** *The 4Ms framework is a guide to care of older adults in all care settings. The 4Ms are to be implemented together as a set of evidence-based elements of high-quality care for older adults. The Mobility component is included as an essential component to ensure that older adults move safely every day in order to maintain function and do What Matters to them (Institute for Healthcare Improvement, 2019).*
- Complete a fall risk assessment for older adults in acute care using a valid and reliable tool such as the Hendrich II Fall Risk Model. **EB:** *It is quick to administer and provides a determination of risk for falling based on gender, mental and emotional status, symptoms of dizziness, and known categories of medications increasing risk (Hendrich, 2013). This tool screens for primary prevention of falls and is integral in a postfall assessment for the secondary prevention of falls (Goodwin et al, 2014; Greenberg, 2020; Hendrich, 2013).*

▲ If there is new onset of falling, assess for laboratory abnormalities, signs and symptoms of infection and dehydration, and blood glucose level for diabetics, and check blood pressure and pulse rate with client in supine, sitting, and standing positions for hypotension and orthostatic hypotension. If the client has borderline high blood pressure, the risk of falling because of the administration of antihypertensives may outweigh the benefits of the antihypertensive medication. Discuss with the health care provider on a client-to-client basis. **EB:** *If orthostatic hypotension is present and there is minimal change in the heart rate, most likely the baroreceptors are not working to maintain blood pressure on arising. This is common in older adults and may be caused by hypovolemia resulting from the excessive use of diuretics, vasodilators, or other types of drugs; dehydration; or prolonged bed rest, as well as cardiovascular disease, neurological disease, or the adverse effects of another medication (NINDS, 2019).*

- Complete a fear of falling assessment for older adults. This includes measuring fear of falling, or the level of concern about falling, and falls self-efficacy, which is the degree of confidence a person has in

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

performing common activities of daily living without falling. Fear of falling may be measured by a single-item question asking about the presence of fear of falling or rating severity of fear of falling on a 1 to 4 Likert scale as is commonly done in studies. Falls self-efficacy may be measured using a valid and reliable tool such as the Falls Efficacy Scale—International (Yardley et al, 2005; Greenberg, 2012; Greenberg et al, 2016; Greenberg 2019a).

- ● Encourage the client to wear glasses and use walking aids when ambulating.
- ● If the client experiences dizziness because of orthostatic hypotension when getting up, teach methods to decrease dizziness, such as rising slowly, remaining seated several minutes before standing, flexing feet upward several times while sitting, sitting down immediately if feeling dizzy, and trying to have someone present when standing. **EB:** *Always have the client dangle at the bedside before standing to evaluate for postural hypotension. Watch the client closely for dizziness during increased activity. Postural hypotension can be detected in up to 30% of older clients. These methods can help prevent falls and maintain adequate fluid intake (Goodwin et al, 2014).*
- ▲ If the client is experiencing syncope, determine symptoms that occur before syncope and note medications that the client is taking. Refer for medical care. The circumstances surrounding syncope often suggest the cause. **EB:** *Use of many medications, including diuretics, antihypertensives, digoxin, beta-blockers, and calcium channel blockers, can cause syncope. Use of the tilt table can be diagnostic in incidences of syncope (Goodwin et al, 2014; Fick & Mion, 2018).*
- ▲ Observe client for signs of anemia, and refer to health care provider for testing if appropriate.
- ● Evaluate client for chronic alcohol intake and mental health and neurological function.
- ▲ Refer to physical therapy for strength training, using free weights or machines, and suggest participation in exercise programs. **EB:** *Exercise can prevent falls in older people. Greater relative effects are seen in programs that include exercises that challenge balance, use a higher dose of exercise, and do not include a walking program. Service providers can use these findings to design and implement exercise programs for falls prevention (Grabiner, 2014; Hirase et al, 2014; National Council on Aging, 2021).*
- ▲ Evidence-based guidelines for preventing falls in older adults were published by the American Geriatrics Society (AGS) and British Geriatrics Society (BGS) collaboratively and specify recommendations for all clinical settings. The Centers for Disease Control and Prevention's Stopping Elderly Accidents, Deaths, & Injuries (STEADI) initiative related to older adult fall prevention provides implementation strategies. These recommendations include screening and assessment and interventions. Examples of interventions include (1) exercise for balance and for gait and strength training, such as tai chi or physical therapy; (2) environmental adaptation to reduce fall risk factors in the home and in daily activities; (3) cataract surgery when indicated; (4) medication reduction with particular attention to medications that affect the brain such as sleeping medications and antidepressants; (5) assessment and treatment of postural hypotension; (6) identification and appropriate treatment of foot problems; and (7) vitamin D supplementation for those with vitamin D deficiency (American Geriatrics Society [AGS], 2011; Centers for Disease Control and Prevention & National Center for Injury Prevention and Control, 2020; Centers for Disease Control and Prevention, 2021)
- ▲ Refer community-dwelling older adults to evidence-based community-based programs (National Council on Aging, 2021). **EB:** *A Matter of Balance is a group intervention focusing on increasing activity levels and decreasing concerns about falling. The program helps community-based older adults gain confidence by setting goals to increase activity and mobility, decrease fall risk factors in the home, and promote exercise to increase strength and improve balance (Alexander et al, 2015). CAPABLE (Community Aging in Place—Advancing Better Living for Elders) is a 5-month structured program delivered at home to decrease fall risk, improve safe mobility, and improve the ability to safely conduct functional tasks and activities (Ruiz et al, 2017).*

Home Care

- ● Some of the previously mentioned interventions may be adapted for home care use.
- ● Implement evidence-based fall prevention practices in community settings and home health care programs for older adults (National Council on Aging, 2021).
- ▲ If delirium is present, assess for cause of delirium and/or falls with the use of an multiprofessional team. Consult with the health care provider immediately. Assess and monitor for acute changes in cognition and behavior. **EB:** *An acute and fluctuating change in cognition and behavior is the classic presentation of delirium. Delirium is reversible and should be considered a medical emergency. Delirium can become chronic if untreated, and clients may be discharged from hospitals to home care in states of undiagnosed delirium.* **EB:** *Falls may be a precipitating event or an indication of frailty consistent with delirium (Goodwin et al, 2014).*

- Assess home environment for threats to safety, including clutter, slippery floors, scatter rugs, and other potential hazards. Additionally, assess external environment (e.g., uneven pavement, unleveled stairs/steps). **EB:** *Clients suffering from impaired mobility, impaired visual acuity, and neurological dysfunction, including dementia and other cognitive functional deficits, are all at risk for injury from common hazards. These recommendations were shown to be effective to reduce falls (AGS, 2011; Goodwin et al, 2014; National Council on Aging, 2021).*

▲ Institute a home-based, nurse-delivered exercise program to reduce falls or refer to physical therapy services for client and family education of safe transfers and ambulation and for strengthening exercises for the client (Grabiner, 2014; National Council on Aging, 2021).

▲ Instruct the client and family or caregivers on how to correct identified hazards for those with visual impairment. Refer to physical and occupational therapy services for assistance if needed. **EB:** *Interventions to improve home safety were shown to be effective in people at high risk, such as those with severe visual impairment (National Council on Aging, 2021).*

▲ Use a multifactorial assessment along with interventions targeted to the identified risk factors. Key components of the interventions include evaluating need for all medications, balance, gait, and strength training, use of strategies to deal with postural hypotension if present, home safety evaluation with needed modifications, and any needed cardiovascular treatment. **EB:** *As people age, they may fall more often for multiple reasons including problems with balance, poor vision, and dementia. Fear of falling can result in self-restricted activity levels (National Council on Aging, 2021).*

- If the client lives alone or spends a great deal of time alone, teach the client what to do if he or she falls and cannot get up, and make sure he or she has a personal emergency response system or a mobile phone that is available from the floor (AGS, 2011; National Council on Aging, 2021).
- Ensure appropriate nonglare lighting in the home. Ask the client to install indoor strip or "runway" type of lighting to baseboards to help clients balance. Install motion-sensitive lighting that turns on automatically when the client gets out of bed to go to the bathroom.
- Have the client wear supportive, low-heeled shoes with good traction when ambulating. Avoid use of slip-on footwear. Wear appropriate footwear in inclement weather. **EB:** *Supportive shoes provide the client with better balance and protect the client from instability on uneven surfaces. Anti-slip shoe devices worn in icy conditions have been shown to reduce falls (AGS, 2011; National Council on Aging, 2021).*
- Provide a signaling device for clients who wander or are at risk for falls. Orienting a vulnerable client to a safety net relieves the anxiety of the client and caregiver and allows for rapid response to a crisis situation.
- Provide medical identification bracelet for clients at risk for injury from dementia, diabetes, seizures, or other medical disorders.
- Suggest a tai chi class designed for older adults and selected clients who have sufficient balance to participate. **EB:** *Participation in once-per-week tai chi classes for 16 weeks can prevent falls in relatively healthy community-dwelling older people (AGS, 2011; National Council on Aging, 2021).*

Client/Family Teaching and Discharge Planning

- Teach the client and the family about the fall reduction measures that are being used to prevent falls (The Joint Commission, 2020).
- Providing education on safety guidelines to prevent falls is an important nursing intervention that should be completed as part of discharge planning (*National Council on Aging, 2021*)
- Teach the client how to safely ambulate at home, including using safety measures such as handrails in bathroom, reaching for items on high shelves, and avoiding carrying things or performing other tasks while walking.
- Teach the client the importance of maintaining a regular exercise program. If the client is afraid of falling while walking outside, suggest that he or she walk the length of a local mall. **EB:** *Exercise can prevent falls in older people. Greater relative effects are seen in programs that include exercises that challenge balance and use a higher dose of exercise than just walking programs (AGS, 2011; Grabiner, 2014; Hirase et al, 2014).*

F

Risk for Child Falls

Domain 11 Safety/protection Class 2 Physical injury

Sherry A. Greenberg, PhD, RN, GNP-BC, FGSA, FAANP, FAAN and Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Child susceptible to experiencing an event resulting in coming to rest inadvertently on the ground, floor, or other lower level, which may compromise health.

F

Risk Factors

Caregiver Factors

Changes diapers on raised surfaces; exhaustion; fails to lock wheels of child equipment; inadequate knowledge of changes in developmental stages; inadequate supervision of child; inattentive to environmental safety; inattentive to safety devices during sports activities; places child in bouncer seat on raised surfaces; places child in infant walkers; places child in mobile seat on raised surfaces; places child in seats without a seat belt; places child in shopping cart basket; places child on play equipment unsuitable for age group; postpartum depressive symptoms; sleeps with child in arms without protective measures; sleeps with child on lap without protective measures

Physiological Factors

Decreased lower extremity strength; dehydration; hypoglycemia; hypotension; impaired physical mobility; impaired postural balance; incontinence; malnutrition; neurobehavioral manifestations; obesity; sleep disturbances

Unmodified Environmental Factors

Absence of stairway gate; absence of stairway handrail; absence of wheel locks on child equipment; absence of window guard; cluttered environment; furniture placement facilitates access to balconies; furniture placement facilitates access to windows; high chairs positioned near tables or counters; inadequate anti-slip material on floors; inadequate automobile restraints; inadequate lighting; inadequate maintenance of play equipment; inadequate restraints on elevated surfaces; inattentive to pets; objects out of reach; seats without arms; seats without backs; uneven floor; unfamiliar setting; use of furniture without anti-tipping devices; use of non–age appropriate furniture; use of throw rugs

Other Factors

Factors identified by standardized, validated screening tool; inappropriate clothing for walking; inappropriate footwear

At-Risk Population

Boys; children <12 years of age; children born to economically disadvantaged families; children experiencing prolonged prescribed fasting period; children exposed to overcrowded environment; children in the labor force; children whose caregivers have low educational level; children whose caregivers have mental health issues; children with history of falls; children with stressed caregivers; children with young caregivers; children within the first week of hospitalization

Associated Conditions

Assistive devices for walking; feeding and eating disorders; musculoskeletal diseases; neurocognitive disorders; pharmaceutical preparations; sensation disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Fall Prevention Behavior; Knowledge: Child Physical Safety; Knowledge: Fall Prevention; Risk Control: Falls

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NOC Outcome with Indicators

Fall Prevention Behavior as evidenced by the following indicators: Uses assistive devices correctly/ Eliminates clutter, spills, glare from floors, places barriers to prevent falls (Rate each indicator of **Fall Prevention Behavior:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of falls
- Verbalize environmental conditions to prevent falls
- Have a decreased risk of injury if sustains a fall
- Adapt environment to minimize the incidence of falls
- Explain methods to prevent injury

F

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Fall Prevention; Surveillance: Safety

Example NIC Activities—Fall Prevention

Provides close supervision and/or restraining device (e.g., infant seat with seat belt) when placing infants/ young children on elevated surfaces (e.g., highchair and hand securely on child when on changing table)

Nursing Interventions and *Rationales*

- Provide and review home safety plans with parents. **CEB:** *A Cochrane review found that home safety plans were an inexpensive and effective way to reduce child harm. Education that encouraged the use of fitted stair gates reduced the risk of child falls by more than 50% (Kendrick et al, 2012).*
- Follow national guidelines to teach parents and guardians about fall safety for children.
  - Playground safety includes ensuring surfaces under equipment are soft and well maintained.
  - Home safety addresses guards on windows that are above ground level and use of stair gates and guard rails.
  - Use helmets and wrist, knee, and elbow pads/protective gear during recreation and sports activities.
  - Keep fire safety ladder available near window on floors above ground level.
  - Close supervision of young children is essential to reduce fall risks.

  EB: *The Centers for Disease Control and Prevention (CDC, 2019) provides information for parents, guardians, and teachers to protect children from falls and fall-related injuries, including head injuries.*
- Explore possible concerns of harm indirectly or directly resulting in a child fall. **EB:** *Multiple factors influence violence against a child, including individual, community, and social factors. Assess characteristics of the fall that may not be consistent with history and inform provider for additional evaluation (CDC, 2021).*
- Children younger than 4 years of age and those with special needs that increase caregiver burden are at greater risk of harm from unintentional falls (Chaudhary et al, 2018; CDC, 2021).
- Assess height from which the child fell and possible impact. **EB:** *Research exploring the mechanism and risk of children who fell with injuries found that children younger than 1 more likely fell from a caregiver's arms or from a higher surface due to improper safety device use (e.g., safety straps/seatbelts); younger children ages 2 to 6 are more prone to falls from furniture, down stairs, on playgrounds, or from balconies; and older children ages greater than 10 fall from higher surfaces, trampolines, and so on (Chaudhary et al, 2018). Providing age-specific fall prevention information to parents and caregivers may reduce the risk of injury with pediatric falls (CDC, 2019, 2021).*
- Safety guidelines suggest that a pediatric fall risk assessment tool should be completed to assess fall risk. **EBN:** *An integrative review of pediatric fall risk tools identified that factors most associated with pediatric falls in hospital settings include medication use (e.g., seizure medications, sedation), cognitive impairment, prolonged length of stay, orthopedic diagnosis, environmental circumstances, and history of falls. The hospital environment is different than home, thus assessing a child for risk of falls using a valid and reliable tool is essential to reduce risk and harm from falls (DiGerolamo & Davis, 2017).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

- Use a valid and reliable fall risk assessment tool to assess the client risk for falling (DiGerolamo & Davis, 2017). **CEBN:** *The Humpty Dumpty Fall Scale (HDFS) places pediatric clients at low or high risk of falling based on age, gender, diagnosis, cognitive impairment, environmental changes, response to surgery/sedation/anesthesia, and medication (Hill-Rodriquez et al, 2009). Another pediatric fall assessment tool, the I'M SAFE tool, has been found to assist with fall risk assessment in children and evaluates risk variables of impairment, medications, sedation/anesthesia, admitting diagnosis, fall history, and environment of care (Neiman et al, 2011).* **CEBN:** *Another tool, CHAMPS looks, has been found to predict risk of falls and includes four risk factors: change in mental status, history of falls, age less than 36 months, and mobility impairment (Razmus & Davis, 2012).*
- Screen children for balance and mobility skills (i.e., supine to sit, sitting supported and unsupported, sit to stand, standing, walking and turning around, transferring, stooping to floor and recovering, and sitting down). Use tools such as the Pediatric Balance Scale (Franjoine et al, 2003) or the Performance-Oriented Mobility Assessment–Gait (POMA-G) (Phillips et al, 2018). **CEB/EB:** *It is helpful to determine the client's functional abilities and then plan for ways to improve problem areas or determine methods to ensure safety (Franjoine et al, 2003; Phillips et al, 2018).*
- Keep the path to the bathroom clear, label the bathroom, and leave the door open.

▲ Refer to physical therapy or other programs for exercise programs that target strength, balance, flexibility, or endurance. **EB:** *Balance training programs with sessions at least two times a week were found to have the greatest impact on improving balance and reducing falls in adolescents (Gebel et al, 2018).*

Home Care

- Some of the previously mentioned interventions may be adapted for home care use.
- Encourage the child to engage in exercise and activities that are appropriate for development age to strengthen balance and muscles. **EB:** *Engaging children with Down syndrome in regular exercise was found to reduce incidence of falls, improve overall balance, and reduce severity of falls (Maïano et al, 2019).*
- Assess home environment for threats to safety, including clutter, slippery floors, scatter rugs, and other potential hazards. Additionally, assess external environment (e.g., uneven pavement, unleveled stairs/steps). *Clients suffering from impaired mobility, impaired visual acuity, neurological dysfunction, and immaturity in age are all at risk for injury from common hazards.*

▲ Institute a home-based, balance performance program to improve youth core strength and balance. **EB:** *A systematic review and meta-analysis found that frequency of balance training improved youths' overall strength, endurance, balance, and health (Gebel et al, 2018).*

▲ Use a multifactorial assessment along with interventions targeted to the identified risk factors. Key components of the interventions include evaluating all medications, balance, gait and strength training, home safety evaluation with needed modifications, and any needed safety equipment. **EB:** *Reviewing in home safety should be completed as risks will vary from hospital settings. Understanding changes in the child's physical needs, including changes in treatment plans and pharmaceutical preparations, is essential to reduce fall risks at home (DiGerolamo & Davis, 2017).*

- Ensure appropriate nonglare lighting in the home. Ask the client to install indoor strip or "runway" type of lighting to baseboards to help clients balance. Install motion-sensitive lighting that turns on automatically when the client gets out of bed to go to the bathroom.
- Provide medical identification bracelet for clients at risk for injury from diabetes, seizures, or other medical disorders.

Client/Family Teaching and Discharge Planning

- Teach the client and the family about the fall reduction measures that are being used to prevent falls (CDC, 2019).
- Providing education on safety guidelines to prevent falls is an important nursing intervention that should be completed as part of discharge planning (CDC, 2019)
- Teach the child and parent how to safely ambulate at home, including using safety measures such as handrails, avoid reaching for items or performing other tasks while walking.

Dysfunctional Family Processes

Domain 7 Role relationship Class 2 Family relationships

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Family functioning which fails to support the well-being of its members.

Defining Characteristics

Behavioral

Altered academic performance; altered attention; conflict avoidance; contradictory communication pattern; controlling communication pattern; criticizing others; decreased physical contact; denies problems; difficulty accepting a wide range of feelings; difficulty accepting help; difficulty adapting to change; difficulty dealing constructively with traumatic experiences; difficulty expressing a wide range of feelings; difficulty having fun; difficulty meeting the emotional needs of members; difficulty meeting the security needs of members difficulty meeting the spiritual needs of its members; difficulty receiving help appropriately; difficulty with intimate interpersonal relations; difficulty with life-cycle transition; enabling substance misuse pattern; escalating conflict; harsh self-judgment; immaturity; inadequate communication skills; inadequate knowledge about substance misuse; inappropriate anger expression; loss of independence; lying; maladaptive grieving; manipulation; nicotine addiction; orientation favors tension relief rather than goal attainment; paradoxical communication pattern; pattern of broken promises; power struggles; psychomotor agitation; rationalization; refuses to accept personal responsibility; refuses to get help; seeks affirmation; seeks approval; self-blame; social isolation; special occasions centered on substance misuse; stress-related physical illness; substance misuse; unreliable behavior; verbal abuse of children; verbal abuse of parent; verbal abuse of partner

Feelings

Anxiety; confuses love and pity; confusion; depressive symptoms; dissatisfaction; emotionally controlled by others; expresses anger; expresses distress; expresses embarrassment; expresses fear; expresses feeling abandoned; expresses feeling of failure; expresses feeling unloved; expresses frustration; expresses insecurity; expresses lingering resentment; expresses loneliness; expresses shame; expresses tension; hopelessness; hostility; loss; loss of identity; low self-esteem; mistrust of others; moodiness; powerlessness; rejection; reports feeling different from others; reports feeling emotionally isolated; reports feeling guilty; reports feeling misunderstood; repressed emotions; taking responsibility for substance misuser's behavior; unhappiness; worthlessness

Roles and Relationships

Altered family relations; altered role function; chronic family problems; closed communication system; conflict between partners; deterioration in family relations; diminished ability of family members to relate to each other for mutual growth and maturation; disrupted family rituals; disrupted family roles; family denial; family disorganization; inadequate family cohesiveness; inadequate family respect for autonomy of its members; inadequate family respect for individuality of its members; inadequate interpersonal relations skills; inconsistent parenting; ineffective communication with partner; neglects obligation to family member; pattern of rejection; perceived inadequate parental support; triangulating family relations

Related Factors

Addictive personality; inadequate problem-solving skills; ineffective coping strategies; perceived vulnerability

At-Risk Population

Economically disadvantaged families; families with history of resistance to treatment regimen; families with member with history of substance misuse; families with members with genetic predisposition to substance misuse

Associated Conditions

Depression; developmental disabilities; intimacy dysfunction; surgical procedures

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Family Coping; Family Functioning; Family Health Status; Substance Addiction Consequences

Example NOC Outcome with Indicators

Family Coping as evidenced by the following indicators: Confronts/manages family problems/Involves family members in decision-making. (Rate the outcome and indicators of **Family Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Family/Client Will (Specify Time Frame)

- State one way that alcoholism has affected the health of the family
- Identify three healthy coping behaviors that family members can use to facilitate a shift toward improved family functioning
- Express feelings
- Meet physical, psychosocial, and spiritual needs of members
- Seek appropriate assistance
- Participate in the development of the plan of care

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Family Process Maintenance; Substance Use Treatment

Example Activities—Family Process Maintenance

Identify effects of role changes on family process; Assist family members to use existing support mechanisms

Nursing Interventions and *Rationales*

- Refer to care plans for Interrupted **Family** Process, Ineffective **Denial,** and Defensive **Coping** for additional interventions.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Assess family members for adverse childhood experiences (ACEs). **EB:** *A systematic review found a cumulative impact of ACEs with higher ACE counts being associated with higher health risks (Hughes, Hardcastle, & Bellis, 2016).*
- Acknowledge the range of emotions and feelings that may be experienced when the health status of a family member changes. **EBN:** *A study of family involvement during hospitalization found family health decreased with hospitalization (Misto, 2019).*
- Adopt a strength-oriented psychoeducational approach to assist family functioning. **EBN**: *A randomized controlled trial of a strength-oriented psychoeducational program on conventional stroke rehabilitation for family caregivers showed improvements in caregiving competence, problem-solving coping abilities, social support satisfaction, and family functioning (Cheng, Chair, & Chau, 2018).*
- Allow and encourage family members to assist in the client's treatment. **EBN:** *A convenience sample of 374 critical care nurses in the United States found that there are barriers to family caregiver involvement despite the positive outcomes for client and family (Hetland et al, 2018).*
- Support family members during emotional and conflict-type situations in the clinical setting. **EBN:** *A study found that bereaved parents identified nurses as "good" if the nurses looked out for the parents by providing emotional support, comfort, and using presence (Butler et al, 2018).*
- Screen clients for at-risk drinking during routine primary care visits and before surgery using the US Alcohol Use Disorders Identification Test (USAUDIT). **EB:** *The USAUDIT adapts the WHO AUDIT to 14-g standard drink and the US low-risk drinking guidelines. It provides greater accuracy in measuring alcohol consumption than the AUDIT-C (Higgins-Biddle & Babor, 2018).*

▲ Refer for family therapy and other family-oriented resources. **EB:** *Evidence-based interventions targeting affected family members have been shown to improve health outcomes for all family members, result in better addiction treatment outcomes, and prevent adolescent substance use (Ventura & Bagley, 2017).*

▲ Behavioral screening and intervention (BSI) should be integrated into all health care settings. Different terminology has evolved for screening, intervention, and referral for various behavioral issues. The five As—ask, advise, assess, assist, and arrange—apply to tobacco use. Screening, brief intervention, and referral to treatment (SBIRT) pertains to alcohol and drug use. **EB:** *The US Preventive Services Task Force recommends universal screening and intervention for tobacco use, excessive drinking, and depression. These services improve health outcomes, decrease health care costs, enhance public safety, and generate substantial return on investment (Babor, Del Boca, & Bray, 2017).*

Pediatric

▲ Encourage early intervention. When parental depression, childhood exposure to conflict and violence, and childhood experience with abuse and neglect coexist with parental substance abuse, their children are more likely to engage in increased teacher-rated unfavorable student behavioral problems. **EB:** *Early intervention with children of substance abusers (COSAs) is necessary to reach children while they are more receptive to treatment (Usher, McShane, & Dwyer, 2015).*

- Assess for the illness beliefs of the pediatric client as well as illness beliefs of the family. **EB:** *A systematic review of family-based interventions used for pediatric clients with functional somatic symptoms found that illness beliefs present important treatment targets (Hulgaard, Dehlholm-Lambertsen, & Rask, 2019).*
- Educate family members about available educational and support programs and encourage no/limited alcohol use in the home. **EBN:** *Both individual and multiperson interventions exert an influential role in family-based therapy for treatment of adolescent drug abuse (Gilligan et al, 2019).*
- Encourage adolescents to attend a 12-step program as needed. **EB:** *Wendt et al (2017) demonstrated that adolescents who attend 12-step groups after alcohol and other drug (AOD) treatment are more likely to remain abstinent and to avoid relapse.*
- Provide interactive school-based drug-prevention program to middle school students. **EB:** *A meta-analysis found support for the use of interactive school-based programs to prevent cannabis use among middle school students in North America (Lize et al, 2017).*

Geriatric

- Include the assessment of possible alcohol abuse when assessing older family members. **EB:** *Alcohol abuse and dependence in older people are important problems that frequently remain undetected by health services (Draper et al, 2015). The majority of older alcoholics are married, have low education levels, and do not belong to high social classes (Draper et al, 2015).*

Multicultural

- Acknowledge racial/ethnic differences at the onset of care. **EBN:** *Acknowledgment of race/ethnicity issues will enhance communication, establish rapport, and promote treatment outcomes (Giger & Davidhizar, 2016).*
- Assess lesbian, gay, bisexual, or transgender (LGBTQ) youth for factors that contribute to family rejection. **EB:** *A recent study found that poverty and family instability are often precursors to family rejection and ultimately homelessness for LGBTQ youth (Robinson, 2018).*

Home Care

Note: In the community setting, alcoholism as a cause of dysfunctional family processes must be considered in two categories: (1) when the client suffers personally from the illness, and (2) when a significant other suffers from the illness, that is, the client is not the active alcoholic but may depend on the alcoholic for caregiving. The following considerations apply to both situations with appropriate adaptation for the circumstances.

- The previous interventions may be adapted for home care use.

Client/Family Teaching and Discharge Planning

- Provide education for the family. **EB:** *An intervention treatment focused on family education about bipolar disorder and the need for the caregiver health and mental health was found to reduce both caregiver and client depression scores (Perlick et al, 2018).*
- Facilitate participation in mutual help groups (MHGs). **EB:** *Client participation in 12-step groups is associated with lower substance use and problems over time (Humphreys et al, 2020).*

Interrupted Family Processes

Domain 7 Role relationship Class 2 Family relationships

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Break in the continuity of family functioning which fails to support the well-being of its members.

Defining Characteristics

Altered affective responsiveness; altered communication pattern; altered family conflict resolution; altered family satisfaction; altered interpersonal relations; altered intimacy; altered participation in decision-making; altered participation in problem-solving; altered somatization; altered stress-reduction behavior; assigned tasks change; decreased emotional support availability; decreased mutual support; ineffective task completion; power alliance change; reports conflict with community resources; reports isolation from community resources; ritual change

Related Factors

Altered community interaction; altered family role; difficulty dealing with power shift among family members

At-Risk Population

Families with altered finances; families with altered social status; families with member experiencing developmental crisis; families with member experiencing developmental transition; families with member experiencing situational transition

Associated Conditions

Altered health status

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Family Coping; Family Functioning; Family Normalization; Psychosocial Adjustment: Life Change, Role Performance

Example NOC Outcome with Indicators

Family Coping as evidenced by the following indicators: Confronts/manages family problems/Involves family members in decision-making. (Rate the outcome and indicators of **Family Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Family/Client Will (Specify Time Frame)

- Express feelings (family)
- Identify ways to cope effectively and use appropriate support systems (family)
- Treat impaired family member as normally as possible to avoid overdependence (family)
- Meet physical, psychosocial, and spiritual needs of members or seek appropriate assistance (family)
- Demonstrate knowledge of illness or injury, treatment modalities, and prognosis (family)
- Participate in the development of the plan of care to the best of ability (significant person)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Family Integrity Promotion; Family Process Maintenance; Normalization Promotion

Example NIC Activities—Family Integrity Promotion

Collaborate with family in problem-solving and decision-making; Counsel family members on additional effective coping skills for their own use

Nursing Interventions and *Rationales*

- Recognize informal roles in medical decision-making by family members. **EBN:** *Informal roles emerge in critical situations to help fill the gaps in how family members respond to the challenge of end-of-life decision-making (Connor & Chase, 2015).*
- Acknowledge the range of emotions and feelings that may be experienced when the health status of a family member changes. **EBN:** *A study of family involvement during hospitalization found that family health decreased with hospitalization (Misto, 2017).*
- Adopt a strength-oriented psychoeducational approach to assist family functioning. **EBN:** *A randomized controlled trial of a strength-oriented psychoeducational program on conventional stroke rehabilitation for family caregivers showed improvements in caregiving competence, problem-solving coping abilities, social support satisfaction, and family functioning (Cheng, Chair, & Chau, 2018).*
- Establish relationships among clients, their families, and health care professionals. **EBN:** *A progressively engaging approach to relationships with clients and their families emphasizes trust and reciprocity, which supports joint decision-making with nurses in acute care settings (Segaric & Hall, 2015).*
- Encourage family to visit the client; adjust visiting hours to accommodate the family's schedule. **EBN:** *A 10-month quality improvement collaborative was implemented to address person- and family-centered care engagement initiatives with open visitation, integration of families on rounds, establishing a client and family advisory committee, and using client and family diaries. After the implementation, family members reported statistically significant increases in overall family satisfaction, satisfaction with decision-making, and satisfaction with quality of care (Kleinpell et al, 2019).*
- Allow and encourage family members to assist in the client's treatment. **EBN:** *A convenience sample of 374 critical care nurses in the United States found that there are barriers to family caregiver involvement despite the positive outcomes for client and family (Hetland et al, 2018).*
- Support family members during emotional and conflict-type situations in the clinical setting. **EBN:** *A study found that bereaved parents identified nurses as "good" if the nurses looked out for the parents by providing emotional support, comfort, and using presence (Butler et al, 2018).*
- Anticipate and implement family reunification efforts after a disaster. **EB:** *Family reunification after disasters should be prioritized and included in plans at all emergency response levels. A family reunification tool can be accessed at https://www.aap.org/en-us/Documents/AAP-Reunification-Toolkit.pdf (American Academy of Pediatrics, 2018).*
- Refer to the care plan Readiness for Enhanced **Family** Processes for additional interventions.

Pediatric

- Carefully assess potential for reunifying children placed in foster care with their birth parents. **EB:** *Reunifying children placed in foster care with their birth parents is a primary goal of the child welfare system (Orsi et al, 2018).*
- Assess for the influence of family socioeconomic status on family processes. **EB:** *A study found that familial socioeconomic status was a significant factor in family processes and child behavior (Hosokawa & Katsura, 2017).*
- Provide prebirth risk assessments to identify prebirth and postbirth supports for high-risk pregnant women. **EB:** *Prebirth risk assessment is a process by which circumstances affecting an unborn child can be identified and support for mother and infant embedded into care (Harnett et al, 2018).*
- Provide parents with both general information and professional support by family-centered early childhood intervention services to their families. **EB:** *Providing families with general information in addition to specialized information about their children is most important to empower parents and increase family resiliency (Frantz et al, 2018).*
- Encourage and support parents/family to assist in client's care. **EBN:** *A study found that parental involvement in their child's care can improve the child's pain experience, reduce parental anxiety, and increase parents' satisfaction in care (Vasey et al, 2019).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Assess military families for the influence of deployment on family functioning. **EB:** *A study of families with a service member concurrently deployed at the time of a child neglect incident were at higher risk for failure to provide physical needs, lack of supervision, and educational neglect (Cozza et al, 2018).*
- ▲ Refer parents and other primary caregivers to a mindfulness-based stress reduction (MBSR) program. **EB:** *A systematic review found that caregivers, children, and adults who received MBSR all reported significant gains in subjective well-being immediately after the intervention (Hartley, Dorstyn, & Due, 2019).*

Geriatric

- Encourage family members to be involved in the care of relatives who are in residential care settings. **EBN:** *Family involvement and inclusion in residential long-term care represents person-centered care (Puurveen, Baumbusch, & Gandhi, 2018).*
- ▲ Refer for Family Life Review (FLR) therapy. **EB:** *A study of older adults who participated in FLR therapy found that it facilitated positive connections, enhanced existing relationships, and promoted self-acceptance (O'Hora & Roberto, 2018).*
- ▲ Refer family for counseling with a psychotherapist who is knowledgeable about gerontology.
- Refer to care plan for Readiness for Enhanced **Family** Processes for additional interventions.

Multicultural

- Assess lesbian, gay, bisexual, transgender, and queer (LGBTQ) youth for factors that contribute to family rejection. **EB:** *A recent study found that poverty and family instability are often precursors to family rejection and ultimately homelessness for LGBTQ youth (Robinson, 2018a).*
- Refer to the care plan Readiness for Enhanced **Family** Processes for additional interventions.

Home Care

- The nursing interventions described in the care plan for Compromised Family **Coping** should be used in the home environment with adaptations as necessary.
- Encourage family members to find meaning in life with a serious illness. **EB:** *A study found that families dealing with chronic illness move through the process of healing and eventually shift the focus away from illness and toward living (Robinson, 2018b).*

Client/Family Teaching and Discharge Planning

- Refer to Client/Family Teaching and Discharge Planning in Compromised Family **Coping** and Readiness for Enhanced Family **Coping** for suggestions that may be used with minor adaptations.

Readiness for Enhanced Family Processes

Domain 7 Role relationship Class 2 Family relationships

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

A pattern of family functioning to support the well-being of members, which can be strengthened.

Defining Characteristics

Expresses desire to enhance balance between personal autonomy and family cohesiveness; expresses desire to enhance communication pattern; expresses desire to enhance energy level of family to support activities of daily living; expresses desire to enhance family adaptation to change; expresses desire to enhance family dynamics; expresses desire to enhance family psychological resilience; expresses desire to enhance growth of family members; expresses desire to enhance interdependence with community; expresses desire to enhance maintenance of boundaries between family members; expresses desire to enhance respect for family members; expresses desire to enhance safety of family members

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Family Coping; Health-Promoting Behavior; Health-Seeking Behavior; Parent-Infant Attachment; Parenting Performance

Example NOC Outcome with Indicators

Family Coping as evidenced by the following indicators: Confronts/Manages family problems/Obtains family assistance. (Rate the outcome and indicators of **Family Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Family/Client Will (Specify Time Frame)

- Identify ways to cope effectively and use appropriate support systems (family)
- Meet physical, psychosocial, and spiritual needs of members or seek appropriate assistance (family)
- Demonstrate knowledge of potential environmental, lifestyle, and genetic risks to health and use appropriate measures to decrease possibility of risk (family)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Focus on wellness, disease prevention, and maintenance (family and individual)
- Seek balance among exercise, work, leisure, rest, and nutrition (family and individual)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Decision-Making Support; Family Integrity Promotion; Family Involvement Promotion; Family Mobilization; Family Process Maintenance; Parent Education: Adolescent; Childrearing Family; Risk Identification; Role Enhancement

Example NIC Activities—Risk Identification

Determine availability and quality of resources (e.g., psychological, financial, education level, family and other social, and community)

Nursing Interventions and *Rationales*

- Assess the structure, resources, and coping abilities of families and use these assessments in selecting interventions and formulating care plans. **EBN:** *It is critical to understand the resiliency and coping capabilities of families; the use of established assessment instruments (e.g., Family Assessment Device, Family Assessment Measure) can provide insight into family dynamics, coping styles, and resources of family systems (Sawin, 2016).*
- Acknowledge, assess, and support the spiritual needs and resources of families and clients. **EB/EBN:** *Spirituality has been found to be an important, yet often overlooked, coping resource for families and clients during illness and recovery (Hodge, 2015; Prouty et al, 2016).*
- Develop, provide, and encourage family members to use counseling services and interventions. **EBN:** *Family-centered counseling interventions have been shown to be effective, particularly in situations regarding serious illness and difficult family decisions (Creasy et al, 2015).*
- Consider the use of family-centered theory as the conceptual foundation to help guide interventions. **EBN:** *Working closely with pediatric clients and their families helps the nurse to plan care with the family in mind (Cady et al, 2015).*
- Establish rapport with families and empower their decision-making through effective communication and person- and family-centered care. **EBN:** *Effective communication and person- and family-centered care approaches can help to establish rapport, personalize treatment plans, and empower families in their caregiving activities and decision-making capacities (Mitchell et al, 2016; Coombs et al, 2017).*
- Provide family members with educational and skill-building interventions to alleviate caregiving stress and to facilitate adherence to prescribed plans of care. **EBN:** *The provision of psychoeducational and supportive interventions may enable family members to gain a sense of control in the caregiving role and to become more comfortable in providing care and making informed decisions (Dockham et al, 2016).*

Pediatric

- Provide educational and supportive interventions for families caring for children with illness and disability. **EBN:** *Providing information, training parents in care management, and offering supportive programs can reduce stress levels in parents and lead to better outcomes for children (Golfenshtein, Srulovici, & Deatrick, 2016).*
- Encourage participation in virtual support groups. **EB:** *A study found that foster families viewed the virtual support group as usable and expressed satisfaction with group membership (Miller et al, 2019).*
- Encourage families with children and adolescents to have family meals. **EB:** *Research found that dinnertime rituals can potentially moderate the effects of parenting stress on child outcomes (Yoon et al, 2015).*

Geriatric

- Provide educational and therapeutic interventions to family caregivers that focus on knowledge and skill building. **EBN:** *Psychoeducational interventions that are accessible and tailored to individual needs can be highly valued and useful to family caregivers (Bakas, McCarthy, & Miller, 2017).*
- Encourage use of information and communications technologies (ICT) for social networking; social integration; and social engagement with friends, children, and relatives. **EB:** *Older adult use of ICT was*

associated with themes of connection, self-worth/esteem and personal development, productivity, occupation, self-sufficiency, being in control, and enjoyment in older adult ICT users (Hasan & Linger, 2016).

Multicultural

- Understand and incorporate cultural differences into interventions to enhance the impact of family interventions. **EB:** *Tailoring interventions to the customs, beliefs, preferences, and strengths of specific groups may increase effectiveness (McCalman et al, 2017).*
- With the client's consent, facilitate a group meeting for family members to discuss how the family is functioning. **EBN:** *Communication with the client and the family encourages discussion about the wants and needs of each individual and keeps each informed of what is occurring with the client (Kisvetrová et al, 2016).*
- Facilitate modeling and role playing for the client and family regarding healthy ways to start a discussion about the client's prognosis. **EBN:** *It is helpful to practice communication skills in a safe environment before trying them in a real-life situation (Waite & McKinney, 2016).*
- Encourage family mealtimes. **EB:** *Encouraging family mealtimes enhances the health and well-being of the family and can decrease parental stress (Yoon et al, 2015).*

Home Care

- The previous nursing interventions should be used in the home environment with adaptations as necessary.
- ▲ Encourage participation in virtual support groups to family caregivers. **EB:** *A systematic review of virtual support groups for informal caregivers of dementia found that participants identified many participation benefits (Armstrong & Alliance, 2019).*

Client/Family Teaching and Discharge Planning

- Refer to Client/Family Teaching and Discharge Planning for Readiness for Enhanced Family **Coping** for suggestions that may be used with minor adaptations.

Fatigue Domain 4 Activity/rest Class 3 Energy balance

Barbara A. Given, PhD, RN, FAAN and David M. Wikstrom, BSN, RN, CMSRN

NANDA-I

Definition

An overwhelming sustained sense of exhaustion and decreased capacity for physical and mental work at the usual level.

Defining Characteristics

Altered attention; apathy; decreased aerobic capacity; decreased gait velocity; difficulty maintaining usual physical activity; difficulty maintaining usual routines; disinterested in surroundings; drowsiness; expresses altered libido; expresses demoralization; expresses frustration; expresses lack of energy; expresses nonrelief through usual energy-recovery strategies; expresses tiredness; expresses weakness; inadequate role performance; increased physical symptoms; increased rest requirement; insufficient physical endurance; introspection; lethargy; tiredness

Related Factors

Altered sleep-wake cycle; anxiety; depressive symptoms; environmental constraints; increased mental exertion; increased physical exertion; malnutrition; nonstimulating lifestyle; pain; physical deconditioning; stressors

At-Risk Population

Individuals exposed to negative life event; individuals with demanding occupation; pregnant women; women experiencing labor

Associated Conditions

Anemia; chemotherapy; chronic disease; chronic inflammation; dementia; fibromyalgia; hypothalamus-pituitary-adrenal axis dysregulation; myasthenia gravis; neoplasms; radiotherapy; stroke

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Concentration; Endurance; Energy Conservation/Restoration; Nutritional Status; Energy; Vitality

Example NOC Outcome with Indicators

Endurance as evidenced by the following indicators: Performance of daily activities/Energy restored after rest/Blood oxygen level with activity/Muscle endurance. (Rate the outcome and indicators of **Endurance:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify potential etiology of fatigue
- Identify potential factors that precipitate, aggravate, and relieve fatigue
- Describe ways to assess and monitor patterns of fatigue over time (e.g., within a day, a few days, a week, a month)
- Describe ways in which fatigue affects the ability to accomplish activities of daily living (ADLs)
- Verbalize increased energy and improved vitality
- Explain energy conservation plan to offset fatigue
- Verbalize ability and capacity to concentrate and make decisions
- Verbalize strategies for energy restorative activities

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Energy management, including both conservation and restoration; conservation interventions are targeted at preserving an individual's energy, whereas restorative interventions are intended to reestablish vitality and energy

Example NIC Activities—Energy Management

Assess client's physiological and psychological status for deficits resulting in fatigue within the context of age, development, and stage of disease or illness. Determine client's/significant other's perception of causes of client's fatigue and factors that contribute to the relief. Assessing the pattern of reoccurrence and severity within a 24-hour period can be used to recommend usual daily activity.

Nursing Interventions and *Rationales*

- Assess severity of fatigue on a scale of 0 to 10 (average fatigue, worst and best levels); assess frequency of fatigue (number of days per week and time of day), activities and symptoms associated with increased fatigue (e.g., pain), activities that relieve, ability to perform ADLs and instrumental ADLs, interference with social and role function, times of the day for increased energy, ability to concentrate, mood, usual pattern of physical activity, and interference with sleep cycles. Consider use of an instrument such as the Profile of Mood State Short Form Fatigue Subscale (PROMIS), the Multidimensional Assessment of Fatigue, the Lee Fatigue Scale, the Fatigue Symptom Inventory, the Multidimensional Fatigue Inventory, the HIV-Related Fatigue Scale, the Brief Fatigue Inventory, Short Form Vitality Subscale, Fatigue Impact Scale, Fatigue Assessment Instrument, or Nottingham of Chronic Illness Therapy Fatigue Scale, Fatigue Severity Scale. **EBN:** *These assessments have all been shown to have good internal reliability. The Fatigue Severity Scale (9 items), Modified Fatigue Impact Scale (21 items), Brief Fatigue Inventory (9 items), and PROMIS Fatigue Scale (7 items) are short with good psychometric properties, making them clinically useful. These measures have shown the ability to detect changes in fatigue over time and the PROMIS measures appear to be the most commonly used and assess a range of symptoms from mild to overwhelming, debilitating, and sustained sense of exhaustion (Gibbons et al, 2017). PROMIS is a validated and effective survey for measuring fatigue in cancer clients (Jensen et al, 2017). Varying populations may respond differently to instruments and there are a number of scales for specific disease such as stroke, inflammatory bowel disease, rheumatoid arthritis, multiple sclerosis, Parkinson's disease, and sleep disorders (Matura et al, 2018). Poststroke clients may have severe fatigue without depression (Drummond et al, 2017).*
- Evaluate adequacy of nutrition and sleep hygiene (weight loss, anorexia, napping throughout the day, inability to fall asleep or stay asleep). Encourage the client to get adequate rest, limit naps (particularly in the late afternoon or evening), use a routine sleep/wake schedule, plan and prioritize for daily activities as tolerated, allow exposure to bright light during daytime hours, use relaxation techniques before bedtime such as meditation, music, or guided imagery (Dikmen & Terzioglu, 2019), avoid caffeine in the late afternoon or evening, and eat a well-balanced diet that includes fresh fruits, vegetables, and lean meats. Mindfulness interventions also result in improved sleep quality (Gok Metin et al, 2019). **EBN:** *Dysfunction in sleep (too much, too little, or too many interruptions) can aggravate fatigue (Silva et al, 2020).*
- Refer to **Imbalanced Nutrition: Less Than Body Requirements** or **Insomnia** if appropriate.
- Evaluate fluid status and assess for dehydration. Encourage at least eight glasses of water a day. Avoid caffeine, which can cause further dehydration. **EB:** *Dehydration may result in fatigue in acute stroke clients (Bahouth et al, 2018). Older adults and those with other medical conditions are more susceptible to dehydration, often due to symptoms such as diarrhea and vomiting or from treatments such as diuretics (Paulis et al, 2018).*

▲ Collaborate with the primary provider to identify physiological and/or psychological causes of fatigue that could be treated, such as nutritional deficit, pain, electrolyte imbalance (e.g., altered potassium levels, vitamin D deficiency), dehydration, thyroid disorders, anemia, arthritis, depression, anxiety, sleep disturbances (insomnia/sleep deprivation), acute or chronic infection, medication use or side effects, alcohol use/abuse, metabolic disorders (diabetes), or a preexisting comorbidity or disease (multiple sclerosis, cancer or cancer treatment, respiratory disease, fibromyalgia, cardiac disease, renal disease, Parkinson's

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

disease). **EB/EBN:** *Vitamin D deficiency has been linked to fatigue in older clients (Pennisi et al, 2019). Fatigue is also related to psychological distress, medication side effects, and nutritional deficit (due to change in taste or cancer affecting swallowing or the digestive tract) (Baguley et al, 2019) and from chemotherapy and radiotherapy in cancer (Kolak et al, 2017). Fatigue also negatively affects a client's quality of life (Matura et al, 2018). Tumor necrosis and recently identified proinflammatory cytokines are associated with fatigue (Kolak et al, 2017; Matura et al, 2018).*

▲ Work with the primary care or specialty provider to determine if the client has chronic fatigue syndrome. Chronic fatigue syndrome is unexplained fatigue lasting 6 months or longer that is not associated with a diagnosed physical or psychological condition but may include muscle pain, memory problems, headaches, sleep problems, joint pain, and diarrhea (Milrad et al, 2018). **EB:** *Proinflammatory cytokines may contribute to these symptoms (Montoya et al, 2017). Studies also suggest there is a genetic component to chronic fatigue syndrome (Wang et al, 2017).*

● Encourage clients to express feelings, attribution of cause, and behaviors about fatigue, including potential causes of fatigue, and interventions that they use to alleviate or moderate the fatigue. Such interventions could include setting small, easily achieved short-term goals and developing energy management and energy conservation techniques; use active listening techniques to help identify sources of hope. In addition, help them determine the time of day when they have the most energy to do important things. Assess clients' level of motivation and willingness to adopt new behaviors or change behaviors that can improve symptoms of fatigue. **EBN/EB:** *Cognitive behavioral therapy (CBT) and self-efficacy interventions have been shown to be effective in reducing fatigue (Poort et al, 2020). Education and counseling have also been shown to be effective for identifying strategies to manage fatigue (Savina & Zaydiner, 2019).*

● Encourage the client to keep a journal of activities (or record using one of the many apps available) that contribute to symptoms of fatigue, patterns of symptoms across days/weeks/months, and feelings, including how fatigue affects the client's normal daily activities and roles. Have client identify the activities that contribute the most to fatigue. **EB:** *Clients may have physical activity enhanced by self-guided nutrition and physical activity (Henson et al, 2020) using technology that results in improvement of fatigue (Kiss et al, 2019).*

● Assist the client to identify sources of support and prioritize essential and nonessential tasks to determine which tasks need to be completed and which can be delegated and to whom. Give the client permission to limit or change or remove social and role demands if needed (e.g., switch to part-time employment, simplify meal preparation, give up activities for a short period, hire cleaning service). **EBN:** *Psychoeducational mindfulness, or behavioral therapy strategies, that include fatigue education, self-care, coping techniques, and activity management have been shown to be effective in reducing cancer-related fatigue (Corbett et al, 2019). Emotional support has been linked to decreased level of physical symptoms, including fatigue, for heart failure clients (Heo et al, 2018).*

▲ Collaborate with the primary provider regarding the appropriateness of referrals to physical therapy for carefully monitored and prescribed aerobic exercise program. **EBN:** *Physical activity and exercise, particularly aerobic exercise, can reduce cancer-related fatigue (Poort et al, 2020).*

● Encourage the client to use complementary and alternative therapies such as relaxation, meditation, and mindfulness to support other strategies. **EB:** *Mindfulness–CBT has exhibited improved outcomes for those experiencing cancer-related fatigue (Corbett et al, 2019).*

▲ Refer the client to diagnosis-appropriate support groups such as the American Parkinson Disease Association, National Chronic Fatigue Syndrome Association, National Parkinson Foundation, PatientsLikeMe, National Multiple Sclerosis Society, American Heart Association, American Cancer Society, National Comprehensive Cancer Network, Chronic Myalgic Encephalomyelitis, and Chronic Fatigue Society.

▲ For an individual with cardiac disease, recognize that fatigue is common with myocardial infarction, congestive heart failure, or chronic cardiac insufficiency (Matura et al, 2018). Refer to cardiac rehabilitation for a carefully prescribed and monitored exercise and rehabilitation program.

● If fatigue is associated with cancer or cancer-related treatment, assess for other symptoms that may increase fatigue (e.g., pain, insomnia, anemia, emotional distress, electrolyte imbalance [nausea, vomiting, diarrhea], or depression). **EB:** *There is evidence to support that depressive symptoms, anxiety, distress, sleep disturbances, lower physical activity levels, pain, difficulty coping, dysfunctional cognitions, and social support are related to fatigue and should be targets for intervention (Abrahams et al, 2018).*

▲ Refer the client for CBT to improve coping and self-management of fatigue. **EB:** *Fatigue associated with rheumatoid arthritis can affect a client's quality of life and coping. CBT has been shown to be effective in improving fatigue self-management, coping, and fatigue severity. CBT involves using self-management skills such as problem-solving to improve self-efficacy while achieving, priority planning, and pacing activities (Poort et al, 2020).*

▲ Collaborate with primary provider to identify attentional fatigue, which may manifest itself as the inability to direct attention necessary to perform usual activities. Attentional fatigue is associated with sleep disturbances, depressive symptoms, anxiety, and psychosocial stressors and can lead to inability to concentrate, plan goals, control emotions, or engage in social interactions. **EBN:** *A meta-analysis reported that persons with chronic fatigue syndrome had deficits in the areas of attention, memory, and reaction time (Geraghty et al, 2019).*

▲ Collaborate with primary providers to identify potential pharmacological treatment for fatigue. **EBN:** *Pharmacological treatment to reduce inflammation has been shown to reduce fatigue (Matura et al, 2018). Pharmacological therapy has not been shown to be effective in reducing fatigue in cancer clients (Mustian et al, 2017).*

Geriatric

- Evaluate fatigue in geriatric clients routinely, particularly in clients with limited physical function and lower levels of social support. **EB:** *Chronic conditions related to age can contribute to fatigue in the geriatric client, such as cancer, dyspnea, anemia, multiple medication usage and side effects from medication, depression, insomnia, nutritional deficiencies, electrolyte imbalance, and comorbidities and cardiac disease (Matura et al, 2018; Vardar-Yagli et al, 2019). Age-related changes in food consumption and body composition influence the perception of fatigue in the geriatric population (Azzolino et al, 2020).*
- Review medications to determine possible side effects or interaction effects that could cause fatigue. **EB:** *Polypharmacy may be related to frailty in older adults (Gutiérrez-Valencia et al, 2018).*
- Review comorbid conditions that may contribute to fatigue, such as congestive heart failure, pulmonary disease, cardiac disease, multiple sclerosis, arthritis, obesity, anemia, depression, Parkinson's disease, insomnia, cancer, and viral infections (e.g., COVID-19).
- Identify recent losses, even loss of physical function; monitor for depression or loneliness as a possible contributing factor to fatigue. **EB:** *Depression is associated with fatigue in geriatric clients and has a reciprocal relationship with frailty (Soysal et al, 2017).*
- Review other symptoms the client may be experiencing. Fatigue is often associated with other symptom clusters such as depression and sleep disturbances (National Comprehensive Cancer Network, 2021a). **EB:** *Clusters may be independent of age (Agasi-Idenburg et al, 2017). Depression, fatigue, and immune activation are interrelated (Lee & Giuliani, 2019).*

▲ Review medications for side effects. *Certain medications (e.g., diuretics with associated loss of potassium, antihypertensives, antihistamines, pain medications, anticonvulsants, chemotherapeutic agents, antipsychotics, antivirals, opioids, immune modulating agents, skeletal muscle relaxants, and corticosteroids) may result in fatigue in older adults (National Comprehensive Cancer Network, 2021b).*

Home Care

The previously mentioned interventions may be adapted for home care use as well.

- Assess the client's history and current patterns of fatigue as they relate to the home environment and environmental and behavioral triggers of increased fatigue. **EB:** *Fatigue may be more pronounced in specific settings for physical, environmental (e.g., stairs required to reach bathroom, patterns of movement around home, cleaning activities that require high energy), or psychological reasons (Gay et al, 2019). Frailty and or comorbidity may be related to the fatigue for the elderly (Soysal et al, 2017).*

▲ Encourage planned exercise regimens or physical activities such as walking or light aerobic exercises. This activity can be organized in the home, mall, on a treadmill, or in a setting such as senior centers or wellness facilities. **EB:** *Continued physical activity after cancer treatment has been associated with improved functioning in both physical and social realms (Hoffman et al, 2017). After a stroke, frail elderly also responded to an individualized exercise program with increased physical endurance and self-efficacy (Drummond et al, 2017; Liu et al, 2017).*

▲ Refer to occupational and/or physical therapy if substantial intervention is needed to assist the client in adapting to home and daily patterns. **EB:** *Interventions in older adults led by occupational and physical therapists have been associated with less difficulty in ADLs and instrumental ADLs, which may lead to lower*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

levels of fatigue. Occupational and physical therapy rehabilitation has also been shown to decrease fatigue in cancer survivors (Dalzell et al, 2017). Home-based exercise in clients with stage IV lung and colorectal cancer has shown improvement in levels of fatigue (Hoffman et al, 2017).

- For clients receiving chemotherapy, intervene to:
  - ❍ Relieve symptom distress (anxiety, nausea and vomiting, diarrhea, lack of appetite, emotional distress, difficulty sleeping)
  - ❍ Encourage as much physical activity as possible with a specific recommendation (Hoffman et al, 2017)
- Teach the client and family the importance of and methods for setting priorities for activities, especially those with high energy demand (e.g., home or family events). Instruct in realistic expectations and behavioral pacing. **EBN:** *Prioritization of activities can be effective in restoring energy (Poort et al, 2020).*
  - ❍ Identify with clients ways in which they continue to be a valued part of their social environment.
  - ❍ Identify with clients ways in which they continue to maintain daily activity or social activities.
  - ❍ Encourage the client to maintain regular family routines (e.g., meals, daily activities, sleep patterns), as well as physical activity, as much as possible.

Client/Family Teaching and Discharge Planning

- Help the client to reframe cognitively; share information about fatigue, how to live with it, and how to moderate it, including need for positive self-talk. **EBN:** *Cognitive behavioral approaches to managing fatigue have been shown to have a positive effect with fatigue related to multiple sclerosis and cancer (Wendebourg et al, 2017; Poort et al, 2020).*
- Teach strategies for energy conservation that can result in improved fatigue level (e.g., sitting instead of standing during showering, limiting trips up and down stairs). **EB:** *Energy conservation strategies can decrease the amount of energy used (Blikman et al, 2017).*
- Teach the client to carry a pocket calendar, make lists of required activities, use electronic reminders, and post reminders around the house. *Apps that record steps will help clients understand their use of energy from moving around.*
- Teach the importance of following a healthy lifestyle with adequate nutrition, fluids, and rest; pain relief; insomnia correction; and appropriate exercise to decrease fatigue (i.e., energy restoration).
- Engage in outdoor relaxation and use of nature as an option to relieve fatigue.

Fear Domain 9 Coping/stress tolerance Class 2 Coping responses

Nadia Ali Muhammad Ali Charania, PhD, RN

NANDA-I

Definition

Basic, intense emotional response aroused by the detection of imminent threat, involving an immediate alarm reaction (American Psychological Association).

Defining Characteristics

Physiological Factors

Anorexia; diaphoresis; diarrhea; dyspnea; increased blood pressure; increased heart rate; increased respiratory rate; increased sweating; increased urinary frequency; muscle tension; nausea; pallor; pupil dilation; vomiting; xerostomia

Behavioral/Emotional

Apprehensiveness; concentration on the source of fear; decreased self-assurance; expresses alarm; expresses fear; expresses intense dread; expresses tension; impulsive behaviors; nervousness; psychomotor agitation

Related Factors

Communication barriers; learned response to threat; response to phobic stimulus; unfamiliar situation

At-Risk Population

Children; individuals exposed to traumatic situation; individuals living in areas with increased violence; individuals receiving terminal care; individuals separated from social support; individuals undergoing surgical procedure; individuals with family; individuals with history of falls; older adults; pregnant women; women; women experiencing childbirth

Associated Conditions

Sensation disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Fear Self-Control

Example NOC Outcome with Indicators

Fear Self-Control as evidenced by the following indicators: Eliminates precursors of fear/Seeks information to reduce fear/Plans coping strategies for fearful situations. (Rate the outcome and indicators of **Fear Self-Control:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize known fears
- State accurate information about the situation
- Identify, verbalize, and demonstrate those coping behaviors that reduce own fear
- Report and demonstrate reduced fear

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Anxiety Reduction; Coping Enhancement; Security Enhancement

Example NIC Activities—Anxiety Reduction

Use a calm, reassuring approach; Stay with the client to promote safety and reduce fear

Nursing Interventions and *Rationales*

- Assess the source of fear in the client. **EB:** *A systematic review and meta-analysis found that fear of needles is common in clients requiring preventive care and in those undergoing treatment. Identifying sources of fear can promote interventions that alleviate fear in high-risk groups* (*McLenon & Rogers, 2019*).
- Assess for presence of fear avoidance beliefs. **EB:** *A study using the Fear Avoidance Beliefs Questionnaire (FABQ) found that a high level of fear avoidance is a risk factor for long-term sickness absence among workers with musculoskeletal pain regardless of the level of occupational physical activity (Jay et al, 2018).*
- Provide counseling to enhance client's self-efficacy. **EBN:** *A midwife-led study provided a series of counseling interventions for women with a fear of childbirth. Results indicated an increase in self-efficacy and a decrease in childbirth fears after the intervention (Firouzan et al, 2020).*
- Engage clients in skills that promote and contribute to their psychological flexibility, such as acceptance and openness to one's experience; cognitive defusion, or holding one's thoughts lightly; flexible attention to the here and now; having a stable and transcendental sense of self; clarification of and living based on deeply meaningful chosen values; and committed purposeful action. **EB:** *The use of psychological flexibility skills could address the rigid and repertoire narrowing effects of coronavirus-induced anxiety and fear (Presti et al, 2020).*
- Engage clients with a fear of cancer recurrence about cognitive-behavioral therapies that include teaching skills to identify patterns of thoughts, emotions, and behaviors; skills to identify triggers of fear of cancer recurrence; reframing skills to cope with cognitive appraisals of uncontrollability to make them as less threatening; skills for problem-solving; and behavioral exposure skills to confront avoidance of cancer-related stimuli. **EB:** *A systematic review and meta-analysis of randomized controlled trials* (n = *19) pointed toward the effectiveness of mind-body interventions for reducing fear of cancer recurrence during the intervention, and after the intervention to some extent (small to medium effect sizes) (Hall et al, 2018).*
- Engage clients in a mindfulness-based training program. **EBP:** *A study found that mindfulness-based interventions enhance fear extinction and foster stress resilience (Sevinc et al, 2019).*
- Engage pregnant women with fear of childbirth in individual or group psychoeducation sessions or therapeutic conversations during pregnancy. **EB:** *A systematic review of research studies focused on interventions for relief of severe fear of childbirth in pregnancy and their underlying conceptual foundation pointed to the evidence that cognitive therapy sessions and theory-based group psychoeducation with relaxation are effective interventions (Striebich, Mattern, & Ayerle, 2018).*
- Provide antenatal education to women with fear of childbirth. **EB:** *A systematic review and meta-analysis of both quasi-randomized* (n = *2) and randomized* (n = *8) clinical trials supported that both educational-based interventions and self-hypnosis may reduce the fear of childbirth. Moreover, educational-based interventions appeared to be twice as effective as hypnosis-based interventions (Hosseinia, Nazarzadehb, & Jahanfar, 2018).*
- Provide brief psychoeducation to a client who has fear about surgery. **EBN:** *A systematic review and meta-analysis found that preoperative education can effectively decrease anxiety in clients undergoing cardiac surgery (Ramesh et al, 2017).*
- Offer psychological interventions for clients with a fear of public speaking. The psychological interventions can be delivered through traditional (face-to-face) or technology-assisted formats. **EB:** *The result of the meta-analysis of randomized control trials revealed that psychological interventions delivered using either traditional or technology-driven formats are effective in reducing fear of public speaking (Ebrahimi et al, 2019).*
- Assist clients with fear of lower back pain through a combination of strategies focused on reconceptualizing clients' knowledge about their lower back pain (e.g., "explain pain" and exposure in vivo). Strategies are targeted to assist clients to gain control over pain and responses to pain as a way to make sense of their lower back pain experience. **EB:** *The clinical commentary illustrated how Leventhal's common-sense model may assist physical therapists to understand the broader sense-making processes involved in the fear-avoidance cycle, and how they can be altered to facilitate a reduction in clients' fear by applying a combination of strategies (Bunzli et al, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Integrate psychologically informed practices for athletes who experience fear of reinjury through self-report questionnaires to quantify fear of reinjury at various key points of rehabilitation journey, education to reduce fear-avoidance beliefs, quota-based exercise, and graded exposure. **EB:** *Incorporating principles of psychologically informed practice into sports injury rehabilitation could improve rehabilitation outcomes for athletes with high fear of reinjury (Hsu et al, 2017).*

▲ Refer client for cognitive behavioral therapy (CBT). **EB:** *A systematic review and meta-analysis evaluating the effects of CBT on reducing fear of falling found that CBT appears to be effective in reducing fear of falling and improving balance among older people (Liu et al, 2018).*

- See care plan for **Anxiety.**

Pediatric

- Use distraction techniques to reduce fear of painful procedures. **EBN:** *The Buzzy device is a bee-shaped gadget producing vibrations and cooling through freezable wings. A study found a significant difference between the Buzzy intervention and control groups in terms of levels of pain and fear during intramuscular injections (Yilmaz & Alemdar, 2019).*
- Incorporate play therapy as an intervention to reduce fears during painful procedures. **EBN:** *The results of a systematic review found that the implementation of therapeutic play for hospitalized children decreases postoperative pain, improves behavior and attitude, and reduces anxiety during the hospital stay (Godino-Iáñez et al, 2020).*
- For adolescents with disordered eating behaviors, assess for a fear of food. **EB:** *Researchers found a specific, direct prospective relationship between fear of food and drive for thinness and conclude that intervening on fear of food may prevent drive for thinness (Levinson et al, 2017).*

▲ For children with cancer, refer children and families to screening for cancer-related posttraumatic stress symptoms (PTSS) and other stressors. **EB:** *Children with cancer may experience cancer-related PTSS and posttraumatic stress disorder (PTSD), which can lead to long-term impairment. Screening and referrals are necessary to enhance mental health throughout treatment and survivorship (Marusak et al, 2019).*

Geriatric

- Engage clients with a fear of falling in CBT-based multicomponent interventions, including cognitive restructuring, motivational interviewing, or goal-setting. **EB:** *A systematic review and meta-analysis of interventions used to reduce the fear of falling among community-dwelling older adults found that CBT-based multicomponent interventions appear to be effective in immediate, short-term (i.e., ≤6 months postintervention), and long-term (i.e., ≥6 months postintervention) periods. Moreover, CBT-based multicomponent interventions improve the confidence to perform activities requiring functional mobility, thus older adults with the fear of falling become more likely to engage in functional mobility–associated activities such as walking, getting up from a chair, bathing, and toileting (Chua et al, 2019).*
- Engage clients with a fear of falling in an intervention program that includes both CBT and exercise (focused primarily on balance and strength training or tai chi). **EB:** *The scoping review of the literature to identify effective evidence-based interventions for fear of falling among community-dwelling older adults found that the efficacious interventions typically were multicomponent programs including CBT and exercise (Whipple, Hamel, & Talley, 2018).*
- Provide mind-body interventions involving meditative movements (e.g., tai chi, qigong, yoga, and Pilates) for clients with fear of falling. **EB:** *Mind-body interventions encompassing meditative movements showed promising signs of improvements in psychological health including fear of falling among older adults without mental disorders (Weber et al, 2020).*
- Pair cognitive-behavioral strategies with exercises to improve physical skills and mobility to decrease fear of falling. **EBN:** *A study found that the combination of cognitive-behavioral strategies with exercises decreased fear of falling while increasing mobility and muscle strength (Huang et al, 2016).*
- Engage clients with the fear of death and dying in intervention strategies including psychotherapy, mindfulness exercises, and virtual reality. **EB:** *The review of literature on psychotherapy, mindfulness (traditional interventions), virtual reality, and use of psychedelics (innovative interventions) found that they might have a positive impact on addressing fear of death and dying, but was inconclusive in determining which out of the four is the most effective intervention strategy (Blomstroma et al, 2020).*
- See care plan for **Anxiety** or Death **Anxiety.**

Multicultural

- Assess for fears of racism in culturally diverse clients. **EB:** *The differential experience of racism can contribute to posttraumatic stress and other fear-related responses (Williams, Peña, & Mier-Chairez, 2017).*
- Assess for fear of health care providers. **EB:** *A fear of physicians was associated with the client perceptions that physicians accommodated cultural differences related to issues of personal space and time and with perceptions of physicians' provision of person-centered care (Ahmed & Bates, 2017).*
- Provide education, support, and guidance to engage clients in their care. **EB:** *Research found that fears of serious medical diagnosis, stigma, medical distrust, and racism emerged as factors inhibiting health care utilization (Connell et al, 2019).*

Home Care

- The previous interventions may be adapted for home care use.
- Refer to care plan for **Anxiety.**

Client/Family Teaching and Discharge Planning

Assess for fears related to discharge from hospital. **EBN:** *A qualitative study of parents of premature infants found that the parents experience ambivalent feelings; joy is mixed with the fear of caring for a premature child at home (Osorio Galeano, Ochoa Marín, & Semenic, 2017).*

- See care plan for **Anxiety.**

Ineffective Infant Feeding Dynamics

Domain 2 Nutrition Class 1 Ingestion

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Altered parental feeding behaviors resulting in over or under eating patterns.

Defining Characteristics

Food refusal; inadequate appetite; inappropriate transition to solid foods; overeating; undereating

Related Factors

Abusive interpersonal relations; attachment issues; disengaged parenting; intrusive parenting; lack of confidence in child to develop healthy eating habits; lack of confidence in child to grow appropriately; lack of knowledge of appropriate methods of feeding infant for each stage of development; lack of knowledge of infant's developmental stages; lack of knowledge of parent's responsibility in infant feeding; media influence on feeding infant high caloric unhealthy foods; media influence on knowledge of high caloric unhealthy foods; multiple caregivers; uninvolved parenting

At-Risk Population

Abandoned infants; infants born to economically disadvantaged families; infants experiencing homelessness; infants experiencing life transition; infants experiencing prolonged hospitalization; infants living in foster care; infants who are small for gestational age; infants with history of hospitalization in neonatal intensive care; infants with history of unsafe eating and feeding experiences; premature infants

Associated Conditions

Chromosomal disorders; cleft lip; cleft palate; congenital heart disease; inborn genetic diseases; neural tube defects; parental psychiatric disorder; physical challenge with eating; physical challenge with feeding; physical health issue of parent; prolonged enteral nutrition; psychological health issue of parent; sensory integration dysfunction

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Bottle Feeding Establishment: Infant; Bottle Feeding Performance; Breastfeeding Establishment: Infant; Breastfeeding Maintenance; Breastfeeding Weaning; Parenting Performance: Infant; Knowledge: Parenting

Example NOC Outcome with Indicators

Parenting Performance Infant as evidenced by the following indicators: Exhibits a loving relationship/Interacts with infant to promote trust/Provides age-appropriate nutrition/Provides appropriate weaning. (Rate the outcome and indicators of **Nutritional Status:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Infant will consume adequate calories to support growth and development
- Caregiver will follow healthy infant feeding practices
- Caregiver will identify infant behavioral cues related to hunger and satiety
- Caregiver and infant will engage in positive interactions during feeding

F

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Infant Care; Bottle Feeding; Teaching: Infant Nutrition

Example NIC Activities—Teaching: Infant Nutrition

Provide parents with written materials appropriate to identified knowledge needs; Instruct parent/caregiver to feed only breast milk or formula for first year (no solids before 4 months)

Nursing Interventions and *Rationales*

- Assess weight and height of the infant and use a growth chart to help determine growth pattern, which reflects nutrition. Age-related growth charts are available from www.cdc.gov/growthcharts/ (Centers for Disease Control and Prevention, 2016).
- Assess mothers for symptoms of postpartum depression. **EB:** *A study found an association between postpartum depression and poor infant nutritional status (Madeghe et al, 2016).*
- Encourage parent–child interactions that promote attachment. **EB:** *A study found that insecure attachment was significantly associated with higher body mass index (Maras et al, 2016).*
- Encourage overweight and obese mothers to follow current infant feeding guidelines. **EB:** *Research indicated that compared with normal weight mothers, overweight/obese mothers were less likely to breastfeed exclusively at infant age 2 months; they were more likely to breastfeed at low intensity during the first 2 months, and more likely to initiate early introduction of solid foods (Kitsantas et al, 2016).*
- Encourage individualized breastfeeding support as appropriate. **EB:** *A study highlights the need for individualized assistance to breastfeeding mothers, with special attention to personal experiences (Colombo et al, 2018).*
- Teach infant caregivers to recognize the following infant communication: infants signal appetite through interest or disinterest in food; infants use rapid and transient facial expressions to signal liking; and they use subtle or potent gestures, body movements, and vocalizations to express wanting. **EB:** *Research demonstrated the bidirectionality and interdependence of infant communication feeding, with more responsive feeding associated with more proficient communication by the infant (Hetherington, 2017).*
- Provide teaching and resources during pregnancy about recommended infant feeding practices. **EB:** *The results of a clinical trial testing a prenatal–postpartum individual nutrition/breastfeeding counseling program with follow-up nutrition and parenting support groups showed increased exclusive breastfeeding and reduced complementary foods and liquids in 3-month-old infants (Gross et al, 2016).*
- Provide caregivers of infants with teaching to encourage the early development of healthy eating patterns. **EB:** *Breastfed infants displayed more engagement and disengagement clues, which may make it easier to interpret the hunger/satiation cues (Wood et al, 2020).*
- Provide caregivers of infants with teaching on the importance of synchrony (offering the infant food and their willingness to eat) during the infant feeding time. **EB:** *A longitudinal study found that synchrony during feeding was related to the infant's willingness to eat (Costantini et al, 2018).*
- Encourage caregiver co-eating during infant feeding times. **EB:** *A longitudinal study found that co-eating during infant feeding was positively related to the infant's willingness to eat (Costantini et al, 2018).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Provide caregivers of infants with teaching about the strong association between sugar-sweetened beverages, obesity, and related chronic diseases. **EB:** *A systematic review suggests that consumption of sugar-sweetened beverages is positively associated with or has an effect on obesity indices in children (Luger et al, 2017).*
- Assist mothers to identify infant engagement and disengagement cues during breastfeeding or formula feeding. **EB:** *A study found that breastfeeding and formula-fed infants exhibited engagement and disengagement during feeding. Supporting a mother's ability to identify engagement and disengagement cues may promote more responsive feeding strategies (Shloim et al, 2017).*
- Provide mothers with unconditional positive regard in their choice of breast, formula, or mixed feeding of their infant. **EB:** *A study of breastfeeding women found that women experienced feelings of pressure and judgment around their infant feeding decisions (Hunt & Thomson, 2017).*

Multicultural

- Assess for cultural beliefs, values, and practices related to the feeding of infants. **EB:** *In a systematic review, familial and cultural influences provided the basis of many infant feeding decisions (Harrison, Brodribb, & Hepworth, 2017).*
- Identify the support persons of the infant caregiver and extend healthy infant feeding education and information to those support persons. **EB:** *A study of first-time African American mothers and breastfeeding indicated that over half of the mothers intended to exclusively breastfeed but were unable to because of life stressors and experiences. An informed support person could promote healthy infant feeding practices (Asiodu et al, 2017).*

Home Care

- The interventions previously described may be adapted for home care use.

Client/Family Teaching and Discharge Planning

- Many of the interventions previously described involve teaching.

Risk for Female Genital Mutilation

Domain 11 Safety/protection Class 3 Violence

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to full or partial ablation of the female external genitalia and other lesions of the genitalia, whether for cultural, religious or any other non-therapeutic reasons, which may compromise health.

Risk Factors

Lack of family knowledge about impact of practice on physical health; lack of family knowledge about impact of practice on psychosocial health; lack of family knowledge about impact of practice on reproductive health

At-Risk Population

Women belonging to ethnic group in which practice is accepted; women belonging to family in which any female member has been subjected to practice; women from families with favorable attitude towards practice; women planning to visit family's country of origin in which practice is accepted; women residing in country where practice is accepted; women whose family leaders belong to ethnic group in which practice is accepted

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Cessation; Abuse Protection; Abuse Recovery; Abuse Recovery: Emotional; Abuse Recovery: Physical

Example NOC Outcome with Indicators

Abuse Protection as evidenced by the following indicators: Plan for avoiding abuse/Implementation of plan to avoid abuse/Safety of self/Safety of child/Self-advocacy. (Rate the outcome and indicators of **Abuse Protection:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client/Family Outcomes

Client Will (Specify Time Frame)

- Express effects of family/culture on beliefs about female genital mutilation (FGM)
- Demonstrate evidence that FGM has not occurred
- Express/implement a plan for avoiding FGM
- Maintain safety of female children
- Demonstrate the ability to make decisions independent of cultural group
- Demonstrate self-advocacy skills

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Abuse Protection Support; Abuse Protection Support: Child; Abuse Protection Support: Religious

Example NIC Activities—Abuse Protection Support: Child

Identify parents who demonstrate an increased need for parent education; Determine whether a child demonstrates signs of physical abuse; Report suspected abuse or neglect to proper authorities; Refer families to human services and counseling professionals as needed

Nursing Interventions and *Rationales*

- Use therapeutic and culturally competent communication when asking women about FGM. **EBN:** *Asking about FGM with compassionate communication was a theme that emerged from the qualitative data of women living with FGM (Ormrod, 2019).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Identify the decision-making process related to the practice of FGM. **EB:** *The decision to undergo FGM is often a community decision and not an individual or family decision. Some survivors of FGM report that relatives or other community members performed FGM on them without their consent or the consent of their parents (Burrage, 2016).*
- Identify the type of FGM for which the female client is at risk. **EB:** *The World Health Organization (WHO) classifies types of FGM as follows.* ***Type 1:*** *Clitoridectomy, which is partial or total removal of the clitoris (a small sensitive and erectile part of the female genitals) and, in rare cases, removal of the prepuce only (the fold of skin surrounding the clitoris).* ***Type 2:*** *Excision, which is partial or total removal of the clitoris and labia minora with or without removal of the labia majora (the labia are "the lips" that surround the vagina).* ***Type 3:*** *Infibulation, which is narrowing of the vaginal opening through the creation of a covering seal. The seal is formed by cutting and repositioning the labia minora or majora with or without removal of the clitoris.* ***Type 4:*** *Other, which includes all other harmful procedures to the genitals for nonmedical reasons, for example, pricking, piercing, incision, scraping, and cauterizing the genital area (WHO, 2016). WHO's best practice standards indicated that nurses and health care providers are knowledgeable and aware of the types of FGM (WHO, 2016).*
- Assess and identify geographic, environmental, familial, religious, and/or other cultural factors that increase risk for FGM. **EB:** *Research indicated that the following are risk factors identified with FGM: older mothers, rural mothers, less educated mothers, maternal fears of social stigma, and mothers who have had FGM (Pashaei et al, 2016). FGM is most common in 30 countries of the western, eastern, and northeastern regions of Africa, in some countries in Asia and the Middle East, and among migrants from these areas. Countries with the highest rates of FGM are Egypt, Ethiopia, and Somalia (WHO, 2016).*
- Encourage the mothers of at-risk daughters to express their beliefs and attitudes toward FGM. **EB:** *Nurses and health care providers have to first understand the beliefs and attitudes toward FGM before implementing interventions to address the beliefs and attitudes. Among the beliefs for FGM are female cleanliness, beauty, safeguarding virginity, and as a rite of passage to adult womanhood (Pashaei et al, 2016).*
- Assess the mothers of at-risk daughters for positive affect (expression of feelings) and attitudes toward FGM. **EB:** *A recent Iranian study concluded that mothers' attitudes were the strongest predictor of their intention to allow their daughters to undergo FGM, suggesting that mothers with a more favorable attitude toward FGM are more likely to show the intention of mutilating their daughters (Pashaei et al, 2016).*
- In a respectful and nonjudgmental manner, provide men, fathers, and male partners with health education to address beliefs about FGM and provide information about the negative health outcomes associated with FGM. **EB:** *A study of anti-FGM advocates identified encouraging fathers' involvement in the upbringing of their daughters as an action to fight FGM (Mwenda et al, 2020).*
- In a respectful and nonjudgmental manner, convey accurate and clear information about FGM, using language and methods that can be readily understood by clients. **EB:** *Best practices indicated that individuals have the right to be fully informed by appropriately trained personnel with the assistance of an interpreter, if necessary (WHO, 2016).*
- In a respectful and nonjudgmental manner, provide the client, the client's parents, and the client's family with information that FGM is not a universal practice and that it is an illegal practice in many parts of the world. **EB:** *Women from countries that practice FGM may have inadequate knowledge of their bodies and biological facts and be shocked or angry to learn that FGM is not a universal practice and is illegal in the United States (Costello, 2015).*
- In a respectful and nonjudgmental manner, provide the client, the client's parents, and the client's family with health education to address false beliefs about female and clitoral anatomy and the physiology of women. **EB:** *Women from countries that practice FGM may have inadequate knowledge of their bodies and biological facts. Health education needs to convey that there are no known health benefits from FGM, and that women and children who experience FGM have lifelong health complications (WHO, 2016).*
- In a respectful and nonjudgmental manner, provide the client, the client's parents, and the client's family with health education to inform about the negative health outcomes associated with FMG. **EB:** *The negative health outcomes are both immediate and long-term. Immediate complications include bleeding, urinary retention, wound infection, sepsis, and death. Long-term complications include dysmenorrhea, dyspareunia, recurrent vaginal and urinary tract infections, infertility, difficult labor and delivery, and sexual dysfunction (Craven et al, 2016).*
- In a respectful and nonjudgmental manner, address false ideas or beliefs about FGM. **EB:** *A qualitative study found that FGM myths related to health, hygiene, religion, and the sexuality of women are used as justification by men and women in order to uphold the practice of FGM (Jiménez Ruiz, Almansa Martínez, & Alcón Belchí, 2017).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

- In a respectful and nonjudgmental manner, provide the client, the client's parents, and the client's family with health education to inform about the negative birth outcomes associated with mothers who have had FMG. **EB:** *A study found that mothers with FGM experienced the following obstetric complications: increased risk of neonatal resuscitation, low birth rate, stillbirth, and early neonatal death (Reisel & Creighton, 2015).*
- In a respectful and nonjudgmental manner, provide the client, the client's parents, and the client's family with health education to inform about the negative mental health outcomes associated with FGM. **EB:** *A cross-sectional study of female Somali refugees found that FGM was strongly associated with posttraumatic stress disorder, as well as depressive, anxiety, and somatic symptoms (Im et al, 2020).*
- Use therapeutic and culturally competent communication to focus on the current and future safety of the female child at risk for FGM. **EB:** *Therapeutic and culturally competent communication will acknowledge cultural practices without blame or judgment and will leverage parental love and concern to prevent harm to the child (Costello, 2015).*
- Use a cultural mediator to interpret cross-cultural norms about FGM. **EB:** *Cultural mediators are community leaders who are respected and known in their community for their opposition to FGM (Costello, 2015).*
- In a respectful and nonjudgmental manner, provide fathers with health education to address beliefs about FGM and provide information about the negative health outcomes associated with FGM. **EB:** *A systematic review found that the level of education of men was one of the most important indicators for men's support for the abandonment of FGM practices (Varol et al, 2015).*

▲ Refer families to counseling services. **EB:** *Family counseling will ensure that the family understands the reasons for the health care interventions and legislative/legal response and facilitate support of each other through the transition (Costello, 2015).*

- See care plans for **Post-Trauma** Syndrome, Impaired **Parenting,** and **Social** Isolation.

Pediatric

- Identify a system for assessment and referral of female infants at risk of FGM born to mothers who have undergone FGM. **EB:** *A British study assessed the effectiveness of a questionnaire to examine the level of risk of FGM if a girl is born to a mother who has undergone FGM. Study results indicated that the questionnaire formalized the referral process; identified infants at high risk; and helped to stratify risk into low, medium, and high. The questionnaire also indicated the demographics of those at highest risk (Flower et al, 2015).*
- For female children who may be survivors of FGM, or are at risk of FGM, notify Child Protective Services and other law enforcement authorities. **EB:** *FGM is child abuse. Nurses are mandated reporters and are legally obligated to report all instances of suspected child abuse and neglect. Notification of Child Protective Services and law enforcement allows appropriate health care intervention and may provide protection for siblings and other girls in the family against FGM (Creighton et al, 2016). All individuals have the right to the highest attainable standard of health and the right to life and physical integrity, including freedom from violence and the right to freedom from torture or cruel, inhumane, or degrading treatment (WHO, 2016).*
- Implement a school-based intervention to provide FGM health education to adolescent females. **EB:** *A study found that school-based health education had a positive impact on both the knowledge and attitude of female students toward FGM in Sudan (Mahgoub et al, 2019).*

Risk for Imbalanced Fluid Volume

Domain 2 Nutrition Class 5 Hydration

Dina Hewett, PhD, RN, NEA-BC

NANDA-I

Definition

Susceptible to a decrease, increase, or rapid shift from one to the other of intravascular, interstitial, and/or intracellular fluid, which may compromise health.

Risk Factors

Altered fluid intake; difficulty accessing water; excessive sodium intake; inadequate knowledge about fluid needs; ineffective medication self-management; insufficient muscle mass; malnutrition

At-Risk Population

Individuals at extremes of weight; individuals with external conditions affecting fluid needs; individuals with internal conditions affecting fluid needs; women

Associated Conditions

Active fluid volume loss; deviations affecting fluid absorption; deviations affecting fluid elimination; deviations affecting fluid intake; deviations affecting vascular permeability; excessive fluid loss through normal route; fluid loss through abnormal route; pharmaceutical preparations; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Fluid Balance; Electrolyte and Acid-Base Balance; Hydration

Example NOC Outcome with Indicators

Fluid Balance as evidenced by the following indicators: Blood pressure/Peripheral pulses palpable/Skin turgor/Moist mucous membranes/Serum electrolytes/Hematocrit/Body weight stable/24-hour intake and output balanced/Urine specific gravity. (Rate each indicator of **Fluid Balance:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Lung sounds clear, respiratory rate 12 to 20 and free of dyspnea
- Urine output greater than 0.5 mL/kg/hr
- Blood pressure, pulse rate, temperature, and oxygen saturation within expected range

- Laboratory values within expected range, that is, normal serum sodium, hematocrit, and osmolarity
- Extremities and dependent areas free of edema
- Mental orientation appropriate based on previous condition

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Autotransfusion; Bleeding Precautions; Bleeding Reduction: Wound; Electrolyte Management; Fluid Management; Fluid Monitoring; Hemodynamic Regulation; Hypervolemia Management; Hypovolemia Management; Intravenous Therapy; Invasive Hemodynamic Monitoring; Shock Management: Volume; Vital Signs Monitoring

Example NIC Activities—Fluid Management

Maintain accurate intake and output record; Monitor vital signs

Nursing Interventions and *Rationales*

Surgical Clients

- Monitor the fluid balance. If there are symptoms of hypovolemia, refer to the interventions in the care plan for Deficient **Fluid** Volume. If there are symptoms of hypervolemia, refer to the interventions in the care plan for Excess **Fluid** Volume.

Preoperative

- Collect a thorough history and perform a preoperative assessment to identify clients with increased risk for hemorrhage or hypovolemia, that is, clients who take herbal supplements; those with recent traumatic injury, abnormal bleeding or altered clotting times, complicated kidney or liver disease, diabetes, cardiovascular disease, major organ transplant, history of aspirin and/or nonsteroidal antiinflammatory drug (NSAID) use, or anticoagulant therapy; or history of hemophilia, von Willebrand's disease, or disseminated intravascular coagulation. Assess the client's use of over-the-counter agents, including herbal products. **EB:** *Use of dietary herbal supplements (DHSs) causes the potential for DHS–drug interactions, which may lead to serious adverse events. Although drug-induced adverse events are thought to be responsible for up to 12% of hospitalizations, drug–drug interactions are estimated to be the direct cause of up to 2.8% of hospital admissions. Descriptions of adverse DHS–drug interactions in the surgical setting are found mostly in case reports and animal studies. These interactions mainly affected bleeding tendencies and level of sedation (Levy et al, 2017).*
- Recognize that nothing per mouth (NPO) at midnight may or may not be appropriate for each surgical client. Guidelines from the American Society of Anesthesiologists Committee (2011) recommended that healthy clients having elective surgery should be allowed to have clear liquids up to 2 hours before surgery. **EB:** *Current evidence has shown the value of allowing healthy clients to consume clear liquids up to 2 hours before surgery, but the practice is not consistent (Powers, 2017).* **EB:** *Many clients are unnecessarily dehydrated from lack of fluid for an extended period, which can complicate postoperative recovery. It is important to provide clear communication to the client that only clear liquids and/or carbohydrate-rich drinks can be safely consumed up to 2 hours before surgery (Myles et al, 2017).*
- Determine length of time the client has been without normal intake, been NPO, or experienced fluid loss (e.g., vomiting, diarrhea, bleeding)**.** **EB:** *The length of time and severity of these factors, along with the presence of a fluid deficit, allow the health care provider to determine a general estimate of preoperative fluid loss, which can affect intraoperative fluid management. However, laboratory testing of hemoglobin, hematocrit, blood urea nitrogen (BUN), and creatinine should be used to corroborate the assessment (Kear, 2017).*
- Assess and document the client's mental status. A baseline assessment is important so that changes in mental status during the postoperative period can be easily identified.
- Recognize that there is conflicting evidence regarding liberal intraoperative fluid management versus restrictive fluid management. Fluid administration during surgery is more restrictive to prevent pulmonary complications associated with excessive fluid administration (Myles et al, 2017). **CEB:** *Hypovolemia and hypervolemia decrease tissue perfusion and may result in organ failure. Measurements to assess volume status include measuring mean arterial pressure (MAP), central venous pressure (CVP), and observing urine output. However, CVP shows a poor correlation to blood volume, is inadequate to detect hypovolemia*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

reliably, and most notably cannot sense a decreased cardiac output (CO) and tissue oxygen debt in an early state. Furthermore, changes in CVP after volume administration do not allow any conclusions to changes in stroke volume (SV) or CO. Other signs such as hypotension and tachycardia may be more reliable indicators of volume assessment (Strunden et al, 2011). Urine output is a measure of glomerular filtration and can be an effective indicator of fluid status (Macedo et al, 2011; Strunden et al, 2011).

- To reduce fluid administration volume, colloids rather than crystalloid fluids may be administered during surgery (Myles et al, 2017).
- Recognize that an individualized fluid management plan would be developed incorporating client-specific assessment parameters (e.g., existing comorbid diseases, age) and type of surgical procedure (Myles et al, 2017; Lindahl, 2020). **EB:** *Perioperative hemodynamic and fluid management that is goal directed improved both short- and long-term outcomes and can be achieved easily (Lindahl, 2020).*
- Recognize the effects of general anesthetics, inhalational agents, and regional anesthesia on perfusion in the body and the potential for decreasing the blood pressure. **EB:** *In humans undergoing general anesthesia there is almost no relationship between mean arterial blood pressure and delivery of oxygen (DO_2), presumably because of widely varying systemic vascular resistance. Control of blood pressure requires measurement, an algorithm of action, and an intervention, such as medications or fluid administration (Bartels, Esper, & Thiele, 2016).*
- Monitor for signs of intraoperative hypovolemia such as dry skin, dry mucous membranes, tachycardia, decreased urinary output, decreased CVP, hypotension, increased pulse, and/or deep rapid respirations.
- Monitor for signs of intraoperative hypervolemia such as dyspnea, coarse crackles, increased pulse and respirations, decreased oxygenation, and decreased urinary output, all of which could progress to pulmonary edema.
- In the critically ill surgical client a pulmonary artery catheter or other minimally invasive CO monitoring device may be used to determine fluid balance and guide fluid and vasoactive intravenous (IV) drip administration. **EB:** *Devices that directly (pulmonary artery catheter or arterial line) or indirectly (minimally or noninvasive such as ongoing blood pressure monitoring) assess the client's cardiac status and fluid volume status may be used to "optimize" cardiac function by allowing better fluid regimens. Fluids must be individually titrated based on each client's changes in monitored variables (Bartels, Esper, & Thiele, 2016).*
- Monitor the client for hyponatremia with symptoms such as headache, anorexia, nausea and vomiting, diarrhea, tachycardia, general malaise, muscle cramps, weakness, lethargy, change in mental status, disorientation, seizures, and death. **EB:** *Many pathologies can predispose the client to hyponatremia, including adrenal insufficiency, brain tumor, cirrhosis, hypothyroidism, lung cancer, meningitis, renal disease, tuberculosis, use of complementary therapies, and head trauma (Icin et al, 2017).*
- Monitor clients undergoing laparoscopic or hysteroscopic procedures for the development of hyponatremia, hypervolemia, and pulmonary edema when an irrigation fluid is used. **EB:** *Use of local or spinal anesthesia for these operations can cause the client to develop symptoms of hyponatremia and hypervolemia sooner than with other anesthetics (Lindahl, 2020).*
- Monitor clients undergoing transurethral resection of the prostate (TURP) procedures for development of hyponatremia and hypervolemia with symptoms of TURP syndrome including headache, visual changes, agitation, lethargy, vomiting, muscle twitching, bradycardia, diminished pupillary reflexes, hypertension, and respiratory distress. **EB:** *Considerable fluid absorption occurs during TURP procedures and gynecological procedures, which can result in hyponatremia and/or hypervolemia (Pasha et al, 2015).*
- Measure the irrigation fluid used during urological and gynecological procedures accurately for volume deficit such as amount of irrigation used minus amount of irrigation recovered via suction. **EB:** *Absorption of large amounts of fluid can cause complications for the client (Lindahl, 2020).*
- Monitor intraoperative intake and output including blood loss, urine output, and third-space losses to provide an estimate of fluid volume. **CEB:** *Weighing used sponges can provide an estimate of blood loss (Blanchard & Burlingame, 2012).* **EB:** *Weighing fluid used and returned provides a more accurate measurement of fluid deficit than measuring the fluids (Silva et al, 2013). The use of balanced electrolyte IV solutions has been shown to be safer than the use of isotonic saline alone (Myles et al, 2017).*
- Observe the surgical client for hyperkalemia with symptoms including dysrhythmias, heart block, asystole, abdominal distention, and weakness. **EB:** *Hyperkalemia can occur intraoperatively because of massive blood transfusions, tissue breakdown from surgery, shifting of potassium from the cells into the extracellular fluid, decreased potassium excretion caused by renal failure or hypovolemia, crush injuries, or burns (Drury & Denker, 2020).*
