Situational Low Self-Esteem

Domain 6 Self-perception Class 2 Self-esteem

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

S

Definition

Change from positive to negative perception of self-worth, self-acceptance, self-respect, competence, and attitude toward self in response to a current situation.

Defining Characteristics

Depressive symptoms; expresses loneliness; helplessness; indecisive behavior; insomnia; loneliness; nonassertive behavior; purposelessness; rumination; self-negating verbalizations; underestimates ability to deal with situation

Related Factors

Behavior incongruent with values; decrease in environmental control; decreased mindful acceptance; difficulty accepting alteration in social role; difficulty managing finances; disturbed body image; fatigue; fear of rejection; impaired religiosity inadequate attachment behavior; inadequate family cohesiveness; inadequate respect from others; inadequate social support; ineffective communication skills; low self efficacy; maladaptive perfectionism; negative resignation; powerlessness; stigmatization; stressors; unrealistic self-expectations; values incongruent with cultural norms

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

At-Risk Population

Individuals experiencing a change in living environment; individuals experiencing alteration in body image; individuals experiencing alteration in economic status; individuals experiencing alteration in role function; individuals experiencing death of a significant other; individuals experiencing divorce; individuals experiencing new additions to the family; individuals experiencing repeated failure; individuals experiencing unplanned pregnancy; individuals with difficult developmental transition; individuals with history of being abandoned; individuals with history of being abused; individuals with history of being neglected; individuals with history of loss; individuals with history of rejection

Associated Conditions

Depression; functional impairment; mental disorders; physical illness

NOC (Nursing Outcomes Classification)

Refer to Chronic Low **Self-Esteem** for suggested NOC outcomes.

Client Outcomes

Client Will (Specify Time Frame)

- State effect of life events on feelings about self
- State personal strengths
- Acknowledge presence of guilt and not blame self if an action was related to another person's appraisal
- Seek help when necessary
- Demonstrate self-perceptions are accurate given physical capabilities
- Demonstrate separation of self-perceptions from societal stigmas

NIC (Nursing Interventions Classification)

Refer to Chronic Low **Self-Esteem** for suggested NIC interventions.

Nursing Interventions and *Rationales*

▲ Assess the client for signs and symptoms of depression and potential for suicide and/or violence. If present, immediately notify the appropriate personnel of symptoms. **EB:** *Research supported the vulnerability model of low self-esteem and depression with findings that indicated that individuals with high self-esteem have a lower risk for developing depression (Orth et al, 2016).* See care plans for Risk for Other-Directed **Violence** and Risk for **Suicidal Behavior.**

- Assess the client's environmental and everyday stressors, including evidence of abusive relationships. **EB:** *Research showed that dysfunctional forms of self-esteem were significantly associated with the number of negative events reported and an increased risk of developing stress-related symptoms (Alessandri et al, 2017).*
- Assess the client's self-esteem using valid and established tools such as the Rosenberg Self-Esteem Scale. **CEB:** *The use of valid and established measures of self-esteem will facilitate the identification of appropriate nursing interventions that strengthen self-esteem (Rosenberg, 1965).*
- Encourage expressions of gratitude through a gratitude journal or kind acts. **EB:** *Research shows that gratitude is significantly and positively associated with several domains of life satisfaction and overall life satisfaction in both the United States and Japan (Robustelli & Whisman, 2018).*
- Use a cognitive approach such as problem-solving education (PSE) to assist in the identification of problems and situational factors that contribute to problems and offer options for resolution. **EB:** *A study found that supplementing drug abuse treatment with PSE reduced relapse rates and enhanced self-efficacy and self-esteem among clients (Habibi et al, 2016).*
- Mutually identify strengths, resources, and previously effective coping strategies. **EB:** *A study showed that a behavioral intervention focusing on the individual's strengths showed a reduction of psychological distress and improvement of self-esteem, optimism, and quality of life compared with the control group (Victor, Teismann, & Willutzki, 2017).*
- Encourage self-affirmations by reflecting on values and strengths, in response to daily threats. **EB:** *A study found that engaging in spontaneous self-affirmation was related to greater happiness, hopefulness, optimism, subjective health, personal health efficacy, and less anger and sadness (Emanuel et al, 2018).*
- Accept client's own pace in working through grief or crisis situations. **EB:** *Rigid adherence to stage or timeline models of grief models is too simplistic and limited; they fail to represent the complex emotions and processes of grief and grieving (Stroebe et al, 2017).*

- Encourage the client to accept their own defenses, feelings, and urges in dealing with the crisis. **EB:** *Acceptance and commitment therapy (ACT) is an intervention that enhances well-being and reduces distress (Wersebe et al, 2018).*
- Teach the client mindfulness techniques to cope more effectively with strong emotional responses. **EB:** *A study found that mindfulness was significantly and positively related to high self-esteem (Park & Dhandra, 2017).*
- Encourage objective appraisal of self and life events and challenge negative or perfectionist expectations of self. **EB:** *Self-critical perfectionism has been reliably associated with poor goal progress (Moore et al, 2018).*
- Acknowledge the presence of societal stigma. Teach management tools. **EBN:** *Stigma toward mental illness affects both self-esteem and recovery and treatment adherence (Vass et al, 2017).*
- Validate the effect of negative past experiences on self-esteem and work on corrective measures. **EB:** *Negative life events influence current self-esteem (Tetzner et al, 2016).*

Pediatric, Geriatric, and Multicultural

- See care plan for Chronic Low **Self-Esteem.**

Home Care

- Establish an emergency plan and contract with the client for its use. Having an emergency plan is reassuring to the client. Establishing a contract validates the worth of the client and provides a caring link between the client and society.
- Access supplies that support a client's success at independent living.
- See care plan for Chronic Low **Self-Esteem.**

Client/Family Teaching and Discharge Planning

- Previously discussed interventions may be used in the home care setting.
- ▲ Refer to appropriate community resources or crisis intervention centers.
- ▲ Refer to resources for handicap and/or disability services.
- See care plan for Chronic Low **Self-Esteem.**

Risk for Chronic Low Self-Esteem

Domain 6 Self-perception Class 2 Self-esteem

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to long-standing negative perception of self-worth, self-acceptance, self-respect, competence, and attitude toward self, which may compromise health.

Risk Factors

Decreased mindful acceptance; difficulty managing finances; disturbed body image; fatigue; fear of rejection; impaired religiosity; inadequate affection received; inadequate attachment behavior; inadequate family cohesiveness; inadequate group membership; inadequate respect from others; inadequate sense of belonging; inadequate social support; ineffective communication skills; insufficient approval from others; low self efficacy; maladaptive grieving; negative resignation; repeated negative reinforcement; spiritual incongruence; stigmatization; stressors; values incongruent with cultural norms

At-Risk Population

Economically disadvantaged individuals; individuals experiencing repeated failure; individuals exposed to traumatic situation; individuals with difficult developmental transition; individuals with history of being abandoned; individuals with history of being abused; individuals with history of being neglected; individuals with history of loss

Associated Conditions

Depression; functional impairment; mental disorders; physical illness

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* and References

Refer to care plan for Chronic Low **Self-Esteem.**

Risk for Situational Low Self-Esteem

Domain 6 Self-perception Class 2 Self-esteem

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to change from positive to negative perception of self-worth, self-acceptance, self-respect, competence, and attitude toward self in response to a current situation, which may compromise health.

Risk Factors

Behavior incongruent with values; decrease in environmental control; decreased mindful acceptance; difficulty accepting alteration in social role; difficulty managing finances; disturbed body image; fatigue; fear of rejection; impaired religiosity; inadequate attachment behavior; inadequate family cohesiveness; inadequate respect from others; inadequate social support; individuals experiencing repeated failure; ineffective communication skills; low self efficacy; maladaptive perfectionism; negative resignation; powerlessness; stigmatization; stressors; unrealistic self-expectations; values incongruent with cultural norms

At-Risk Population

Individuals experiencing a change in living environment; individuals experiencing alteration in body image; individuals experiencing alteration in economic status; individuals experiencing alteration in role function; individuals experiencing death of a significant other; individuals experiencing divorce; individuals experiencing new additions to the family; individuals experiencing unplanned pregnancy; individuals with

difficult developmental transition; individuals with history of being abandoned; individuals with history of being abused; individuals with history of being neglected; individuals with history of loss; individuals with history of rejection

Associated Conditions

Depression; functional impairment; mental disorders; physical illness

NOC (Nursing Outcomes Classification)

See Chronic Low **Self-Esteem** for suggested NOC outcomes

Client Outcomes

Client Will (Specify Time Frame)

- State accurate self-appraisal
- Demonstrate the ability to self-validate
- Demonstrate the ability to make decisions independent of primary peer group
- Express effects of media on self-appraisal
- Express influence of substances on self-esteem
- Identify strengths and healthy coping skills
- State life events and change as influencing self-esteem

NIC (Nursing Interventions Classification)

See Chronic Low **Self-Esteem** for suggested NIC interventions

Nursing Interventions and *Rationales*

- Assist client to challenge negative perceptions of self and performance. **EB:** *A study found that more often than not, self-critical thoughts were viewed as facts and would rarely be seen as distorted or biased (Kolubinski et al, 2016).*
- Assess the client's self-esteem using valid and established tools such as the Rosenberg Self-Esteem Scale. **CEB:** *The use of valid and established measures of self-esteem will facilitate the identification of appropriate nursing interventions that strengthen self-esteem (Rosenberg, 1965).*
- Encourage client to maintain highest level of community functioning. **EB:** *Research found that the community feeling is positively connected with self-esteem and psychological well-being (Kałużna-Wielobób, 2017).*
- Encourage self-affirmations by reflecting on values and strengths, in response to daily threats. **EB:** *A study found that engaging in spontaneous self-affirmation was related to greater happiness, hopefulness, optimism, subjective health, and personal health efficacy and less anger and sadness (Emanuel et al, 2018).*
- Encourage realistic and achievable goal setting and resources and identify impediments to achievement. **EB:** *A combined decision support and goal-setting intervention improved diet quality, diabetes-related self-efficacy, and empowerment and reduced diabetes-related distress and depressive symptoms (Swoboda et al, 2017).*
- ▲ Assess the client for symptoms of depression and anxiety. Refer to specialist as needed. Prompt and effective treatment can prevent exacerbation of symptoms or safety risks. **EB:** *Research supported the vulnerability model of low self-esteem and depression with findings that indicated that individuals with high self-esteem have a lower risk for developing depression (Orth et al, 2016).*
- See care plans for Disturbed personal Identity, Situational Low **Self-Esteem,** and Chronic Low **Self-Esteem.**

Pediatric

- Assess children/adolescents who are either a victim or an offender of cyberbullying for low self-esteem. **EB:** *A moderate and statistically significant relationship exists between low self-esteem and experiences with cyberbullying (Lin et al, 2018).*
- Encourage attendance at social support groups. **EB:** *A study found that lesbian, gay, bisexual, transgender, and queer (LGBTQ) youth who attended a Hatch group-level intervention that consisted of unstructured social time, consciousness-raising (education), and a youth-led peer support group had higher levels of self-esteem (Wilkerson et al, 2017).*
- ▲ Encourage a combination of extracurricular activity for adolescents in a safe, supportive, and empowering environment. **EB:** *Research suggested that enabling relations within the family, school, peer, and community are factors related to youth self-satisfaction (Simon, 2020).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Geriatric

- Support humor as a coping mechanism. **EB:** *This paper identified that humor has a positive effect on all of these issues with an increasing sense of well-being and life satisfaction for the elder (Lurie & Monahan, 2015).*
- Support client in identifying and adapting to functional changes. **EBN:** *A study outlined the importance of enquiring about feelings of uselessness, which is linked to both psychological and physical health status, especially in older people who need help in daily activities (Curzio et al, 2017).*
- Encourage participation in intergenerational social activities. **EB:** *Older adults reported that their participation in the "Time After Time" intergenerational program enhanced their confidence, self-esteem, and social skills; contributed to their emotional and overall health and well-being; and enabled them to learn about others and feel connected to their community (Teater, 2016).*
- Support meaning and purpose in the lives of older adults through a focus on everyday well-being and facilitation of personally treasured activities. **EBN:** *An exploratory study found four key experiences that promote meaning and purpose in life: (1) physical and mental well-being, (2) belonging and recognition, (3) personally treasured activities, and (4) spiritual closeness and connectedness (Drageset et al, 2017).*
- Use an approach that reduces the emphasis put on ageist self-concept attributions when working with older clients. **EB:** *Ageism includes cognitive, behavioral, and emotional manifestations. Ageism tends to reinforce social inequalities because it is more pronounced toward older women, poor people, or those with dementia (Ayalon et al, 2017).*
- See care plans for Situational Low **Self-Esteem** and Chronic Low **Self-Esteem.**

Home Care

- Previously discussed interventions may be used in the home care setting.
- See care plans for Situational Low **Self-Esteem** and Chronic Low **Self-Esteem.**

Client/Family Teaching and Discharge Planning

▲ Refer the client to community agencies that offer support and environmental resources. Make referrals as needed.

- See care plans for Situational Low **Self-Esteem** and Chronic Low **Self-Esteem.**

Risk for Self-Mutilation

Domain 11 Safety/protection Class 3 Violence

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to deliberate self-injurious behavior causing tissue damage with the intent of causing nonfatal injury to attain relief of tension.

Risk Factors

Absence of family confidant; altered body image; dissociation; disturbed interpersonal relations; eating disorder; excessive emotional disturbance; feeling threatened with loss of significant interpersonal relations; impaired self-esteem; inability to express tension verbally; ineffective communication between parent and adolescent; ineffective coping strategies; irresistible urge for self-directed violence; irresistible urge to cut self; labile behavior; loss of control over problem-solving situation; low self-esteem; mounting tension that is intolerable; negative feelings; pattern of inability to plan solutions; pattern of inability to see long-term consequences; perfectionism; requires rapid stress reduction; social isolation; substance misuse; use of manipulation to obtain nurturing interpersonal relations with others

At-Risk Population

Adolescents; battered children; incarcerated individuals; individuals experiencing family divorce; individuals experiencing family substance misuse; individuals experiencing loss of significant interpersonal relations; individuals experiencing sexual identity crisis; individuals living in nontraditional setting; individuals whose peers self-mutilate; individuals with family history of self-destructive behavior; individuals with history of childhood abuse; individuals with history of childhood illness; individuals with history of childhood surgery; individuals with history of self-directed violence; individuals witnessing violence between parental figures

Associated Conditions

Autism; borderline personality disorder; character disorder; depersonalization; developmental disabilities; psychotic disorders

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching, and References

Refer to care plan for **Self-Mutilation.**

Self-Mutilation

Domain 11 Safety/protection Class 3 Violence

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Deliberate self-injurious behavior causing tissue damage with the intent of causing nonfatal injury to attain relief of tension.

Defining Characteristics

Abrading skin; biting; constricting a body part; cuts on body; hitting; ingested harmful substance; inhaled harmful substance; insertion of object into body orifice; picking at wound; scratches on body; self-inflicted burn; severing of a body part

Related Factors

Absence of family confidant; altered body image; dissociation; disturbed interpersonal relations; eating disorder; excessive emotional disturbance; feeling threatened with loss of significant interpersonal relations;

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

impaired self-esteem; inability to express tension verbally; ineffective communication between parent and adolescent; ineffective coping strategies; irresistible urge for self-directed violence; irresistible urge to cut self; labile behavior; loss of control over problem-solving situation; low self-esteem; mounting tension that is intolerable; negative feelings; pattern of inability to plan solutions; pattern of inability to see long term consequences; perfectionism; requires rapid stress reduction; social isolation; substance misuse; use of manipulation to obtain nurturing interpersonal relations with others

At-Risk Population

Adolescents; battered children; incarcerated individuals; individuals experiencing family divorce; individuals experiencing family substance misuse; individuals experiencing loss of significant interpersonal relations; individuals experiencing sexual identity crisis; individuals living in nontraditional setting; individuals whose peers self-mutilate; individuals with family history of self-destructive behavior; individuals with history of childhood abuse; individuals with history of childhood illness; individuals with history of childhood surgery; individuals with history of self-directed violence; individuals witnessing violence between parental figures

Associated Conditions

Autism; borderline personality disorder; character disorder; depersonalization; developmental disabilities; psychotic disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Self-Control; Distorted Thought Self-Control; Impulse Self-Control; Mood Equilibrium; Risk Detection; Self-Mutilation Restraint

Example NOC Outcome with Indicators

Self-Mutilation Restraint as evidenced by the following indicators: Refrains from gathering means for self-injury/Obtains assistance as needed/Upholds contract not to harm self/Maintains self-control without supervision/Refrains from injuring self. (Rate the outcome and indicators of **Self-Mutilation Restraint:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Have injuries treated
- Refrain from further self-injury
- State appropriate ways to cope with increased psychological or physiological tension
- Express feelings
- Seek help when having urges to self-mutilate
- Maintain self-control without supervision
- Use appropriate community agencies when caregivers are unable to attend to emotional needs

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening; Anger Control Assistance; Behavior Management: Self-Harm; Calming Technique; Environmental Management: Safety; Limit Setting; Mood Management; Mutual Goal Setting; Risk Identification; Self-Responsibility Facilitation

Example NIC Activities—Behavior Management: Self-Harm

Anticipate trigger situations that may prompt self-harm and intervene to prevent it; Teach client and reinforce effective coping behaviors and appropriate expression of feelings

Nursing Interventions and *Rationales*

- Before implementing interventions for nonsuicidal self-injury (NSSI), nurses should examine their own knowledge base and emotional responses to incidents of self-harm. **EBN:** *A study of mental health and emergency department nurses' perceptions about NSSI found that nurses from both groups had an accurate understanding of NSSI and positive attitudes about clients who self-injure. Confidence was higher among mental health nurses, and greater knowledge of NSSI was correlated with increased confidence, positive attitudes, and empathy (Ngune et al, 2021).*
- Assess clients with a diagnosis of borderline personality disorder or an eating disorder for NSSI. **EB:** *A systematic literature review found comorbidity with borderline personality disorder and eating disorders (Cipriano, Cella, & Cotrufo, 2017).*
- Assess veterans seeking treatment for posttraumatic stress disorder (PTSD) for NSSI behaviors. **EB:** *A study found that veterans who reported engaging in NSSI in the past year reported increased levels of PTSD and depressive symptoms (Calhoun et al, 2017).*
- A nonjudgmental approach to clients is critical. **EBN:** *A qualitative study of nurses' experiences caring for clients who self-harmed indicated the need for acceptance of the client (Moola, 2017).*
- Consider using a measure of self-harm risk that is available for clients: **EBN:** *A systematic review of multiple instruments rated most of their support as Grade B. The Suicide Attempt Self-Injury Interview (SASII) was reviewed as Level 3, although its length was noted as an issue (Li, 2017).*

▲ Provide medical treatment for injuries. Use aseptic technique when caring for wounds. Care for the wounds in a matter-of-fact manner. **EB:** *Clinical guidelines for the treatment of NSSI wounds indicate that the first steps in care are to examine for the depth and size of the wound, evaluate for possible contamination, and determine tetanus vaccination status. Wounds should also be evaluated for potential surgical consultation (Plener et al, 2018).*

- Assess for risk of suicide or other self-damaging behaviors. **EB:** *A study found that NSSI emerged as a robust predictor of recent suicide attempts and the strength of the relationship did not change in the presence of protective factors (Muehlenkamp & Brausch, 2019). Refer to the care plan for Risk for Suicidal Behavior.*
- Assess for the presence of hallucinations. Ask specific questions: "Do you hear voices that other people do not hear?" "Are they telling you to hurt yourself?" **EB:** *Command hallucinations occurring with schizophrenia or brief psychotic episodes may direct the client to hurt himself or herself or others. A systematic review found an association between psychosis and risk for self-injurious thoughts and behaviors (Hielscher et al, 2018).*
- Monitor the client's behavior closely, using engagement and support as elements of safety checks while avoiding intrusive overstimulation. **EBN:** *When lack of control exists, client safety is an important issue, and close observation is essential. Clients may feel overstimulated by intrusive close observation, resulting in agitation (Moola, 2017).*
- Focus on understanding the function that self-harm serves for the client and on managing the client's distress. **EB:** *Self-harm is a form of distress management. A qualitative study of mental health staff interventions and efficacy suggested that individualized care plans highlighting management of distress and identification of obstacles to interventions are more effective. If clients are unable to self-harm, prevention can lead to power struggles and the use of more harmful methods by the client (Thomas & Haslam, 2017).*
- Establish trust, listen to client, convey safety, and assist in developing positive goals for the future. **EB:** *Therapeutic alliance is the nature of the relationship between the client and the nurse. A systematic review of therapeutic alliance and treatment outcome found that therapeutic alliance has a positive impact on treatment outcomes among individuals engaging in or at risk for aggressive behaviors (Fahlgren, Berman, & McCloskey, 2020).*

▲ Refer for Treatment for Self-Injurious Behaviors (T-SIB) therapy. **EB:** *T-SIB is an intervention that consists of nine 1-hour-long individual weekly sessions designed to decrease the frequency of NSSI behaviors and urges. Research found decreased NSSI frequency in the T-SIB group using intent-to-treat analyses (Andover et al, 2017).*

Pediatric

- Assess children and adolescents placed in psychiatric settings for NSSI. **EBN:** *A study of 126 mostly nursing staff found that a minority of staff reported having formal NSSI training, and a third of respondents indicated that they did not typically assess for NSSI at all. Despite a substantial percentage of the respondents self-reporting comfort and confidence with assessing and treating NSSI, fewer than 10% demonstrated accurate skill (Pluhar et al, 2019).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Assess adolescents with a diagnosis of borderline personality disorder or an eating disorder for NSSI. **EB:** *A systematic literature review found that NSSI is most common among adolescents and young adults, with the age of onset between 12 and 14 years. The review also found comorbidity with borderline personality disorder and eating disorders (Cipriano, Cella, & Cotrufo, 2017).*
- Assess children and adolescents for experiences of bullying or rejection by peers. **EB:** *Study results indicate that being involved in bullying (as bullies, victims, or bully-victims) increases the likelihood of engagement in NSSI. Being rejected by peers increased the probability of using NSSI, for both victims and bully-victims (Esposito, Bacchini, & Affuso, 2019).*
- Ask adolescent clients directly if they use social media to post communication about or share images of wounds related to self-injury. **EB:** *Pictures that directly depicted wounds on Instagram were investigated. Researchers concluded that pictures of NSSI wounds are frequently posted on Instagram and social reinforcement might play a role in the posting of NSSI pictures (Brown et al, 2018).*

▲ Refer adolescents who self-harm to cognitive behavioral therapy (CBT) treatments. **EB:** *A study comparing the efficacies of a brief cognitive behavioral psychotherapy manual, the Cutting Down Programme (CDP), and treatment as usual (TAU) in the treatment of adolescent NSSI found that CDP was equally effective and achieved faster recovery compared with a significantly more intensive TAU (Kaess et al, 2020).*

▲ Refer self-injuring students for psychological or psychiatric treatment. Treatment includes starting therapy and medications, increasing coping skills, facilitating decision-making, encouraging positive relationships, and fostering self-esteem. **EB:** *Although the repeat rate of self-harm is around 21%, clients may have a very low treatment follow-up rate. Access to care must be a consideration (Hunter et al, 2018).*

Home Care and Client/Family Teaching and Discharge Planning

- Provide family teaching about NSSI and treatments. **EBN:** *Interviews of parents of adolescents with NSSI found that parents lack knowledge about NSSI and its treatment and experience emotional distress (Fu et al, 2020).*

▲ Refer family and client to outpatient family-focused cognitive behavioral treatment (F-CBT). **EB:** *A randomized trial found that F-CBT was associated with reductions in suicidality, depression, and NSSI (Esposito-Smythers et al, 2019).*

▲ Refer family and client to dialectical behavior therapy (DBT). **EB:** *A pilot study found that parents who received a DBT-based brief intervention reported reductions in parent self-reported depressive symptoms, emotion dysregulation, caregiver strain, psychiatric symptom distress, and interpersonal sensitivity from baseline to 6-month follow-up. Youth in the study also showed decreases in total self-harm from baseline to 6-month follow-up (Berk et al, 2020).*

Self-Neglect

Domain 4 Activity/rest Class 5 Self-care

Mary Rose Day, DN, MA, PGDip PHN, BSc, RPHN, RM, RGN and Susanne W. Gibbons, PhD, C-ANP/GNP

NANDA-I

Definition

A constellation of culturally framed behaviors involving one or more self-care activities in which there is a failure to maintain a socially accepted standard of health and well-being (Gibbons, Lauder, & Ludwick, 2006).

Defining Characteristics

Inadequate environmental hygiene; inadequate personal hygiene; nonadherence to health activity

Related Factors

Fear of institutionalization; impaired executive function; inability to maintain control; lifestyle choice; neurobehavioral manifestations; stressors; substance misuse

Associated Conditions

Capgras syndrome; frontal lobe dysfunction; functional impairment; learning disability; malingering; mental disorders; psychotic disorders

NOC (Nursing Outcomes Classification)

S

Suggested NOC Outcomes

Cognitive Function; Executive Function; Depression; Alcohol and Other Substance Use; Activities of Daily Living (ADLs), Instrumental Activities of Daily Living (IADLs); Safety; Nutritional Status; Social Support; Medication Safety Assessment

Examples of NOC Outcome with Indicators

Self-Neglect Status as evidenced by the following indicators: Maintains personal cleanliness and health/ Recognizes safety needs in the home. (Rate outcome and indicators of **Self-Neglect Status:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Reveal improvement in cognition (e.g., if reversible and treatable)
- Show improvement in mental health problems (e.g., depression)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Show improvement in chronic medical problems
- Demonstrate improvement in functional status (e.g., basic and IADLs)
- Demonstrate adherence to health activities (e.g., medications and medical appointments)
- Exhibit improved personal hygiene
- Exhibit improved environmental hygiene
- Have fewer hospitalizations and emergency room visits
- Increase safety of client
- Increase safety of community in which client lives
- Agree to necessary personal and environmental changes that eliminate risk/endangerment to self or others (e.g., neighbors)
- Improve social networks and social engagement
- Identify eligibility for public services and other benefits

Note: Because self-neglect is present along a continuum of severity and includes an array of behavioral and environmental issues, a change in a client's status must occur in such a way that it balances obligation for protection and respects individual rights (e.g., autonomy and self-determination) while ensuring individual health and well-being. This is accomplished through a client–provider partnership that keeps the door open, even though the client may initially decline help. Building a relationship with the client will improve trust and assist in developing an individually tailored care plan to address problems contributing to self-neglect. *Multiprofessional* collaboration and teamwork, and in some instances assistance of next of kin and/or adult protective services (APS) may be needed (e.g., a state agency or local social services program).

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Self-Neglect; Self-Care Assistance: Activities of Daily Living; Support System Enhancement

Example NIC Activities—Self-Care Assistance: Instrumental Activities of Daily Living
Determine individual's need for assistance with IADLs (e.g., shopping, cooking, housekeeping, laundry, use of transportation, managing money, managing medications, use of communication, and use of time)

Nursing Interventions and *Rationales*

- Monitor individuals with acute or chronic mental and physical illness for defining characteristics for self-neglect. **EBN:** *Holistic assessment includes medical and social history, cognitive status, state of mental health, well-being, physical function, social networks, medication, alcohol use, and observation of factors that limit persons' coping and self-care ability and threaten their personal safety and health (Mulcahy, Leahy-Warren, & Day, 2018; Touza & Prado, 2019).*
- Assist individuals with complex mental and physical health issues to adopt positive health behaviors so that they may maintain their health status in the community. **EB:** *Consequences of self-neglect can include suicidal ideation and mental health concerns (Dong, Xu, & Ding, 2017), and greater severity of self-neglect was associated with an increased 30-day hospital readmission rate (Dong & Simon, 2015).*
- Assist individuals with reconnecting with family, friends, communities, and other social networks available. **EBN:** *Poorer neighborhood cohesion (people do not share the same values, absent community spirit, poorer relationships, and people are unwilling to trust or help each other) (Hei & Dong, 2017), neighborhood disorder (e.g., visible signs of neglect, physical disorganization and dangerous conditions, high crime rates) (Hei & Dong, 2018), and social isolation are risk factors for self-neglect (Day, McCarthy, & Fitzpatrick, 2018; Mulcahy, Leahy-Warren, & Day, 2018).*
- Assist individuals whose self-care is failing with managing their medication regimen. **EB:** *Individuals who exhibit self-neglect may have difficulty managing medications because of complex medication regimens, and low adherence is significant among older adults who self-neglect (Alpert, 2014; Abada et al, 2019).*
- Assist persons with self-care deficits caused by impairments in activities of daily living (ADLs) or instrumental ADLs (IADLs). **EB:** *Individuals with self-care deficits may have difficulty with ADLs and IADLs because greater self-neglect severity has been associated with lower levels of physical function among older adults (Hildebrand, Taylor, & Bradway, 2014).*

- Assess persons with failing self-care for changes in cognitive function (e.g., dementia or delirium). **EB:** *Individuals with failing self-care may have changes in cognition. Decline in executive function has been associated with risk of reported and confirmed elder self-neglect, and decline in global cognitive function has been associated with risk of greater self-neglect severity (Mackay, 2017; Mills & Naik, 2018).*

▲ Refer persons with failing self-care to appropriate specialists (e.g., psychologist, psychiatrist, social worker) and therapists (e.g., physical therapy, occupational therapy). **EBN/EB:** *Individuals with self-care deficits may need assistance from other health professionals using an multiprofessional team approach, open communication, and collaboration (Braye, Orr, & Preston-Shoot, 2014; Burnett et al, 2014).*

▲ Responding to clients with self-neglect requires that plan of care be person centered and outcome focused and clarify how real and potential risks will be addressed, by whom, and within what timeframe. Professional judgment and complexity of cases and situations can present an exceptionally fine line in making decisions and judgments. **EBN/EB:** *Building relationships with the person, knowing the person's narrative/story, legal literacy, finding creative interventions, and effective multiagency working are key (Day, McCarthy, & Fitzpatrick, 2018).*

- Use behavioral modification as appropriate (describing all options and consequences of refusing care or treatment) to bring about client changes that lead to improvement in personal hygiene, environmental hygiene, and adherence to medical regimen. **EB:** *Person-centered interventions that take account of the circumstances, historical and current wishes and feelings of the client, the client's preferred options, and (if possible) negotiated approaches to offering support can offer better outcomes (Braye, Orr, & Preston-Shoot, 2014; Preston-Shoot, 2019).*
- Monitor persons with substance abuse disorders (i.e., drugs, alcohol, smoking) and depression for adequate health and safety. **EBN/EB:** *Because mental health and substance use disorders can go unrecognized and untreated in this population, identified self-neglecting clients should be screened as appropriate (Alpert et al, 2014; Hansen et al, 2016; Yu et al, 2019).*

▲ Refer persons with failing self-care who are significantly impaired cognitively (e.g., executive function, dementia) or functionally and/or who are suspected victims of abuse to APS. **EB/CEB:** *Self-neglect has been associated with mistreatment in older adults, especially those who live alone (Pavlou & Lachs, 2008).*

Geriatric

▲ Assess client's socioeconomic status and refer for appropriate support. **EBN/EB:** *Providers are advised to assess available financial and other resources to help older adults and their families obtain essential goods and services (Zhao et al, 2017; Mulcahy, Leahy-Warren, & Day, 2018).*

▲ Refer persons demonstrating a significant decline in self-care abilities (e.g., posing a threat to themselves or to their community) for formal evaluation of capacity and executive function. **EB:** *Current evidence highlights the importance of understanding the nuances of decision-making capacity and mental capacity to help clients who are self-neglecting. Tensions between autonomy and beneficence complicate decisional capacity (Day, Leahy-Warren, & McCarthy, 2016; Niforatos, Rutecki, & Yates, 2018).*

Multicultural

- Deliver health care that is sensitive to the culture and philosophy of individuals whose self-care appears inadequate. **EBN:** *Providers must be careful not to prematurely judge clients' health choices or living arrangements because personal values and beliefs that might appear as self-neglect do not necessarily indicate self-neglect. However, when client behavior poses a risk to self and/or others, providers have an ethical obligation to intervene (Braye, Orr, & Preston-Shoot, 2017; Braye, Orr, & Preston-Shoot, 2014; Wu et al, 2020).*

Sexual Dysfunction

Domain 8 Sexuality Class 2 Sexual function

Laura King, DNP, RN, MSN, CNE

NANDA-I

Definition

A state in which an individual experiences a change in sexual function during the sexual response phases of desire, arousal, and/or orgasm, which is viewed as unsatisfying, unrewarding, or inadequate.

Defining Characteristics

Altered interest in others; altered self-interest; altered sexual activity; altered sexual excitation; altered sexual role; altered sexual satisfaction; decreased sexual desire; perceived sexual limitation; seeks confirmation of desirability; undesired alteration in sexual function

Related Factors

Inaccurate information about sexual function; inadequate knowledge about sexual function; inadequate role models; insufficient privacy; perceived vulnerability; unaddressed abuse; value conflict

At-Risk Population

Individuals without a significant other

Associated Conditions

Altered body function; altered body structure

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Recovery: Sexual; Knowledge: Sexual Functioning, Physical Aging; Psychosocial Adjustment: Life Change; Risk Control: Sexually Transmitted Diseases (STDs); Sexual Functioning; Sexual Identity

Example NOC Outcome with Indicators

Sexual Functioning as evidenced by the following indicators: Expresses comfort with sexual expression/Expresses comfort with body/Expresses sexual interest. (Rate the outcome and indicators of **Sexual Functioning:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify individual cause of sexual dysfunction
- Identify stressors that contribute to dysfunction
- Discuss alternative, satisfying, and acceptable sexual practices for self and partner
- Identify the degree of sexual interest by the client and partner
- Adapt sexual technique as needed to cope with sexual problems
- Discuss with partner concerns about body image and sex role

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Sexual Counseling; Teaching: Sexuality

Example NIC Activities—Sexual Counseling

Provide privacy and ensure confidentiality; Discuss necessary modifications in sexual activity, as appropriate; Provide referral/consultation with other members of the health care team, as appropriate

Nursing Interventions and *Rationales*

- Gather the client's sexual history, noting normal patterns of functioning and the client's vocabulary, and encouraging clients to ask questions or discuss sexual problems experienced. **EBN:** *A large majority of men experiencing erectile dysfunction desire for providers to initiate the subject of sexual health (Burbage-Vieth, 2020).* **EB:** *Sexuality is considered to be a normal component of being healthy, and as such, assessing the client's sexual history patterns along with sexual experience provides a reference base in which to evaluate potential problems (Mernone et al, 2019).* **EB:** *In a large cross-sectional study of men, the prevalence of erectile dysfunction (ED) increased for those with comorbidities such as hypertension, diabetes mellitus, depression, or benign prostatic hypertrophy (BPH) (Mulhall et al, 2016).*
- Gather a sexual history for transgender clients, including their view and importance of sexuality and the presence of coexisting sexual dysfunctions such as low desire, inability to achieve orgasm, disturbance in body image, or experiencing pain with sexual intercourse. **EB:** *Evaluation of the client's history is important to understand sexual dysfunction. Creating a supportive, open, and nonjudgmental environment promotes communication when evaluating the client's history to better understand the transgender client's risk for sexual dysfunction (Holmberg et al, 2019).*

▲ Assess duration and risk factors for sexual dysfunction and explore potential causes such as medications, medical problems, aging process, or psychosocial issues. **EBN:** *In a descriptive, cross-sectional survey assessing client risk factors, the number of medications taken, smoking, depression, history of stroke, and those clients taking angiotensin-converting enzyme inhibitors and statin drugs reported reduced sexual activity (Dusenbury et al, 2020).* **EB:** *Transgender clients undergoing medical transition may experience decreased sexual desire related to hormone therapy or psychopharmacological drugs, pain from surgical procedures, inability to achieve orgasm, or a disturbance in body image (Holmberg et al, 2019).* **EBN:** *In a population-based sample comparing those with a cardiac condition to those without a cardiac condition, those with*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

coronary artery disease, angina, and myocardial infarction reported significantly less sexual activity, as did those who smoked, had a weight problem, had lung problems, had depression, had shortness of breath or chest pain with exertion, or took certain medications. This illustrated that multiple factors affect sexual activity and may contribute to sexual dysfunction (Steinke et al, 2018).

▲ Assess for history of sexual abuse. **EB:** *Clients reporting a history of childhood sexual abuse experienced higher levels of sexual dysfunction and the development of posttraumatic stress disorder (PTSD) symptoms compared with those who report no experience of abuse. It is important to identify the history of abuse and to identify symptoms of PTSD (Gerwitz-Meydan & Lahav, 2020).* **EB:** *Men who were forced to have sex by a woman had greater risks such as higher number of lifetime partners and greater alcohol and drug use, compared with non-victimized men, putting them at increased risk of sexually transmitted infections (Cook et al, 2016).*

▲ Assess and provide treatment for sexual dysfunction, involving the person's partner in the process, and evaluating pharmacological and nonpharmacological interventions. **EB:** *Results of a systematic review of men and women found that dehydroepiandrosterone (DHEA) improved sexual interest, pain, arousal, lubrication, orgasm, and frequency of sexual activity, particularly for women and those with sexual dysfunction, whereas some men had improved erectile function, but others did not (Peixoto et al, 2017).* **EBN:** *Treatment of ED in men should involve the sexual partner and can include a variety of treatment options, including lifestyle modifications, the use of various oral medications such as phosphodiesterase type 5 (PDE5) inhibitors, sildenafil citrate, Tadalafil, and/or the use of vacuum erection devices or penile implants to help the client achieve sexual satisfaction (Schreiber, 2019).* **EB:** *Sexual dysfunction as a result of cancer in female clients has been shown to be improved with the use of pelvic floor exercises, as well as vaginal lubricants or moisturizers, including those with dehydroepiandrosterone (DHEA). Cognitive behavioral therapy, couples therapy, and participation in sexual health programs have also demonstrated improved sexual function (Valpey, Kucherer, & Nguyen, 2019).*

● Assess risk factors for sexual dysfunction, especially with varying sexual partners. **EB:** *In substance-dependent men who were polydrug users, having occasional sexual partners resulted in 14 times the risk of ED compared with married men, illustrating the importance of a complete sexual history and evaluation of risks for sexual dysfunction (Clemente et al, 2017).*

● Observe for stress and anxiety as possible causes of dysfunction. **EBN:** *Low levels of sexual desire in women have been attributed to increased levels of stress and anxiety (Dahlen, 2019).* **EB:** *In women, fibromyalgia significantly affected sexual function, and the severity and duration of fibromyalgia, the duration of the sexual partnership, and severity of anxiety significantly increased the degree of sexual dysfunction (Hayta & Mert, 2017).* **EB:** *The most prevalent reasons identified by women unable to achieve orgasm were stress and anxiety; therefore, managing high levels of both is often an important objective in sexual therapy (Rowland et al, 2018).*

▲ Assess for depression as a possible cause of sexual dysfunction and institute appropriate treatment. **EBN:** *In women who had given birth in the prior 12 months, 24% reported postnatal depression, which was significantly associated with sexual dysfunction, not initiating partnered sexual activity, and relationship dissatisfaction, illustrating the importance of assessment and early intervention for both depression and sexual dysfunction (Khajehei & Doherty, 2017).* **EB:** *A large matched control study found that depression rates in the transgender population have been documented to be higher than that of the general population (Whitcomb et al, 2018).* **EB:** *Studies consistently identify depression in women as a factor in experiencing sexual dysfunction (Basson & Gilks, 2018).*

● Observe for grief-related loss (e.g., amputation, mastectomy, ostomy) because a change in body image often precedes sexual dysfunction. See care plan for Disturbed **Body** Image. **EBN:** *In men after lower anterior resection for rectal cancer, ED occurred in 97% compared with 76% in those undergoing colectomy, with worse overall sexual function for those with lower anterior resection, particularly for those with a stoma. This illustrates the importance of discussing sexual function and loss in those diagnosed with rectal cancer (Shieh et al, 2016).* **EB:** *Women are highly affected by body image concerns related to surgical loss of breast, as well as stomas from gastrointestinal and colorectal cancers. Perceived alterations in body image can lead to decreased sexual activity and function (Valpey, Kucherer, & Nguyen, 2019).*

▲ Explore physical causes of sexual dysfunction such as diabetes, cardiovascular disease, arthritis, or BPH. **EBN:** *Men and women with cardiovascular disease experience sexual difficulties more often than those without the disease (Gök & Korkmoz, 2018).*

▲ Consider that ED may indicate the presence of cardiovascular disease, and screening and referral of men is recommended. **EB:** *ED has been related to diseases such as diabetes and cardiovascular disease, indicating that it is a cardiovascular disease predictor (Hernández-Cerda et al, 2020).*

S

- Certain chronic diseases such as cancer often have significant effects on sexual function, and both the disease process and treatment can contribute to sexual dysfunction. **EBN:** *Although women after gynecological cancer were sexually active, 54% had impaired sexual satisfaction and experienced problems such as vaginal dryness and discomfort with vaginal penetration during sexual activity (Sekse et al, 2017).* **EB:** *For individuals with chronic diseases such as cardiovascular disease, diabetes mellitus, renal failure, asthma, and hypertension, disease symptoms and side effects lead to changes in sexuality and affect overall perceptions of health (Sabanciogullari et al, 2016).*
- Consider that neurological diseases can affect sexual function directly, with secondary effects caused by disability related to the illness and social and emotional effects. **EB:** *Studies estimate the prevalence of clients with multiple sclerosis experiencing sexual dysfunction to be 40% to 80% in women and 50% to 90% in men related to paresthesia, sensory numbness, loss of libido, decreased lubrication, and erectile dysfunction (Domingo et al, 2018).*
- Explore behavioral or other causes of sexual dysfunction, such as smoking, dietary factors, or obesity. **EB:** *A meta-analysis from 89 studies found that smoking and alcohol intake increase the risk for ED in men, whereas participation in physical activity and consuming a healthy diet lower the risk for both ED and female sexual dysfunction (Allen & Walter, 2018).*
- ▲ Consider medications as a cause of sexual dysfunction. **EBN:** *Evaluating all cardiac medications used by clients for potential sexual side effects is important in identifying potential causes of sexual dysfunction (Dusenbury et al, 2020).* **EB**: *The use of psychotropic drugs is known to increase the risk for sexual dysfunction in women (Leveque et al, 2020).*
- ▲ Refer to appropriate medical providers for consideration of medication for premature ejaculation, ED, or orgasmic problems. **EB:** *Premature ejaculation is the most commonly diagnosed sexual dysfunction and is best treated with a combination of behavioral techniques and pharmacotherapy, including selective serotonin reuptake inhibitors, tricyclic antidepressants, or PDE5 inhibitors (Pereira-Lourenço et al, 2019).* **EB:** *Treatment response for the ED drug sildenafil was better than placebo in men with no comorbidity and for those with cardiovascular disease/hypertension only, diabetes only, or depression only, regardless of age (Goldstein et al, 2017).*
- Refer to the care plan Ineffective **Sexuality** Pattern for additional interventions.

Geriatric

- ▲ Carefully assess the sexuality needs and sexual dysfunction of older adults and refer for counseling if needed. **EBN:** *Treatment approaches for ED in older adults include behavioral and lifestyle changes (e.g., smoking cessation, healthy diet, physical activity, limiting alcohol intake), pelvic floor muscle exercises, PDE5 inhibitors, psychotherapy, and assistive devices (Marchese, 2017).*
- Teach about normal changes that occur with aging that may be perceived as sexual dysfunction, such as reduction in vaginal lubrication and reduction in duration and resolution of orgasm for women; for men these changes include increased time required for erection and for subsequent erections, erection without ejaculation, less firm erection, and decreased volume of seminal fluid. **EBN:** *Sexual dysfunction may decrease the quality of life for the older adult and lack of knowledge of normal physiological changes may lead to that dysfunction; health care professionals must be comfortable in discussing issues related to sexual intimacy and providing information related to normal physiological changes as they relate to aging and sexual function (March, 2018).*
- If prescribed, instruct clients with chronic pain to take pain medication before sexual activity. **EB:** Clients experiencing vulvodynia may experience a decrease in pain during intercourse with the use of antiinflammatory medications and lidocaine on a short-term basis (*Goldstein et al, 2016*).
- See care plan for Ineffective **Sexuality** Pattern.

Multicultural

- ✱ Evaluate culturally influenced risk factors for sexual function and dysfunction. **EBN:** *Bisexual women had greater sexual coercion, more lifetime partners, physical and sexual violence, traded sex for resources, and posttraumatic stress disorder symptoms, illustrating the importance of history-taking, screening protocols, and counseling, taking into account race, ethnicity, gender, class, and sexual identity (Alexander et al, 2016).*
- Validate client feelings and emotions regarding the changes in sexual behavior by letting the client know that the nurse heard and understands what was said, promoting the nurse–client relationship. **EB:** *Culturally sensitive approaches with older adults include discussing sexual function and dysfunction regardless of culture, sexual orientation, age, gender, or marital status, and inquiring about culture in a nonjudgmental way (Atallah, 2016).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Home Care

- Previously discussed interventions may be adapted for home care use.
- ▲ Identify specific sources of concern about sexual dysfunction and provide reassurance and instruction on appropriate expectations as indicated. **EB:** *Although women with breast cancer have concerns regarding sexual health, many may not feel comfortable voicing those concerns; therefore, it is important for health care professionals to facilitate communications regarding sexual function with clients (Reese et al, 2019).*
- ▲ Confirm that physical reasons for dysfunction have been addressed, and refer for therapy and/or support groups if appropriate. **EB:** *Most individuals with sexual problems would benefit from both pharmacological and psychological treatment, including sexual counseling and therapy (Almås, 2016).*
- See care plan for Ineffective **Sexuality** Pattern.

Client/Family Teaching and Discharge Planning

- Provide accurate information for clients regarding interventions for sexual dysfunction. **EB:** *To address sexual problems in those with cancer, psychosexual counseling should be offered to both men and women. Women may benefit from pelvic floor physiotherapy, hormonal therapy for vasomotor symptoms (if safe), and vaginal lubricants, whereas men might be offered PDE5 inhibitors, vacuum erectile devices, and intracavernosal injection (Barbera et al, 2017).*
- Include the partner/family in discharge instructions because partner concerns are often overlooked regarding sexual issues. **EB:** *Women as cervical cancer survivors wanted both information and practical advice in dealing with sexual dysfunction; physical functioning, sexual distress, relationship satisfaction, and partner perspectives should be assessed, with interventions tailored to the particular needs of the couple (Vermeer et al, 2016).*
- Teach the client and partner about condom use, for those at risk. **EB:** *In couples, feelings of commitment to the sexual partner resulted in reduced perceived sexual risk, illustrating that interventions for couples should include discussion of sexual risk, prevention of HIV risk (including condom use), and monogamy agreements before condoms are discontinued (Agnew et al, 2017).*
- ▲ Refer to appropriate community resources, such as a clinical specialist, family counselor, or cardiac rehabilitation, including the partner if appropriate; for complex issues, a referral to a sex counselor, urologist, gynecologist, or other specialist may be needed. **EB:** *Young adult clients diagnosed with cancer have many questions regarding sexual function and prefer to have those questions addressed by professionals, as well as being directed to reliable online resources (Martins et al, 2018).* **EB:** *Men and their partners need comprehensive information before and after treatment for prostate cancer, including support groups to help clients and partners gain education and support (Albaugh et al, 2017).*
- ▲ Refer for medical advice when ED lasts longer than 2 months or is recurring. **EB:** *Erectile dysfunction is a common condition in males and can be managed through a variety of treatments; therefore, it is important for providers to carefully assess at-risk clients (Irwin, 2019).*
- Teach the following interventions to decrease the likelihood of ED: limit or avoid the use of alcohol, stop smoking, exercise regularly, reduce stress, get enough sleep, deal with anxiety or depression, and see a health care provider for regular checkups and medical screening tests. **EB:** *In a study of nondiabetic men with cardiovascular risk factors, those with ED were more likely to be smokers and sedentary and consumed more alcohol, whereas those consuming more nuts and vegetables had less ED, illustrating the importance of counseling regarding lifestyle and its effect on ED (Ramírez et al, 2016).*
- See care plan for Ineffective **Sexuality** Pattern.

Ineffective Sexuality Pattern

Domain 8 Sexuality Class 2 Sexual function

Laura King, DNP, RN, MSN, CNE

NANDA-I

Definition

Expressions of concern regarding own sexuality.

Defining Characteristics

Altered sexual activity; altered sexual behavior; altered sexual partner relations; altered sexual role; difficulty with sexual activity; difficulty with sexual behavior; value conflict

Related Factors

Conflict about sexual orientation; conflict about variant preference; fear of pregnancy; fear of sexually transmitted infection; impaired sexual partner relations; inadequate alternative sexual strategies; inadequate role models; insufficient privacy

At-Risk Population

Individuals without a significant other

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Recovery: Sexual; Body Image; Child Development: Middle Childhood/Adolescence; Client Satisfaction: Teaching; Knowledge: Pregnancy and Postpartum Sexual Functioning; Knowledge: Sexual Functioning; Psychosocial Adjustment: Life Change; Risk Control: Sexually Transmitted Diseases (STDs); Risk Control: Unintended Pregnancy; Role Performance; Self-Esteem; Sexual Functioning; Sexual Identity

Example NOC Outcome with Indicators

Risk Control: Sexually Transmitted Diseases (STDs) as evidenced by the following indicators: Acknowledges personal risk factors for STD/Uses strategies to prevent STD transmission. (Rate the outcome and indicators of **Risk Control: Sexually Transmitted Diseases (STDs):** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State knowledge of difficulties, limitations, or changes in sexual behaviors or activities
- State knowledge of sexual anatomy and functioning
- State acceptance of altered body structure or functioning
- Describe acceptable alternative sexual practices
- Identify importance of discussing sexual issues with significant other
- Describe practice of safe sex with regard to pregnancy and avoidance of sexually transmitted infections (STIs)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Abuse Protection Support: Child; Abuse Protection Support: Domestic Partner; Abuse Protection Support: Elder; Abuse Protection Support: Religious; Behavior Management: Sexual; Sexual Counseling; Teaching: Safe Sex; Teaching: Sexuality

Example NIC Activities—Sexual Counseling

Provide privacy and ensure confidentiality; Provide information about sexual functioning, as appropriate

Nursing Interventions and *Rationales*

- After establishing rapport or therapeutic relationship, give the client permission to discuss issues dealing with sexuality, for example, "Have you been or are you concerned about functioning sexually because of your health status?" **EBN:** *Nurses can use the PLISSIT (permission, limited information, specific suggestions, referral to intensive therapy) model to initiate communication regarding sexual concerns with clients (Kautz & Van Horn, 2017).* **EB:** *Use of the PLISSIT model has been shown to elicit information that can be used to help improve sexual function in women with multiple sclerosis (MS) (Khakbazan et al, 2016).*
- Use assessment questions and standardized instruments to assess sexual problems, where possible. **EB:** *Use of standardized scales and validated instruments to obtain information regarding current levels of sexual activity can assist in the evaluation for sexual dysfunction (Hatzichristou et al, 2016).*

▲ Assess any risks associated with sexual activity, particularly coronary risks. **EBN:** *For men and women, cardiac conditions including coronary heart disease, angina, and a history of myocardial infarction, along with risk factors such as smoking and obesity, and other comorbidities, symptoms, and medications can negatively affect sexual activity (Steinke et al, 2018).*

- Assess knowledge about sexual functioning and return to sexual activity after experiencing a health problem with both clients and partners. **EB:** *A population-based study found an association between coronary heart disease and reduction in sexual activity (Steptoe et al, 2016).*
- Encourage the client to discuss concerns with his or her partner. **EB:** *A systematic review of articles found that, in men with traumatic spinal cord injuries, providing information regarding the importance of communication of sexual concerns between partners, and offering resources to facilitate that communication, was beneficial for improving overall sexual health (Aikman et al, 2018).*
- Explore attitudes about sexual intimacy and changes in sexuality patterns. **EBN:** *After breast cancer, women had reduced sexual desire, frequency, and satisfaction, with no association between sexual performance and body image (Dorneles de Morais et al, 2016).* **EB:** *A cross-sectional study found that assessing attitudes and sexual patterns of individuals diagnosed with a chronic disease enabled health care professionals to recognize sexual dysfunction, which resulted in the planning of interventions to improve the quality of life and life satisfaction (Sabanciogullari et al, 2016).*
- Assess psychosocial function such as anxiety, fear, depression, and low self-esteem. **EBN:** *In a population-based study, men who had sex with men had greater depressive symptoms compared with those with partners of the opposite sex (Scott, Lasiuk, & Norris, 2016).* **EB:** *Mental health illness is a major risk factor for sexual dysfunction in women (Basson & Gilks, 2018).*
- Discuss alternative sexual expressions for altered body functioning or structure, including closeness and sexual and nonsexual touching as other forms of expression. **EBN:** *Women with fibromyalgia experienced pain with sexual activity, postcoital stiffness, anxiety about sex, and altered body image, although maintaining an active sex life was important; therefore discussion of sexual concerns, individual symptoms, and psychoemotional needs can assist in developing approaches for sexual activity, such as changes in position or alternatives to sexual intercourse when symptom burden is high (Matarín Jiménez et al, 2017).***EB:** *Alternative expressions of intimacy may play an important role in facilitating intimate relationships in women with gynecological cancers, and providing information on these alternatives can help to increase sexual health (Lee et al, 2020).*
- Assess the client's sexual orientation and usual pattern of sexual activities, and discuss prevention of illnesses for which the client may be at increased risk (e.g., anorectal cancer), asking specific questions about sexual orientation, for example, "Do you have sexual relationships with men, women, or both?" Assess use of safer sex practices (e.g., condom use); the frequency of anal intercourse; number of sexual partners in the last year; last HIV screening/results; and use of medications, alcohol, and illicit drugs. **EBN:** *Transgender women had low levels of HIV risk perception and knowledge about HIV risk and transmission, illustrating the importance of assessing transgender women's sexual health care needs and educating regarding risks (De Santis et al, 2017).*
- Specific guidelines for sexual activity for clients who have had total hip arthroplasty (THA) include the following: sexual activity can be generally resumed 1 to 2 months after surgery, and positioning to avoid hip dislocation, for example, a supine position ("missionary") at maximum abduction in extension, or the man and woman standing, with the woman's legs slightly bent and the man approaching the woman from behind (Issa et al, 2017). **EB:** *In a systematic review of THA and sexual activity, 76% of individuals identified hip arthritis as contributing to sexual problems, whereas post-THA, 44% reported improvement in sexual satisfaction, 27% reported increased intercourse frequency, and most returned to sexual activity at 4 months post-THA. Health care professionals and surgeons should discuss return to sexual activity after THA, including the best positions postsurgery (Harmsen et al, 2017).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Specific guidelines for those who have had a myocardial infarction (MI) include the following: sexual activity can generally be resumed 1 week after MI unless complications are experienced, such as arrhythmias or cardiac arrest, if the client does not have cardiac symptoms during mild to moderate physical activity; begin with activities that require less exertion, such as fondling or kissing, building confidence in tolerance for sexual activity before sexual intercourse; engage in sexual activity in familiar surroundings with the usual partner; have a comfortable room temperature, and be well rested to minimize cardiac stress; avoid heavy meals or alcohol for 2 to 3 hours before sexual activity; and choose a position of comfort to minimize stress of the cardiac client (Steinke et al, 2016). **EB:** *A healthy sexual life is important for all humans and it is essential for health care providers to provide clients who have experienced MI information on safely resuming sexual activity, as well as addressing client concerns in order to improve their quality of life (Farhan et al, 2020).*
- Specific guidelines include that those who have had complete coronary revascularization, in addition to those mentioned with MI, including those with successful percutaneous cardiovascular revascularization without complication, can resume sex within a few days, and those who have had standard coronary artery bypass grafting or noncoronary open heart surgery may resume sex in 6 to 8 weeks. Incisional pain with sexual activity can be managed by premedicating with a mild pain reliever, and reassurance should be provided to the partner that sexual activity will not harm the sternum as long as direct pressure is avoided (Jelavić et al, 2018). **EB:** *Women, particularly those with large breasts, may report more issues related to pain in the breast, chest numbness, and difficulty healing; therefore encourage these women to choose a position of comfort, support with pillows, and take a pain reliever such as acetaminophen before sexual activity (Steinke et al, 2016).*
- Specific guidelines for those with an implantable cardioverter defibrillator (ICD) include returning to sexual activity is generally safe after ICD implantation if moderate physical activity does not precipitate arrhythmias; avoid strain on the incision at the implant site; assure the client and partner that fears about being shocked during sexual activity are normal; if the ICD discharges with sexual activity, the client should stop, rest, and later notify the health care provider that the device fired so that a determination can be made if this was an appropriate shock or not; and report any dyspnea, chest pain, or dizziness with sexual activity (Steinke et al, 2016). **EB:** *Although most clients with ICD reported the ability to engage in sexual activity (64.6%), 51% chose to avoid sexual activity, citing reasons such as fear of shock, fear of increased heart rate, and no desire, illustrating the importance of evaluating and discussing both psychological and physical aspects of return to sexual activity (Streur et al, 2020).*
- Specific guidelines for those with chronic lung disease include planning for sexual activity when energy level is highest; use of controlled breathing techniques; avoiding physical exertion before sexual activity; using positions that minimize shortness of breath, such as a semireclining position; engaging in sexual activity when medications are at peak effectiveness; use of an oxygen cannula, if prescribed, to provide oxygen before, during, or after sex; and use of continuous positive airway pressure (CPAP) therapy, if prescribed (Steinke et al, 2016). **EB:** *In a systematic review of sexual dysfunction and obstructive sleep apnea in men, CPAP improved daytime sleepiness and erectile and orgasmic dysfunction, although sildenafil was superior to CPAP in improving erectile dysfunction; intervention studies for women were not available (Steinke et al, 2016).*
- Specific guidelines for those with MS include treatment of symptoms with prescribed medications, assessing changes in body image, and supportive therapies to assist with a more satisfying sexual experience, including treatment of neuropathic pain, sexual positions that are most supportive, discussing changes in sensation and stimulation with the partner, use of stretching exercise for tight muscles before sexual activity, and avoiding a distended bowel or bladder that may cause discomfort. **EB:** *Women with MS attending a 12-week sexual therapy program significantly improved sexual desire, arousal, lubrication, orgasm, satisfaction, overall quality of life, energy, cognitive function, and social function; designing targeted educational and sexual interventions is important to improve sexual and overall quality of life (Zamani et al, 2017).*
- Refer to the care plan **Sexual** Dysfunction for additional interventions.

Pediatric

- Initiate discussions regarding sexual health, attitudes, and knowledge about sexual behavior and sexual abstinence, providing information that is age appropriate and accurate regarding sexual activity and risky sexual behaviors. **EBN:** *Lack of information regarding sexual health contributes to vulnerability and adolescents acknowledge the need for accurate information to decrease risky sexual behaviors (Grigsby, 2018).* **EB:** *Focus groups conducted in black churches with senior pastors, youth ministers, parents of youth, and youth ages 13 to 19 years, on the topic of youth sexual and reproductive health, resulted in the themes of engaging stakeholders, the authenticity of the curriculum, making the curriculum relevant to youth, discussion of*

relationships, and adaptation, providing an example that implementing sexual health programs in new settings can be successful in reaching youth and the community (Weeks et al, 2016).

- Provide age-appropriate information for adolescents regarding HIV/AIDS and sexual behavior, and discuss STIs, particularly human papillomavirus, including the risks of perinatal transmission and methods to reduce risks among adolescents with HIV. **EB:** *Communication between African American fathers and their sons is an important factor in decreasing sexual risk behaviors and HIV risk (Harris et al, 2019).*
- Provide age-appropriate information regarding potential for sexual abuse. **EBN:** *A structured teaching program on prevention of sexual abuse with high school students resulted in improved knowledge of prevention strategies, illustrating the importance of education and directly addressing this sensitive issue (Fulgen, 2017).*

Geriatric

- Carefully assess the sexuality needs of the older client and refer for counseling as needed. **EB:** *Positive affect and life satisfaction was associated with increased sexual behavior in community-dwelling older men and women, regardless of depressive symptoms, physical health, and chronic diseases, whereas unpartnered adults' life satisfaction was linked with more physical tenderness and less sexual behavior, demonstrating the importance of sexual assessment of all older adults and in promoting psychological and sexual well-being (Freak-Poli et al, 2017a).*

▲ Explore possible changes in sexuality related to health status, menopause, medications, and sexual risk, and make appropriate referrals. **EB:** *Although two-thirds of older adults had experienced some sexual problems, most were not distressed by it, reporting positive sexual well-being, with positive sexual self-esteem and attitudes toward sex, high sexual satisfaction and interest, and frequently engaging in sexual activity, illustrating that although some older adults may experience challenges regarding sexual activity, many report positive sexual health (Santos-Iglesias et al, 2016).* **EB:** *Sexual risk-taking was prevalent among older adults, with 49% reporting engaging in vaginal sex and 43% engaging in oral sex without a condom in the prior 6 months, although 65.5% of the sample believed they were not susceptible to STIs, revealing the need for assessment, education, and intervention related to sexual risk (Syme, Cohn, & Barnack-Tavlaris, 2017).*

- Allow the client to verbalize feelings regarding loss of sexual partner, and acknowledge problems such as disapproving children, lack of available partner for women, and environmental variables that make forming new relationships difficult. **EB:** *Health status, frequency of sexual activity, and importance of sexual behavior were important predictors of quality of life, and these findings were independent of the presence of a spouse/partner, illustrating the importance of health care providers evaluating sexual activity as a component of quality of life with all clients (Granville & Pregler, 2018).*

▲ Provide a milieu that allows for discussion of sexual issues and a higher level of sexual satisfaction, including allowing couples to room together and the provision of privacy. **EBN:** *Sexual expression and consent should be openly addressed in long-term care settings, and results from a qualitative study of directors of long-term care facilities revealed the common themes of addressing the issue, making environmental changes, identifying staff expertise, providing education and training, assessing sexuality initially and recurrently, establishing policies and procedures for sexual expression management, developing assessment tools, and clarifying legal issues. These are all important areas that staff in long-term care facilities can use to improve the sexual health of their residents (Syme et al, 2016).*

- See care plan for **Sexual** Dysfunction.

Multicultural

✱ Assess for the influence of cultural beliefs, norms, and values on client's perceptions of sexual behavior. **EBN:** *Among Hispanic men who had sex with men, parental knowledge and rejection of their sexual orientation contributed to greater depressive symptoms and no effect on safer sex behaviors, although acculturation (Americanism) may have had a protective role. These findings emphasized the importance of educating and supporting both the individual and family, including assessing mental health (Mitrani et al, 2017).*

Home Care

- Previously discussed interventions may be adapted for home care use. Also see care plan for **Sexual** Dysfunction.
- Help the client and significant other identify a place and time in the home and daily living for privacy in sharing sexual or relationship activity, and, if necessary, help the client communicate the need for privacy to family members. **EB:** *In community-dwelling older adults, most reported experiencing physical tenderness and about half engaged in sexual activity, with sexual activity more likely in those of younger age, those*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

with greater social support, those with healthier behaviors, and those with better psychological and physical health, illustrating the importance of maintaining sexual quality of life regardless of setting, not assuming that the older person is not interested in sexual pleasure, and having health care professionals proactively address sexuality and sexual health (Freak-Poli et al, 2017b).

- Confirm that physical reasons for dysfunction have been addressed, and provide support for coping behaviors, including participation in support groups or therapy if appropriate. **EB:** *A pilot study using a psychoeducational group intervention in women with MS and spinal cord injury resulted in improved sexual functioning, particularly for sexual desire and arousal, demonstrating the importance of supportive interventions to improve sexual functioning (Hocaloski et al, 2016).*

Client/Family Teaching and Discharge Planning

▲ Refer to appropriate community agencies (e.g., certified sex counselor, Reach to Recovery, Ostomy Association, American Association of Sex Educators, Counselors, and Therapists). **EB:** *Sexuality concerns should be addressed with all clients for whom sexual function might be impaired (Morton, 2017).*

▲ Sexuality education is important to all populations, whether hearing or deaf, sighted or blind, disabled or not disabled; discuss contraceptive choices as appropriate, safer sexual practices, and refer to a health professional (e.g., gynecologist, urologist, nurse practitioner). **EB:** *Sexuality education of older adults is often overlooked, and they may have inaccurate perceptions regarding sexual risk behaviors and STIs (Syme et al, 2017).*

Risk for Shock

Domain 11 Safety/protection Class 2 Physical injury

Nicole Huntley, MS, RN, APN, ACCNS-AG

NANDA-I

Definition

Susceptible to an inadequate blood flow to tissues that may lead to cellular dysfunction, which may compromise health.

S

Risk Factors

Bleeding; deficient fluid volume; factors identified by standardized, validated screening tool; hyperthermia; hypothermia; hypoxemia; hypoxia; inadequate knowledge of bleeding management strategies; inadequate knowledge of infection management strategies; inadequate knowledge of modifiable factors; ineffective medication self-management; nonhemorrhagic fluid losses; smoking; unstable blood pressure

At-Risk Population

Individuals admitted to the emergency care unit; individuals at extremes of age; individuals with history of myocardial infarction

Associated Conditions

Artificial respiration; burns; chemotherapy; diabetes mellitus; embolism; heart diseases; hypersensitivity; immunosuppression; infections; lactate levels ≥2 mmol/L; liver diseases; medical devices; neoplasms; nervous system diseases; pancreatitis; radiotherapy; sepsis; sequential organ failure assessment (SOFA) score ≥3; simplified acute physiology score (SAPS III >70); spinal cord injuries; surgical procedures; systemic inflammatory response syndrome (SIRS); trauma

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Cardiac Pump Effectiveness; Fluid Balance; Infection Severity; Respiratory Status: Gas Exchange; Neurological Status: Autonomic; Tissue Perfusion: Cellular

Example NOC Outcome with Indicators

Neurological Status: Autonomic as evidenced by the following indicators: Apical heart rate/Systolic blood pressure/Urinary elimination pattern/Thermoregulation. (Rate the outcome and indicators of **Neurological Status: Autonomic:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Discuss precautions to prevent complications of disease
- Maintain adherence to agreed-on medication regimens
- Maintain adequate hydration
- Monitor for infection signs and symptoms
- Maintain a mean arterial pressure (MAP) above 65 mm Hg
- Maintain a heart rate between 60 and 100 with a normal rhythm
- Maintain urine output greater than 0.5 mL/kg/hr
- Maintain warm, dry skin

NIC (Nursing Intervention Classification)

Suggested NIC Interventions

Admission Care; Allergy Management; Cardiac Care; Cerebral Perfusion Promotion; Electrolyte Monitoring; Fever Treatment; Fluid Management; Hemodynamic Regulation; Infection Precaution; Medication Management; Oxygen Therapy; Postanesthesia Care; Risk Identification; Shock Prevention; Teaching: Disease Process; Temperature Regulation; Vital Signs Monitoring

Example NIC Activities—Shock Prevention

Monitor circulatory status; Monitor for signs of inadequate tissue oxygenation; Administer oxygen and/or mechanical ventilation, as appropriate; Instruct client and/or family on precipitating factors of shock

Nursing Interventions and *Rationales*

- Review data pertaining to client risk status including age, primary diseases, immunosuppression, antibiotic use, and presence of hemodynamic alterations such as tachycardia, tachypnea, and decrease in blood pressure (BP). **EB:** *Many clients who develop shock have underlying circumstances that predispose them to shock states, as evidenced by hypotension and inadequate organ perfusion (Kleinpell, Schorr, & Balk, 2016; Balentine, 2019).*
- Review client's medical and surgical history, noting conditions that place the client at higher risk for shock, including trauma, myocardial infarction, pulmonary embolism, head injury, dehydration, infection, endocrine problems, certain medications, and pregnancy. **EB:** *Certain clinical conditions place clients at higher risk for shock, which requires prompt identification and treatment to improve morbidity and mortality outcomes (American Heart Association [AHA], 2016; Singer et al, 2016; Balentine, 2019).*
- Complete a full nursing physical examination. *A full nursing physical examination is crucial in identifying all factors that might place that client at risk for the development of shock, such as hypoperfusion of internal organs (manifesting as decreased urinary output and shortness of breath or laboratory values such as creatinine, coagulation measures, and adrenal insufficiency) and tissue hypoperfusion (manifesting as cool, clammy, mottled skin and diminished pulses).* **EB:** *The use of extremity skin temperatures alone as a predictor of decreased cardiac output (CO) cannot be validated or supported because of a lack of consensus in the literature (Hiemstra et al, 2017). However, the presence of skin mottling, especially over the knees, ears, and fingers, suggests tissue hypoperfusion states often seen in shock (Contou & de Prost, 2016; Neviere, 2021).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

S

- Monitor circulatory status (e.g., BP, MAP, skin color, skin temperature, heart sounds, heart rate and rhythm, presence and quality of peripheral pulses, pulse oximetry, and end-tidal carbon dioxide monitoring [$EtCO_2$]). Anticipate additional studies that will evaluate dynamic changes in cardiac tissue such as ultrasonography. **EB:** *The initial phase of shock is characterized by decreased CO and tissue perfusion, which results in immediate compensatory changes evidenced by a drop in BP, increased heart rate, and shunting of blood away from the periphery, resulting in pale, cooler, damp skin, and mottling with reduced peripheral pulses. Trending changes in contractile function can further guide treatment (Contou & de Prost, 2016; Kleinpell, Schorr, & Balk, 2016; Simmons & Ventetuolo, 2017).*
- Maintain intravenous (IV) access and provide isotonic IV fluids such as 0.9% normal saline or Ringer's lactate as ordered; these fluids are commonly used in the prevention and treatment of shock. **EB:** *Restrictive fluid resuscitation and permissive hypotension (achievement of systolic pressure around 90 mm Hg, or MAP around 65 mm Hg) may have an advantage over standard higher volume fluid resuscitation regarding overall and early intraoperative survival benefit in trauma clients experiencing shock (Carrick et al, 2016; Marik & Weinmann 2019).* **EB:** *Septic shock hypoperfusion should be initially managed with a 30 mL/kg bolus of crystalloid fluid for clients who have no underlying comorbidities (e.g., congestive heart failure or chronic renal conditions) (Rhodes et al, 2017).* There is evidence to support administering full fluid volumes to chronic organ dysfunction clients such as heart failure and liver failure. **EB:** *Sepsis mortality rates were found to be decreased in the presence of full intervention bundle application (Chang et al, 2014; Prasad et al, 2017).*
- Monitor for inadequate tissue oxygenation (e.g., apprehension, increased anxiety, altered mental status, agitation, oliguria, cool/mottled periphery) and determinants of tissue oxygen delivery (e.g., Pao_2, SpO_2, $ScvO_2/SvO_2$, MAP, hemoglobin levels, lactate levels, CO). **EB:** *Assessment of tissue oxygen delivery and oxygenation patterns provides data to assess trends in client's status and evaluates treatment responses (Standl et al, 2018; Scheeren & Ramsay, 2019). Changes in client's mental status are highly sensitive to changes in perfusion and oxygenation (Singer, 2016).* **EB:** *Invasive monitoring has not been shown to improve overall mortality. Many clinicians are using noninvasive monitoring even for hemodynamically unstable clients, including the use of bedside ultrasonography and infrared spectroscopy (Seymour & Rosengart, 2015; Rhodes et al, 2017).* **EB:** *Reduction in mortality was observed with interventions aimed at lactate-guided resuscitation (Rhodes et al, 2017).*
- ▲ Maintain vital signs (BP, pulse, respirations, and temperature) and pulse oximetry within normal parameters. **EB:** *Trending of vital signs using an early warning score (EWS) is a quick, cost-effective way to identify early clients at risk of deterioration and intervene in a timely manner (Albur, Hamilton, & MacGowan, 2016) and is more accurate than quick Sequential [sepsis-related] Organ Failure Assessment (qSOFA) (Churpek et al, 2017).* **EB:** *Increased heart rate (above 90 beats per minutes), hypotension (BP below 90 mm Hg systolic, or MAP < 65 mm Hg), tachypnea (greater than 20 breaths per minute), hypoxia (SpO_2 below 90%), lactate levels (above 2 mmol/L), and change in mentation are indicators of shock (Singer, 2016; Singer et al, 2016; Rhodes et al, 2017). Temperature greater than 38°C or less than 36°C with white blood cell count greater than 12,000/mm^3 or less than 4000/mm^3 plus symptoms listed earlier are indicators of SIRS (Bok, 2020; Singer et al, 2016; Rhodes et al, 2017).* **EB:** *qSOFA, which looks at altered mentation, systolic BP of 100 mm Hg or less, and respiratory rate greater than 22 breaths per minute, has been shown to identify clients who are likely to have poor outcomes (Singer, 2016; Singer et al, 2016; Churpek et al, 2017).*
- ▲ Administer oxygen immediately to maintain SpO_2 greater than 90%, and antibiotics and other medications as prescribed to any client presenting with symptoms of early shock. **EBN:** *The experienced nurse has an important role in the implementation of the Surviving Sepsis Campaign (SSC), which includes specific early goal-directed therapies that enhance client survival (Kleinpell, Schorr, & Balk, 2016).* **EB:** *Early goal-directed therapy protocols focusing on administration of oxygen, fluid resuscitation, antibiotics administered within an hour, and vasoactive medications provide early correction of risks for shock and improve survival of shock. Antibiotics as prescribed administered within 1 hour of diagnosis of a sepsis state facilitate a better rate of survival. For each hour in delayed antibiotic administration, survival decreases by 7.6% (Seymour & Rosengart, 2015; Rhodes et al, 2017).*
- ▲ Monitor trends in noninvasive hemodynamic parameters (e.g., MAP) as appropriate. **EB:** *MAP less than 60 to 65 mm Hg for any extended time period is associated with poor outcomes (Leone et al, 2015).* **EB:** *Restoring MAP to desired levels (above 65 mm Hg) facilitates adequate perfusion to organs (Singer, 2016; Rhodes et al, 2017).* **EB:** *An overarching goal of cardiovascular support is optimization of blood flow to tissues; however, there is no single optimum MAP that can be applied to all. In clients with chronic arterial hypertension, a higher MAP (75–85 mm Hg) may be preferable (Leone et al, 2015; Rhodes et al, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Monitor hydration status including daily weights, postural BP changes, serum electrolytes (sodium, potassium, chloride, bilirubin, creatinine, and blood urea nitrogen), intake and output, and skin turgor. Consider insertion of an indwelling urinary catheter as ordered to measure hourly output for a goal of 0.5 mL/kg/hr (Kleinpell, Schorr, & Balk, 2016).

▲ Monitor serum lactate levels and interpret them within the context of each client. **EB:** *Elevations in serum lactate (above 2 mmol/L) may indicate circulatory failure and resultant tissue hypoxia from anaerobic metabolism that results in toxin accumulation, cellular inflammation, and cellular death with higher lactate levels predictive of higher mortality (Casserly et al, 2015).* **EB:** *Progression to septic shock may result as characterized by the onset of SIRS (Rhodes et al, 2017). Two or more of the following indicators suggest SIRS: altered temperatures; heart rates above 90 beats per minute; tachypnea or hypocarbia; and/or leukocytosis/leukopenia, which may or may not be related to infection as other causative factors exist (Rhodes et al, 2017). The degree of serum lactate elevation correlates with morbidity and mortality in sepsis; early detection facilitates early treatment and is a more accurate triage tool than vital signs (Casserly et al, 2015). Monitor blood glucose levels frequently and administer insulin as prescribed to targeted blood glucose levels of <180 mg/dL (Rhodes et al, 2017).*

Critical Care

▲ Prepare the client for the placement of an additional IV line, a central line, and/or a pulmonary artery catheter as prescribed. Adequate IV and central line access may be required for fluid resuscitation and medication delivery. Maintaining more than one IV access ensures rapid IV medication and fluid delivery in a crisis situation. Large amounts of fluid can be delivered more efficiently through centrally placed vascular access sites. Most vasoactive agents, especially vasopressors, should be delivered only through central lines because of risk of tissue sloughing. **EB:** *A Cochrane systematic review of 13 studies on 5686 clients found no difference in mortality rates or days spent in an intensive care unit (ICU) between those clients with a pulmonary artery catheter and those without (Rajaram et al, 2013).*

▲ Monitor trends in hemodynamic parameters (e.g., central venous pressure [CVP], CO, cardiac index [CI], systemic vascular resistance [SVR], pulmonary artery pressure [PAP], MAP) as appropriate. **EB:** *Hemodynamic indices will be altered depending on the underlying form of shock (hypovolemic, distributive, or cardiogenic). Dehydration will result in reduced CVP, CO, PAP, and ultimately MAP because of hypovolemia. Vasodilation as seen in distributive shock patterns (forms of third spacing as in neurogenic, anaphylactic, and septic shock states) will decrease BP and CVP (a surrogate for intravascular volume) and other hemodynamic indices. Cardiogenic shock will result in low CO and MAP with higher PAP and CVP indices caused by heart failure and subsequent congestion of the cardiopulmonary systems. Compensatory mechanisms to address reductions in CO and MAP include tachycardia and reduced urinary output (less than 0.5 mL/kg/hr). Both CO and SVR may temporarily increase with the onset of shock because of compensatory mechanisms; however, as shock progresses, both CO and SVR decline (Standl et al, 2018; Kislitsina et al, 2019).*

▲ Monitor electrocardiography. Myocardial ischemia can present as ST segment changes, which can be seen before a decrease in BP as a compensatory mechanism. **EB:** *As oxygen demands increase, tachycardia and cardiac dysrhythmias may be evident, such as ST segment changes (Goldberger & Prutkin, 2020).*

▲ Monitor arterial blood gases, coagulation, blood chemistries, blood glucose, cardiac enzymes, blood cultures, and hematology laboratory test results. **EB:** *Abnormalities can identify the cause of the perfusion deficits and identify complications related to the decreased perfusion or shock state. Cardiogenic shock may be identified by elevations in cardiac enzymes as a result of myocardial infarction in association with low MAP. Elevation/reduction in white blood cell counts may be indicative of septic shock when associated with alterations in MAP (Rhodes et al, 2017).*

▲ Administer vasopressor agents as prescribed. **EB:** *Norepinephrine is the vasopressor of choice for septic shock (Avni et al, 2015; Gamper et al, 2016; Rhodes et al, 2017). Norepinephrine should be administered through a central line.* **EB:** *Low-dose dopamine should not be started for renal protection (Gamper et al, 2016; Rhodes et al, 2017).*

● If the client is in shock, refer to the following care plans: Risk for Ineffective **Renal** Perfusion, Risk for Ineffective **Gastrointestinal** Perfusion, Impaired **Gas** Exchange, and Decreased **Cardiac** Output.

Client/Family Teaching and Discharge Planning

▲ Teach client and family or significant others about any medications prescribed. Instruct the client to report any adverse side effects to his or her health care provider. Medication teaching includes the drug name, purpose, administration instructions (e.g., with or without food), and any side effects. **EB:** *Provision of such information using clear communication principles and with an understanding of what the health*

literacy level of the client/family/significant others may be can facilitate appropriate adherence to the therapeutic regimen (Balentine, 2019; Crane Cutilli, 2020; National Institutes of Health [NIH], 2021).

- Instruct the client and family on disease process and rationale for care. **EB:** *Tailoring interventions to the needs and education levels of the client and caregivers enhances learning and retention of material (Ha Dinh, 2016; Crane Cutilli, 2020; Marin, 2021).*
- Instruct clients and their family members on the signs and symptoms of low BP to report to their health care provider (dizziness, lightheadedness, fainting, dehydration and unusual thirst, lack of concentration, blurred vision, nausea, cold, clammy, pale skin, rapid and shallow breathing, fatigue, and depression). **EBN:** *Teach-back methods are among the most recommended techniques to verify client retention. Use of the teach-back method enhances individual and caregiver knowledge and adherence behaviors (Crane Cutilli, 2020). Early recognition and treatment of these symptoms may avoid more serious sequelae (AHA, 2016; Singer et al, 2016; Churpek et al, 2017).*
- Promote a culture of client safety and individual accountability. **EB:** *Organizations that promote a just culture of safety help to reduce or prevent errors and improve overall health care quality (Agency for Healthcare Research and Quality [AHRQ], 2019). Include health literacy strategies into all aspects of client-centered care and weave into organizational values (Crane Cutilli, 2020).*

Impaired Sitting

Domain 4 Activity/rest Class 2 Activity/exercise

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CNEcl, CHSE, ANEF, FAAN

NANDA-I

Definition

Limitation of ability to independently and purposefully attain and/or maintain a rest position that is supported by the buttocks and thighs, in which the torso is upright.

Defining Characteristics

Difficulty adjusting position of one or both lower limbs on uneven surface; difficulty attaining postural balance; difficulty flexing or moving both hips; difficulty flexing or moving both knees; difficulty maintaining postural balance; difficulty stressing torso with body weight

Related Factors

Insufficient energy; insufficient muscle strength; malnutrition; neurobehavioral manifestations; pain; self-imposed relief posture

Associated Conditions

Impaired metabolism; mental disorders; neurological disorder; orthopedic surgery; prescribed posture; sarcopenia

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Activity Tolerance; Balance; Body Mechanics Performance; Body Positioning: Self-Initiated; Endurance; Tissue Perfusion: Peripheral; Self Care Status; Skeletal Function

Example NOC Outcome with Indicators

Body Mechanics Performance: as evidenced by the following indicators: Uses correct sitting posture/ Uses supportive devices correctly. (Rate outcome and indicators of **Body Mechanics Performance:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize importance of being able to sit as a method to engage in activities of daily living
- Understand somatic physiology of posture control
- Choose health care options that enhance ability to sit

- Engage in physical conditioning exercises to enhance sitting ability
- Understand relationship of posture and emotions
- Control pain to increase ability to sit

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Activity Therapy; Body Mechanics Promotion; Fall Prevention; Energy Management; Exercise Promotion: Strength Training; Exercise Therapy: Balance, Joint Mobility, Muscle Control; Functional Ability Enhancement; Positioning; Pressure Ulcer Prevention

Example NIC Activities—Exercise Therapy: Sitting

Assist client to use chair that facilitates sitting and prevents injury; Transfer safely from bed to chair; Encourage to sit in chair, as tolerated; Provide activities that can be completed while sitting

Nursing Interventions and *Rationales*

- Acknowledge the importance of being able to sit as a method to engage in activities of daily living. **EB:** *Park, Gong, and Yim (2017) investigated upper limb function, balance, gait, and quality of life in two groups of stroke clients* (n = *26) before and after a sitting boxing program and found that the Stroke-Specific Quality of Life (SS-QOL) questionnaire scores were significantly improved in the boxing group, concluding that the sitting boxing program group had positive effects on upper extremity function, balance, gait, and quality of life.* **EB:** *Shambaugh et al (2020) studied clients* (n = *121) with hamstring ruptures that were repaired and found that if the repair was done 6 weeks or more after the injury was sustained, there was greater sitting intolerance. This study suggests that hamstring ruptures should be repaired as soon as possible to promote normal sitting patterns without pain and discomfort.*
- Understand the somatic physiology of posture control. **EB:** *Lee et al (2017) studied trunk muscle activities in four types of seated postures—cross-legged, long, side, and* W*-shaped—in adults* (n = *8) and found that trunk muscle activity did not significantly differ between the four types of sitting postures.* **EB:** *Massaad and colleagues (2020) studied adults with spinal deformities and found that their quality of life was adversely affected by poor postural sitting alignment. Poor posture affected every aspect of their activities of daily living.* **EB:** *Lee, Lee, and Shin (2017) studied forward head posture in seven different posture conditions in clients* (n = *20), including sitting comfortably and sitting with the back straight, and found that head posture evaluation is a reliable assessment for evaluating proper sitting conditions.*
- Encourage engagement in physical conditioning exercises to enhance proper sitting ability. **EB:** *Molik et al (2017) investigated disabled clients playing volleyball in a sitting position and found that the vertical sitting position and degree of disability directly related to performance, but the exercise was beneficial.* **EB:** *Alghdir, Zafar, and Iqbal (2017) studied the effects of upright and slouch sitting postures and voluntary teeth clenching on hand grip strength (HGS) in clients* (n = *100) and found that HGS was actually stronger during slouching than sitting upright and HGS had no effect on teeth clenching, indicating that sitting posture may matter when testing HGS in a physical assessment evaluation.* **EB:** *Chrisman et al (2020) studied college students* (n = *22) using sitting and standing desks and the majority of participants preferred sitting to standing. The study informs health care providers of the need for education on standing desks to encourage positive physical activity in the college population.*
- Understand the relationship of posture and emotions. **EB:** *Oki et al (2017) investigated physical and psychological effects of the Shiatsu Stimulation (SS) (finger pressure) in a sitting position on clients* (n = *20). The SS demonstrated significant change in all six mood states (tension-anxiety, depression-dejection, fatigue, and confusion decreased, whereas vigor elevated).* **CEB:** *A classic study about slumped and upright posture by Nair et al (2015) observed 74 participants and the results found that an upright sitting position during a stressful time can assist to maintain self-esteem, reduce negative mood, and promote a positive mood compared to those participants in a slumped posture.*
- Maintain pain levels below 3 to 4 on a 0-to-10 scale to increase ability to sit. **EB:** *Joshi et al (2017) studied neuropathy of the posterior femoral cutaneous nerve, which can cause pain while sitting, and performed magnetic resonance–guided cryoablation to successfully treat sitting pain caused by neuropathy.* **EB:** *Harvard Health (2020) reports that sore backsides during sitting can be relieved with stretching and exercise. Stretching and exercise can also reduce the incidence of sciatica and piriformis nerve discomfort.*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Pediatric

- Promote proper sitting ability to increase cognitive and physical functioning. **EB:** *Rethlefsen et al (2020) compared the way children (n = 104) sit (W-sitting to non–W-sitting) in relation to hip dysplasia and found no difference. The mode of sitting was not a causative factor for hip dysplasia in this observational study.* **EBN:** *Hitchcock (2017) reviewed the research regarding safe infant sleeping and addressed the fact that sitting devices are not recommended. Nurses should model recommended behaviors for safe infant sleep and teach parents about safe infant sleep throughout the hospital stay.*

Geriatric

- Promote proper sitting ability to increase cognitive and physical functioning. **EB:** *Researchers studied the effects of aging on clients' (n = 39) muscle control during transition from lying to sitting positions using myotonometry measurements of tone, stiffness, and elasticity; results suggested that increased age increases stiffness and tone and decreases the elasticity of muscles (Kocur et al, 2017).* **EBN:** *A meta-analysis was completed by Fazio et al (2020) and demonstrated that geriatric adults who are hospitalized spend 87% to 100% of the time sitting or lying in bed. The study suggests that tools be developed to assess mobility and that immobility be decreased to decrease health complications in this population.*

Multicultural

- Understand the importance of unimpaired sitting to different populations. **EB:** *A case study analyzed in Japan discussed the researchers' novel "hip prosthesis in the sitting posture" on a client who was an amputee and found that implanting a hip prosthesis in a sitting position enabled the client to better stand, walk, and begin balance training (Shimizu et al, 2017).* **CEB:** *Erikson et al (2011) completed a multicultural observational study about how older adults spend time in different cultures and found that there were 16 activities associated with Asian adults and one important activity among the 16 was the ability to sit and think.*

Home Care

- Encourage proper sitting posture in the home environment to promote health. **EB:** *Li et al (2017) studied clients (n = 16) in four modes of reclining wheelchairs with and without different sitting devices and found that the lumbar support with femur upward with back reclined mode provided the most significant reduction in stress load on the ischial area.* **EB:** *Arundell et al (2020) studied the amount of screen time consumed by families (n = 542). Screen time is directly related to the amount of sitting done by family members in the home. Increased screen time is inversely related to activity time needed for musculoskeletal development in children and in this study was found to affect parenting behaviors, role modeling, and the child's schooling.*

Impaired Skin Integrity

Domain 11 Safety/protection Class 2 Physical injury

JoAnn Coar, MSN, RN-BC, A-GNP-C, CWOCN

NANDA-I

Definition

Altered epidermis and/or dermis.

Defining Characteristics

Abscess; acute pain; altered skin color; altered turgor; bleeding; blister; desquamation; disrupted skin surface; dry skin; excoriation; foreign matter piercing skin; hematoma; localized area hot to touch; macerated skin; peeling; pruritus

Related Factors

External Factors

Excessive moisture; excretions; humidity; hyperthermia; hypothermia; inadequate caregiver knowledge about maintaining tissue integrity; inadequate caregiver knowledge about protecting tissue integrity; inadequate use of chemical agent; pressure over bony prominence; psychomotor agitation; secretions; shearing forces; surface friction; use of linen with insufficient moisture wicking property

Internal Factors

Body mass index above normal range for age and gender; body mass index below normal range for age and gender; decreased physical activity; decreased physical mobility; edema; inadequate adherence to incontinence treatment regimen; inadequate knowledge about maintaining tissue integrity; inadequate knowledge about protecting tissue integrity; malnutrition; psychogenic factor; self mutilation; smoking; substance misuse; water-electrolyte imbalance

At-Risk Population

Individuals at extremes of age; individuals in intensive care units; individuals in long-term care facilities; individuals in palliative care settings; individuals receiving home-based care

Associated Conditions

Altered pigmentation; anemia; cardiovascular diseases; decreased level of consciousness; decreased tissue oxygenation; decreased tissue perfusion; diabetes mellitus; hormonal change; immobilization; immunodeficiency; impaired metabolism; infections; medical devices; neoplasms; peripheral neuropathy; pharmaceutical preparations; punctures; sensation disorders

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Integrity: Skin and Mucous Membranes; Wound Healing: Primary Intention, Secondary Intention

Example NOC Outcome with Indicators

Tissue Integrity: Skin and Mucous Membranes will be intact as evidenced by the following indicators: Skin integrity/Skin lesions not present/Tissue perfusion/Skin temperature/Skin thickness. (Rate the outcome and indicators of **Tissue Integrity: Skin and Mucous Membranes:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Regain integrity of skin surface
- Report any altered sensation or pain at site of skin impairment
- Demonstrate understanding of plan to heal skin and prevent reinjury or complications
- Describe measures to protect and heal the skin and to care for any skin lesion

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Incision Site Care; Pain Management; Pressure Ulcer Care (currently referred to as Pressure Injury Care [National Pressure Ulcer Advisory Panel (NPUAP), 2016]); Pressure Ulcer Prevention (Pressure Injury Prevention [NPUAP, 2016]); Risk Identification; Skin Care: Topical Treatments; Skin Surveillance; Wound Care; Wound Irrigation

Example NIC Activities—Pressure Ulcer Care (Pressure Injury Care [NPUAP, 2016])

Monitor color of wound bed, temperature, edema, erythema, moisture, and appearance of surrounding skin; Note characteristics of any drainage

Nursing Interventions and *Rationales*

- NPUAP redefined the definition of a pressure ulcer, now referred to as pressure injuries, during the NPUAP 2016 Staging Consensus Conference. The new definitions more accurately define alterations in tissue integrity from pressure as the following: A pressure injury is localized damage to the skin and underlying soft tissue usually over a bony prominence or related to a medical or other device. The injury can present as intact skin or an open ulcer and may be painful. The injury occurs as a result of intense and/or prolonged pressure or pressure in combination with shear. The tolerance of soft tissue for pressure and shear may also be affected by microclimate, nutrition, perfusion, comorbidities, and condition of the soft tissue *(NPUAP, 2016)*.
- Pressure ulcer is no longer a current clinical term; rather, pressure injury is used to describe an alteration in tissue integrity from pressure (NPUAP, 2016). Similarly, hospital-acquired pressure ulcers (HAPUs) are currently referred to as hospital-acquired pressure injuries (HAPIs).
- Assess site of skin impairment and determine cause or type of wound (e.g., acute or chronic wound, burn, dermatological lesion, pressure injury, skin tear). **EB:** *Identification of etiological factors, or what is causing the impairment, is the first step and requires a thorough assessment of the individual, not only the impairment. The assessment should include the medical history, current medical status, medications, and family history (Baranoski & Ayello, 2016; Murphree, 2017). Skin and tissue assessment is important in pressure injury prevention, classification, diagnosis, and treatment (NPUAP, 2016; National Pressure Injury Advisory Panel [NPIAP], European Pressure Injury Advisory Panel [EPIAP], & Pan Pacific Pressure Injury Alliance [PPPIA], 2019).*
- Use a risk assessment tool to systematically assess client risk factors for skin breakdown caused by pressure. **EB:** *A validated risk assessment tool such as the Norton scale or Braden scale should be used to identify*

S

clients at risk for immobility-related skin breakdown (NPIAP, EPIAP, & PPPIA, 2019). An individual identified at risk for pressure injury development or who has healed pressure injuries will need to be evaluated for pressure redistributing surfaces (Murphree, 2017). Targeting variables (e.g., age and Braden Scale Risk Category) can focus assessment on particular risk factors (e.g., pressure) and help guide the plan of prevention and care (NPIAP, EPIAP, & PPPIA, 2019).

- Determine the extent of the skin impairment caused by pressure using the revised classification system and definition for pressure injuries (NPUAP, 2016).
  - **Stage 1 Pressure Injury:** Nonblanchable erythema of intact skin. Area of localized nonblanchable erythema that may appear differently in darkly pigmented skin and changes in sensation, temperature, or firmness may precede visual changes. Color changes do not include purple or maroon discoloration, which is more likely to indicate deep tissue pressure injury (NPUAP, 2016).
  - **Stage 2 Pressure Injury:** Partial-thickness skin loss with exposed dermis. Partial-thickness skin loss with exposed dermis in which the wound bed is pink/red and moist and adipose (fat) and deeper tissues are not visible. Granulation tissue, slough, and eschar are not present. A stage 2 pressure injury may also present as an intact or ruptured blister. These injuries commonly result from adverse microclimate and shear in the skin over the pelvis and shear in the heel. This stage should not be used to describe moisture-associated skin damage (MASD) including incontinence-associated dermatitis (IAD), intertriginous dermatitis (ITD), medical adhesive–related skin injury (MARSI), or traumatic wounds (skin tears, burns, and abrasions) (NPUAP, 2016).
  - **Stage 3 Pressure Injury**: Full-thickness skin loss. Full-thickness loss of skin, in which adipose is visible and granulation tissue and epibole (rolled wound edges) are often present and undermining/tunneling may occur. Slough and/or eschar may also be visible. Fascia, muscle, tendon, ligament, cartilage, and/or bone are not exposed. The depth of tissue damage varies by anatomical location, and areas of significant adiposity can develop deep wounds. If slough or eschar obscures the extent of tissue loss, this is an unstageable pressure injury (NPUAP, 2016).
  - **Stage 4 Pressure Injury**: Full-thickness skin and tissue loss. Full-thickness skin and tissue loss with exposed or directly palpable fascia, muscle, tendon, ligament, cartilage or bone, and slough and/or eschar may be visible. Epibole, undermining, and/or tunneling often occur, and depth varies by anatomical location. If slough or eschar obscures the extent of tissue loss, this is an unstageable pressure injury (NPUAP, 2016).
  - **Deep Tissue Pressure Injury:** Persistent nonblanchable deep red, maroon, or purple discoloration. Intact or nonintact skin with localized area of persistent nonblanchable deep red, maroon, or purple discoloration or epidermal separation revealing a dark wound bed or blood-filled blister. Pain and temperature change often precede skin color changes. Discoloration may appear differently in darkly pigmented skin. This injury results from intense and/or prolonged pressure and shear forces at the bone–muscle interface. The wound may evolve rapidly to reveal the actual extent of tissue injury, or it may resolve without tissue loss. If necrotic tissue, subcutaneous tissue, granulation tissue, fascia, muscle, or other underlying structures are visible, this indicates a full-thickness pressure injury (unstageable, stage 3, or stage 4). Do not use the term deep tissue pressure injury to describe vascular, traumatic, neuropathic, or dermatological conditions (NPUAP, 2016).
  - **Unstageable Pressure Injury:** Obscured full-thickness skin and tissue loss. Full-thickness skin and tissue loss in which the extent of tissue damage within the ulcer cannot be confirmed because it is obscured by slough or eschar. If slough or eschar is removed, a stage 3 or stage 4 pressure injury will be revealed. Stable eschar (i.e., dry, adherent, intact without erythema or fluctuance) on the heel or ischemic limb should not be softened or removed (NPUAP, 2016).
  - **Mechanical Device-Related Pressure Injury:** Used to describe alterations in tissue integrity caused by pressure from mechanical devices used in the care of clients (e.g., indwelling urinary catheters, endotracheal tubes, nasogastric tubes, drains). The pressure injury typically conforms to the shape of the device (NPUAP, 2016).
  - **Mucosal Membrane Pressure Injury:** Mucosal membrane pressure injury is found on mucous membranes with a history of a medical device in use at the location of the injury. Because of the anatomy of the tissue, these ulcers cannot be staged (NPUAP, 2016).
- Inspect and monitor site of skin impairment at least once a day for color changes, erythema, edema, warmth, pain, changes in sensation, moisture, or other signs of infection. **EB:** *Consider assessment of temperature and subepidermal moisture as an adjunct to routine skin assessment and in darkly pigmented*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

skin (NPIAP, EPIAP, & PPPIA, 2019). Closely assess high-risk areas such as bony prominences, skinfolds, the sacrum, and heels. Consider use of soft silicone multilayered foam protective dressings over bony prominences (NPIAP, EPIAP, & PPPIA, 2019). Systematic inspection can identify impending problems early (Baranoski & Ayello, 2016; NPIAP, EPIAP, & PPPIA, 2019).

- Monitor the client's skin care practices, noting type of soap or other cleansing agents used, temperature of water, and frequency of skin cleansing. **EB:** *Cleansing should not compromise the skin (Baranoski & Ayello, 2016). Keep the skin clean and hydrated. Provide prompt cleansing after episodes of incontinence, avoiding use of alkaline soaps and cleansers. Protect the skin from exposure to excessive moisture with a barrier product to reduce the risk of pressure damage (NPIAP, EPIAP & PPPIA, 2019). Products to promote healthy skin in the elderly include cleansers that are pH balanced, preferably no-rinse in soft disposable cloths, and superfatted nonalkaline soaps (Murphree, 2017).*
- Consider using physiologically compatible cleansers with each wound dressing change. **EB:** *Normal saline (NS) is the least cytotoxic and when delivered at a pressure of 4 to 15 PSI can safely remove wound debris (NPUAP, 2016; Cox, 2019; NPIAP, EPIAP, & PPPIA, 2019; NPUAP 2016).*
- Maintain good skin hygiene, using mild nondetergent soap, drying gently, and lubricating with lotion or emollient to reduce the risk of dermal trauma; improve circulation; and promote comfort. **EB:** *Avoid vigorous rubbing (NPIAP, EPIAP, & PPPIA, 2019). Provide client education on good skin hygiene practices (Doenges, Moorhouse, & Murr, 2016).*
- Urinary and fecal incontinence can cause skin breakdown. **EB:** *Develop and implement an individualized continence management plan. Cleanse the skin promptly after episodes of incontinence. Protect the skin from exposure to excessive moisture with a barrier product to reduce the risk of pressure damage (NPIAP, EPIAP, & PPPIA, 2019).* **EB:** *Chronic exposure to moisture macerates the skin, impairing its protective mechanisms and disrupting normal skin flora, which can lead to cutaneous infection (Cox, 2019).*
- For clients with limited mobility and activity, use a risk assessment tool to systematically assess immobility and activity-related risk factors. **EB:** *A validated risk assessment tool such as the Norton scale or Braden scale should be used to identify clients at risk for immobility-related skin breakdown (NPIAP, EPIAP, & PPPIA, 2019).* **EBN:** *At an organizational level, maximize workforce goals as a part of quality improvement and include evidence-based care to prevent pressure injury development. Assess the knowledge of health care professionals and provide a multifaceted education program for pressure injury prevention and treatment (NPIAP, EPIAP, & PPPIA, 2019).*
- Do not position the client on site of skin impairment. If consistent with overall client management goals, reposition the client as determined by individualized tissue tolerance and overall condition. Reposition and transfer the client with care to protect against the adverse effects of external mechanical forces such as pressure, friction, and shear. Maintain the head of the bed as flat as possible. Use a 30-degree lateral positioning (NPIAP, EPIAP, & PPPIA, 2019). **EB:** *Do not position an individual directly on a pressure injury. Continue to turn/reposition the individual regardless of the support surface in use. Establish turning frequency based on the characteristics of the support surface and the individual's response (NPIAP, EPIAP, & PPPIA, 2019). If the goal of care is to keep the client (e.g., a terminally ill client) comfortable, turning and repositioning may not be appropriate (NPIAP, EPIAP, & PPPIA, 2019).*
- Evaluate for use of support surfaces (specialty mattresses, beds), chair cushions, or devices as appropriate. Maintain the head of the bed at the lowest possible degree of elevation to reduce shear and friction, and use lift devices, pillows, foam wedges, and pressure-reducing devices in the bed (Brienza et al, 2016; NPIAP, EPIAP, & PPPIA, 2019).
- Implement a written treatment plan for topical treatment of the site of skin impairment. **EB:** *A written plan ensures consistency in care and documentation (Baranoski & Ayello, 2016).*
- Select a topical treatment that will maintain a moist wound-healing environment (stage 2) that is balanced with the need to absorb exudate. Stage 1 pressure injuries may be managed by keeping the client off of the area and using a protective dressing (Baranoski & Ayello, 2016). **EBN:** *Choose dressings that provide a moist environment, keep peri-wound skin dry, and control exudate and eliminate dead space (NPIAP, EPIAP, & PPPIA, 2019). Select a wound dressing based on the ability to keep the wound bed moist; need to address bacterial bioburden; nature and volume of wound exudate; condition of the tissue in the wound bed; condition of peri-wound skin; wound size, depth, and location; presence of tunneling and/or undermining; and goals and self-care abilities of the individual or caregiver (NPIAP, EPIAP, & PPPIA, 2019).*
- Avoid massaging around the site of skin impairment and over bony prominences. **EB:** *Research suggested that massage may lead to deep tissue trauma (NPIAP, EPIAP, & PPPIA, 2019).*

S

- Assess the client's nutritional status. Refer for a nutritional consultation and/or institute dietary supplements as necessary. **EB:** *Optimizing nutritional intake, including calories, fatty acids, protein, and vitamins, is needed to promote wound healing. Both the EPIAP and NPIAP (NPIAP, EPIAP, & PPPIA, 2019) endorse the application of reasonable nutritional assessment and treatment for clients at risk for and with pressure injuries.*
- Identify the client's phase of wound healing (inflammation, proliferation, or maturation) and stage of injury. **EBN:** *The selection of the dressing is based on the tissue in the wound bed, the condition of the skin around the wound bed, and the goals of the person with the wound. Generally, maintaining a moist wound bed is ideal when the wound bed is clean and granulating to promote healing and closure (NPIAP, EPIAP, & PPPIA, 2019). No single wound dressing is appropriate for all phases of wound healing.*

Home Care

- The interventions described previously may be adapted for home care use.
- Instruct and assist the client and caregivers in how to change dressings and maintain a clean environment. Provide written instructions and observe the client completing the dressing change before hospital discharge and in the home setting.
- Educate client and caregivers on proper nutrition, signs and symptoms of infection, and when to call the agency and/or health care provider with concerns.

▲ Treating wounds requires a multiprofessional approach with the frontline nurse an essential member (Cox, 2019).

Client/Family Teaching and Discharge Planning

- Teach skin and wound assessment and ways to monitor for signs and symptoms of infection, complications, and healing. Early assessment and intervention help prevent serious problems from developing. **EB:** *Optimize potential for healing by regularly assessing nutritional status and comorbidities and preventing contamination of wounds with regular cleansing and treatments (NPIAP, EPIAP, & PPPIA, 2019).*
- Teach the client why a topical treatment has been selected. **EBN:** *The type of dressing needed may change over time as the wound heals and/or deteriorates (NPIAP, EPIAP, & PPPIA, 2019).*
- If consistent with overall client management goals, teach how to reposition as client condition warrants. **EB:** *If the goal of care is to keep a client (e.g., terminally ill client) comfortable, turning and repositioning may not be appropriate (NPIAP, EPIAP, & PPPIA, 2019).*
- Teach the client to use pillows, foam wedges, chair cushions, and pressure-redistribution devices to prevent pressure injury (Brienza et al, 2016). **EB:** *Individualize the selection and periodic reevaluation of a seating support surface and associated equipment for posture and pressure redistribution with consideration of body size and configuration, the effects of posture and deformity on pressure distribution, and mobility and lifestyle needs (NPIAP, EPIAP, & PPPIA, 2019).*

Risk for Impaired Skin Integrity

Domain 11 Safety/protection Class 2 Physical injury

JoAnn Coar, MSN, RN-BC, A-GNP-C, CWOCN

NANDA-I

Definition

Susceptible to alteration in epidermis and/or dermis, which may compromise health.

Risk Factors

External Factors

Excessive moisture; excretions; humidity; hyperthermia; hypothermia; inadequate caregiver knowledge about maintaining tissue integrity; inadequate caregiver knowledge about protecting tissue integrity; inadequate use of chemical agent; pressure over bony prominence; psychomotor agitation; secretions; shearing forces; surface friction; use of linen with insufficient moisture wicking property

Internal Factors

Body mass index above normal range for age and gender; body mass index below normal range for age and gender; decreased physical activity; decreased physical mobility; edema; inadequate adherence to incontinence treatment regimen; inadequate knowledge about maintaining skin integrity; inadequate knowledge about protecting skin integrity; malnutrition; psychogenic factor; self mutilation; smoking; substance misuse; water-electrolyte imbalance

At-Risk Population

Individuals at extremes of age; individuals in intensive care units; individuals in long-term care facilities; individuals in palliative care settings; individuals receiving home-based care

Associated Conditions

Altered pigmentation; anemia; cardiovascular diseases; decreased level of consciousness; decreased tissue oxygenation; decreased tissue perfusion; diabetes mellitus; hormonal change; immobilization; immunodeficiency; impaired metabolism; infections; medical devices; neoplasms; peripheral neuropathy; pharmaceutical preparations; punctures; sensation disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Immobility Consequences: Physiological; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Tissue Integrity: Skin and Mucous Membranes will be intact as evidenced by the following indicators: Skin intactness/Skin lesions not present/Tissue perfusion/Skin temperature. (Rate the outcome and indicators of **Tissue Integrity: Skin and Mucous Membranes:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Report altered sensation or pain at risk areas as soon as noted
- Demonstrate understanding of personal risk factors for impaired skin integrity
- Verbalize a personal plan for preventing impaired skin integrity

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Positioning: Pressure Management; Pressure Ulcer Care (currently referred to as Pressure Injury Care [National Pressure Ulcer Advisory Panel (NPUAP), 2016]); Pressure Ulcer Prevention (Pressure Injury Prevention [NPUAP, 2016]; Skin Surveillance

Example NIC Activities—Pressure Ulcer Care

Monitor color of wound bed, temperature, edema, erythema, moisture, and appearance of surrounding skin; Note characteristics of any drainage

Nursing Interventions and *Rationales*

- The NPUAP redefined the definition of a pressure ulcer, which is now referred to as a pressure injury, during the NPUAP 2016 Staging Consensus Conference in 2016. The new definition more accurately defines alterations in tissue integrity from pressure as the following: A pressure injury is localized damage to the skin and underlying soft tissue, usually over a bony prominence or related to a medical or other device. The injury can present as intact skin or an open ulcer and may be painful. The injury occurs as a result of intense and/or prolonged pressure or pressure in combinations with shear. The tolerance of soft tissue for pressure and shear may also be affected by microclimate, nutrition, perfusion, comorbidities, and conditions of the soft tissue (NPUAP, 2016).
- Identify clients at risk for impaired skin integrity as a result of immobility, chronological age, malnutrition, incontinence, compromised perfusion, immunocompromised status, or chronic medical condition, such as diabetes mellitus, spinal cord injury, or renal failure. **EB:** *These client populations are known to be at high risk for impaired skin integrity (Baranoski et al, 2016). Targeting variables (e.g., age and Braden Scale Risk Category) can focus assessment on particular risk factors (e.g., pressure) and help guide the plan of prevention and care (National Pressure Injury Advisory Panel [NPIAP], European Pressure Injury Advisory Panel [EPIAP], & Pan Pacific Pressure Injury Alliance [PPPIA], 2019; NPUAP, 2016).*
- Inspect and monitor skin condition at least once a day for color or texture changes, redness, localized heat, edema or induration, pressure damage, dermatological conditions, or lesions and any incontinence-associated dermatitis. Determine whether the client is experiencing loss of sensation or pain. **EB:** *Systematic inspection can identify impending problems early (Baranoski et al, 2016; NPIAP, EPIAP, & PPPIA, 2019). When conducting a skin assessment in an individual with darkly pigmented skin, prioritize assessment of skin temperature, presence of edema, and change in tissue consistency in relation to surrounding tissue (NPIAP, EPIAP, & PPPIA, 2019).*
- Monitor the client's skin care practices, noting type of soap or other cleansing agents used, temperature of water, and frequency of skin cleansing. *Individualize plan according to the client's skin condition, needs, and preferences (Baranoski et al, 2016).*
- Keep skin clean and dry. Cleanse the skin gently with pH-balanced cleansers, avoiding alkaline soaps and cleansers. **EB:** *Avoid vigorous rubbing of skin. Consider use of skin moisturizers to hydrate skin to reduce risk of skin damage. Protect skin from exposure to excessive moisture with a barrier product to reduce the risk of pressure-related damage (NPIAP, EPIAP, & PPPIA, 2019).*
- ▲ Develop and implement an individualized continence management plan. Cleanse the skin promptly after episodes of incontinence. Use incontinence skin barriers including creams, ointments, pastes, or film-forming skin protectants as needed to protect skin and maintain intact skin (Wound, Ostomy and Continence Nurses Society–Wound Guidelines Task Force, 2017). Use highly absorbent incontinence products (NPIAP & EPIAP, 2019). **EB:** *Implementing an incontinence prevention plan with the use of a skin protectant or a cleanser protectant can significantly decrease skin breakdown and pressure ulcer formation (Baranoski et al, 2016; NPIAP, EPIAP, & PPPIA, 2019).*
- For clients with limited mobility, inspect and monitor condition of skin covering bony prominences. **EB:** *Pressure injuries usually occur over bony prominences, such as the sacrum, coccyx, trochanter, and heels, as a result of unrelieved pressure between the prominence and support surface or with shearing and friction (Baranoski et al, 2016; NPIAP, EPIAP, & PPPIA, 2019). Position individuals in the sitting position with special attention to anatomy, weight distribution, postural alignment, and support of feet (Wound, Ostomy and Continence Nurses Society–Wound Guidelines Task Force, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Implement and communicate a client-specific prevention plan. **EB:** *A plan of care clearly documented in the client's electronic health record will assist in ensuring consistency in care and documentation (Baranoski et al, 2016).*
- At-risk clients should be frequently repositioned. **EB:** *Frequency of repositioning will be influenced by variables concerning the individual's independent mobility and the support surface in use. Frequency of repositioning should be determined by the individual's tissue tolerance and medical condition (NPIAP, EPIAP, & PPPIA, 2019). Use of heel suspension devices can remove pressure from the heels and support the lower extremity of individuals who are unable to keep pressure off the heels, without placing pressure on the Achilles tendon and to the popliteal vein (Wound, Ostomy and Continence Nurses Society–Wound Guidelines Task Force, 2017; NPIAP, EPIAP, & PPPIA, 2019).*
- Evaluate for use of specialty mattresses, beds, or devices as appropriate. **EB:** *Select a surface that addresses the individual's need for pressure redistribution (Brienza et al, 2016; NPIAP, EPIAP, & PPPIA, 2019). Maintain the head of the bed at the lowest possible degree of elevation to reduce shear and use lift devices, pillows, foam wedges, and pressure-reducing devices in the bed. If the goal of care is to keep the client (e.g., a terminally ill client) comfortable, turning clients side to side at end of life may not be a priority or feasible. If the duration of pressure cannot be reduced, reducing the intensity may be the only option. An alternating pressure mattress with a low air loss feature is recommended (Hotaling & Black, 2018). Pressure redistributing devices are adjuncts to and not replacements for regular repositioning (Wound, Ostomy and Continence Nurses Society–Wound Guidelines Task Force, 2017).*

▲ Assess the client's nutritional status; refer for a nutritional consultation, and/or institute dietary supplements. **EB:** *Develop and implement an individualized nutritional care plan for individuals with or at risk for pressure injuries. Provide 1.2 to 1.5 g protein/kg body weight/day and 30 to 35 kilocalories body weight/day for individuals with pressure injuries with risk for malnutrition (NPIAP, EPIAP, & PPPIA, 2019).* **EB:** *Meeting nutritional needs of the client is important to prevention of skin breakdown and preventing complications of illness. Adequate nutrition is important for maintaining overall homeostasis and health (O'Hanlon et al, 2015).*

Geriatric

- Limit the number of complete baths to two or three per week, and alternate them with partial baths. Use a tepid water temperature (between 90°F [32.2°C] and 105°F [40.5°C]) for bathing or use a no-rinse alternative product. **EB:** *Excessive bathing, especially in hot water, depletes aging skin of moisture and increases dryness. The ability to retain moisture is decreased in aging skin because of diminished amounts of dermal proteins. One of the most common age-related changes to the skin is damage to the stratum corneum (Baranoski et al, 2016).*
- Use lotions and moisturizers to prevent skin from drying out, especially in the winter. **EB:** *Avoid skin care products that contain allergens such as lanolin, latex, and dyes (Baranoski et al, 2016). Use barrier products to protect aged skin from exposure to excessive moisture to reduce the risk of pressure damage (NPIAP, EPIAP, & PPPIA, 2019).*
- Increase fluid intake within cardiac and renal limits to a minimum of 1500 mL/day. **EB:** *Dry skin is caused by loss of fluid; increasing fluid intake hydrates the skin (Baranoski et al, 2016). Recommend that individuals with nutritional and pressure injury risks consume a minimum of 30 to 35 kcal/kg body weight per day, 1.25 to 1.5 g of protein/kg body weight per day, and 1 mL of fluid intake per kilocalorie per day, if there are no contraindications (Wound, Ostomy and Continence Nurses Society–Wound Guidelines Task Force, 2017).*
- Increase humidity in the environment, especially during the winter, by using a humidifier or placing a container of water on a warm object. Increasing the moisture in the air helps keep moisture in the skin.

Home Care

- Assess client and caregiver ability to recognize potential risk for skin breakdown. Provide resources for client/caregiver to contact health care provider with questions/concerns related to skin and incontinence care as needed. Engage family, caregivers, or legal guardian when establishing goals of care and validate their understanding of these goals. Educate the individual and his or her caregiver regarding skin changes in aging and at end of life. **EB:** *Early interventions can place the individual on the path to healing. Treating wounds requires a multiprofessional approach (Cox, 2019). When provided with the appropriate resources, the nurse can have a positive impact on the client's wound healing trajectory (NPIAP, EPIAP, & PPPIA, 2019).*
- See the care plan for Impaired **Skin** Integrity.

S

Client/Family Teaching and Discharge Planning

- Teach the client skin assessment and ways to monitor for impending skin breakdown. Early assessment and intervention help prevent the development of serious problems. **EB:** *Basic elements of a skin assessment are assessment of temperature, color, moisture, turgor, and intact skin (Baranoski et al, 2016). Seek information from the health care team to address individual pressure injury prevention and treatment needs (NPIAP, EPIAP, & PPPIA, 2019).*
- If consistent with overall client management goals, teach how to turn and reposition the client. **EB:** *Do not position an individual directly on a pressure injury. Continue to turn/reposition the individual even if a low air loss support surface is in use. Establish turning frequency based on the characteristics of the support surface and the individual's response (NPIAP, EPIAP, & PPPIA, 2019). If the goal of care is to keep the client (e.g., a terminally ill client) comfortable, turning and repositioning may not be appropriate (NPIAP, EPIAP, & PPPIA, 2019).*
- Teach the client and/or caregivers to use pillows, foam wedges, and pressure-reducing devices to prevent pressure injury (NPIAP, EPIAP, & PPPIA, 2019). **EB:** *The use of effective pressure-reducing seat cushions for older wheelchair users may significantly prevent sitting-acquired pressure injuries (Brienza et al, 2016). Pressure redistribution devices serve as adjuncts to prevention and do not replace repositioning (Wound, Ostomy and Continence Nurses Society–Wound Guidelines Task Force, 2017).*

Sleep Deprivation

Domain 4 Activity/rest Class 1 Sleep/rest

Judith Ann Floyd, PhD, RN, FNAP, FAAN

NANDA-I

S

Definition

Prolonged periods of time without sustained natural, periodic suspension of relative consciousness that provides rest.

Defining Characteristics

Altered attention; anxiety; apathy; combativeness; confusion; decreased functional ability; drowsiness; expresses distress; fatigue; fleeting nystagmus; hallucinations; heightened sensitivity to pain; irritable mood; lethargy; prolonged reaction time; psychomotor agitation; transient paranoia; tremors

Related Factors

Age-related sleep stage shifts; average daily physical activity is less than recommended for age and gender; discomfort; environmental disturbances; environmental overstimulation; late day confusion; nonrestorative sleep-wake cycle; sleep terror; sleep walking; sustained circadian asynchrony; sustained inadequate sleep hygiene

At-Risk Population

Individuals with familial sleep paralysis

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Associated Conditions

Conditions with periodic limb movement; idiopathic central nervous system hypersomnolence; narcolepsy; neurocognitive disorders; nightmares; sleep apnea; sleep-related enuresis; sleep-related painful erections; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Rest; Sleep; Symptom Severity

Example NOC Outcome with Indicators

Sleep as evidenced by the following indicators: Hours of sleep/Sleep pattern/Sleep quality/Sleep efficiency/Feels rejuvenated after sleep/Sleeps through the night consistently. (Rate the outcome and indicators of **Sleep:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize plan that provides adequate time for sleep
- Identify actions that can be taken to ensure adequate sleep time
- Awaken refreshed once adequate time is spent sleeping
- Be less sleepy during the day once adequate time is spent sleeping

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Sleep Enhancement

Example NIC Activities—Sleep Enhancement

Monitor/record client's sleep pattern and number of sleep hours; Encourage client to establish a schedule that allows age-appropriate hours of sleep with minimal environmental and personal disruptions

Nursing Interventions and *Rationales*

- Minimize care-environmental factors that may lead to sleep deprivation if they persist. See Nursing Interventions and *Rationales* for Disturbed **Sleep** Pattern.
- Address personal client factors that may lead to sleep deprivation if they persist. See Nursing Interventions and *Rationales* for **Insomnia.**
- Assess for hypersensitivity to pain in sleep-deprived clients. **EB:** *In a laboratory experiment using 14 healthy adults, sleep restriction protocols altered processes of pain habituation and sensitization, which may help explain why chronic pain conditions often accompany insufficient sleep* (*Simpson et al, 2018*). **EB:** *In an observational study of postoperative orthopedic surgery subjects (n = 50), a significant correlation was found between increased self-reported pain scores and decreased total sleep time (Miller et al, 2015).*
- Assess the amount of sleep obtained each night compared with the amount of sleep needed given the client's age, medical diagnoses, and personal preferences. **EBN:** *In an observational study (n = 141), subjects reported a large variation in how many hours of sleep they obtained in hospital as compared to home; however, the average reduction in hospital sleep duration, compared to home, was 1.8 hours (an average of 5.3 hours of sleep in hospital vs. 7.1 hours at home) (Delaney et al, 2018).*
- Assess the extent to which clients can be provided 3 to 4 consecutive hours of sleep time that is free from disturbance. **CEB:** *In a meta-analysis using data from 159 studies, a nurse scientist found that the deepest stages of sleep occurred during the first 3 to 4 hours of the sleep period followed by several 90- to 110-minute sleep cycles that consisted of increasingly lower percentages of deep sleep (Floyd, 2002).*
- If sleep-disrupting environmental factors that are inherent in hospitalization cannot be reduced adequately to prevent sleep deprivation, schedule specific times for rest and sleep during the day. **EB:** *Purposefully*

S

scheduled daytime naps may compensate in part for less sleep at night, as well as promote recovery from acute illness (Tan et al, 2019).

- If personal sleep-disrupting factors that are inherent in insomnia cannot be reduced adequately to prevent the client's sleep deprivation, consider scheduling a specific time for rest and sleep during the day. **EB:** *Although the number and duration of daytime naps may need to be limited if the client has difficulty initiating and maintaining nighttime sleep despite use of sleep-promoting interventions for insomnia, a purposefully scheduled nap may compensate in part for less sleep at night (Tan et al, 2019).* **CEB:** *Nurse scientists who conducted observational studies were the first to question the prohibition against all daytime napping by showing that carefully scheduled short naps appeared to supplement, rather than displace, nighttime sleep (Hayter, 1985; Floyd, 1995).*
- If caffeine is used by the client to alleviate daytime drowsiness, monitor amounts and time of use. **CEB:** *An experimental study of 12 participants found that caffeine (400 mg), even when consumed 6 hours before bedtime, had a disruptive effect on both objective and subjective sleep measures (Drake et al, 2013).*
- If naps are inadequate for preventing excessive daytime sleepiness due to sleep deprivation, consider and carefully evaluate use of unstudied, but commonly used, countermeasures for fighting drowsiness. **CEB:** *A descriptive study of 77 middle-aged adults identified the following unstudied strategies as possibly effective interrupters of drowsiness: (1) change physical position, (2) improve ventilation (e.g., get fresh air, turn on fan, open window), (3) reduce air temperature (e.g., turn on air conditioning, turn on fan), (4) increase auditory stimulation (e.g., play music, sing, engage in conversation, listen to debate), and (5) engage in interesting visual activity (e.g., board games, watching TV sports events, watching serial TV dramas) (Davidsson, 2012).*

▲ If daytime drowsiness occurs despite adequate periods of undisturbed nighttime sleep and supplemental daytime naps, consider undiagnosed sleep apnea as a possible cause. **EB:** *Sleep-disordered breathing affects 17% of men and 9% of women in the general population, of whom the majority are undiagnosed and untreated (Tan et al, 2019).*

Pediatric

- Assess the amount of sleep obtained every 24 hours compared with the amount of sleep needed for the child given age, medical diagnoses, and individual differences. **EB:** *Caregivers of 246 hospitalized subjects ages 4 weeks to 18 years reported that subjects slept less in the hospital than at home (Erondu et al, 2019).*
- Encourage daily schedules that allow for late awakening times for adolescents. **EB:** *A review of evidence from 38 reports showed that delaying school start time increased sleep duration among adolescents, primarily by delaying rise times (Wheaton et al, 2016).*
- Encourage an age-appropriate nap schedule that adequately supplements the child's nighttime sleep duration. **EBN:** *A descriptive study of lower-income toddlers (n = 101) found that two-thirds were not getting the recommended 11 to 14 hours of sleep per 24 hours (Armstrong et al, 2019).*
- See the Pediatric section of Nursing Interventions and *Rationales* for Disturbed **Sleep** Pattern.

Geriatric

- Assess the amount of sleep obtained each night compared with the amount of sleep needed for an older adult given advancing age, medical diagnoses, and individual differences. **EB:** *Older adults are at risk for sleep deprivation due to normal aging-related changes in sleep architecture and the additive impact of multiple risk factors including polypharmacy, increased prevalence of symptoms such as pain and nocturia, acute disturbances such as hospitalization, and changes in social roles that normally stabilize the sleep/wake pattern (Dean et al, 2017).*

▲ If an older adult has daytime sleepiness despite adequate nighttime sleep, consider a referral to a sleep laboratory to rule out sleep apnea. **EBN:** *Nurses who studied 49 surgical subjects age 65 and older, as well as reviewed charts for an additional 52 elderly surgical subjects, found that sleep apnea was frequently undiagnosed (Qassamali et al, 2019).*

- Assess how much time the older adult spends in bed unable to sleep and their comfort with low sleep efficiency. **EBN:** *A meta-analysis of results from samples representing 5061 general-population adults showed a steady increase after age 50 in the amount of time in bed resting rather than sleeping, which contributed to a steady decline in sleep efficiency over the lifespan (Floyd, 2017).*
- If a client is obtaining less sleep than required for optimal daytime function, explore if daytime napping will supplement, rather than replace, nighttime sleep. **CEB:** *In a pretest/posttest study of 22 older adults, a consistent regimen of daily napping for 45 minutes enhanced waking function without negatively affecting nighttime sleep (Campbell et al, 2011).*
- See the Geriatric section of Nursing Interventions and Rationales for Disturbed **Sleep** Pattern and **Insomnia.**

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Multicultural

- Be aware of racial and ethnic disparities in sleep deprivation. **EB:** *A national survey of 444,306 American adults found that non-Hispanic black, American Indian/Alaska Native, Native Hawaiian/Pacific Islander, and multiracial populations reported a higher prevalence of sleeping less than 7 hours compared with the rest of the U.S. adult population (Liu et al, 2016).*

Home Care

- Assessments and interventions discussed previously can all be adapted for use in home care.
- ▲ If daytime drowsiness occurs despite adequate periods of undisturbed nighttime sleep and supplemental daytime naps, consider sleep apnea as a possible cause. **CEB:** *In a household survey of more than 7000 adults, unexplained excessive daytime sleepiness was identified as a predictor of undiagnosed sleep apnea (Dosman et al, 2014).*
- Teach family members about the prevalence and long-term consequences of inadequate amounts of sleep for both clients and family caregivers. **EB:** *A national survey of 444,306 American adults found that more than one-third (34.8%) were likely sleep deprived (i.e., slept less than 7 hours per night), an amount at which physiological and neurobehavioral deficits may manifest and become progressively worse under chronic conditions (Liu et al, 2016).* **CEB:** *In an integrative review of 10 studies, insufficient sleep was associated with poor attention, decreased performance, increased mortality and morbidity, and cardiovascular risk factors, including hypertension, insulin resistance, hormonal deregulation, and inflammation (Mullington et al, 2009).*
- ▲ If sleep is deprived due to insomnia, refer client to a nurse practitioner or other sleep specialist trained in cognitive behavioral therapies for insomnia (CBT-I). **EB:** *A meta-analysis of 37 comparative effectiveness studies found that chronic insomnia subjects with comorbid medical and psychiatric conditions improved their ability to initiate and maintain sleep after completion of multicomponent CBT-I programs (Wu et al, 2015).*
- Teach client/family caregivers about the need for those with medical conditions to avoid schedules and commitments that interfere with obtaining adequate amounts of sleep. **EB:** *Critical appraisal of 22 studies provided evidence that sleep disturbance was common in critically ill subjects up to 12 months after hospital discharge (Altman et al, 2017).*
- Promote adoption of behaviors that ensure adequate amounts of sleep for all family members.
- Teach family members ways to avoid chronic sleep loss.
- Advise against chronic use of caffeinated drinks to overcome daytime fatigue and drowsiness while focusing on elimination of factors that lead to chronic sleep loss. **CEB:** *In an integrative review of 26 controlled laboratory studies of adult subjects, caffeine was found helpful in the temporary management of sleepiness, but overuse and late-day use contributed to subsequent sleep disruption and caffeine habituation (Roehrs & Roth, 2008).*

Readiness for Enhanced Sleep

Domain 4 Activity/rest Class 1 Sleep/rest

Judith Ann Floyd, PhD, RN, FNAP, FAAN

NANDA-I

Definition

A pattern of natural, periodic suspension of relative consciousness to provide rest and sustain a desired lifestyle, which can be strengthened.

Defining Characteristics

Expresses desire to enhance sleep-wake cycle

NOC (Nursing Outcomes Classification)

S

Suggested NOC Outcomes

Personal Well-Being; Rest; Sleep

Example NOC Outcome with Indicators

Sleep as evidenced by the following indicators: Hours of sleep/Sleep pattern/Sleep quality/Sleep efficiency/Feels rejuvenated after sleep/Napping appropriate for age. (Rate each indicator of **Sleep:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize a current interest in what constitutes normal sleep
- Reflect on own experiences and beliefs about sleep
- Verbalize an interest in nonpharmacological approaches to sleep promotion
- Take concrete steps to establish an environment conducive to sleep initiation and maintenance

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Sleep Enhancement

Example NIC Activities—Sleep Enhancement

Assess client's sleep/activity pattern; Assist/encourage client to create an environment that facilitates sleep; Assist/encourage client to adopt personal practices that enhance sleep

Nursing Interventions and *Rationales*

- Assess client's current knowledge and beliefs about sleep need and factors affecting sleep quantity and quality. **CEB:** *In a descriptive study of 1707 subjects from nine primary care practices, assessment of knowledge and beliefs about sleep was identified as an essential first step in client education programs (Phillips et al, 2014).* **EB:** *In an observational study of 120 undergraduate students, greater maladaptive beliefs about sleep were related to greater insomnia severity, poorer sleep quality, and less sleep hygiene knowledge (Kloss et al, 2016).*
- Whenever there is a lack of knowledge or false beliefs about sleep requirements, provide information regarding sleep need and encourage clients to identify their personal sleep requirements. **CEB:** *In a meta-analysis (n = 180 studies), a nurse researcher found that normal-population adults averaged 7.5 to 9.0 hours of sleep per night (range of 6.5–10.0 hours) and fell asleep within 20 minutes initially and more quickly if awakened during the night; daytime was characterized by no naps or regularly scheduled brief naps, and little fatigue or sleepiness (Floyd, 2002).* **EB:** *In a review of research by a panel of 15 sleep experts, sleep need was found to be highly variable among adults, but 7 or more hours of sleep on a regular basis was found to promote optimal health and reduce risk of adverse health outcomes; it was unclear if averaging more than 9 hours was associated with health risk among the otherwise healthy adults (Watson et al, 2015).*
- Based on your assessment, focus on one or more of the following sleep hygiene strategies, choosing the most relevant for the client:
  - Regular scheduling of the nighttime sleep period, daytime exposure to light, exercise, napping, and mealtimes characterized by (1) exercise during the day, (2) avoidance of long periods of daytime sleep (unless a night-shift worker), (3) avoidance of large meals before bed, and (4) arising at the same time each day even if sleep was poor during the previous night. **EB:** *An experimental study of 173 young adults suggested that interactions among rest/activity, light/dark, sleep, and other physiological parameters (body temperature, blood pressure, and heart rate) are complex and require more study, but factors that suppress or stimulate melatonin secretion likely play a key role in circadian rhythm interactions (Gubin et al, 2017).*
  - Use of a relaxing bedtime routine that includes (1) activities that calm the mind (e.g., mindfulness or other types of meditation, listening to music, prayer) and (2) activities that relax the body (e.g., warm baths, massage, progressive muscle relaxation). **EBN:** *A review of evidence from nine intervention studies suggested relaxation, meditation, guided imagery, or a combination of these strategies resulted in better sleep and less fatigue in heart-failure clients (Kwekkeboom & Bratzke, 2016).*
  - Use of essential oils. **EBN:** *Adult rehabilitation subjects (n = 42), who were studied using a randomized crossover study design, reported better sleep quality when exposed to essential oils (Lavandula x intermedia [Lavandin Super], Citrus bergamia [bergamot], and Cananga odorata [ylang ylang]) than when exposed to a placebo oil (McConnell & Newcomb, 2019).*
  - Creation of an environment conducive to sleep, including (1) comfortable sleepwear, sleep surface, and room temperature; (2) low or masked levels of light and noise; and (3) a sleep space as free as possible from interruptions from others. **EBN:** *Using qualitative methods, the lived experience of client sleep in hospitals as perceived by nurses (n = 14) included several environmental factors that disturbed clients' sleep, including uncomfortable beds/mattresses/pillows, as well as light, noise, temperature, and smells (Honkavuo, 2018).*
  - Management of any sources of pain as needed before sleep. **EB:** *In a national survey of 1029 noninstitutionalized adults age 18 years or older, pain was associated with lower sleep quality, more sleep disruption, and greater sleep deprivation (National Sleep Foundation, 2015).* (See further Nursing Interventions and Rationales for Acute **Pain** and Chronic **Pain.**)

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

S

- ❍ Avoidance of late-day electronic device use. **EB:** *A descriptive study of 1674 adults found that participants with more screen time from TV watching and use of computers and other electronic devises reported more difficulty falling asleep and staying asleep (Vallance et al, 2015).* **EB:** *A representative survey of 1508 adults found that 90% of Americans used some type of electronics at least a few nights per week before bedtime and also found that adults who reported use of e-readers had reduced evening sleepiness, took longer to fall asleep, and reported reduced next-morning alertness compared with adults who read printed books at bedtime (Chang et al, 2015).*
- ❍ Monitoring of late-day intake of caffeine from all sources, including energy drinks, coffee, colas, teas, and chocolate. **CEB:** *In an experimental study* (n = *12) researchers found that caffeine consumption (400 mg) up to 6 hours before bedtime had a disruptive effect on objectively measured and self-reported symptoms of insomnia (Drake et al, 2013).*
- ❍ Avoidance of alcoholic beverages to induce sleep. **CEB:** *In a descriptive study of 50 oncology outpatients, nurse researchers found that even limited alcohol use (one to two drinks) was related to shortened time to falling asleep and increased depth of sleep the first 2 hours, as well as suppressed rapid eye movement (REM) sleep, which sometimes led to REM rebound (i.e., lighter, more fragmented sleep later in the night) (Dean et al, 2010).*
- ❍ Avoidance of nicotine. **CEB:** *In a national survey of 6400 participants, cigarette smokers took longer to fall asleep and had shorter and lighter nighttime sleep than nonsmokers; however, acute nicotine withdrawal caused even more sleep disruption (Zhang et al, 2006).* **EB:** *In a survey of 498 young adults, all stimulants disturbed sleep; however, nicotine was particularly deleterious (Caviness et al, 2019).*
- ❍ Avoidance of a sedentary lifestyle. **EB:** *In a national survey of 1000 representative adults ages 23 to 60, excessive sitting during waking hours was associated with poor sleep quality (Buman et al, 2015).*

Geriatric

- Interventions discussed previously can all be adapted for use with geriatric clients.
- Counsel the older client regarding normal age-related sleep changes. **CEB:** *In a meta-analysis* (n = *180 studies), a nurse researcher discovered that as adults aged, they increased time needed to fall asleep, increased the frequency and duration of waking after sleep onset, and decreased nighttime sleep amount (Floyd, 2002).* **EBN:** *A meta-analysis of results from samples representing 5061 general-population adults showed a steady increase after age fifty in the amount of time spent in bed with the intent to sleep, which contributed to a steady decline in sleep efficiency with aging (Floyd, 2017).*
- Elicit the older client's beliefs about sleep and correct any misconceptions, which may manifest as undue concern for some elders, but too little concern for others. **CEB:** *In a descriptive study comparing sleep beliefs and behaviors of 41 black and 24 white older women, the majority of women, regardless of race/ethnicity, incorrectly stated that poor sleep did not have negative effects on other health conditions (Grandner et al, 2013).*
- Review older clients' prescription medications; use of over-the-counter (OTC) medications; and use of caffeine, tobacco, and alcohol. **CEB:** *In a review of literature about older adults' sleep, nurse scholars found that older adults may be unaware of how their medications and commonly used psychoactive substances affect sleep (Allen et al, 2013).* **EB:** *A double-blind crossover study (n = 46) of adults in their fifties compared with younger adults found that caffeine interfered with initiation of deep sleep in all and that the older adults experienced even more sensitivity to caffeine intake than the younger adults (Robillard et al, 2015).*
- Assess and refer as appropriate whenever coexisting conditions may be affecting older clients' sleep. **CEB:** *In a review of literature about older-adult sleep, nurse scholars found that depression, sleep apnea, and restless legs syndrome are commonly missed coexisting conditions in older adults (Allen et al, 2013).*
- Expand older clients' awareness of sleep hygiene behaviors for improving sleep. **EBN:** *In a mixed-methods study of 18 elders, none of the study participants who used sleep hygiene practices had done so on the specific advice of a health care provider; rather, they had cobbled together some information from Internet articles and their own experience (Berkley et al, 2020).* **CEB:** *In a descriptive study of 195 older adults, only three strategies were heavily used by elders to address sleep concerns: ignoring the symptoms, staying in bed or resting, and praying (Sandberg et al, 2014).*
- Encourage the older client to walk and engage in other exercise outside unless contraindicated. **EB:** *In an evidence review of 34 research reports, exercise increased sleep efficiency and duration in healthy older adults regardless of the mode and intensity of activity, and even more so in the elderly with chronic conditions such as hypertension, obesity, diabetes, rheumatoid arthritis, or sleep disorders (Dolezal et al, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Home Care

- All interventions discussed previously can be adapted for home care use.
- Assess family caregivers' readiness for enhancing sleep. **EB:** *A secondary analysis of quantitative data from 395 family caregivers of hospice clients found that nearly one-third experienced clinically noteworthy levels of sleep problems and/or anxiety that can interfere with sleep initiation (Washington et al, 2018).* **EB:** *A pretest-posttest pilot study of seven dementia clients and their family caregivers suggested that a caregiver sleep education program resulted in decreased client sleep problems and decreased caregiver depression (Tewary et al, 2018).*
- Assess the conduciveness of the home environment for promoting sleep and the resources needed to improve the sleep environment. **CEB:** *In an experimental study of 122 socioeconomically disadvantaged new mothers, nurse researchers found that approximately two-thirds of homes incorporated sleep hygiene recommendations consistently over 3 months (Lee & Gay, 2011).*

Disturbed Sleep Pattern

Domain 4 Activity/rest Class 1 Sleep/rest

Judith Ann Floyd, PhD, RN, FNAP, FAAN

NANDA-I

Definition

Time-limited awakenings due to external factors.

Defining Characteristics

Difficulty in daily functioning; difficulty initiating sleep; difficulty maintaining sleep state; expresses dissatisfaction with sleep; expresses tiredness; nonrestorative sleep-wake cycle; unintentional awakening

Related Factors

Disruption caused by sleep partner; environmental disturbances; insufficient privacy

Associated Conditions

Immobilization

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Well-Being; Rest; Sleep

Example NOC Outcome with Indicators

Sleep as evidenced by the following indicators: Hours of sleep/Sleep pattern/Sleep quality/Sleep efficiency/Feels rejuvenated after sleep. (Rate the outcome and indicators of **Sleep:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

S

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize plan to implement sleep promotion routines
- Maintain a regular schedule of sleep and waking
- Fall asleep without difficulty
- Remain asleep throughout the night
- Awaken naturally, feeling refreshed and is not fatigued during day

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Sleep Enhancement

Example NIC Activities—Sleep Enhancement

Determine external factors leading to sleep fragmentation; Reduce environmental disrupters of sleep

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Nursing Interventions and *Rationales*

- Assess the client's sleep environment to determine its adequacy for providing undisturbed sleep. **EB:** *Disturbed sleep can have a detrimental impact on health and extend client recovery (Garside et al, 2018).* **EBN:** *Animal model studies conducted by nurse scientists suggest associations between sleep fragmentation and physical health parameters (e.g., mean arterial blood pressure and the gut microbiome/fecal metabolome), which is an association that provides insight into possible links between disrupted sleep and cardiovascular pathology (Maki et al, 2020).*
- Obtain a sleep history to identify the following: (1) the client's perception of smells, noise, and light levels in the sleep environment; (2) the client's preferred bedding; (3) client activities occurring in the sleep environment during hours of sleep, including use of handheld technology; (4) number of times the client typically awakens during the sleep period; and (5) when, during the sleep period, time is available for undisturbed sleep. **EBN:** *A qualitative study of hospital staff, clients, and their surrogates (n = 38) showed that many factors influenced clients' perceptions of sleep disturbances in the intensive care unit (ICU), but most environmental disturbances during hospitalization were caused by noise, light, and provision of care (Ding et al, 2017).* **EBN:** *Using qualitative methods, the lived experience of clients' sleep in hospitals as perceived by nurses (n = 14) included several environmental factors that disturbed clients' sleep, including uncomfortable beds, mattresses, and pillows, as well as light and noise levels, room temperatures, and smells (Honkavuo, 2018).*
- Keep environment as quiet as possible during sleep periods. **EB:** *A descriptive study of environmental characteristics in a 12-bed rehabilitation unit found that average noise levels were above recommended levels, and abrupt increases in noise levels were high enough to cause sleep fragmentation (Yelden et al, 2015).* **EBN:** *An evidence review of 51 papers showed that noise remains a persistent disruption to sleep at night in hospitals and continues to register as a concern on client satisfaction surveys (Fillary et al, 2015).*
- Consider masking hospital noise that cannot be eliminated. **CEB:** *In a systematic review of nine experimental studies, nurse researchers found that recorded natural sounds, music, and music videos were effective for masking noise in health care settings (Hellström et al, 2011).*
- Offer earplugs when feasible. **EBN:** *Results from an experimental study of subjects in intensive care (n = 50) showed that perceptions of nighttime noise decreased significantly in subjects who used earplugs (Hu et al, 2015).* **EBN:** *In a quasi-experimental clinical study of 135 cardiac care unit subjects, Iranian nurse researchers found that the combined use of earplugs and eye masks reduced self-reported sleep disruption (Tabas et al, 2019).*
- Dim the lights during sleep periods. **CEB:** *A sequential prestudy/poststudy (n = 171) found that the number of awakenings decreased when monitored lighting levels were part of a multicomponent program to decrease sleep disruption in intensive care (Patel et al, 2014).*
- Offer eye covers when lighting cannot be dimmed. **EBN:** *Results from an experimental study of subjects in intensive care (n = 50) showed that a combination of nonpharmacological interventions that included eye covers was useful for promoting sleep in ICU adult subjects (Hu et al, 2015).* **EBN:** *In a quasi-experimental clinical study of 135 cardiac care unit subjects, Iranian nurse researchers found that the combined use of earplugs and eye masks reduced self-reported sleep disruption (Tabas et al, 2019).*
- ✱ Be aware that use of eye covers in intubated clients may lead to sensory deprivation and anxiety. **CEB:** *An experimental study of eye cover use in ICU subjects (n = 18) reported less sleep fragmentation, but 72% of intubated subjects refused eye covers or removed them prematurely because of restlessness (30%), discomfort (20%), or anxiety (11%) (Simons et al, 2012).*
- Negotiate use of handheld technology whenever clients have access to electronic devices in the care setting. **EB:** *A representative survey of 1508 adults found that 90% of Americans used some type of electronics at least a few nights per week before bedtime and also found that adults who reported use of e-readers had reduced evening sleepiness, took longer to fall asleep, and reported reduced next-morning alertness compared with adults who read printed books at bedtime (Chang et al, 2015).*
- Consolidate essential care to provide the opportunity for uninterrupted sleep the first 3 to 4 hours of the sleep period. Follow with periods of 90 to 110 minutes between interruptions. **CEB:** *In a meta-analysis using data from 159 studies a nurse researcher found that the deepest stages of sleep occurred during the first 3 to 4 hours of the sleep period followed by several 90- to 110-minute sleep cycles that consisted of increasingly lower percentages of deep sleep (Floyd, 2002).*
- If the client must be disturbed during the first 3 to 4 hours of the sleep period, attempt to protect 90- to 110-minute blocks of time between awakenings. **CEB:** *In three studies of hospitalized subjects, nurse*

researchers found that the high frequency of nocturnal care interactions left subjects with no 90-minute blocks of uninterrupted time for sleep (Missildine, 2008; Missildine et al, 2010a,b). **CEB:** *In an experimental study that included protocols for consolidating care, the number of subject nights that contained a 3-hour window of uninterrupted sleep was increased (Patel et al, 2014).*

- When feasible, schedule newly ordered medications to avoid the need to wake the client the first few hours of the night. **CEB:** *A survey of sleep promotion protocols (n = 68) conducted by nurse researchers identified the need for nurses to plan ahead when initiating new medication regimens to help ensure uninterrupted sleep periods (Hofhuis et al, 2012).*
- Combine the previously mentioned interventions as feasible to create a sleep-promotion care bundle. **EBN:** *A qualitative study describing how experienced nurses promote sleep in hospitals* (n = *8) identified use of a comprehensive set of cost-effective sleep-promoting measures that adapted the hospital environment for sleep and also reduced the use of sedative drugs (Salzmann-Erikson et al, 2016).* **EB:** *A critical appraisal of evidence from eight quantitative and qualitative studies showed that both ICU and acute ward settings affect subjects' sleep and use the same sleep-promoting strategies, including use of pharmacological aids and nonpharmacological aids (reducing noise and disturbances, eye masks, earplugs, and educational and staff behavioral changes) (Aparício & Panin, 2020).*
- Assess for medications and other stimulants that fragment sleep. Use caution when administering sleep medications. See Nursing Interventions and Rationales for **Insomnia.**

Pediatric

✱ Adapt interventions described above with caution because of limited empirical evidence regarding the effects of their use for pediatric clients. **CEB:** *A survey of 341 pediatric critical care providers worldwide found that use of earplugs, eye masks, noise reduction, and lighting optimization for sleep promotion was uncommon (Kudchadkar et al, 2014).* **EBN:** *During a focus-group study, nurses* (n = *30) working on general and critical-care pediatric units identified several interrelated factors that create challenges to promoting children's sleep in hospitals and highlighted the need for formal policy and mentoring related to provision of nursing care at night in pediatric settings (Stremler et al, 2015).*

- Assess use of evening and nighttime texting and consider limiting as needed to protect sleep. **EBN:** *A study of 278 community-based teens found that sending and/or receiving text messages at night was significantly associated with later bedtimes, shorter time in bed, daytime tiredness, and irregular sleep habits (Garmy & Ward, 2018).*

Geriatric

- Most interventions discussed above can all be adapted for use with geriatric clients.
- Use of earplugs and eye covers with ataxic clients and clients with dementia may contribute to disorientation. **CEB:** *A case report and integrative review of the literature suggested that sensory deficits in subjects with dementia, which can be augmented by use of earplugs and eye covers, decrease their quality of life, increase their risk for delirium and falls, and pose a higher risk for poor outcomes (Haque et al, 2012).*

Multicultural

✱ Be aware that cultural sleep practices may alter the kinds of environmental sleep disruptors that require management. **CEB:** *As the result of an integrative review of the literature on family sleep practices, nurse scholars found that bed sharing and other aspects of the sleep environment were influenced most by ethnic factors (Jain et al, 2011).*

Home Care

- Consider the unique characteristics of each home sleep environment when addressing sleep disruption. **CEB:** *A longitudinal study of postpartum women* (n = *142) showed that new mothers' sleep was disturbed 56% of the time by their infant's cries, but other environmental disrupters included (1) family, friends, and pets in the home; (2) sleeping with the television on; (3) traffic sounds; and (4) other outside noise from neighbors (Doering, 2013).*
- In addition, see the Home Care section of Nursing Interventions and Rationales for Readiness for Enhanced **Sleep.**

S

Impaired Social Interaction

Domain 7 Role relationship Class 3 Role performance

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Insufficient or excessive quantity or ineffective quality of social exchange.

Defining Characteristics

Anxiety during social interaction; dysfunctional interaction with others; expresses difficulty establishing satisfactory reciprocal interpersonal relations; expresses difficulty functioning socially; expresses difficulty performing social roles; expresses discomfort in social situations; expresses dissatisfaction with social connection; family reports altered interaction; inadequate psychosocial support system; inadequate use of social status toward others; low levels of social activities; minimal interaction with others; reports unsatisfactory social engagement; unhealthy competitive focus; unwillingness to cooperate with others

Related Factors

Altered self-concept; depressive symptoms; disturbed thought processes; environmental constraints; impaired physical mobility; inadequate communication skills; inadequate knowledge about how to enhance mutuality; inadequate personal hygiene; inadequate social skills; inadequate social support; maladaptive grieving; neurobehavioral manifestations; sociocultural dissonance

At-Risk Population

Individuals without a significant other

Associated Conditions

Halitosis; mental diseases; neurodevelopmental disorders; therapeutic isolation

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Child Development: Middle Childhood, Adolescence; Play Participation; Role Performance; Social Interaction Skills; Social Involvement

Example NOC Outcome with Indicators

Social Involvement as evidenced by the following indicator: Interacts with close friends, neighbors, family members, and members of work groups. (Rate the outcome and indicators of **Social Involvement:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

S

Client Outcomes

Client Will (Specify Time Frame)

- Identify barriers that cause impaired social interactions
- Discuss feelings that accompany impaired and successful social interactions
- Use available opportunities to practice interactions
- Use successful social interaction behaviors
- Report increased comfort in social situations
- Communicate, state feelings of belonging, demonstrate caring and interest in others
- Report effective interactions with others

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Socialization Enhancement

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NIC Activities—Socialization Enhancement

Encourage patience in developing relationships; Help client increase awareness of strengths and limitations in communicating with others

Nursing Interventions and *Rationales*

- Encourage the client to keep a gratitude journal. **EB:** *A study demonstrated that study participants who participated in a gratitude journal intervention experienced more positive emotions during social interactions* (*Drążkowski, Kaczmarek, & Kashdan, 2017*).
- Encourage dancing with Parkinson's programs for individuals with Parkinson's disease. **EB:** *Research demonstrated that dance programs provide opportunities for social interaction and nonverbal communication* (*Bognar et al, 2017*).
- Consider use of social cognition and interaction training (SCIT) to improve social functioning. **EB:** *Study findings suggest that individuals with serious mental illness showed improved emotion recognition skills, assertive behavior, improved relationship quality, and perceived more support from colleagues in social and professional relationships* (*Nienow et al, 2019*).
- Consider use of animal-assisted therapy (AAT). **EB:** *An AAT treatment group showed improvement in negative symptoms of schizophrenia such as apathy, asociality, anhedonia, and alogia* (*Calvo et al, 2016*).
- Encourage visually challenged clients to use text-based computer-mediated communications to facilitate social interaction. **EB:** *A study suggested that the lack of visual cues in text-based computer-mediated communications (CMCs) supported the daily social communication of visually challenged individuals* (*Okonji et al, 2019*).
- Provide management strategies to individuals experiencing auditory hallucinations. **EBN:** *Based on their research, Wang et al (2019) suggest that teaching people with schizophrenia to manage auditory hallucination will enhance their social interaction.*
- Refer to care plans for Risk for **Loneliness** and **Social** Isolation for additional interventions.

Pediatric

- Assess children with social impairments for experiences of bullying or victimization. **EB:** *A study found that children with autism spectrum disorder (ASD) experience more frequent bullying victimization compared to their neurotypical peers due to the increased risk of not being aware of the social situation* (*Forrest, Kroeger, & Stroope, 2020*).
- For adolescent clients, consider use of a peer network intervention to increase social interactions. **EB:** *Study results indicate that peer networks are effective at increasing social interactions of secondary students with ASD* (*Sreckovic, Hume, & Able, 2017*).
- Provide supervised interaction opportunities for children of chronically ill parents. **EBN:** *Research has identified that social isolation is a challenge for children with parents who experience chronic disabling pain* (*Umberger, Risko, & Covington, 2015*).
- Encourage family style dining (FSD) for preschool children to promote social interactions during mealtimes. **EB:** *A study showed that rates of interactions were increased during FSD* (*Lochetta, Barton, & Kaiser, 2017*).
- Use peer-mediated interaction (PMI) to increase social interactions of children on the autistic spectrum. **EB:** *A review of studies showed that PMI was an effective intervention to increase social interaction intervention for promoting social interaction between students with ASD and their peers* (*Watkins et al, 2015*).
- Consider Social Story with self-modeling for children with autism spectrum disorder. **EB:** *A study found that reading a Social Story with self-modeling that illustrated appropriate social behaviors improved children's initiations, responses, and affect* (*Youn Kang & Kim, 2020*).
- Encourage a responsive parenting style for parents of children with autism spectrum disorder. **EB:** *Structural equation models revealed that responsive parenting positively predicted prospective growth in social skills as reported by teachers* (*Caplan, Blacher, & Eisenhower, 2019*).

▲ Refer children with autism spectrum disorder to "Play Time/Social Time" (PT/ST) and "I Can Problem Solve" (ICPS) programs. **EB:** *A study indicated that the PT/ST program was more effective than ICPS in developing interaction skills, but both programs improved children's ability to cope with difficult social situations (Szumski et al, 2019).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

Geriatric

- Assess older clients for hearing loss and refer for hearing aids as needed. **EB:** *A study demonstrated that hearing aid fitting was associated with a subsequent improvement in older person–specific quality of life* (*Yamada, Švejdíková, & Kisvetrová, 2017*).
- Encourage socialization through physical activity and meaningful activities incorporated into normal daily care practices. **EB:** *A study showed that when activities were performed, residents of a green care farm were more engaged and had more social interaction* (*de Boer et al, 2017*).
- Provide live concert music for clients with dementia. **EB:** *A study showed that clients with mild to midstage dementia had increased levels of cooperation, interaction, and conversation after a live music concert* (*Shibazaki & Marshall, 2017*).

▲ Refer depressed clients to services for cognitive-behavioral therapy (CBT). **EB:** *A systematic review indicated that CBT was likely to be efficacious for depression and accompanying symptoms such as impaired social functioning in older people* (*Jayasekara et al, 2015*).

- Refer to care plans for **Frail** Elderly Syndrome, Risk for **Loneliness,** and **Social** Isolation for additional interventions.

Multicultural

- Approach individuals of color with respect, warmth, and professional courtesy. **EBN:** *To provide person- and family-centered care, nurses must acknowledge their cultural differences, be willing to incorporate their beliefs within the health care treatment plan, and respect the values and lifeways of differing cultures* (*Hart & Mareno, 2014*).
- Use professional interpreters as needed. **EBN:** *Professional interpreters are the standard of care and will meet The Joint Commission requirements for addressing language barriers* (*Squires, 2018*).
- Refer to care plan for **Social** Isolation for additional interventions.

Home Care

- Previously discussed interventions may be adapted for home care use.

Client/Family Teaching and Discharge Planning

- Previously discussed interventions may be adapted for client/family teaching and discharge planning.

Social Isolation

Domain 12 Comfort Class 3 Social comfort

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

A state in which the individual lacks a sense of relatedness connected to positive, lasting, and significant interpersonal relationships.

Defining Characteristics

Expresses dissatisfaction with respect from others; expresses dissatisfaction with social connection; expresses dissatisfaction with social support; expresses loneliness; flat affect; hostility; impaired ability to meet expectations of others; low levels of social activities; minimal interaction with others; preoccupation with own thoughts; purposelessness; reduced eye contact; reports feeling different from others; reports feeling insecure in public; sad affect; seclusion imposed by others; sense of alienation; social behavior incongruent with cultural norms; social withdrawal

Related Factors

Difficulty establishing satisfactory reciprocal interpersonal relations; difficulty performing activities of daily living; difficulty sharing personal life expectations; fear of crime; fear of traffic; impaired physical mobility; inadequate psychosocial support system; inadequate social skills; inadequate social support; inadequate transportation; low self-esteem; negative perception of support system; neurobehavioral manifestations; values incongruent with cultural norms

At-Risk Population

Economically disadvantaged individuals; immigrants; individuals living alone; individuals living far from significant others; individuals moving to unfamiliar locations; individuals with history of rejection; individuals experiencing altered social role; individuals experiencing loss of significant other; individuals with history of traumatic event; individuals with ill family member; individuals with no children; institutionalized individuals; older adults; widowed individuals

Associated Conditions

Altered physical appearance; chronic disease; cognitive disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Loneliness Severity; Mood Equilibrium; Personal Well-Being; Play Participation; Social Anxiety Level; Social Interaction Skills; Social Involvement; Social Support

Example NOC Outcome with Indicators

Social Involvement as evidenced by the following indicator: Interacts with close friends, neighbors, family members, and members of work groups. (Rate the outcome and indicators of **Social Involvement:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify feelings of isolation
- Practice social and communication skills needed to interact with others
- Initiate interactions with others; set and meet goals
- Participate in activities and programs at level of ability and desire
- Describe feelings of self-worth

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Socialization Enhancement

Example NIC Activities—Socialization Enhancement

Encourage patience in developing relationships; Help client increase awareness of strengths and limitations in communicating with others

Nursing Interventions and *Rationales*

- Assess the client's feelings regarding social isolation. **EBN:** *Feelings that contribute to the client's perception of social isolation may include loneliness, anger, fear, despair, and sadness (Hadi & Hadi, 2017).*
- Assess individuals in quarantine or other socially isolating situations for the negative psychological effects of social isolation. **EB:** *Most reviewed studies reported negative psychological effects of social isolation, including post-traumatic stress symptoms, confusion, and anger. Stressors included longer quarantine duration, infection fears, frustration, boredom, inadequate supplies, inadequate information, financial loss, and stigma (Brooks et al, 2020).*
- For individuals who require quarantine, provide clear rationale for quarantine and information about protocols, and ensure sufficient supplies are provided. Tell people what is happening and why, explain how long it will continue, provide meaningful activities for them to do while in quarantine, provide clear communication, ensure basic supplies (such as food, water, and medical supplies) are available, and reinforce a sense of altruism. **EB:** *If quarantine is essential, research results suggest that providers should take every measure to ensure that this experience is as tolerable as possible for people (Brooks et al, 2020).*
- Provide the client with social skills training. **EB:** *A study concluded that social skills training can improve cognitive, affective, and behavioral interactions in clients experiencing social isolation (Nihayati et al, 2017).*
- Encourage limits on social media use. **EB:** *Research shows that young adults with high social media use report feeling more socially isolated than their counterparts with lower social media use (Primack et al, 2017).*
- Recommend involvement in organizations and other activities that encourage socialization. **EB:** *Community support and participation in activities that promote social engagement can act as protective factors to counter social isolation (Ray et al, 2019).*
- See the care plan for Risk for **Loneliness.**

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Pediatric

- Assess for experiences of bullying and/or cyberbullying. **EBN:** *Bullying may manifest as social isolation or school refusal in children (Nelson et al, 2018).*
- Encourage limits on technology and social media use for children and adolescents. **EB:** *Research shows that young adults with high social media use report feeling more socially isolated than their counterparts with lower social media use (Primack et al, 2017).*
- Provide positive social support and assist the child to identify supportive adults in their lives. **EBN:** *Social isolation can be diminished when children have access to an adult who provides a secure base of emotional support (Nelson et al, 2018).*
- Promote adequate sleep time. **EB:** *Social isolation is a risk factor for depression and anxiety in early adolescence, but adequate sleep may act as a protective factor (Richardson et al, 2019).*

▲ Refer children and adolescents to mental health treatment as necessary. **EB:** *A randomized controlled trial found that children of substance-abusing parents showed significant improvements in social isolation after implementation of a psychoeducational preventive intervention (Bröning et al, 2019).*

▲ Refer parents of disabled or seriously ill children to support groups. **EB:** *Participation in a family-oriented support group provides community support and possible solutions to common problems in a caring and trusting environment (Mitwalli, Rabaia, & Kienzler, 2018).*

Geriatric

- The interventions described previously may be adapted for use with older clients.
- Assess for risks and experiences associated with social isolation. **EB:** *Research shows that approximately one-quarter of community-dwelling Americans age 65 and older are considered to be socially isolated, and a significant proportion of adults in the United States report feeling lonely (National Academies of Sciences, Engineering, and Medicine, 2020).*
- Identify social engagement activities such as volunteering, engaging in social activities, and growing spirituality that are acceptable to the client. **EB:** *An integrative review found that productive engagement activities are associated with improvement of social isolation in older adults (Gardiner, Geldenhuys, & Gott, 2018).*

▲ Refer client to pet therapy or consider pet ownership if feasible. **EB:** *An integrative review found that individual pet therapy reduced isolation in older adults (Gardiner, Geldenhuys, & Gott, 2018).*

- Consider telephone outreach for isolated older individuals. **EB:** *The Yale Geriatrics Student Interest Group implemented the Telephone Outreach in the COVID-19 Outbreak Program at three nursing homes with initial success. Nursing home residents report looking forward to their weekly phone calls and gratitude for social connectedness (van Dyck et al, 2020).*
- Consider use of technology such as computers, video conferencing, Internet, or apps to alleviate or reduce loneliness or social isolation among older adults. **EB:** *An integrative review found that use of these technologies reduced isolation in older adults (Gardiner, Geldenhuys, & Gott, 2018).*
- Implement fall precautions for clients experiencing social isolation. **EBN**: *Logistic regression models revealed that social isolation significantly predicted falls (odds ratio [OR] = 1.11; 95% confidence interval [CI] [1.05, 1.17]). The relationship remained significant after adjusting for age, gender, and education (OR = 1.08; 95% CI [1.02, 1.14]) (Pohl et al, 2018).*

Multicultural

- The interventions described previously may be adapted for use with diverse clients.
- Assess for experiences of interpersonal and institutional racism. **EB:** *Experiences with overt racism and microaggressions are significantly associated with social isolation and other negative emotional responses (Ayón & Philbin, 2017).*

Home Care

- The interventions described previously may be adapted for home care use.
- Assist clients to interact and engage with neighbors when they move to a supported housing community. **EB:** *Clients transferring to supported housing will be placed in an unfamiliar environment that necessitates the need to develop skills to successfully adapt to their new surroundings (Kirchen & Hersch, 2015).*

Client/Family Teaching and Discharge Planning

- See the care plan for **Caregiver** Role Strain and Risk for **Loneliness.**

Chronic Sorrow

Domain 9 Coping/stress tolerance Class 2 Coping responses

Tracy P. George, DNP, APRN-BC, CNE

NANDA-I

S

Definition

Cyclical, recurring, and potentially progressive pattern of pervasive sadness experienced (by a parent, caregiver, individual with chronic illness or disability) in response to continual loss, throughout the trajectory of an illness or disability.

Defining Characteristics

Expresses feeling that interferes with well-being; overwhelming negative feelings; sadness

Related Factors

Disability management crisis; illness management crisis; missed milestones; missed opportunities

At-Risk Population

Individuals experiencing developmental crisis; individuals experiencing loss of significant other; individuals working in caregiver role for prolonged period of time

Associated Conditions

Chronic disability; chronic disease

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Acceptance: Health Status; Depression Level; Depression Self-Control; Grief Resolution; Hope; Mood Equilibrium

Example NOC Outcome with Indicators

Grief Resolution with plans for a positive future as evidenced by the following indicators: Describes meaning of loss or death/Reports decreased preoccupation with loss/Reports adequate nutritional intake/Reports adequate sleep/Expresses positive expectations about the future. (Rate the outcome and indicators of **Grief Resolution:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Express appropriate feelings of guilt, fear, anger, or sadness
- Identify problems associated with sorrow (e.g., changes in appetite, insomnia, nightmares, loss of libido, decreased energy, alteration in activity levels)
- Seek help in dealing with grief-associated problems
- Plan for the future one day at a time
- Function at normal developmental level

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Grief Work Facilitation; Grief Work Facilitation: Perinatal Death

Example NIC Activities—Grief Work Facilitation

Encourage client to verbalize memories of loss, both past and current; Assist client in identifying personal coping strategies

Nursing Interventions and *Rationales*

- Determine the client's degree of sorrow. **CEB:** *Use the Adapted Burke Questionnaire for the individual or caregiver, which assesses eight mood states (grief, shock, anger, disbelief, sadness, hopelessness, fear, and guilt) on a four-point scale (Whittingham et al, 2013).*
- Assess for the four discrete stages of grieving in clients with chronic disease. **EB:** *The four stages of grief for clients with chronic diseases can be assessed by the Acceptance of Disease and Impairments Questionnaire (Nistiandani et al, 2018).*
- Provide coping strategies for caregivers who may experience chronic sorrow. **EBN:** *Coping strategies for the caregivers of clients with schizophrenia may include discussing their feelings about the situation with others; reading; praying; being physically active; emotional strategies, such as crying; and cognitive strategies, such as thinking positively about the situation (Olwit et al, 2015). See care plan for* ***Caregiver*** *Role Strain.*
- Develop a trusting relationship to care for clients with chronic sorrow. **EBN:** *Nurses should offer compassion, empathy, consideration, and knowledge to those experiencing chronic sorrow (Glenn, 2015).*
- Provide information about support groups and counseling. **EBN:** *Support groups, counseling, and participating in activities are strategies that can be used with clients who are experiencing chronic sorrow (Marcella-Brienza & Mennillo, 2015).*
- Encourage use of positive coping techniques: **EBN:** *Encourage hobbies and physical activity for those experiencing chronic sorrow (Granek et al, 2016).*
- ▲ Refer the client for mental health services as needed. **EB:** *There may be an increase in depression among clients with chronic sorrow, so the nurse may need to refer the client for mental health care (Ghesquiere et al, 2016).*

S

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

▲ Refer clients for financial assistance as needed. **EB:** *Bereavement may be associated with financial burdens caused by the loss of income (Ghesquiere et al, 2016).*

Pediatric

- Encourage the parents of children with uncommon diseases to use online resources to manage their chronic sorrow. **EBN:** *In a study of 16 mothers of children with a rare disease, online communication was used effectively to manage chronic sorrow (Glenn, 2015).*
- Educate parents that an increase in chronic sorrow can occur after stressful events. **EB:** *Worsening of the health care condition and when a child would have met developmental milestones can trigger chronic sorrow (Coughlin & Sethares, 2017).*
- Nurses should assess for chronic sorrow and discuss coping strategies for parents of children who have been in the neonatal intensive care unit (NICU). **EB:** *The loss an infant in the NICU can result in chronic sorrow among parents (Currie et al, 2019).*
- Educate parents that children may grieve differently than adults. **EB:** *Children may grieve intermittently for short periods of time in "grief puddles," certain children may grieve at each developmental stage, and some children may try to console their parents instead of going through the grieving process themselves (Gao & Slaven, 2017).*

▲ Refer grieving children to peer support groups. **EB:** *Peer support groups with other children who are grieving are important for children with chronic sorrow (Gao & Slaven, 2017).*

- Encourage children experiencing grief to participate in bereavement activities and camps. **EB:** *Hanlon et al (2018) found that family-based bereavement camps can be beneficial for parents and siblings who had experienced loss.*
- Encourage children who are grieving to participate in other forms of therapy, in addition to individual counseling and psychotherapy. **EB:** *Art therapy, play therapy, music therapy, and bibliotherapy are useful for children with chronic sorrow (Gao & Slaven, 2017).*
- Help the adolescent with chronic sorrow determine sources of support and refer for counseling if needed. **EB:** *Cognitive-behavioral therapy along with parental counseling has been useful in adolescents who experience prolonged grief (Spuij, Dekovic, & Boelen, 2015).*
- Provide family-centered care to parents of children with disabilities, and encourage parents to attend support groups. **EB:** *In a study of 75 children with cerebral palsy and their caregivers, Zuurmond et al (2018) found that support groups had a positive impact on the caregivers' quality of life scores, as well as their knowledge and confidence as a caregiver.*
- Encourage parents with chronic sorrow to participate in an online support group and learn coping strategies. **EB:** *Online bereavement support groups for parents who have lost children can be a convenient and anonymous way to obtain coping support (Elder & Burke, 2015).* **EB:** *Telehealth can be used to provide support groups especially in rural areas (Chang et al, 2016).*
- Parents of children with chronic illnesses may experience chronic sorrow. **EB:** *Six qualitative themes emerged from interviews of parents of children with chronic illnesses: surreality of diagnosis, unrealistic expectations, the battle, keeping it together, doing whatever it takes, and life goes on (Batchelor & Duke, 2019).*
- Provide information to parents who are experiencing chronic sorrow. **EB:** *Parents felt it was helpful when nurses provided information about the child's condition, procedures, resources, and funding sources (Coughlin & Sethares, 2017).*
- Respite care can be beneficial for parents of children with chronic illnesses. **EB**: *Respite care can be helpful for parents experiencing chronic sorrow who have a child with a chronic illnesses (Coughlin & Sethares, 2017).*
- Recognize that mothers who have a miscarriage or lose an infant often grieve and experience sorrow. **EBN:** *Providers should recognize that women who have experienced perinatal loss may have anxiety, and compassionate care should be provided (Moore & Côté-Arsenault, 2018).*

Geriatric

- Identify previous losses and assess the client for depression. **EB:** *The detection of depression is low in older adults; therefore, older adults should be screened for depression (Ghesquiere et al, 2018).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Evaluate the social support system of the older client and refer for bereavement counseling if needed. **EB:** *Bereavement support groups among older adults can result in improvement in grief, depression, and social support (Chow et al, 2019).*

Home Care

- In-home bereavement follow-up by nurses should be considered if available. **EBN:** *District nurses can be used to provide palliative care as well as bereavement visits after a loss (Johnson, 2015).*
- Assess the client for depression and refer for mental health services if appropriate. **EB:** *Clients experiencing bereavement are at risk for depression, so it is important to assess for depression (Ghesquierre et al, 2018).*
- Provide empathetic communication for family/caregivers. **EB:** *Nurses should offer compassion and empathy to those experiencing chronic sorrow (Glenn, 2015).*
- The interventions described previously may be adapted for home care use.
- See care plans for Chronic Low **Self-Esteem**, Risk for **Loneliness,** and **Hopelessness.**

S

Spiritual Distress

Domain 10 Life principles Class 3 Value/belief/action congruence

Mary E. Desmond, PhD, RN, MA, MSN, AHN-BC and Barbara Baele Vincensi, PhD, RN, FNP-BC

NANDA-I

Definition

A state of suffering related to the impaired ability to integrate meaning and purpose in life through connections with self, others, the world, or a superior being.

Defining Characteristics

Anger behaviors; crying; decreased expression of creativity; disinterested in nature; dysomnias; excessive guilt; expresses alienation; expresses anger; expresses anger toward power greater than self; expresses concern about beliefs; expresses concern about the future; expresses concern about values system; expresses concerns about family; expresses feeling abandoned by power greater than self; expresses feeling of emptiness; expresses feeling unloved; expresses feeling worthless; expresses insufficient courage; expresses loss of confidence; expresses loss of control; expresses loss of hope; expresses loss of serenity; expresses need for forgiveness; expresses regret; expresses suffering; fatigue; fear; impaired ability for introspection; inability to experience transcendence; maladaptive grieving; perceived loss of meaning in life; questions identity; questions meaning of life; questions meaning of suffering; questions own dignity; refuses to interact with others

Related Factors

Altered religious ritual; altered spiritual practice; anxiety; barrier to experiencing love; cultural conflict; depressive symptoms; difficulty accepting the aging process; inadequate environmental control; inadequate interpersonal relations; loneliness; loss of independence; low self-esteem; pain; perception of having unfinished business; self-alienation; separation from support system; social alienation; sociocultural deprivation; stressors; substance misuse

At-Risk Population

Individuals experiencing birth of a child; individuals experiencing death of a significant other; individuals experiencing infertility; individuals experiencing life transition; individuals experiencing racial conflict; individuals experiencing unexpected life event; individuals exposed to death; individuals exposed to natural disaster; individuals exposed to traumatic events; individuals receiving bad news; individuals receiving terminal care; individuals with low educational level

Associated Conditions

Chronic disease; depression; loss of body part; loss of function of a body part; treatment regimen

NOC (Nursing Outcomes Classification)

S

Suggested NOC Outcomes

Coping; Dignified Life Closure; Grief Resolution; Hope; Spiritual Health; Stress Level

Example NOC Outcome with Indicators

Spiritual Health as evidenced by the following indicators: Quality of faith, hope, meaning, and purpose in life/Connectedness with inner-self and with others to share thoughts, feelings, and beliefs. (Rate each indicator of **Spiritual Health:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Express meaning and purpose in life
- Express sense of hope in the future
- Express sense of connectedness with self

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Express sense of connectedness with family/friends
- Express ability to forgive
- Express acceptance of health status
- Find meaning in relationships with others
- Find meaning in relationship with a higher power
- Find meaning in personal and health care treatment choices

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening, Forgiveness Facilitation, Grief Work Facilitation, Hope Inspiration, Humor, Music Therapy, Presence, Referral, Reminiscence Therapy, Self-Awareness Enhancement, Simple Guided Imagery, Simple Massage, Simple Relaxation Therapy, Spiritual Support, Therapeutic Touch, Touch

Example NIC Activities—Spiritual Support

Encourage use of spiritual resources if desired; Be available to listen to client's feelings

Nursing Interventions and *Rationales*

- Observe clients for cues indicating difficulties in finding meaning, purpose, or hope in life. **EB:** *In a correlational study of 132 participants with American Heart Association (AHA)/American College of Cardiology (ACC) classification of stage B heart failure, Mills et al (2015) found that spiritual well-being was associated with fewer depressive episodes, especially when focusing on increasing meaning and peace in clients' lives.* **EB:** *In a state of the science consensus report, spirituality included meaning and peace, hope, forgiveness, and gratitude (Steinhauser et al, 2017).*
- Observe seriously ill clients with poor prognosis or life-changing conditions for loss of meaning, purpose, and hope in life. **EB:** *A scoping review on inpatient spiritual distress with seriously ill clients and family experiences indicated that the majority of studies described clients' spiritual distress in relationship to self and others (Roze des Ordons et al, 2018).*
- Promote a sense of love, caring, and compassion in nursing encounters. **EB:** *Batstone et al (2020), in a systematic literature review to better understand provision of spiritual care by nurses at end of life using 11 studies (10 with palliative care nurses), found three themes: nurse value of holistic care; nurse–client relationship; and provision of nursing care that radiates warmth, love, and acceptance.*
- Be physically present and actively listen to the client. **EBN:** *Desmond et al (2018) developed a spiritual care for a veteran simulation and performance checklist based on a review of the literature, content validity expert review, and pilot testing with practicing nurses who care for veterans and found that spiritual care includes a caring presence and listening.* **EBN:** *In a cross-sectional, correlational study with* (n = 554) *tertiary care nurses, Mamier et al (2019) found that the top three mean scores of nurse self-reported frequency of spiritual therapeutics with clients/family were presence, listening, and spiritual assessment.*
- Assist clients to participate in their usual religious rituals or practices that support coping with cancer and its treatment. **EB:** *In a cross-sectional study with cancer clients in Brazil, Noronha Silva et al (2019) found that those who had negative religious/spiritual coping correlated to higher levels of spiritual distress* ($p < 0.001$) *and those with positive religious coping (prayer/connection to God) had an inverse correlation to spiritual distress.*
- Help the client find a reason for living, be available for support, and promote hope. **EB:** *Swinton et al (2017) conducted 208 semistructured interviews with 70 dying clients, 76 family members, and 150 health care providers in an intensive care unit (ICU) to describe how spirituality was expressed during the dying process. The outcome was the development of a program to support the expressions of spirituality during the dying process (i.e., peace, connections, spiritually enhanced environments, and specific expressions of spirituality).*
- Respect the client's beliefs; avoid imposing your own spiritual beliefs on the client. Be aware of your own belief systems and accept the client's spirituality. **EB:** *In a state of the science consensus report, spirituality is not a monism but is holistic and infuses all aspects of being human and requires honoring individuality, promoting conversations, and capturing the breadth of experience (Steinhauser et al, 2017).*
- Monitor and promote supportive social contacts and spiritual and religious practices. **EB:** *In a meta-analytic review, Sherman et al (2015) found that those with greater spiritual and religious involvement have*

a greater ability to maintain satisfying social roles and relationships in individuals with cancer. **EB:** *In a qualitative study with cancer clients in Turkey, Cinar et al (2018) found three themes that promoted coping with cancer: hope in the future, strength from spiritual practices, and social support from family and friends.*

- Integrate and assist family in searching for meaning in the client's health care situation. **EB:** *A scoping review indicated that spirituality and spiritual practices can support resilience and coping with life-altering conditions, including spinal cord injury (Jones et al, 2016) and palliative care (Balboni et al, 2017).*
- Offer spiritual support to family and caregivers. **EB:** *In a state of the science report, clients and families who experience serious illness have spiritual needs (Balboni et al, 2017).* **EB:** *Borji et al (2019) found that Iranian caregivers of heart failure clients* (n = *71) had significantly decreased anxiety levels* (p = *0.001) 3 weeks after a spiritual care education program using pre-post methodology.*
- Screen for spiritual needs and if a need arises, offer chaplain referral. **EB:** *In a state of the science report, spiritual screening is an initial assessment for spiritual need, whereas chaplains provide a more in-depth assessment (Balboni et al, 2017).* **EBN:** *A qualitative descriptive study by Burkhart et al (2019) with nurses at a Veterans Affairs (VA) health system* (n = *39) found that spiritual care actions when clients are in spiritual distress included referral to other professionals, including the chaplain for religious need, or nonreligious resources such as social worker.*
- Support mind–body interventions (e.g., meditation, guided imagery, relaxation, massage). Support outdoor activities. **EB:** *In a state of the science report, mind–body interventions are encouraged to promote spiritual healing (Balboni et al, 2017).*
- Encourage journaling. **EB:** *In a scoping review, Jones et al (2016) found use of narratives helpful in coping with spinal cord injury.* **EB:** *In a state of the science report, journaling was a spiritual care intervention (Balboni et al, 2017).*
- Provide privacy or a "sacred space." **EB:** *In a state of the science report, meditation and life review were spiritual care interventions that may require privacy (Balboni et al, 2017).*
- Integrate spiritual care in multiprofessional palliative care teams. **EB:** *A state of the science report indicated that multiprofessional palliative care teams incorporate a spiritual care component (Balboni et al, 2017).*
- Encourage life review at end of life, including recalling, evaluating, and integrating life experiences. **EB:** *A state of the science report indicated that life review enhanced a personal sense of legacy and promoted dignity when facing terminal illness (Balboni et al, 2017).*

Geriatric

- Offer opportunities to practice one's religion. **EBN:** *In a descriptive cross-sectional study of older adult clients admitted to a coronary care unit, Elham et al (2015) found a significant difference in the means between those who received spiritual care interventions by nurses regarding state-trait anxiety levels, but not in the control group.*

Pediatric

- Offer adolescents with cancer opportunities for reflection to express their spirituality and spiritual needs to enhance efficient coping strategies. **EB:** *In a single-group, quasi-experimental, pre-post study with 32 adolescents with one type of cancer in an Iranian hospital, Torabi et al (2018) found that participating in a 1:1 spiritual care program over six 45-minute sessions had a statistically significant difference between the pretest and posttest mean coping subscales* ($p < .001$).
- Foster spiritual activities among adolescents. **EB:** *Mirghafourvand et al (2016) found that in a sample of 520 Iranian adolescent girls, spiritual well-being was highly correlated with health-related quality of life* ($r = .60$, $p < .001$).

Multicultural

- Recognize the importance of spirituality and provide culturally competent spiritual care to specific populations:
  - African American. **EBN:** *One of four themes identified in analyzing secondary data with content analysis indicated that spirituality for African American women was a source of inner peace, joy, strength, hope, comfort, calm, coping, and other positive aspects contributing to well-being and potentially supportive of health-promoting behaviors (Conway-Phillips & Janusek, 2016).*
  - Latino/Hispanic. **EB:** *With diabetes having a high prevalence in the Hispanic population, Rivera-Hernandez (2016) found a positive relationship between religiosity/spirituality with diabetes care and blood sugar control in a sample of 2216 Latino/Hispanic population 50 years and older living in Mexico.*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Muslim. **EBN:** *In a cross-sectional descriptive study by Akgül and Karadağ (2016), fecal ostomies were found to be a barrier to incorporating specific religious practices of salat, fasting, and pilgrimage in the lives of 150 Muslims postoperatively, providing an opportunity for nurses to assist clients in meeting their religious needs through adaptation or facilitation around this barrier.*
- Veterans of armed services. Recognize the unique spiritual needs of veterans and provide spiritual support or appropriate referrals. **EB:** *An exploratory study by Ganocy et al (2016) found an inverse relationship to suicidal ideation, posttraumatic stress disorder (PTSD), and alcohol use with existential and spiritual well-being for National Guard members who had ever been deployed overseas at least once.* **EB:** *Desmond et al (2018) developed a spiritual care for a veteran simulation and performance checklist based on a review of the literature, content validity expert review, and pilot testing with practicing nurses who care for veterans and found that spiritual care includes recognition of veteran culture environmental cues to past experiences and current veteran connections.*

Home Care

- All the nursing interventions described previously apply in the home setting.

S

Risk for Spiritual Distress

Domain 10 Life principles Class 3 Value/belief/action congruence

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to an impaired ability to integrate meaning and purpose in life through connectedness within self, literature, nature, and/or a power greater than oneself, which may compromise health.

Risk Factors

Altered religious ritual; altered spiritual practice; anxiety; barrier to experiencing love; cultural conflict; depressive symptoms; difficulty accepting the aging process; inadequate environmental control; inadequate interpersonal relations; loneliness; loss of independence; low self-esteem; pain; perception of having unfinished business; self-alienation; separation from support system; social alienation; sociocultural deprivation; stressors; substance misuse

At-Risk Population

Individuals experiencing birth of a child; individuals experiencing death of significant other; individuals experiencing infertility; individuals experiencing life transition; individuals experiencing racial conflict; individuals experiencing unexpected life event; individuals exposed to death; individuals exposed to natural disaster; individuals exposed to traumatic events; individuals receiving bad news; individuals receiving terminal care; individuals with low educational level

Associated Conditions

Chronic disease, depression; loss of a body part; loss of function of a body part; treatment regimen

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* and References

Refer to care plan for **Spiritual** Distress.

Readiness for Enhanced Spiritual Well-Being

Domain 10 Life Principles Class 2 Beliefs

Mary E. Desmond, PhD, RN, MA, MSN, AHN-BC and Barbara Baele Vincensi, PhD, RN, FNP-BC

NANDA-I

S

Definition

A pattern of integrating meaning and purpose in life through connectedness with self, others, art, music, literature, nature, and/or a power greater than oneself which can be strengthened.

Defining Characteristics

Expresses desire to enhance acceptance; expresses desire to enhance capacity to self-comfort; expresses desire to enhance comfort in one's faith; expresses desire to enhance connection with nature; expresses desire to enhance connection with power greater than self; expresses desire to enhance coping; expresses desire to enhance courage; expresses desire to enhance creative energy; expresses desire to enhance forgiveness from others; expresses desire to enhance harmony in the environment; expresses desire to enhance hope; expresses desire to enhance inner peace; expresses desire to enhance interaction with significant other; expresses desire to enhance joy; expresses desire to enhance love; expresses desire to enhance love of others; expresses desire to enhance meditative practice; expresses desire to enhance mystical experiences; expresses desire to enhance oneness with nature; expresses desire to enhance oneness with power greater than self; expresses desire to enhance participation in religious practices; expresses desire to enhance peace with power greater than self; expresses desire to enhance prayerfulness; expresses desire to enhance reverence; expresses desire to enhance satisfaction with life; expresses desire to enhance self-awareness; expresses desire to enhance self-forgiveness; expresses

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

desire to enhance sense of awe; expresses desire to enhance sense of harmony within oneself; expresses desire to enhance sense of identity; expresses desire to enhance sense of magic in the environment; expresses desire to enhance serenity; expresses desire to enhance service to others; expresses desire to enhance strength in one's faith; expresses desire to enhance surrender

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Health Status; Coping; Dignified Life Closure; Grief Resolution; Hope; Personal Health Status; Psychosocial Adjustment: Life Change; Quality of Life; Social Involvement; Spiritual Health

Example NOC Outcome with Indicators

Hope as evidenced by the following indicators: Expresses expectation of a positive future/Faith/Optimism/Belief in self/Sense of meaning in life/Belief in others/Inner peace. (Rate each indicator of **Hope:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = constantly demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Express hope
- Express sense of meaning and purpose in life
- Express peace and serenity
- Express love
- Express acceptance
- Express surrender
- Express forgiveness of self and others
- Express satisfaction with philosophy of life
- Express joy
- Express courage
- Describe being able to cope
- Describe use of spiritual practices
- Describe providing service to others
- Describe interaction with spiritual leaders, friends, and family
- Describe appreciation for art, music, literature, and nature

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening, Coping Enhancement, Counseling, Crisis Intervention, Decision-Making Support, Grief Work Facilitation, Hope Instillation, Meditation Facilitation, Mutual Goal Setting, Presence, Religious Ritual Enhancement, Imagery, Simple Relaxation Therapy, Socialization Enhancement, Spiritual Growth Facilitation, Spiritual Support, Support System Enhancement, Touch, Values Clarification

Example NIC Activities—Spiritual Support

Encourage use of spiritual resources if desired; Be available to listen to client's expression of feelings

Nursing Interventions and *Rationales*

▲ Perform a spiritual assessment that includes the client's relationship with God, meaning and purpose in life, religious affiliation, and any other significant beliefs. **EBN:** *In a pre/post nonrandomized interventional study, researchers Vlasblom et al (2015) found referrals to spiritual caregivers (chaplains) increased after implementing a spiritual assessment instrument by nurses at client admission, in spite of nurse hesitancy in using the tool.*

● Be present and actively listen to the client. **EB:** *In a state of the science report, spirituality requires observations and understanding of human experience (Steinhauser et al, 2017).* **EBN:** *In a cross-sectional, correlational study*

with (n = 554) tertiary care nurses Mamier et al (2019) found that the top three mean scores of nurse self-reported frequency of spiritual therapeutics with clients/family were presence, listening, and spiritual assessment.

- Encourage the client to engage in other spiritual meditative or mind–body practices. **EBN:** *In a quasi-experimental interprofessional study with nursing, Sun et al (2016) discovered that religious affiliation and practices improved coping, comfort, and faith in palliative care clients.* **EB:** *In a state of the science report, mind–body interventions are encouraged to promote spiritual healing (Balboni et al, 2017).*
- Coordinate or encourage nurses to participate in spiritual care education courses and simulation. **EBN:** *Hu et al (2019), using a nonrandomized controlled trial, found that oncology nurses who received specific education on spiritual care over 12 months in China had significantly higher overall spiritual health, spiritual care competency scores, and higher individual scores ($p < 0.05$) than the control group.* **EBN:** *For use with the veteran population, Desmond et al (2018) developed a spiritual care simulation and performance checklist based on a review of the literature, content validity expert review, and pilot testing with practicing nurses who care for veterans, indicating that simulation and debriefing with a standardized client can be used to teach spiritual care ($p < .001$).*
- Perform actions to address spiritual need. **EBN:** *Burkhart et al (2019) used a qualitative descriptive method to describe spiritual care in practice with nurses in a U.S. veteran health system, finding spiritual care interventions included promoting hope through self-reflection, facilitating both religious and nonreligious spiritual practices, encouraging connection with others, and referral to other professionals.*
- Encourage clients to reflect on what is meaningful to them in life. **EBN:** *A spiritual care for a veteran simulation and performance checklist based on a review of the literature, content validity expert review, and pilot testing with practicing nurses who care for veterans found that spiritual care includes asking about/recognition of importance of veteran culture, past service, and present meaningful connection to veteran groups (Desmond et al, 2018).*
- Offer spiritual support to family and caregivers. **EB:** *In a state of the science report, clients and families who experience serious illness have spiritual needs (Balboni et al, 2017).* **EB:** *Borji et al (2019) found that Iranian caregivers of heart failure clients ($n = 71$) had significantly decreased anxiety levels ($p = 0.001$) 3 weeks after a spiritual care education program using pre-post methodology.*
- Offer opportunities to facilitate religious or spiritual practices, including reflection, prayer, and relaxation techniques with deep breathing and listening to scripture verses. **EB:** *In a quasi-experimental pretest-posttest with control design with clients with gynecological cancer ($n = 108$), Nasution et al (2020) examined the effectiveness of a spiritual intervention on coping and spiritual well-being, finding a statistically significant increase in mean score of coping ($p = 0.001$) and spiritual well-being ($p = 0.006$) in the intervention group.*
- Support spiritual practices, including meditation, guided imagery, journaling, relaxation, and involvement in art, music, or poetry. **EB:** *In a state of the science report, mind–body interventions are encouraged to promote spiritual healing (Balboni et al, 2017).*
- Encourage expressions of spirituality. **EB:** *Swinton et al (2017) conducted 208 semistructured interviews with 70 dying clients, 76 family members, and 150 health care providers in an intensive care unit (ICU) to describe how spirituality was expressed during the dying process. The outcome of these interviews was the development of the 3 Wishes Program to support the expressions of spirituality during the dying process (e.g., peace, connections, spiritually enhanced environments, and specific expressions of spirituality).*
- Encourage integration of spirituality in healthy lifestyle choices. **EBN:** *In a phenomenological study of African-Caribbean women poststroke, Moorley et al (2016) identified one of three themes, which included the use of faith, spirituality, and church, to promote choices for healthy behaviors.*

Geriatric

▲ Offer opportunities to practice one's religion. **EB:** *Moeini et al (2016), in a randomized clinical trial with 52 elderly clients with hypertension in Iran, found that the experimental group who received a religious program based on Islam had mean scores of spiritual well-being significantly higher than in the control group ($p < 0.001$) in both the religious and existential dimensions.* **EB:** *Soriano et al (2016) found, in a sample of 200 Filipino older adults living in a community and institutional setting, that regular visits with chaplains and religious practices enhanced older adults' spiritual contentment and religion and culture quality of life.*

- Encourage social relationships and connections with family for institutionalized older adults. **EB:** *Soriano et al (2016) found that the loss of familial and peer relationships on admission to a nursing home was associated with lower religion and culture quality of life and quality of life overall.*
- For those with chronic disease, encourage individual spiritual practices that promote meaning and peace. **EB:** *Mills et al (2015), in a sample of 132 men and women with asymptomatic stage B heart failure, found that spiritual well-being, particularly meaning and peace, was associated with less depression.*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ For those with terminal illness, encourage clients to attend meaning-centered psychotherapy, spiritual therapy intervention, life review, dignity therapy, yoga, meditation, and mind-body stress reduction if appropriate. **EB:** *Chen et al (2018), in a systematic review of 19 studies with 1548 participants, evaluated effects of spiritual care on quality of life and spiritual well-being on clients with terminal illness and found seven types of spiritual care interventions, with the majority of studies indicating that spiritual care had a potential favorable effect on global quality of life and spiritual well-being of clients.*

- During bereavement, encourage bereavement life review to promote spiritual well-being and alleviate depression. **EB:** *In a sample of 20 bereaved Hawaiian Americans, Ando et al (2015) found that participating in bereavement life review statistically significantly increased spiritual well-being and decreased depression.*

Pediatric

- Offer adolescents with cancer opportunities for reflection and storytelling to express their spirituality and spiritual needs to enhance efficient coping strategies. **EB:** *In a single-group, quasi-experimental, pre-post study with 32 adolescents with one type of cancer in an Iranian hospital, Torabi et al (2018) found that participating in a 1:1 spiritual care program over six 45-minute sessions had a statistically significant difference between the pretest and posttest mean coping subscales* ($p < .001$).
- Foster spiritual activities among adolescents. **EB:** *Mirghafourvand et al (2016) found that, in a sample of 520 Iranian adolescent girls, spiritual well-being was highly correlated with health-related quality of life* ($r = .60$, $p < .001$).

Multicultural

- Recognize the importance of spirituality and provide culturally competent spiritual care to specific populations:
  - **African American.** **EBN:** *One of four themes identified in analyzing secondary data with content analysis indicated that spirituality for African American women was a source of inner peace, joy, strength, hope, comfort, calm, coping, and other positive aspects contributing to well-being and potentially supportive of health-promoting behaviors (Conway-Phillips & Janusek, 2016).*
  - **Armed forces.** **EB:** *An exploratory study by Ganocy et al (2016) found an inverse relationship to suicidal ideation, posttraumatic stress disorder (PTSD), and alcohol use with existential and spiritual well-being for National Guard members who had ever been deployed overseas at least once.*
  - **Chinese.** **EB:** *Leung et al (2015) used a pretest/posttest methodology with 160 Chinese clients diagnosed with chronic disease to study the effects of a psychoeducational death preparation intervention with findings indicating that there was significant improvement in psychological, behavioral, and spiritual dimensions over time related to fear of death and preparation for death.*
  - **Homeless.** **EB:** *A cross-sectional mixed-methods pilot study using the Mantram Repetition Program that teaches mantram (sacred word self-selection) repetition with 29 homeless women found that 88% of the participants repeated their mantram 1 week later, with three themes emerging from the qualitative data: mantram repetition, mantram benefits, and being cared for (Weinrich et al, 2016).*
  - **Indonesian.** **EBN:** *In a quasi-experimental pretest-posttest with control design with a sample of 108 clients with gynecological cancer, the effectiveness of a spiritual intervention (54 each group) on coping and spiritual well-being was examined by Nasution et al (2020), finding a statistically significant increase in mean score of coping ($p = 0.001$) and spiritual well-being ($p = 0.006$) in the intervention group.*
  - **Latino/Hispanic.** **EBN:** *In a cross-sectional secondary analysis of a longitudinal study, Prince et al (2015) found that Hispanic stem cell transplant survivors* ($n = 171$) *had greater spiritual well-being and quality of life than non-Hispanic survivors, even at ≥3 years posttransplant.*
  - **Thai.** **EBN:** *The Thai people were found to be both religious and spiritual, using coping strategies from both areas to help manage concerns and to explain the development of kidney disease in a qualitative study by Yodchai et al (2017). Encourage both religious and spiritual coping strategies to help cope.*

Home Care

- All the nursing interventions described previously apply in the home setting.

Impaired Standing

Domain 4 Activity/rest Class 2 Activity/exercise

Tracy P. George, DNP, APRN-BC, CNE

NANDA-I

Definition

Limitation of ability to independently and purposefully attain and/or maintain the body in an upright position from feet to head.

Defining Characteristics

Difficulty adjusting position of one or both lower limbs on uneven surface; difficulty attaining postural balance; difficulty extending one or both hips; difficulty extending one or both knees; difficulty flexing one or both hips; difficulty flexing one or both knees; difficulty maintaining postural balance; difficulty moving one or both hips; difficulty moving one or both knees; difficulty stressing torso with body weight

Related Factors

Excessive emotional disturbance; insufficient energy; insufficient muscle strength; insufficient physical endurance; malnutrition; obesity; pain; self-imposed relief posture

Associated Conditions

Circulatory perfusion disorder; impaired metabolism; injury to lower extremity; neurological disorder; prescribed posture; sarcopenia; surgical procedures

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Activity Tolerance; Balance; Body Mechanics Performance; Body Positioning: Self-Initiated; Comfort Status: Physical; Endurance; Mobility; Risk Control: Hypotension; Skeletal Function

Example NOC Outcome with Indicators

Mobility as evidenced by the following indicators: Balance/Coordination/Body positioning performance. (Rate outcome and indicators of **Mobility:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate optimal independence and safety when standing
- Demonstrate the proper use of assistive devices
- State benefits of standing

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Body Mechanics Promotion

Example NIC Activities

Instruct client on structure and functional spine and optimal posture for moving and using the body

Nursing Interventions and *Rationales*

- Encourage clients to stand at intervals throughout the day. **EB:** *The use of standing desks reduced self-reported sedentary behaviors by 25% during a 6-month period (Resendiz et al, 2019).* **EB:** *Clients who*

engaged in standing, walking, or cycling during an 8-hour work period had lower 24-hour and postprandial blood sugars than those who sat (Crespo et al, 2016).

- Advise clients of the physical and psychological benefits of being upright and active. **EB:** *In clients 1 to 3 years after suffering a stroke, depression, left hemisphere infarction, visual neglect, and difficulty with mobility and balance were associated with being less active* (*Kunkel et al, 2015*).
- Educate clients about the health risks of sitting. **EB:** *In a study of 2074 clients, sitting, for long periods of time and difficulty with standing were associated with a higher mortality rate* (*Olaya et al, 2018*).

Geriatric

- Advise older clients who have difficulty standing to use assistive devices. **EB:** *Assistive devices may allow older adults to carry out usual daily activities and participate in daily life (Freedman et al, 2017).*
- Encourage the use of trunk exercises along with walking and balance exercises in older adults. **EB:** *In a randomized controlled trial of 64 older adults, walking and balance exercises along with trunk strengthening exercises improved the results on the 30-second Chair Stand Test, Sitting and Rising Test, Forward Reach Test, Backward Reach Test, and Timed Up and Go Test* (*Shahtahmassebi et al, 2019*).
- Encourage clients who are unable to stand to consider chair exercises. **EB:** *In a study of 100 older adults with lower extremity osteoarthritis, the 40 adults who participated in chair yoga twice a week for 8 weeks reported less pain than the 60 participants who participated in a health education program two times per week for 8 weeks* (*Park et al, 2016*).
- Encourage poststroke clients to participate in rehabilitation interventions that promote standing. **CEB:** *In a meta-analysis using 11 studies, interventions used after strokes to improve standing were associated with faster sitting-to-standing position times and improved lateral symmetry during sitting-to-standing position changes (Pollock et al, 2014).* **EB:** *A study of seven participants found that a home-based intervention, Rehab@home, can be used effectively to improve the rehabilitation of balance and the movement from the sitting to standing position in clients with neurological deficits, without the presence of a physical therapist* (*Faria, Silva, & Campilho, 2015*).
- Mechanical sit-stand lifts can be used with clients who require assistance with transfers. **EB:** *Sit-stand lifts can be used with clients to prevent back and shoulder injuries among nurses (Tang et al, 2017).*
- Educate older adults who have fallen about the need for balance and muscle training of the ankle joint. **EB:** *In a randomized controlled trial of 26 older clients who were at risk of falling and had fallen previously, Choi and Kim (2015) found that balance and ankle muscle training resulted in improvements in the gait of older adults.*
- Educate adults older than age 80 years on the need for vitamin D. **EB:** *In a systematic review and meta-analysis, vitamin D deficiency was associated with a higher prevalence of orthostatic hypotension* (*Ometto et al, 2016*).
- Assess for risk of falls among older adults with difficulty standing. **EB:** *In a study among Japanese older adults, Arai et al (2020) found that the ability to stand on one leg from a 40-cm-high seat was found to predict falls in older adults, which is part of the Stand-Up Test (SUT).*
- Advise older clients who are at risk for falls to avoid doing multiple tasks at one time while standing. **EB:** *In a study of 243 adults ages 65 years and older, older participants' standing balance was worse than that seen in younger participants; the standing balance was worse when clients were performing a second task, which is important when considering the risk of falls* (*Coelho et al, 2016*).

Client/Family Teaching and Discharge Planning

- Educate clients that standing can be beneficial for their health. **EB:** *In a study of participants with chronic pain* (n = *18) and participants without chronic pain* (n = *19), Raijmakers et al (2015) found that clients with chronic pain spent more time lying and less time sitting and standing over a 1-week period.*
- Teach clients about the need to take frequent breaks when standing for long periods. **EB:** *Gallagher et al (2019) found that 58% (11/19) of participants who had no walking breaks when standing for 2 hours developed low back pain, compared to 26% of clients when 5-minute walking breaks were included every 25 minutes during 2-hour standing intervals.*
- Instruct clients about the use of yoga for individuals who have difficulty with standing balance. **EB:** *In a randomized control of obese adults with poor standing balance, participation in yoga classes three times per week was associated with improved static and dynamic standing balance* (*Jorrakate et al, 2015*).

Stress Overload

Domain 9 Coping/stress tolerance Class 2 Coping responses

Meredith Ford, MSN, RN, CNE

S

NANDA-I

Definition

Excessive amounts and types of demands that require action.

Defining Characteristics

Difficulty with decision-making; expresses feeling pressured; expresses increased anger; expresses tension; impaired functioning; increased impatience; negative impact from stress

Related Factors

Inadequate resources; repeated stressors; stressors

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Anxiety Level; Caregiver Stressors; Stress Level; Health-Promoting Behavior; Knowledge: Stress Management

Example NOC Outcome with Indicators

Stress Level as evidenced by the following indicators: Increased blood pressure, restlessness, emotional outbursts, anxiety, diminished attention to detail. (Rate the outcome and indicators of **Stress Level:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Review the amounts and types of stressors in daily living
- Identify stressors that can be modified or eliminated
- Mobilize social supports to facilitate lower stress levels
- Reduce stress levels through use of health promoting behaviors and other strategies

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening; Anger Control Assistance; Anxiety Reduction; Aroma Therapy; Counseling; Crisis Intervention; Emotional Support; Family Integrity Promotion; Presence; Support System Enhancement

Example NIC Activities—Support System Enhancement

Identify psychological response to situation and availability of support system; Determine adequacy of social networks; Explain to concerned others how they can help; Refer to a self-help group or Internet-based resource as appropriate; Provide services in a caring and supportive manner

Nursing Interventions and *Rationales*

- Assist client in identification of stress overload during vulnerable life events. **EBN:** *Research suggested that role overload, associated with high stress levels, among nurses and volunteer caregivers may negatively affect health, well-being, and job performance* (*Dageid et al, 2016*). **EB:** *When surrogates experience acute stress from participating in treatment decisions for others, it translates into posttraumatic stress disorder (PTSD), anxiety, depression, and grief in the months after the client's death* (*Barnato et al, 2017*). **EB:** *Women with breast cancer who were involved in group therapy focusing on stress reduction gained positive effects on mood and self-esteem while prolonging survival, which indirectly resulted in decreased stress* (*Gosain et al, 2020*). *Job strain has a clinically significant risk of death to men with cardiometabolic disease* (*Kivimäki et al, 2018*).
- Listen actively to descriptions of stressors and the stress response. **EBN:** *In a recent study focusing on stress and depression, these conditions are independently related to major adverse cardiovascular events* (*Hou et al, 2020*). **EB:** *Adolescents exposed to daily stress demonstrate increased risky decision-making compared with those with low stress* (*Uy & Galván, 2017*).
- In younger adult women, assess interpersonal stressors. **EB:** *A sample of 450 young adults, 62% of them being female, were at high risk for depression and anxiety related to the psychosocial effects of the COVID-19 pandemic* (*Kujawa et al, 2020*). **CEB:** *A systematic review and meta-analysis of 30 studies found that maternal exposure to the stress of domestic violence results in significantly increased risk of low birth weight and preterm birth* (*Shah & Shah, 2010*).
- Categorize stressors as modifiable or nonmodifiable. **EB:** *Strategizing on nonavoidance coping and increased socialization along with enhanced personal mastery and self-efficacy in use of problem-solving coping may minimize depression symptoms in Alzheimer's disease caregivers* (*Grano et al, 2017*). **EBN:** *Removing or minimizing some stressors, changing responses to stressors, and modifying the long-term effects of stress are all actions that can assist those with chronic illnesses and stress* (*Chiang et al, 2018*).
- Help clients modify or mitigate stressors identified as modifiable. **EBN:** *A study of 150 married working women demonstrated that role overload has a significant impact on job performance and stress* (*Mittal & Bhakar, 2018*). **CEB:** *There are numerous possible strategies to modify stressors among nurses, including team interaction and support, organizational change and enlightened leadership, and the need for a space for nurses to gather and interact* (*Happell et al, 2013*).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Help clients distinguish among short-term, chronic, and secondary stressors. **EB:** *PTSD status in combination with severe trauma in Korean males who were active military in the Vietnam War had a decrease in telomere length* (*Kim et al, 2017*). **EBN:** *Social support is a critical dimension of health and health promotion and serves as a buffer in the stress response* (*Mette et al, 2020*).
- Provide information as needed to reduce stress responses to acute and chronic illnesses. **EBN:** *Nursing interventions including strategies to deal with child behavior, a focus on physical health, and planning to meet resource needs may enhance the well-being of African American grandmothers raising grandchildren (Chan et al, 2019). Proactive nursing interventions including assessment of caregiver needs for support and preparedness including early psychoeducational interventions can enhance caregiver ability to navigate the challenges associated with caring for a child with a chronic illness (Mowla et al, 2017).*

▲ Explore possible therapeutic approaches such as cognitive-behavioral therapy, biofeedback, neurofeedback, acupuncture, pharmacological agents, and complementary and alternative therapies. **EBN:** *Nonpharmacological nursing interventions, through the use of nature-based sounds played through headsets, were found to effectively decrease the stress response in mechanically ventilated clients (Rajora et al, 2019).* **EB:** *Those who exercised regularly were more resistant to acute stress (Bernstein & McNally, 2018). Mindfulness techniques have been suggested as an effective means of reducing stress in adolescents (Perry-Parrish et al, 2016), nursing personnel (Yang et al, 2018), and older adults (Hazlett-Stevens et al, 2019).*

- Help the client to reframe his or her perceptions of some of the stressors. **EBN:** *Researchers found that optimism and adaptive coping help students prevent academic burnout, positively affecting academic performance* (*Vizoso et al, 2019*).
- Assist the client to mobilize social supports for dealing with recent stressors. **EBN:** *When clients experience stronger social supports, they have less financial threat, stress, anxiety, and depression (Viseu et al, 2018).*

Pediatric

- With children, nurses should work with parents to help them reduce children's stressors. **EB:** *Prenatal stress and anxiety have been shown to increase stress-induced cortisol response in adolescents and adversity in early life, for example, interparental aggression and emotional maternal withdrawal* (*van Bodegom et al, 2017*; *Van Tieghem & Tottenham, 2018*).
- Help children to manage their feelings related to self-concept. **CEB:** *Perceived isolation as experienced in high school associated with victimization results in higher stress and longer-lasting negative psychological outcomes* (*Newman, Holden, & Delville, 2005*).
- Help children to deal with bullies and other sources of violence in schools and neighborhoods. **EB:** *Violence in schools and neighborhoods has significant effects on children's stress. A recent study of 1993 participants, ages 9 to 13 years, indicated that being bullied (victimized) was associated with increased stress, behavioral problems, and needing psychological counseling* (*Garaigordobil & Machimbarrena, 2019*).
- Help children to manage the complexities of chronic illnesses. **EB:** *Children with a chronic illness have reported moderate levels of self-management, which indicates potential problems with physical, emotional, social, and mental domains* (*Bravo et al, 2020*). **EB:** *Teenagers who had recently been diagnosed with diabetes described high levels of stress that often related to the complexities of managing the illness* (*Chao et al, 2016*).

Geriatric

- Assess for chronic stress with older adults and provide a variety of stress relief techniques. **EB:** *PTSD is associated with increased odds of cardiovascular, musculoskeletal, gastrointestinal, respiratory, and neurological conditions, as well as cancer, sleep disorders, and anemia* (*Sommer et al, 2021*).

▲ Encourage older adults to seek appropriate counseling. **EB:** *Treatment modalities for PTSD in older adults may vary depending on whether the PTSD was experienced early or late in life; however, trauma confrontation and cognitive restructuring combined with age-specific life review in cognitive-behavioral therapy may hold the most promise (Bottche et al, 2016).* **CEB:** *Bereavement-related major depression differs from major depression seen in other stressful life events only in relation to older age at onset. Individuals are more likely to be female; have lower levels of treatment-seeking; and have higher levels of guilt, fatigue, and loss of interest; therefore, they should not be excluded from a diagnosis of major depression (Kendler, Myers, & Zisook, 2008).*

Multicultural

✱ Review cultural beliefs and acculturation level in relation to perceived stressors. **EBN:** *A study done to assess time-varying association of premigration and postmigration stressors in refugees' mental health indicated that there was an association between the difficulties in adjustment to life and their mental health during the resettlement period (Wu et al, 2020). Assess families for whether they experience high stress or low stress.* **EB:** *In a sample of 26,670 Italian fifth-grade students, first- and second-generation immigrant pupils reported being victimized more frequently than their native peers, although the incidence for second-generation pupils was lower than first generation (Alivernini et al, 2019).* **CEB:** *Stress related to racial microaggressions experienced by African Americans may have a negative cumulative effect on health outcomes (Sue et al, 2007).*

Home Care

- The preceding interventions may be adapted for home care use.
- Develop community-based programs for stress management as needed for groups with increased risk of stress overload (e.g., firefighters, policemen, military personnel, nurses). **CEB:** *Some situations have higher risks of stress overload. Stress management interventions may prevent or modify the experience of stress overload (McNulty, 2005).*
- Support and encourage neighborhood stability. **CEB:** *A "significant proportion of health differentials across neighborhoods is due to disparate stress levels across [Detroit] neighborhoods," and neighborhood stability was a buffer to reduce the negative effects of high stress (Boardman, 2004).*

Client/Family Teaching and Discharge Planning

- Diagnose the possibility of stress overload before teaching.
- Establish readiness for learning.
- Provide manageable amounts of information at the appropriate educational level.
- Evaluate the need for additional teaching and learning experiences.

S

Acute Substance Withdrawal Syndrome

Domain 9 Coping/stress tolerance Class 3

Neurobehavioral stress

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Serious, multifactorial sequelae following abrupt cessation of an addictive compound.

Defining Characteristics

Acute confusion (00128); anxiety (00146); disturbed sleep pattern (00198); nausea (00134); risk for electrolyte imbalance (00195); risk for injury (00035)

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

Related Factors

Developed dependence to addictive substances; excessive use of an addictive substance over time; malnutrition; sudden cessation of an addictive substance

At-Risk Population

Individuals with history of withdrawal symptoms; older adults

Associated Conditions

Significant comorbidity

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Anxiety Level; Comfort Status; Drug Abuse Cessation Behavior; Electrolyte Balance; Seizure Severity; Substance Addiction Consequences; Substance Withdrawal Severity; Symptom Severity; Vital Signs

Example NOC Outcome with Indicators

Substance Withdrawal Severity as evidenced by the following indicators: Substance cravings/Change in vital signs/Irritability/Nausea. (Rate the outcome and indicators of **Substance Withdrawal Severity:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Stabilize and remain free from physical injury
- Verbalize effects of substances on body
- Maintain vital signs and laboratory values within normal range
- Verbalize importance of adequate nutrition

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Behavior Management; Drug Withdrawal; Electrolyte Monitoring; Emotional Support; Nausea Management; Seizure Precautions; Smoking Cessation Assistance; Substance Use Treatment: Alcohol Withdrawal; Substance Use Treatment: Anxiety Reduction

Example NIC Activities—Substance Use Treatment: Alcohol Withdrawal

Monitor vital signs during withdrawal, Monitor for delirium tremens, Administer medications, Provide symptom management, Implement seizure precautions

S

Nursing Interventions and *Rationales*

Alcohol-Induced Withdrawal Syndrome

- Assess for the client's pattern of alcohol use, last drink, and current blood alcohol levels. **EB:** *Because of ethanol's short action, withdrawal symptoms begin within 6 to 8 hours after blood alcohol levels decrease, peak at 72 hours, and are markedly reduced by days 5 through 7 (Long, Long, & Koyfman, 2017).*
- Implement seizure precautions. **EB:** *Clients in alcohol withdrawal are at risk for developing withdrawal seizures related to central nervous system hyperstimulation caused by loss of gamma-aminobutyric acid inhibitory effect (Long, Long, & Koyfman, 2017). The development of acute symptomatic seizures during an alcohol withdrawal episode is associated with a fourfold increase in the mortality rate that is caused by complications of severe alcohol use disorder (Jesse et al, 2017).*
- Rule out other causes of symptoms. **EB:** *The presence of other disease processes requires immediate treatment and stabilization (Long, Long, & Koyfman, 2017). Other assessments should include a check of blood*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

gases, a review of glucose and electrolyte laboratory panels, a review of potential medication reactions, presence of infection, and other conditions.

- Monitor vital signs. **EB:** *Tachycardia and hypertension are among the broad symptoms of alcohol withdrawal (Long, Long, & Koyfman, 2017).*
- Assess for progression of withdrawal symptoms such as insomnia, anxiety, nausea/vomiting, tremulousness, headache, diaphoresis, palpitations, increased body temperature, tachycardia, and hypertension. **EB:** *These are the broad symptoms of alcohol withdrawal that can progress in intensity without treatment (Makic, 2017).*
- Monitor severity of withdrawal symptoms with the Clinical Institute Withdrawal Assessment (CIWA-Ar). **CEB:** *The CIWA-Ar is a 10-item scale for clinical quantification of the severity of the alcohol withdrawal syndrome (Sullivan et al, 1989). The CIWA-Ar scale is available at* https://umem.org/files/uploads/110421 2257_CIWA-Ar.pdf.
- Evaluate the client for progression to delirium tremens (DTs). **EB:** *DTs are severe and life-threatening withdrawal symptoms that occur in 3% to 5% of clients on about the third day of withdrawal. DT symptoms have a rapid onset and include the broad alcohol withdrawal symptoms, fluctuating levels of cognition and attention, and autonomic instability. Associated risk factors are previous DTs, untreated seizures, CIWA-Ar score >15, heart rate >100, history of sustained drinking, systolic blood pressure >150 mm Hg, alcohol intake >2 days, age >30 years, recent misuse of benzodiazepines, and concurrent medical illness* (*Long, Long, & Koyfman, 2017*).
- Assess nutritional status for risk of malnutrition. Assess for thiamine (B_1) deficiency, which is associated with chronic alcohol abuse, folate deficiency, and vitamin D deficiency associated with a history of inadequate exposure to sunlight. Consult with health care provider as needed for supplement order. **EB:** *Alcoholism is a major cause of malnutrition in the United States. Thiamine deficiencies contribute to the development of Korsakoff's syndrome and Wernicke's encephalopathy, which are neurological complications of alcohol abuse (Dugum & McCullough, 2015). Vitamin D insufficiency is associated with cognitive impairment (Goodwill & Szoeke, 2017).*
- Address hydration needs. **EB:** *Clients in alcohol withdrawal require administration of fluids to correct dehydration (Mirijello et al, 2015; Long, Long, & Koyfman, 2017).*
- Determine hepatic and renal functioning before administration of medications. **EB:** *Hepatic or renal disease can slow the clearance of medications and lead to complications or toxicities (Long, Long, & Koyfman, 2017).*

Opioid-Induced Withdrawal Syndrome

- Assess for the client's opioid of choice, last use, and current withdrawal symptoms. **EB:** The onset of withdrawal symptoms depends on the half-life of the opioid used. Heroin withdrawal occurs 6 to 8 hours after the last use, and methadone and fentanyl withdrawal occur 1 to 3 days after the last dose (*Donroe & Tetrault, 2017*).
- Monitor severity of withdrawal symptoms with the Clinical Opiate Withdrawal Scale (COWS). **CEB:** *A standardized assessment tool is necessary for evaluating and treating opioid withdrawal. The COWS is scored numerically based on severity, with values summed to give a cumulative score. A threshold score indicates when treatment should be initiated (Wesson & Ling, 2003).*
- Nurses should wait to administer the first dose of buprenorphine to opioid-dependent clients until clients are experiencing mild to moderate opioid withdrawal symptoms. **EB:** *The American Society of Addiction Medicine (ASAM) National Practice Guidelines recommended waiting to administer the first dose of buprenorphine until clients are experiencing mild to moderate opioid withdrawal symptoms to reduce the risk of precipitated withdrawal (Kampman & Jarvis, 2015).*
- Assess and manage early opioid withdrawal symptoms (agitation, anxiety, insomnia, muscle aches, increased lacrimation, rhinorrhea, sweating, and yawning) and late opioid withdrawal symptoms (abdominal cramping, diarrhea, pupillary dilation, nausea, vomiting, and piloerection). **EBN:** *Severe withdrawal can lead to fluid and electrolyte imbalances, cardiac dysrhythmias, acute kidney injury, or rhabdomyolysis. A failure to treat could result in client injury or in clients leaving the clinical setting against medical advice (Turner et al, 2018).*
- Monitor vital signs. **EBN:** *Parameters for blood pressure should be followed especially for clients treated with clonidine or other alpha-2 agonists, which can cause hypotension* (*Turner et al, 2018*).
- Teach the client about the anticipated withdrawal symptoms and opioid cravings while offering support and encouragement. **EBN:** *A lack of knowledge and decreased nurse empathy and engagement are barriers to treatment (Worley, 2017).*

▲ Monitor laboratory reports and report to health care provider. **EBN:** *Serum electrolytes are closely evaluated for abnormalities and replaced as indicated (Turner et al, 2018).*

▲ Refer client for buprenorphine, methadone, or naltrexone treatment. **EB:** *Using medications for opioid withdrawal management is recommended over abrupt cessation of opioids. Abrupt cessation of opioids may lead to strong cravings, which can lead to continued use (Kampman & Jarvis, 2015). A study showed that emergency department–initiated buprenorphine was associated with increased engagement in addiction treatment and reduced illicit opioid use during the 2-month interval when buprenorphine was continued in primary care (D'Onofrio et al, 2017).*

Benzodiazepine-Induced Withdrawal Syndrome

● Assess for the client's last benzodiazepine use and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms occurs within 1 to 3 days of drug cessation. Common withdrawal symptoms include any of the following: autonomic instability (tachycardia, elevated blood pressure), tremulousness, diaphoresis, insomnia, anxiety, depression, psychosis (hallucinations, delusions), sensory hypersensitivity (photophobia, hyperacusis), perceptual distortions, depersonalization, agoraphobia, flulike symptoms, paresthesias, muscle stiffness, ataxia, visual disturbances, DTs, and seizures* (*Puening et al, 2017*).

● Implement seizure precautions. **EB:** *Clients withdrawing from benzodiazepines may also experience seizures on withdrawal (Puening et al, 2017).*

● Rule out delirium from other causes or other withdrawal syndromes. **EB:** *The symptoms of benzodiazepine withdrawal appear similar to delirium, as well as barbiturate or alcohol withdrawal (Puening et al, 2017).*

▲ Anticipate use of the same treatment protocols as for alcohol withdrawal and use of a long-acting benzodiazepine in tapering doses over time. **EB:** *A tapering schedule will assist with prevention of relapse (Donroe & Tetrault, 2017).*

Cocaine/Methamphetamine-Induced Withdrawal Syndrome

● Assess for the client's last stimulant use and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms occurs within 24 hours after abrupt discontinuation of using high amounts of amphetamine-type substances over a prolonged period of time. Common stimulant withdrawal symptoms include depressed mood with any of the following: fatigue, vivid dreams, insomnia, increased appetite, psychomotor retardation, and agitation. Cocaine withdrawal is mild and treated supportively. Methamphetamine use can result in significant psychiatric withdrawal symptoms and intense craving after abrupt cessation (Donroe & Tetrault, 2017).*

Cannabis-Induced Withdrawal Syndrome

● Assess for the client's last cannabis use and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms occurs within a week of cannabis cessation. Common cannabis withdrawal symptoms include any of the following: anxiety, irritability, malaise, dysphoria, decreased appetite, restlessness, and sleep disturbances* (*Zehra et al, 2018*).

● Direct nursing actions to address anxiety, irritability, sleep disturbances, and decreased appetite. **EB:** *Nursing care should target the specific symptoms of cannabis withdrawal as part of a treatment that targets cannabis use reduction and prevention of relapse (Zehra et al, 2018).*

Nicotine-Induced Withdrawal Syndrome

● Assess for the client's last nicotine use and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms occurs within hours of last use. Common nicotine withdrawal symptoms include craving for nicotine, irritability, anger, frustration, anxiety, difficulty concentrating, restlessness, decreased heart rate, increased appetite, weight gain, tremor, headaches, craving, delirium, and sleep disturbance* (*Ginige, 2016*).

● Rule out nicotine withdrawal as the cause of delirium in critically ill clients. **EB:** *Chronic consumption of nicotine can cause desensitization and upregulation of acetylcholine receptors. In an acute nicotine withdrawal state, the lack of sufficient nicotinic stimulation leads to acetylcholine deficiency, which is associated with delirium* (*Ginige, 2016*).

All Withdrawal Syndromes

● Obtain a drug and/or alcohol history using a tool such as the AUDIT-C or the DAST-10. **EB:** *The Audit-C is a simple 3-question screen for hazardous or harmful drinking that can stand alone or be incorporated into*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

general health history questionnaires. The DAST-10 is a 10-item, yes/no self-report instrument that takes less than 8 minutes to complete (Mulvaney-Day et al, 2018).

- Implement and follow institutional withdrawal protocols. **EB:** *A study suggested that using a protocol for treatment of critical care clients with alcohol withdrawal leads to decreased intensive care unit (ICU) length of stay and reduced ICU cost (Tavani et al, 2018).*
- Assess for signs of recent trauma or head injury. **EB:** *A study found that trauma clients who present to the hospital in a delayed fashion have unique characteristics and are more likely to suffer negative outcomes, including substance withdrawal (Kao et al, 2017).*
- Assess the client's level of consciousness, monitor for changes in behavior, and orient to reality as needed. **EB:** *Reality orientation will support the client with changes in level of consciousness or behavior and may indicate progression of withdrawal (Mirijello et al, 2015).*
- Assess vital signs and monitor for existing medical conditions and current medications. **EB:** *Withdrawal symptoms can be exacerbated or masked by existing medical conditions, medications, or treatments (Long, Long, & Koyfman, 2017).*
- Assess and monitor for expression of psychological distress. **EB:** *Withdrawal can cause or exacerbate current emotional, psychological, or mental problems (Harford et al, 2018).*
- Collect urine/serum samples for laboratory tests. **EB:** *Routine treatment for substance withdrawal should include serum (or breath) alcohol concentrations, complete blood count, renal function tests, electrolytes, glucose, liver enzymes, urinalysis, and urine toxicology screening (Mirijello et al, 2015).*
- Address craving for substances with mindfulness-based techniques. **EB:** *Compared with those receiving usual care, a study found that mindfulness-based addiction treatment participants reported lower anxiety, concentration difficulties, craving, and dependence, as well as higher self-efficacy for managing negative affect without smoking (Spears et al, 2017).*
- Respond to agitated behavior with deescalation techniques. **EBN:** *Research shows that staff intervention can modify processes and reduce further conflict (Berring, Pedersen, & Buus, 2016).*
- Administer as-needed (PRN) medications for agitation and symptom control as ordered. **EB:** *A study found that symptom-triggered treatment for alcohol withdrawal syndrome individualizes treatment, is safe, decreases treatment duration and the use of benzodiazepines, and consequently reduces health care costs (Soravia et al, 2018).*
- Provide a quiet room without dark shadows, noises, or other excessive stimuli. **EB:** *Supportive care includes controlling environmental stimuli that may increase client agitation or irritability (Mirijello et al, 2015).*
- Provide suicide precautions and 1:1 staffing for clients who are delirious or who may present a danger to themselves or others. **EB:** *A study showed that substance use disorders are associated with self- and other-directed violence (Harford et al, 2018).*

Client/Family Teaching and Discharge Planning

- ▲ After withdrawal symptoms have subsided, refer the client to substance use treatment and long-term management. **EB:** *Collaborative discharge planning can increase the likelihood of the client's success with substance abstinence. Referral to appropriate services can reduce discharges against medical advice and increase follow-up in postdischarge addiction treatment centers (Donroe & Tetrault, 2017).*
- ▲ Refer for smoking cessation services that target nicotine craving. **EB:** *A study found that nicotine craving may be a useful therapeutic target for increasing the effectiveness of smoking-cessation treatment (Magee, Lewis, & Winhusen, 2016).*

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Anxiety Level; Comfort Status; Drug Abuse Cessation Behavior; Electrolyte Balance; Seizure Severity; Substance Addiction Consequences; Substance Withdrawal Severity; Symptom Severity; Vital Signs

Example NOC Outcome with Indicators

Substance Withdrawal Severity as evidenced by the following indicators: Substance cravings/Change in vital signs/Irritability/Nausea. (Rate the outcome and indicators of **Substance Withdrawal Severity:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Stabilize and remain free from physical injury
- Verbalize effects of substances on body
- Maintain vital signs and laboratory values within normal range
- Verbalize importance of adequate nutrition

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Anxiety Reduction; Behavior Management; Electrolyte Monitoring; Emotional Support; Nausea Management; Seizure Precautions; Smoking Cessation Assistance; Substance Use Treatment: Alcohol Withdrawal; Substance Use Treatment: Drug Withdrawal

Example NIC Activities—Substance Use Treatment: Alcohol Withdrawal

Monitor vital signs during withdrawal, Monitor for delirium tremens, Administer medications, Provide symptom management, Implement seizure precautions

Nursing Interventions and *Rationales*

Risk for Alcohol-Induced Withdrawal Syndrome

- Assess for the client's pattern of alcohol use, last drink, and current blood alcohol levels. **EB:** *Because of ethanol's short action, withdrawal symptoms begin within 6 to 8 hours after blood alcohol levels decrease, peak at 72 hours, and are markedly reduced by days 5 through 7 (Long, Long, & Koyfman, 2017).*
- Implement seizure precautions. **EB:** *Clients in alcohol withdrawal are at risk for developing withdrawal seizures related to central nervous system hyperstimulation caused by loss of gamma-aminobutyric acid inhibitory effect (Long, Long, & Koyfman, 2017). The development of acute symptomatic seizures during an alcohol withdrawal episode is associated with a fourfold increase in the mortality rate caused by complications of severe alcohol use disorder (Jesse et al, 2017).*
- Rule out other causes of symptoms. **EB:** *The presence of other disease processes requires immediate treatment and stabilization (Long, Long, & Koyfman, 2017). Other assessments should include a check of blood gases, a review of glucose and electrolyte laboratory panels, a review of potential medication reactions, presence of infection, and other conditions.*
- Monitor vital signs. **EB:** *Tachycardia and hypertension are among the broad symptoms of alcohol withdrawal (Long, Long, & Koyfman, 2017).*
- Assess for progression of withdrawal symptoms such as insomnia, anxiety, nausea/vomiting, tremulousness, headache, diaphoresis, palpitations, increased body temperature, tachycardia, and hypertension. **EBN:** *These are the broad symptoms of alcohol withdrawal that can progress in intensity without treatment (Makic, 2017).*

- Monitor severity of withdrawal symptoms with the Clinical Institute Withdrawal Assessment (CIWA-Ar). **CEB:** *The CIWA-Ar is a 10-item scale for clinical quantification of the severity of the alcohol withdrawal syndrome (Sullivan et al, 1989; Kattimani & Bharadwaj, 2013). The CIWA-Ar scale is available at* https://umem.org/files/uploads/1104212257_CIWA-Ar.pdf.
- Evaluate the client for progression to delirium tremens (DTs). **EB:** *DTs are severe and life-threatening withdrawal symptoms that occur in 3% to 5% of clients on about the third day of withdrawal. DT symptoms have a rapid onset and include the broad alcohol withdrawal symptoms, fluctuating levels of cognition and attention, and autonomic instability. Associated risk factors are previous DTs, untreated seizures, CIWA-Ar score >15, heart rate >100, history of sustained drinking, systolic blood pressure >150 mm Hg, alcohol intake >2 days, age >30 years, recent misuse of benzodiazepines, and concurrent medical illness (Long, Long, & Koyfman, 2017).*
- Assess nutritional status for risk of malnutrition, thiamine (B_1) deficiency associated with chronic alcohol abuse, folate deficiency, and vitamin D deficiency–associated history of inadequate exposure to sunlight. Consult with health care provider as needed for supplement order. **EB:** *Alcoholism is a major cause of malnutrition in the United States. Thiamine deficiencies contribute to the development of Korsakoff's syndrome and Wernicke's encephalopathy, which are neurological complications of alcohol abuse (Dugum & McCullough, 2015). Vitamin D insufficiency is associated with cognitive impairment (Goodwill & Szoeke, 2017).*
- Address hydration needs. **EB:** *Clients in alcohol withdrawal require administration of fluids to correct dehydration (Mirijello et al, 2015; Long, Long, & Koyfman, 2017).*
- Determine hepatic and renal functioning before administration of medications. **EB:** *Hepatic or renal disease can slow the clearance of medications and lead to complications or toxicities (Long, Long, & Koyfman, 2017).*

Risk for Opioid-Induced Withdrawal Syndrome

- Assess for the client's opioid of choice, last use, and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms depends on the half-life of the opioid used. Heroin withdrawal occurs 6 to 8 hours after the last use, and methadone and fentanyl withdrawal occur 1 to 3 days after the last dose (Donroe & Tetrault, 2017).*
- Monitor severity of withdrawal symptoms with the Clinical Opiate Withdrawal Scale (COWS). **CEB:** *A standardized assessment tool is necessary for evaluating and treating opioid withdrawal. The COWS is scored numerically based on severity, with values summed to give a cumulative score. A threshold score indicates when treatment should be initiated (Wesson & Ling, 2003).*
- Assess and manage early opioid withdrawal symptoms (agitation, anxiety, insomnia, muscle aches, increased lacrimation, rhinorrhea, sweating, and yawning) and late opioid withdrawal symptoms (abdominal cramping, diarrhea, pupillary dilation, nausea, vomiting, and piloerection). **EBN:** *Severe withdrawal can lead to fluid and electrolyte imbalances, cardiac dysrhythmias, acute kidney injury, or rhabdomyolysis. A failure to treat could result in client injury or in clients leaving the clinical setting against medical advice (Turner et al, 2018).*
- Monitor vital signs. **EBN:** *Parameters for blood pressure should be followed especially for clients treated with clonidine or other alpha-2 agonists, which can cause hypotension (Turner et al, 2018).*
- Clients should be taught about risk of relapse and other safety concerns from using opioid withdrawal management as stand-alone treatment for opioid use disorder. **EB:** *Opioid withdrawal management on its own is not a treatment method (Kampman & Jarvis, 2015).*
- Teach the client about the anticipated withdrawal symptoms and opioid cravings, while offering support and encouragement. **EBN:** *A lack of knowledge and decreased nurse empathy and engagement are barriers to treatment (Worley, 2017).*

▲ Monitor laboratory reports and report to health care provider. **EBN:** *Serum electrolytes are closely evaluated for abnormalities and replaced as indicated (Turner et al, 2018).*

▲ Refer client for buprenorphine or methadone treatment. **EB:** *Using medications for opioid withdrawal management is recommended over abrupt cessation of opioids. Abrupt cessation of opioids may lead to strong cravings, which can lead to continued use (Kampman & Jarvis, 2015). A study showed that emergency department–initiated buprenorphine was associated with increased engagement in addiction treatment and reduced illicit opioid use during the 2-month interval when buprenorphine was continued in primary care (D'Onofrio et al, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Risk for Benzodiazepine-Induced Withdrawal Syndrome

- Assess for the client's last benzodiazepine use and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms occurs within 1 to 3 days of drug cessation. Common withdrawal symptoms include any of the following: autonomic instability (tachycardia, elevated blood pressure), tremulousness, diaphoresis, insomnia, anxiety, depression, psychosis (hallucinations, delusions), sensory hypersensitivity (photophobia, hyperacusis), perceptual distortions, depersonalization, agoraphobia, flulike symptoms, paresthesia, muscle stiffness, ataxia, visual disturbances, DTs, and seizures (Puening et al, 2017).*
- Implement seizure precautions. **EB:** *Clients withdrawing from benzodiazepines may also experience seizures on withdrawal (Puening et al, 2017).*
- Rule out delirium from other causes or other withdrawal syndromes. **EB:** *The symptoms of benzodiazepine withdrawal appear similar to delirium, as well as barbiturate or alcohol withdrawal (Puening et al, 2017).*

▲ Anticipate use of the same treatment protocols as for alcohol withdrawal and use of a long-acting benzodiazepine in tapering doses over time. **EB:** *A tapering schedule will assist with prevention of relapse (Donroe & Tetrault, 2017).*

Risk for Cocaine/Methamphetamine-Induced Withdrawal Syndrome

- Assess for the client's last stimulant use and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms occurs within 24 hours after abrupt discontinuation of using high amounts of amphetamine-type substances over a prolonged period of time. Common stimulant withdrawal symptoms include depressed mood with any of the following: fatigue, vivid dreams, insomnia, increased appetite, psychomotor retardation, and agitation. Cocaine withdrawal is mild and treated supportively. Methamphetamine use can result in significant psychiatric withdrawal symptoms and intense craving after abrupt cessation (Donroe & Tetrault, 2017).*

Risk for Cannabis-Induced Withdrawal Syndrome

- Assess for the client's last cannabis use and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms occurs within a week of cannabis cessation. Common cannabis withdrawal symptoms include any of the following: anxiety, irritability, malaise, dysphoria, decreased appetite, restlessness, and sleep disturbances (Zehra et al, 2018).*
- Direct nursing actions to address anxiety, irritability, sleep disturbances, and decreased appetite. **EB:** *Nursing care should target the specific symptoms of cannabis withdrawal as part of a treatment that targets cannabis use reduction and prevention of relapse (Zehra et al, 2018).*

Risk for Nicotine-Induced Withdrawal Syndrome

- Assess for the client's last nicotine use and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms occurs within hours of last use. Common nicotine withdrawal symptoms include craving for nicotine, irritability, anger, frustration, anxiety, difficulty concentrating, restlessness, decreased heart rate, increased appetite, weight gain, tremor, headaches, craving, delirium, and sleep disturbance (Ginige, 2016).*
- Rule out nicotine withdrawal as the cause of delirium in critically ill clients. **EB:** *Chronic consumption of nicotine can cause desensitization and upregulation of acetylcholine receptors. In an acute nicotine withdrawal state, the lack of sufficient nicotinic stimulation leads to acetylcholine deficiency, which is associated with delirium (Ginige, 2016).*

All Withdrawal Syndromes

- Obtain a drug and/or alcohol history using a tool such as the AUDIT-C or the DAST-10. **EB:** *The Audit-C is a simple 3-question screen for hazardous or harmful drinking that can stand alone or be incorporated into general health history questionnaires. The DAST-10 is a 10-item, yes/no self-report instrument that takes less than 8 minutes to complete (Mulvaney-Day et al, 2018).*
- Implement and follow institutional withdrawal protocols. **EB:** *A study suggested that using a protocol for treatment of critical care clients with alcohol withdrawal leads to decreased intensive care unit (ICU) length of stay and reduced ICU cost (Tavani et al, 2018).*
- Assess for signs of recent trauma or head injury. **EB:** *A study found that trauma clients who present to the hospital in a delayed fashion have unique characteristics and are more likely to suffer negative outcomes, including substance withdrawal (Kao et al, 2017).*

S

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

- Assess the client's level of consciousness, monitor for changes in behavior, and orient to reality as needed. **EB:** *Reality orientation will support the client with changes in level of consciousness or behavior and may indicate progression of withdrawal (Mirijello et al, 2015).*
- Assess vital signs and monitor for existing medical conditions and current medications. **EB:** *Withdrawal symptoms can be exacerbated or masked by existing medical conditions, medications, or treatments (Long, Long, & Koyfman, 2017).*
- Assess and monitor for expression of psychological distress. **EB:** *Withdrawal can cause or exacerbate current emotional, psychological, or mental problems (Harford et al, 2018).*
- Collect urine/serum samples for laboratory tests. **EB:** *Routine treatment for substance withdrawal should include serum (or breath) alcohol concentrations, complete blood count, renal function tests, electrolytes, glucose, liver enzymes, urinalysis, and urine toxicology screening (Mirijello et al, 2015).*
- Address craving for substances with mindfulness-based techniques. **EB:** *Compared with those receiving usual care, a study found that mindfulness-based addiction treatment participants reported lower anxiety, concentration difficulties, craving, and dependence, as well as higher self-efficacy for managing negative affect without smoking (Spears et al, 2017).*
- Respond to agitated behavior with deescalation techniques. **EBN:** *Research shows that staff intervention can modify processes and reduce further conflict (Berring, Pedersen, & Buus, 2016).*
- Administer as-needed (PRN) medications for agitation and symptom control as ordered. **EB:** *A study found that symptom-triggered treatment for alcohol withdrawal syndrome individualizes treatment, is safe, decreases treatment duration and the use of benzodiazepines, and consequently reduces health care costs (Soravia et al, 2018).*
- Provide a quiet room without dark shadows, noises, or other excessive stimuli. **EB:** *Supportive care includes controlling environmental stimuli that may increase client agitation or irritability (Mirijello et al, 2015).*
- Provide suicide precautions and 1:1 staffing for clients who are delirious or who may present a danger to themselves or others. **EB:** *A study showed that substance use disorders are associated with self- and other-directed violence (Harford et al, 2018).*

Client/Family Teaching and Discharge Planning

▲ After withdrawal symptoms have subsided, refer client to substance use treatment. **EB:** *Collaborative discharge planning can increase the likelihood of the client's success of substance abstinence. Referral to appropriate services can reduce discharges against medical advice and increase follow-up in postdischarge addiction treatment centers (Donroe & Tetrault, 2017).*

▲ Refer for smoking cessation services that target nicotine craving. **EB:** *A study found that nicotine craving may be a useful therapeutic target for increasing the effectiveness of smoking-cessation treatment (Magee, Lewis, & Winhusen, 2016).*

Ineffective Infant Suck-Swallow Response

Domain 2 Nutrition Class 1 Ingestion

Margaret Quinn, DNP, CPNP, CNE

NANDA-I

Definition

Impaired ability of an infant to suck or to coordinate the suck-swallow response.

Defining Characteristics

Arrhythmia; bradycardic events; choking; circumoral cyanosis; excessive coughing; finger splaying; flaccidity; gagging; hiccups; hyperextension of extremities; impaired ability to initiate an effective suck; impaired ability to sustain an effective suck; impaired motor tone; inability to coordinate sucking, swallowing, and breathing; irritability; nasal flaring; oxygen desaturation; pallor; subcostal retraction; time-out signals; use of accessory muscles of respiration

Related Factors

Hypoglycemia; hypothermia; hypotonia; inappropriate positioning; unsatisfactory sucking behavior

At-Risk Population

Infants born to mothers with substance misuse; infants delivered using obstetrical forceps; infants delivered using obstetrical vacuum extraction; infants experiencing prolonged hospitalization; premature infants

Associated Conditions

Convulsive episodes; gastroesophageal reflux; high flow oxygen by nasal cannula; lacerations during delivery; low Appearance, Pulse, Grimace, Activity, & Respiration (APGAR) scores; neurological delay; neurological impairment; oral hypersensitivity; oropharyngeal deformity; prolonged enteral nutrition

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Bottle Feeding Establishment: Infant; Bottle Feeding Performance; Breastfeeding Establishment: Infant, Maternal; Breastfeeding: Maintenance; Hydration; Nutritional Status: Food and Fluid Intake

Example NOC Outcome with Indicators

Breastfeeding Establishment: Infant as evidenced by the following indicators: Proper alignment and latch-on/Correct suck and tongue placement/Urinations per day appropriate for age/Weight gain appropriate for age. (Rate the outcome and indicators of **Breastfeeding Establishment: Infant:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client Outcomes

Infant Will (Specify Time Frame)

- Consume adequate calories that will result in appropriate weight gain and optimal growth and development
- Have opportunities for skin-to-skin experiences
- Have opportunities for "trophic" (i.e., small volume of breast milk/formula) enteral feedings prior to full oral feedings
- Progress to stable, neurobehavioral organization (e.g., motor, state, self-regulation, attention-interaction)
- Demonstrate presence of mature oral reflexes that are necessary for safe feeding
- Progress to safe, self-regulated oral feedings
- Coordinate the suck-swallow-breathe sequence while nippling
- Display clear behavioral cues related to hunger and satiety
- Display approach/engagement cues, with minimal avoidance/disengagement cues
- Have opportunities to pace own feeding, taking breaks as needed
- Display evidence of being in the "quiet-alert" state while nippling
- Progress to and engage in mutually positive parent/caregiver–infant/child interactions during feedings

Parent/Family Will (Specify Time Frame)

- Recognize necessity of adequate calories for appropriate weight gain and optimal growth and development
- Learn to read and respond contingently to infant's behavioral cues (e.g., hunger, satiety, approach/engagement, stress/avoidance/disengagement)
- Learn strategies that promote organized infant behavior
- Learn appropriate positioning and handling techniques
- Learn effective ways to relieve stress behaviors during nippling
- Learn ways to help infant coordinate suck-swallow-breathe sequence (i.e., external pacing techniques)
- Engage in mutually positive interactions with infant during feeding
- Recognize ways to facilitate effective feedings: feed in quiet-alert state; keep length of feeding appropriate; burp; prepare/structure environment; recognize signs of sensory overload; encourage self-regulation; respect need for breaks and breathing pauses; avoid pulling and twisting nipple during pauses; allow infant to resume sucking when ready; provide oral support (cheek and/or jaw) as needed; use appropriate nipple hole size and flow rate

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Bottle Feeding; Fluid Monitoring; Kangaroo Care; Lactation Counseling; Nutritional Monitoring; Teaching: Infant Safety

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NIC Activities—Lactation Counseling

Provide information about psychological and physiological benefits of breastfeeding; Refer to a lactation consultant

Nursing Interventions and *Rationales*

- Refer to care plans for Disorganized **Infant** Behavior, Ineffective **Breastfeeding**, Interrupted **Breastfeeding,** Insufficient **Breast Milk Production**, Ineffective Infant **Feeding** Dynamics as needed.

Mother–Baby Dyad Interventions

- Assess for any factors that may disrupt successful breastfeeding after birth. **EBN:** *Interventions after birth, separation of mother and baby, or excessive newborn suctioning may negatively affect the newborn transition and breastfeeding (Lau et al, 2018).*
- Provide opportunities for skin-to-skin care. **EBN:** *Placing a newborn skin to skin on the mother is the essential first step to promote and establish successful breastfeeding (Jefferson & Bibb, 2019).*
- Allow the stable newborn to breastfeed within the first 30 to 60 minutes after birth. **EBN:** *The first hour after birth is the optimal time to achieve successful breastfeeding because the sucking effort of the newborn peaks within 45 minutes of birth and declines during the next 2 hours (Jefferson & Bibb, 2019).*
- Encourage rooming-in. **EBN:** *Exclusive rooming-in enhances breastfeeding (Jefferson & Bibb, 2019).*
- Assess and document the effectiveness of mixed breastfeeding and bottle-feeding. **EBN:** *The Neonatal Eating Assessment Tool (NeoEAT—Mixed Feeding) for mixed breastfeeding and bottle-feeding is a parent-report assessment of symptoms of problematic feeding in infants who are fed by both breast and bottle. The reported reference values may be used to identify infants that require further assessment, referral, and intervention (Pados, Johnson, & Nelson, 2020).*
- Position infant in semiupright position, with head, shoulders, and hips in a straight line facing the mother with the infant's nose level with the mother's nipple. **EB:** *Breastfeeding improves in the semireclined position because the infant is more positionally stable and better able to coordinate sucking, swallowing, and breathing (Douglas & Keogh, 2017).*

▲ Refer to a multiprofessional team (e.g., neonatal/pediatric nutritionist, physical or occupational therapist, speech pathologist, lactation specialist) as needed. **EBN:** *Follow-up visits with lactation consultants, nurses, and health care providers are beneficial for breastfeeding mothers' support after delivery (Keenan-Devlin et al, 2019).*

Maternal Interventions

- Assess for any maternal issues related to breastfeeding. **EBN:** *A study found that breastfeeding self-efficacy was a dominant factor affecting maternal breastfeeding satisfaction. Researchers concluded that increased breastfeeding satisfaction may promote breastfeeding (Awaliyah, Rachmawati, & Rahmah, 2019).*
- Support the mother's confidence in her ability to breastfeed. **EBN:** *Nurses have the unique opportunity to assist with the physical initiation and maintenance of breastfeeding (Shattnawi, 2017).*
- Educate mothers to recognize and respond to their infant's cues for feeding. **EB:** *Hands to mouth, sucking motions, rooting, and body flexion are all common infant feeding cues. A study found that significantly more frequent feeding cues were observed at the beginning of feeding than at the end, showing that cue frequency changes with satiation (Shloim et al, 2017).*
- Assess for proper latch at the breast. **EB:** *Latching on is the first step for essential breastfeeding. A neonate with a correct latch will have the lips flanged, will have the tongue under the nipple and extending over the gum line, and will be sucking behind the nipple on the areola (Smith, 2016).*
- Determine the reason for the poor latch, including inverted nipples, flat nipples, ankyloglossia, small mandible, or nipple confusion, and offer alternatives to mothers for unsuccessful latch. **EB:** *Treatment may consist of help with positioning, nipple shell or shields, and counseling from a lactation specialist (Smith, 2016).*
- Council mothers on various feeding positions to encourage successful latch. **EB:** *Teaching the mother to change the newborn's position on the breast will prevent persistent pressure in one area of the nipple and areola and facilitate emptying of all quadrants of the breast (Smith, 2016).*

Infant Interventions

- Observe coordination of infant's suck, swallow, and gag reflex. **EB:** *Adequate coordination of sucking, swallowing, and breathing is essential for safe feeding (Geddes et al, 2017).*
- Assess for neonatal signs of inadequate milk supply/intake. **EBN:** *Adequate intake can be assessed by 8 to 12 feedings in 24 hours with the number of wet and stool diapers equaling the newborn's age in days and increasing each day after birth (Jefferson & Bibb, 2019).*

Premature Infants/Infants Requiring Specialty/Intensive Care

- Provide developmentally supportive neonatal intensive care for preterm infants. **EB:** *Early term delivery is independently associated with lower rates of breastfeeding compared to delivery after 39 weeks gestation (Keenan-Devlin et al, 2019).*
- Foster direct breastfeeding as early as possible and enable the first oral feed to be at the breast in the neonatal intensive care unit (NICU). **EB:** *Breast milk feeding is associated with lower neonatal morbidity in the very preterm infant (<32 weeks gestation) and breastfeeding is beneficial for maternal health (Wilson et al, 2018).*
- Before the infant is ready for oral feedings, implement gavage feedings (or other alternative) as ordered, using expressed breast milk whenever possible. **EB:** *The transition from gavage to oral feeding requires coordination of sucking, swallowing, and breathing and organized sleep/wake cycles in premature infants (Unal et al, 2019).*
- Provide a naturalistic environment for tube feedings (naso-orogastric, gavage, or other) that approximates a pleasurable oral feeding experience: hold infant in semiupright/flexed position; offer nonnutritive sucking; pace feedings; allow for semidemand feedings contingent with infant cues; offer rest breaks; burp, as appropriate. **EBN:** *Nonnutritive sucking reduces the time infants need to transition from tube to full oral feeding, and from start of oral feeding to full oral feeding. It also reduces the length of hospital stay (Foster, Psaila, & Patterson, 2016).*
- Continue to provide support for the mother discharged before the infant by encouraging skin-to-skin technique and regular breastfeeding. **EBN:** *The Academy of Breastfeeding Medicine recommends follow-up for ongoing support and troubleshooting (Noble et al, 2018).*

Home Care

- The previously mentioned appropriate interventions may be adapted for home care use.
- Provide breastfeeding mothers instruction on the technique of expressing milk by hand or pump. **EB:** *The mother should be taught how to alleviate engorgement, increase her milk supply, maintain her milk supply, and obtain milk for feeding to the infant should she and the infant be separated or if the infant is unable to feed directly from the breast (Jefferson & Bibb, 2019).*

▲ Provide lists of various local peer support groups and services (e.g., mother-to-mother support groups such as La Leche League; hospital/clinic-based support groups; and governmental supported groups such as Special Supplemental Nutrition Program for Women, Infants, and Children [WIC] in the United States, with phone numbers, contact names, and addresses). **EB:** *The Academy of Breastfeeding Medicine recommends providing a written discharge summary for the parents and primary care physician that includes detailed nutrition support recommendations, community support referrals, visiting nurse, skilled lactation consultant visits, and social services (Noble et al, 2018).*

S

Client/Family Teaching and Discharge Planning

- Before discharge, anticipation of breastfeeding problems should be assessed based on maternal and/or infant risk factors. **EB:** *The Academy of Breastfeeding Medicine recommends assessing the adequacy of breastfeeding and addressing any problems or potential problems (Noble et al, 2018).*
- Include mothers and appropriate others (e.g., fathers, partners, grandmothers, support persons) in teaching of anticipatory guidance for key discharge issues. **EB:** *The Academy of Breastfeeding Medicine recommends providing a written discharge summary for the parents and primary care physician that includes detailed nutrition support recommendations, community support referrals, visiting nurse, skilled lactation consultant visits, and social services (Noble et al, 2018).*

Risk for Sudden Infant Death

Domain 11 Safety/protection Class 2 Physical injury

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Infant susceptible to unpredicted death.

Risk Factors

Delayed prenatal care; inadequate prenatal care; inattentive to second-hand smoke; infant < 4 months placed in sitting devices for routine sleep; infant overheating; infant overwrapping; infant placed in prone position to sleep; infant placed in side-lying position to sleep; soft sleep surface; soft, loose objects placed near infant

At-Risk Population

Boys; infants aged 2-4 months; infants exposed to alcohol in utero; infants exposed to cold climates; infants exposed to illicit drug in utero; infants fed with expressed breast milk; infants not breastfed exclusively; infants of African descent; infants whose mothers smoked during pregnancy; infants with postnatal exposure to alcohol; infants with postnatal exposure to illicit drug; low birth weight infants; Native American infants; premature infants

S

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Knowledge: Infant Care; Parenting Performance; Safe Home Environment; Safe Sleep Environment

Example NOC Outcome with Indicators

Knowledge: Infant Care as evidenced by the following indicators: Proper infant positioning/Age-appropriate cardiopulmonary resuscitation techniques. (Rate the outcome and indicators of **Knowledge: Infant Care:** 1 = no knowledge, 2 = limited knowledge 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Explain appropriate measures to prevent sudden infant death syndrome (SIDS)
- Demonstrate correct techniques for positioning and blanketing the infant, protecting the infant from harm

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Infant Care; Teaching: Infant Safety 0 to 3 Months

Example NIC Activities—Teaching: Infant Safety

Instruct parent/caregiver to place infant on back to sleep and keep loose bedding, pillows, and toys out of crib; Instruct parent/caregiver to avoid holding infant while smoking or holding hot liquids

Nursing Interventions and *Rationales*

- Position the infant supine to sleep during naps and night; do not position in the prone position or side-lying position. **EB:** *In a research review, evidence showed that sleeping prone or in a side-lying position is associated with an increased risk of SIDS (Carlin & Moon, 2017).*
- Avoid overbundling, overheating, and swaddling the infant. The infant should not feel hot to touch. **EB:** *Swaddling increases the risk of SIDS twofold in infants 6 months or younger (Pease et al, 2016). Swaddling has been associated with infant death, especially when the infant has shown the ability to roll over (Carlin & Moon, 2017).*

Home Care

- Most of the interventions and client teaching information are relevant to home care.
- Evaluate home for potential safety hazards, such as inappropriate cribs, cradles, or strollers.
- Determine where and how the child sleeps, and provide instructions on safe sleeping positions and environments as needed.

Multicultural

- Safe to Sleep recommendations should be tailored to include the mother's culture and experience, provided to all members of the family, and reviewed frequently. **EB:** *An ethnographic study found that African American mothers were aware of the Safe to Sleep recommendations but did not follow because of lack of comfort, feeling they are unable to comply, finding it unnecessary to comply, or finding the effort too stressful (Stifler, Matemachani, & Crane, 2020).*
- Provide teaching to African American mothers on how pacifier use reduces SIDS risk. **EB:** *A study of African American mothers found that many parents were unaware that pacifier use reduces SIDS risk (Joyner, Oden, & Moon, 2016).*
- Recommend to African American and Hispanic mothers the need to abstain from smoking during the prenatal period. **EB:** *A study found that prenatal smoking may explain a substantial portion of the disparities in birth adverse outcomes and SIDS for African American and Hispanic women (Mohlman & Levy, 2016).*

Client/Family Teaching and Discharge Planning

- Teach the safety guidelines for infant care in the previous interventions.
- Teach parents and caregivers the following measures for a Safe Infant Sleeping Environment recommended by the American Academy of Pediatrics (AAP) Task Force on Sudden Infant Death Syndrome (2016):
  - Place infant in supine positioning.
  - Use a firm sleep surface.
  - Room-sharing without bed-sharing.
  - Avoidance of soft bedding.
  - Avoid overheating.
  - Offer infant a pacifier.
  - Avoid smoke exposure during pregnancy and after birth.
  - Avoid alcohol and illicit drug use during pregnancy and after birth.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- ❍ Infants should be immunized in accordance with AAP and Centers for Disease Control and Prevention (CDC) recommendations.
- ❍ Do not use home cardiorespiratory monitors as a strategy to reduce the risk of SIDS.
- ❍ Breastfeeding is a protective factor.

- Provide parents of both term and preterm infants with verbal and written education about SIDS and ways to reduce the risk of SIDS before discharge to home. **EBN:** *Study results demonstrated that providing current written material along with modeling safe sleep practices in the hospital before discharge to home can help further reduce the incidence of SIDS (Dufer & Godfrey, 2017).*
- Recommend breastfeeding. **EB:** *A review identified breastfeeding as a protective factor (Carlin & Moon, 2017).*
- Teach the need to stop smoking during pregnancy and to not smoke around the infant. Do not allow the infant to be exposed to any secondhand smoke. **EB:** *Maternal smoking remains the strongest prenatal modifiable risk factor for SIDS (Friedmann et al, 2017).*

Risk for Suffocation

Domain 11 Safety/protection Class 2 Physical injury

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to inadequate air availability for inhalation, which may compromise health.

Risk Factors

Access to empty refrigerator/freezer; eating large mouthfuls of food; excessive emotional disturbance; gas leak; inadequate knowledge of safety precautions; low-strung clothesline; pacifier around infant's neck; playing with plastic bag; propped bottle placed in infant's crib; small object in airway; smoking in bed; soft sleep surface; unattended in water; unvented fuel-burning heater; vehicle running in closed garage

Associated Conditions

Altered olfactory function; face/neck disease; face/neck injury; impaired motor functioning

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Knowledge: Infant Care; Parenting: Adolescent Physical Safety, Early/Middle Childhood Physical Safety, Infant/Toddler Physical Safety; Personal Safety; Risk Control; Risk Detection; Safe Home Environment; Substance Addiction Consequences

Example NOC Outcome with Indicators

Knowledge: Infant Care as evidenced by the following indicators: Strategies to prevent choking/Appropriate activities for child's developmental level/First aid techniques. (Rate the outcome and indicators of **Knowledge: Infant Care:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Undertake appropriate measures to prevent suffocation
- Demonstrate correct techniques for emergency rescue maneuvers (e.g., Heimlich maneuver, rescue breathing, cardiopulmonary resuscitation [CPR]) and describe situations that require them

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Aspiration Precautions; Environmental Management: Safety; Infant Care; Positioning; Security Enhancement; Surveillance; Surveillance: Safety; Teaching: Infant Safety

Example NIC Activities—Environmental Management: Safety

Identify safety hazards in the environment (e.g., physical, biological, and chemical); Remove hazards from the environment, when possible

Nursing Interventions and *Rationales*

- Identify hospitalized clients at particular risk for suffocation, including the following:
  - Clients with altered levels of consciousness
  - Infants or young children
  - Clients with developmental delays
  - Clients with mental illness, especially schizophrenia
  - Clients who have been physically or chemically restrained
- Practice caution with physical restraints and follow all institutional policies and procedures as restraint use has been associated with mortality. **EB:** *A review of restraint use in nursing home clients found evidence of physical restraint–associated deaths. Neck compression was found to be the most common mechanism that resulted in asphyxia (Bellenger et al, 2018).*
- Institute safety measures such as proper positioning and feeding precautions. See the care plans for Risk for **Aspiration** and Impaired **Swallowing** for additional interventions.
- Vigilance and special protective measures are necessary for clients at greater risk for suffocation. **EB:** *Swallowing disorders are common in schizophrenia with associated morbidity and mortality from either acute asphyxia from airway obstruction or from aspiration and pneumonia. The death rate from acute asphyxia is significantly higher in these clients (up to 100 times greater than the general population) (Kulkarni, Kamath, & Stewart, 2017).*

Pediatric

- Provide families with education about interventions and modifiable risk factors to prevent infant suffocation:
  - Use a firm sleep surface with a fitted sheet.
  - Do not place infants in adult beds, on couches, or in armchairs to sleep.
  - Do not overbundle the infant.
  - Avoid soft bedding and do not have loose bedding in crib with infant.
  - Use caution with infant head coverings and keep blanket end at infant chest.
  - Do not practice bed sharing or co-sleeping with infants.

  EB: *The American Academy of Pediatrics Task Force has identified recommendations to reduce the risk of other sleep-related infant deaths such as suffocation, entrapment, and asphyxia (see care plan Risk for*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Sudden Infant Death *for further interventions) (Moon & Task Force on Sudden Infant Death Syndrome, 2016).*

- Conduct risk factor identification, noting special circumstances in which preventive or protective measures are indicated. Note the presence of environmental hazards, including plastic bags; cribs with slats wider than 2 inches; ill-fitting crib mattresses that can allow the infant to become wedged between the mattress and crib; pillows/loose bedding in cribs; placement of crib near windows with blinds or cords; cosleeping; abandoned large appliances such as refrigerators, dishwashers, or freezers; clothing with cords or hoods that can become entangled; bibs; pacifiers on a string; necklaces in infants and children; drapery cords; and pull-toy strings. **EB:** *Bed sharing is associated with accidental suffocation and strangulation and sudden infant death. The risk of infant bed sharing is increased in infants who have no identified place to sleep, have health or care issues, and are breastfed. Education should support breastfeeding without bed sharing, highlight the need for safe sleep places, and address the risk factors for sleep-related deaths (Heere et al, 2017).*
- Counsel families to evaluate household furniture for safety, including large dressers, televisions, bookshelves, and appliances, which may need to be anchored to the wall to prevent the child from climbing on the furniture and it falling forward and suffocating the child. **EB:** *Injuries to children by falling televisions have become more frequent. Dressers and other furniture not designed for holding televisions were commonly involved. Toddlers ages 1 to 3 most frequently suffer head and neck injuries. Small children may suffer secondary brain injuries or death by mechanical asphyxia because of their small size compared with the size of the television (Cusimano & Parker, 2016).*
- Counsel families about items that are most associated with choking in children. **EB:** *A study found that food (hot dogs, grapes, and steak), coins, balloons, and other toys were the most common objects associated with choking in children (Duckett, Bartman, & Roten, 2020).*
- Counsel families to keep the following items away from the sight and reach of infants and toddlers: buttons, beads, jewelry, pins, nails, marbles, coins, stones, magnets, and balloons. Choose age-appropriate toys and games for children and check for any small parts that may be a choking hazard because children have the need to put everyday objects in their mouths. **EB:** *Reviews of foreign body injuries found that pearls, balls, coins, nuts, seeds, and toy parts were common objects ingested by children and resulted in increased morbidity and mortality (choking) (Passali et al, 2015).*
- Stress water and pool safety and stress including vigilant, uninterrupted parental supervision. **EB:** *A review of risk factors associated with drowning found that inadequate surveillance, inadequate availability of first responders, developmental delay, seizure disorders, lack of swimming ability, and substance misuse in adolescents were associated with an increased risk for drowning (Davey et al, 2019).*
- Underscore the necessity of not allowing children to play with or near electric garage doors and of keeping garage door openers out of the reach of young children. *Children close to the ground may not be large enough to trigger reversal mechanisms on the door and may become trapped.*
- For adolescents, watch for signs of depression that could result in suicide by suffocation. **EB:** *A surveillance data review of suicide in children and early adolescents found that compared with adolescents who commit suicide, in death by suicide in children, the victims were commonly male, Black, and died by hanging, strangulation, or suffocation. Children who died by suicide often experienced relationship problems with family, girlfriends, or boyfriends (Sheftall et al, 2016).*

Geriatric

- Monitor client during feeding for coughing or choking when eating and drinking, being unable to chew food properly, and losing food and drink from the front of the mouth. **EBN:** *These are common signs of dysphagia (Atkinson, 2019).*
- A swallowing assessment by a speech-language pathologist is recommended in clients with suspected or confirmed dysphagia to ensure the appropriate type and consistency of diet to mitigate choking and aspiration risk. **EBN:** *Safe nursing care includes a consultation with a speech-language pathologist whenever doubts arise regarding a client's ability to tolerate oral-supported nutrition in any form (Teasell et al, 2018).*
- Ensure proper positioning during and after feeding to decrease the risk of aspiration. **EB:** *Dysphagia in the elderly results in increased morbidity and mortality. It is important to recognize the relationship between dysphagia and aspiration pneumonia in the elderly because of the high mortality rate associated with this (Smukalla et al, 2017).*

- Recognize that older adults in depression may use hanging, strangulation, and suffocation as a means of suicide. **EB:** *Suicide attempts in seniors often result in death. Social isolation, poor health, frailty, loneliness, and depression are thought to be possible contributing factors. Regardless of age, suffocation, which includes hanging and strangulation, accounted for almost half of the suicides in Canada in 2012 (Skinner et al, 2016).*

Home Care

- Assess the home for potential safety hazards and refer as needed to community resources. **EB:** *A study found that a Mobile Safety Center's home safety educational program significantly increased home safety knowledge and spurred home safety device use (Furman et al, 2020).*
- Assist the family to develop an emergency preparedness plan for potential escape routes from the home in the event of detectors going off, fire, or other emergencies. **EB:** *A study of emergency preparedness found that only 24% of respondents had an Emergency Evacuation Plan (Ekenga & Ziyu, 2019).*

Client/Family Teaching and Discharge Planning

- Recommend that families who are seeking day care or in-home care for children, geriatric family members, or at-risk family members with developmental or functional disabilities inspect the environment for hazards and examine the first aid preparation and vigilance of providers. **EBN:** *A home accident prevention training for informal caregivers improved the knowledge, reported practices, and attitudes regarding home accident prevention among preschool children (Sabra, El-Maksoud, & El-Sayed Hegazy, 2019).*
- Ensure family members learn and practice rescue techniques, including treatment of choking and lack of breathing, as well as CPR. **EB:** *Family members need preparation to deal with emergency situations and should take part in the American Heart Association Basic Lifesaving Course or the American Red Cross Infant/Child CPR Course (Zackoff et al, 2020).*

Risk for Suicidal Behavior

Domain 11 Safety/protection Class 3 Violence

Kathleen L. Patusky, PhD, MA, RN, CNS and Mamilda Robinson, DNP, APN, PMHNP-BC

NANDA-I

Definition

Susceptible to self-injurious acts associated with some intent to die.

Related Factors

Behavioral

Apathy; difficulty asking for help; difficulty coping with unsatisfactory performance; difficulty expressing feelings; ineffective chronic pain self-management; self-injurious behavior; self-negligence; stockpiling of medication; substance misuse

Psychological

Anxiety; depressive symptoms; hostility; expresses deep sadness; expresses frustration; expresses loneliness; low self-esteem; maladaptive grieving; perceived dishonor; perceived failure; reports excessive guilt; reports helplessness; reports hopelessness; reports unhappiness; suicidal ideation

Situational

Easy access to weapon; loss of independence; loss of personal autonomy

Social

Dysfunctional family processes; inadequate social support; inappropriate peer pressure; legal difficulty; social deprivation; social devaluation; social isolation; unaddressed violence by others

At-Risk Population

Adolescents; adolescents living in foster care; economically disadvantaged individuals; individuals changing a will; individuals experiencing situational crisis; individuals facing discrimination; individuals giving away possessions; individuals living alone; individuals obtaining potentially lethal materials; individuals preparing a will; individuals who frequently seek care for vague symptomatology; individuals with disciplinary problems; individuals with family history of suicide; individuals with history of suicide attempt; individuals with history of violence; individuals with sudden euphoric recovery from major depression; institutionalized individuals; men; Native American individuals; older adults

Associated Conditions

Depression; mental disorders; physical illness; terminal illness

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Depression Level; Impulse Self-Control; Loneliness Severity; Mood Equilibrium; Risk Detection; Suicide Self-Restraint

Example NOC Outcome with Indicators

Suicide Self-Restraint as evidenced by the following indicators: Expresses feelings/Refrains from attempting suicide/Verbalizes suicidal ideas/Controls impulses. (Rate the outcome and indicators of **Suicide Self-Restraint:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Not harm self

- Maintain connectedness in relationships
- Disclose and discuss suicidal ideas and plan if present; seek help
- Express decreased anxiety and control of impulses
- Talk about feelings; express anger appropriately
- Identify a safety plan
- Identify protective factors
- Refrain from using mood-altering substances
- Obtain no access to harmful objects
- Yield access to harmful objects
- Maintain self-control without supervision

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Anxiety Reduction; Coping Enhancement; Crisis Intervention; Delusion Management; Mood Management; Substance Use Prevention; Suicide Prevention; Support System Enhancement; Surveillance

Example NIC Activities—Suicide Prevention

Determine presence and degree of suicidal risk; Encourage client to seek out care providers to talk to as urge to harm self occurs

Nursing Interventions and *Rationales*

The American Psychiatric Nurses Association (APNA, 2015) has adapted a set of essential competencies for psychiatric nurses, all of which can be useful for generalist nurses. These competencies have been incorporated in the following sections.

- Assess using suicide risk measures that are available for nurses. **EBN:** *Measures include the Nurses' Global Assessment of Suicide Risk (van Veen et al, 2015); the Center for Epidemiological Studies Depression Scale, which measures depressed mood level (Yang, Jai, & Quin, 2015); the Beck Suicide Intent Scale, which identifies a strong intent to die and may be best used in conjunction with the Karolinska Interpersonal Violence Scale (Stefansson et al, 2015); and the Suicide Assessment Checklist (Yoon, Park, & Choi, 2020).*
- Before implementing interventions in the face of suicidal behavior, nurses should examine their own emotional responses to incidents of suicide to ensure that interventions will not be based on countertransference reactions. **EBN:** *Understanding of nurses' responses to suicidal clients can facilitate suicide prevention and recovery (APNA, 2015; Morrissey & Higgins, 2019).*
- Pursue an understanding of suicide as a phenomenon at all levels of nursing practice. **EBN:** *Elements to be considered include the terminology used with suicidality and self-harm phenomena, the epidemiology of suicide, the risk of and protective influences on suicide, and the evidence-based best practices in preventing and responding to suicidality (APNA, 2015).*
- Assess for suicidal ideation when the history reveals the following: depression; substance abuse; bipolar disorder; schizophrenia; anxiety disorders, posttraumatic stress disorder, dissociative disorder, eating disorders, substance use disorders, or antisocial or other personality disorders; attempted suicide, current or past; recent stressful life events (divorce and/or separation, relocation, problems with children); recent unemployment; recent bereavement; adult or childhood physical or sexual abuse; LGBTQ+ identities, family history of suicide; and history of chronic trauma. **EBN:** *Clinicians should be alert for suicide when the previously mentioned factors are present in asymptomatic persons (American Psychiatric Association [APA], 2016).*
- Assess all medical clients and clients with chronic illnesses, traumatic injuries, or pain for their perception of health status and suicidal ideation. **EB:** *A study found that nearly all physical health conditions increased suicide risk, even after adjustment for potential confounding variables (Ahmedani et al, 2017).*
- Be alert for the following warning signs of suicide: making statements such as, "I can't go on," "Nothing matters anymore," "I wish I were dead"; becoming depressed or withdrawn; behaving recklessly; getting affairs in order and giving away valued possessions; showing a marked change in behavior, attitudes, or appearance; abusing drugs or alcohol; and suffering a major loss or life change. **EB:** *A meta-analysis found*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

that about half of the individuals who complete suicide communicate their intentions before death (Pompili et al, 2016).

- Take suicide notes seriously and ask if a note was left in any previous suicide attempts. Consider themes of notes in determining appropriate interventions. **EB:** *An analysis of suicide notes by writers who died by their attempt were more likely to combine a dislike of themselves and a concern for loved ones (Synnott et al, 2018).*
- Question family members regarding the preparatory actions mentioned. **EBN:** *Clinicians should be alert for suicide when these factors are present in asymptomatic persons (APA, 2016).*
- Determine the presence and degree of suicidal risk. A number of questions will elicit the necessary information: "Have you been thinking about hurting or killing yourself?" "How often do you have these thoughts and how long do they last?" "Do you have a plan?" "What is it?" "Do you have access to the means to carry out that plan?" "How likely is it that you could carry out the plan?" "Are there people or things that could prevent you from hurting yourself?" "What do you see in your future a year from now?" "Five years from now?" "What do you expect would happen if you died?" "What has kept you alive up to now?" **EB:** *The nurse can evaluate the client's suicide risk by identifying factors associated with suicidal risk in major mood disorders (Baldessarini et al, 2019).*
- Observe, record, and report any changes in mood or behavior that may signify increasing suicide risk and document results of regular surveillance checks. **EBN:** *Suicidal ideation often is not continuous; it may decrease and then increase in response to negative thinking or exposure to stressors (e.g., family visits). Documentation of surveillance will alert all members of the health care team to changes in the clients' potential risk for suicide so they may be prepared to respond in the event of suicidal behavior (APNA, 2015).*
- Develop a positive therapeutic relationship with the client; do not make promises that may not be kept. Clarify with the clients that anything they share will be communicated only to other staff involved in their care. **EBN:** *Nurses reconnect suicidal clients with humanity by guiding the client, helping them learn how to live, and helping them connect appropriately with others. Positive support can buffer against suicide, whereas conflictual interactions can increase suicide risk (APNA, 2015).*
- Express desire to help client. Provide education about suicide and the effectiveness of intervention. Validate the client's experience of psychological pain while maintaining a safe environment for the client. **EBN:** *The nurse must reconcile their goal of preventing suicide with recognition of the client's goal to alleviate their psychological pain (APNA, 2015).*

▲ Refer for mental health counseling and possible hospitalization if evidence of suicidal intent exists, which may include evidence of preparatory actions (e.g., obtaining a weapon, making a plan, putting affairs in order, giving away prized possessions, preparing a suicide note). **EBN:** *Clients vary in the preparation for suicide attempts, and professional assessment is required to determine the need for hospitalization (APA, 2016).*

- Perform risk assessment for possible suicidality on admission to the hospital and thereafter during hospitalization. Alert treatment team to level of risk. **EBN:** *Risk assessment includes evaluating each client's risk factors, ameliorating factors, stated suicidal intent, mental status, history of physical or psychological trauma, triggers that prompt distress, tendency to minimize or exaggerate symptoms, sources of assistance, warning signs of acute risk, and history of previous suicidal or self-harm behavior (APNA, 2015).*
- Determine client's need for supervision and assign a hospitalized client to a room located near the nursing station. **EBN:** *Close assignment increases ease of observation and availability for a rapid response in the event of a suicide attempt (APNA, 2015).*
- Search the newly hospitalized client and the client's personal belongings for weapons or potential weapons and hoarded medications during the inpatient admission procedure, as appropriate. Remove dangerous items. **EBN:** *Clients who are intent on suicide may bring the means with them. Action is necessary to maintain a hazard-free environment and client safety (APNA, 2015).*
- Monitor the client during the use of potential weapons (e.g., razor, scissors) and limit access to windows and exits unless locked and shatterproof, as appropriate. **EBN:** *Clients with suicidal intent may take advantage of any opportunity to harm themselves (APNA, 2015).*
- Increase surveillance of a hospitalized client at times when staffing is predictably low (e.g., staff meetings, change of shift report, periods of unit disruption). **EB:** *A large U.S. study of hospital suicide incidence and methods found that most inpatient suicides occurred through hanging and in private areas of the hospital unit (e.g.., bathrooms, bedrooms, closets). In the data, the method for monitoring clients to ensure their safety before the suicide was poorly documented and could not be reliably determined (Williams et al, 2018).*

- Ensure that all oncoming staff members have adequate information to assist the client, using the acronym SBARR. **EBN:** *SBARR stands for the following: situation (current status, observations), background (relevant client history), assessment (including nurse's current risk assessment and relevant laboratory findings), recommendations (what the nurse believes is necessary going forward), and response feedback (verification of oncoming staff members' understanding) (APNA, 2015).*

▲ If imminent suicide is suspected or an attempt has occurred, call for assistance and do not leave the client alone. Client and staff safety will be served by assistance in the response. The client may attempt additional self-harm if left alone. **EBN:** *Staff require specialized training to respond appropriately to suicidal behaviors. A study of mental health nurses found that some participants noted the lack of competence among temporary and/or inexperienced staff led to higher demands on experienced nurses and poorer care, which may contribute to increased behavior among clients (Hagen, Knizek, & Hjelmeland, 2017).*

- Place the client in the least restrictive, safe, and monitored environment that allows for the necessary level of observation. Assess suicidal risk at least daily and more frequently as warranted. **EBN:** *Close observation of the client is necessary for safety as long as intent remains high. Suicide risk should be assessed at frequent intervals to adjust suicide precautions and limitations on the client's freedom of movement and to ensure that restrictions continue to be appropriate. Inpatient root cause analyses of suicide attempts and environmental safety checklists for units can be helpful in maintaining safety (APNA, 2015; Gøtzsche & Gøtzsche, 2017).*

▲ Refer for treatment and participate in the management of any mental illness or symptoms that may be contributing to the client's suicidal ideation or behavior. **EB:** *A systematic review found that individuals with a mental illness had a nearly eightfold increased risk of suicide compared with those without a mental disorder (Too et al, 2019).*

▲ Verify that the client has taken medications as ordered (e.g., conduct mouth checks after medication administration). **EB:** *Nurses have to prevent access to possible lethal means of harm. The client may attempt to hoard medications for a later suicide attempt (Harmer et al, 2021).*

▲ Maintain increased surveillance of the client whenever use of an antidepressant has been initiated or the dose increased. **EB:** *Main predictors of increased suicide risk are related to the presence of a depressive disorder and to suicidal behavior. Data suggest that depressed clients presenting at baseline with active suicidal ideation or a history of suicide attempt seem to display a poorer short-term response to antidepressants. Consequently, depressed clients with the highest risk of suicidal ideation or attempts may be poor responders to available antidepressants (Courtet, Nobile, & Lopez-Castroman, 2017).*

- Involve the client in treatment planning and self-care management of psychiatric disorders. **EB:** *A qualitative study explored experiences of treatment with clients formerly hospitalized for suicidal behaviors. The former clients reported a sense of companionship with the staff and that receiving individualized treatment and care was important for the participants (Hagen, Knizek, & Hjelmeland, 2018).*
- Explore with the client all circumstances and motivations related to the suicidality. Listen to the client's own views on his or her problems. **EBN:** *Primary reasons for suicide attempts were found to be feelings of loneliness or hopelessness and mental illness/psychological problems (APA, 2016).*
- Explore with the client reasons to live and sources of hope. **EB:** *A systematic review found that reasons to live and hope provided significant protective effects against suicide (Li, Dorstyn, & Jarmon, 2020).*
- Keep discussions oriented to the present and future. **EB:** *A factor analysis study examined factors that influence suicide resilience and found that the Positive Future factor negatively predicted suicide ideation (Clement et al, 2020).*

▲ Document client behavior in detail to support involuntary commitment or an overnight psychiatric observation program for an actively suicidal client. **EB:** *Failure to document suicide risk assessments, client behaviors, and interventions may lead the legal system to conclude that the documentation was not done (Sadek, 2019).*

- Use cognitive-behavioral techniques that help the client to modify thinking styles that promote depression, hopelessness, and a belief that suicide is a valid means of escaping the current situation. **EB:** *A randomized controlled trial found that Cognitive Behavioural Suicide Prevention therapy did show improvements in suicidal ideation and suicide probability (Haddock et al, 2019).*
- Engage the client in group interventions that can be useful to address recurrent suicide attempts. **EB:** *A study of a suicide-focused group therapy for veterans found that more frequent session attendance was significantly related to less suicidal ideation at 1-month measure (Johnson et al, 2019).*
- See the care plans for Risk for Self-Directed **Violence, Hopelessness,** and Risk for **Self-Mutilation.**

S

Pediatric

- The previously discussed interventions may be appropriate for pediatric clients.
- Assess specifically for bullying and cyberbullying. **EBN:** *A chart review of adolescents who presented to the emergency department at two Canadian hospitals found that 77% of the individuals had experienced bullying and 68.9% had suicide ideation. After controlling for age, gender, grade, psychiatric diagnosis, and abuse, a history of bullying was the most significant predictor of suicidal ideation (Alavi et al, 2017).*
- Assess for exposure to trauma and other adverse childhood experiences. **EB:** *A retrospective chart review of youth (n = 861) found that 52% of youth reported at least one type of trauma exposure. Emotional abuse, physical abuse, and sexual abuse/assault were found to be associated with suicidality and after controlling for other variables, children experiencing emotional abuse had a 3.2-fold increase in suicidality (Marr et al, 2021).*
- Assess for exposure to suicide of a significant other. **EB:** *A cross-sectional analysis of a health and well-being survey of 8500 New Zealand high school students found that students exposed to suicide attempts or completed suicide among friends and/or family members were at increased risk of reporting attempted suicide and repeated nonsuicidal self-injury (Chan et al, 2018).*
- Assess for the presence of school victimization around lesbian, gay, bisexual, and transgender (LGBT) issues and be prepared to advocate for the client. **EB:** *A four-stage, stepwise logistic regression for suicide attempts, suicidal ideation, and suicide planning found that anti-LGBT victimization, sexual orientation, and fear of violence at school were associated with suicidal ideation, suicide planning, and suicide attempts (Barnett et al, 2019).*
- Evaluate for the presence of self-mutilation and related risk factors. **EB:** *Data from self-report surveys found that nonsuicidal self-injury (NSSI) was associated with increased odds of subsequent suicide ideation and attempt. NSSI was also associated with increased risk of transitioning to a suicidal plan among those with suicidal ideation, as well as suicidal attempt among those with a plan (Kiekens et al, 2018).* Refer to care plan for Risk for **Self-Mutilation** for additional information.
- Support the implementation of school-based suicide prevention programs. *School nurses can be key to early intervention.* **EB:** *A randomized controlled trial including more than 11,000 students in the European Union divided the students into the following three groups: a question and refer group, a mental health awareness group, and a professional screening group. No differences between the groups showed up at 3 months. At 12 months the mental health awareness group showed significant reduction in suicide attempts and severe suicidal ideation (Wasserman et al, 2015).*

Geriatric

- Evaluate the older client's perceived mental and physical health status and financial stressors. **EB:** *Data from community-dwelling older adults with a current diagnosis of major depression found that perceived stress is associated with a higher risk of suicide-related ideation (Bickford et al, 2020).*
- Explore with the client perceived pressures about being a burden or being burdensome. **EB:** *A preliminary examination of convergent validity evidence found significant moderate correlations between the Geriatric Feelings of Burdensomeness Scale and measures of conceptually related constructs (hopelessness, suicidality, perceived burdensomeness, thwarted belongingness) (Lutz et al, 2020).*
- Conduct a thorough assessment of clients' medications. **EB:** *Drugs commonly used for insomnia (eszopiclone, zolpidem, and zaleplon) were associated with suicidal ideation (odds ratio [OR]=1.32 [1.14–1.54]), suicide planning (OR=1.44 [1.19–1.75]), and suicide attempts (Tubbs et al, 2021). A study of older adults found that past-year opioid misuse (adjusted odds ratio [AOR] = 1.84, 95% confidence interval [CI] = 1.07–3.19) and benzodiazepine misuse (AOR = 2.00, 95% CI = 1.01–3.94) were significantly associated with past-year suicidal ideation (Schepis, Simoni-Wastila, & McCabe, 2019).*
- When assessing suicide risk factors, note a higher degree of risk for older men and for some older adults who have lost a loved one in the previous year. **EB:** *A systematic review of suicide risk factors in older men found that being unmarried, single, divorced, or widowed were among the risk factors with the strongest evidence predicting suicidal behavior (Richardson, Robb, & O'Connor, 2021).*
- An older adult who shows self-destructive behaviors should be evaluated to rule out a diagnosis of dementia. **EB:** *A study found that clients with frontotemporal dementia had the highest prevalence of suicidal behavior (4%), with nearly 0.5% with a suicidal plan/attempt (Lai et al, 2018).*

▲ Refer older adults in primary care settings for integrated care management. **EB:** *A study found that geriatric client-aligned care team (GeriPACT) mental health integration is less than 50% within the Veterans Health Administration. The authors conclude that population differences between general primary care and geriatric primary care may require different care approaches and provider competencies (Moye et al, 2019).*

● Consider telephone contacts as an effective intervention for suicidal older adults. **EB:** *A systematic review of interventions to prevent suicidal behaviors and reduce suicidal ideation in older people found that telephone counseling was an effective intervention (Okolie et al, 2017).*

Multicultural

● Assess for the influence of cultural beliefs, norms, and values on the client's perceptions of suicide and on the nurse's perception and approach to suicide. **EB:** *A study of multinational students found three fundamental conditions for preventing suicidal thoughts: (1) a high degree of belongingness, (2) accessibility to help-related information, and (3) healthy perceived cultural responses toward mental health (Nguyen et al, 2021).*

● Validate the individual's feelings regarding concerns about the current crisis and family functioning. **EBN:** *Validation lets the client know that the nurse has heard and understood what was said, and it promotes the nurse–client relationship (APNA, 2015).*

Home Care

● Communicate the degree of risk to family and caregivers; assess the family and caregiving situation for the ability to protect the client and to understand the client's suicidal behavior. **EB:** *A study found communication gaps between health care providers and families of individuals who had died from suicide in the month before the suicide. The authors concluded that suicide prevention strategies need strengthening of communication between these two groups (Draper et al, 2018).*

● Assess access to lethal means in the home. **EB:** *A study of lethal means assessment among emergency department (ED) clients with a positive suicide risk screen found that among 545 suicidal clients discharged home from the ED, 85% had no documentation that any provider assessed access to lethal means (Betz et al, 2018).*

● Assist the client and family to develop a suicide safety plan that includes lethal means reduction, brief problem solving and coping skills, increasing social support, and identifying emergency contacts to use during a suicide crisis. **EB:** *The Assess, Intervene and Monitor for Suicide Prevention (AIM-SP) model is a framework that recommends a safety plan that incorporates evidence-based suicide risk reduction strategies (Brodsky, Spruch-Feiner, & Stanley, 2018).*

Client/Family Teaching and Discharge Planning

● Involve the family in discharge planning (e.g., illness/medication teaching, recognition of increasing suicidal risk, client's plan for dealing with recurring suicidal thoughts, community resources). **EB:** *A qualitative study of family and friends bereaved by suicide found that family cited failures in detecting symptoms and behavioral changes, the inability of the health care provider to understand the needs of the client and their social context, and a perceived overreliance on antidepressant treatment (Leavey et al, 2017).*

● Teach cognitive-behavioral activities to the client and family, such as active problem-solving, reframing (reappraising the situation from a different perspective), or thought stopping (in response to a negative thought, picturing a large stop sign and replacing the image with a prearranged positive alternative). Teach the client to confront his or her own negative thought patterns (or cognitive distortions), such as catastrophizing (expecting the very worst), dichotomous thinking (perceiving events in only one of two opposite categories), or magnification (placing distorted emphasis on a single event). **EB:** *A randomized control trial of a cognitive-behavioral family treatment for suicide attempt prevention found that the results supported the intervention for preventing suicide attempts in adolescents presenting with recent self-harm (Asarnow et al, 2017).*

▲ Refer family members and friends to local mental health agencies and crisis intervention centers if the client has suicidal ideation or a suspicion of suicidal thoughts exists. **EBN:** *Clients at risk should receive evaluation and help (APA, 2016).*

▲ In the event of successful suicide, refer the family to a therapy group for survivors of suicide. **EB:** *A study revealed that 63% of the bereaved had elevated scores on a measure of complicated grief and that the complicated grief scores correlated moderately but positively with depression and hopelessness and negatively with subjective happiness and satisfaction with life (Bellini et al, 2018).*

Delayed Surgical Recovery

Domain 11 Safety/protection Class 2 Physical injury

Monica Brock, MS, RN, CCRN, CNEcl

NANDA-I

Definition

Extension of the number of postoperative days required to initiate and perform activities that maintain life, health, and well-being.

Defining Characteristics

Anorexia; difficulty in moving about; difficulty resuming employment; excessive time required for recuperation; expresses discomfort; fatigue; interrupted surgical area healing; perceived need for more time to recover; postpones resumption of work; requires assistance for self-care

S

Related Factors

Delirium; impaired physical mobility; increased blood glucose level; malnutrition; negative emotional response to surgical outcome; obesity; persistent nausea; persistent pain; persistent vomiting; smoking

At-Risk Population

Individuals aged ≥80 years; individuals experiencing intraoperative hypothermia; individuals requiring emergency surgery; individuals requiring perioperative blood transfusion; individuals with American Society of Anesthesiologists (ASA) Physical Status Classification score ≥3; individuals with history of myocardial infarction; individuals with low functional capacity; individuals with preoperative weight loss >5%

Associated Conditions

Anemia; diabetes mellitus; extensive surgical procedures; pharmaceutical preparations; prolonged duration of perioperative surgical wound infection; psychological disorder in postoperative period; surgical wound infection

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Endurance; Infection Severity; Mobility; Pain Control; Self-Care: Activities of Daily Living (ADLs); Surgical Recovery: Convalescence/Immediate Postoperative; Wound Healing: Primary Intention

Example NOC Outcome with Indicators

Surgical Recovery: Convalescence as evidenced by the following indicators: Extent of physiological, psychological, and role function after discharge from postanesthesia care to the final postoperative clinic visit/Vital signs/Performance of normal activities, self-care activities. (Rate the outcome and indicators of **Surgical Recovery: Convalescence:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Have surgical area that shows evidence of healing: no redness, induration, draining, dehiscence, or immobility
- State that appetite is regained
- State that no nausea is present
- Demonstrate ability to move about
- Demonstrate ability to complete self-care activities
- State that no fatigue is present
- State that surgical pain is controlled or relieved
- Resume employment activities/ADLs
- State no depression or anxiety related to surgical procedure

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Incision Site Care; Nutrition Management; Pain Management; Self-Care Assistance; Surgical Assistance

Example NIC Activities—Incision Site Care

Teach the client and/or the family how to care for the incision, including signs and symptoms of infection; Inspect the incision site for redness, swelling, signs of dehiscence, or evisceration

Nursing Interventions and *Rationales*

- Encourage smoking cessation before surgery. **EB:** *Smoking cessation restores tissue oxygenation and metabolism important to wound healing; research indicates that smoking cessation can reduce the rate of surgical site infections by more than half, as compared with active smokers (Martin et al, 2016).*
- Perform a thorough preoperative assessment of the client's health literacy level. **EB:** *Low health literacy, common among surgical clients, is associated with poor health outcomes (Chang et al, 2020).*
- Assess for the presence of medical conditions and treat appropriately before surgery. **EB:** *A chronically malnourished client may benefit from nutritional therapy before surgery (Morgensen et al, 2018). If the client is diabetic, maintain normal blood glucose levels before surgery.* **EB:** *High blood glucose levels slow healing and increase the risk of infection. The American Diabetes Association (ADA) recommended that blood glucose should be less than 180 mg/dL for people in the hospital or having surgery (ADA, 2019).*
- Carefully assess the client's use of herbal and dietary supplements such as feverfew, fish oil, ginkgo biloba, garlic, ginseng, ginger, valerian, kava, St. John's wort, ephedra (Ma huang or metabolite), and echinacea. It is recommended that all dietary supplements are stopped at least 1 week before major surgical or diagnostic procedures. **EB:** *Because herbal and dietary supplements can have unintended medical side effects as well as potential interactions with anesthetic drugs, it is important for anesthetists to be aware of their use (Levy et al, 2017).*

- Assess and treat for depression and anxiety in a client before surgery and postoperatively. **EB:** *Clients with higher levels of preoperative anxiety and depression report increased postoperative pain, nausea, and fatigue (Ghoneim & O'Hara, 2016).*
- Play music of the client's choice preoperatively, intraoperatively, and postoperatively. **EBN:** *Listening to self-selected music during the perioperative period can effectively reduce anxiety levels (Sibanda et al, 2019).*
- Consider using healing touch and other mind-body-spirit interventions such as stress control, therapeutic massage, and imagery. **EBN:** *Research indicates that use of holistic therapies in the perioperative setting can decrease pain and anesthesia complications, leading to increased client satisfaction with health care (Acar & Aygin, 2019; Guo et al, 2020).*
- Maintain perioperative normothermia. Use reflective blankets to reduce heat loss during surgery. **EBN:** *A randomized control trial found that reflective blankets were a more effective method of passive warming than warm blankets (Koenen et al, 2017).*
- Postoperatively, discuss vital sign parameters with the surgeon, as well as signs and symptoms that could indicate early postoperative infection. **EB:** *Surgical site infections are a leading cause of prolonged hospitalization, which increase cost of care and are associated with poorer client outcomes (Badia et al, 2017).*
- Use careful aseptic technique when caring for wounds. **EBN:** *Handwashing continues to be the most important factor in reducing health care–associated infection, but the use of an aseptic technique will further reduce the risk of infection (Berríos-Torres et al, 2017).*
- Clients should bathe before surgery. **EBN:** *Preoperative bathing with soap and water reduces skin colonization of microorganisms, reducing the rate of clean surgery surgical site infections by up to threefold (Maciel de Castro Franco et al, 2017; Webster & Osborne 2015).* **EBN:** *In an analysis of recent studies, there was no observed difference in the occurrence of surgical site infection when comparing clients undergoing preoperative bathing with soap and water or with an antiseptic agent (Maciel de Castro Franco et al, 2017).*
- Clients should be allowed to shower after surgery to maintain cleanliness, if not contraindicated because of the presence of pacemaker wires or other contraindications. **EB:** *In an analysis of existing studies, there was no statistically significant increase in wound infection related to early bathing. The decision to bathe the client immediately postoperatively should be specific to surgical type and site (Ljungqvist et al, 2017).*
- Optimize the client's preoperative, intraoperative, and postoperative condition to minimize client stress and retain homeostasis. **EB:** *Enhanced Recovery After Surgery is a multiprofessional, multimodal approach to caring for the surgical client that includes changes from overnight fasting to carbohydrate drinks 2 hours before surgery, minimally invasive approaches, management of intravenous fluids to maintain euvolemia, early removal of drains and tubes, early mobilization, and early postoperative oral intake of food and fluids. Enhanced Recovery After Surgery protocols have reduced hospital length of stay by 30% to 50% with similar reductions in complications, and have been shown to improve outcomes in nearly all major surgical specialties (Ljungqvist et al, 2017).*
- Carefully assess functional status of the client postoperatively using a fall-risk stratification tool, such as the Morse Fall Scale, to identify clients at high risk for fall. **EBN:** *The Morse Fall Scale has been validated in numerous studies, and it helps identify clients at high risk for falls. All clients identified as high risk should have increased monitoring and safety precautions in place (Jewell et al, 2020).*
- See care plans for **Anxiety,** Acute **Pain, Fatigue,** Risk for Perioperative **Positioning** Injury, Impaired Physical **Mobility,** and **Nausea.**

Pediatric

- Provide age-appropriate procedural information and postoperative expectations, including pain, function, and emotional care needs. **EBN:** *Parents and children report higher levels of satisfaction, decreased preoperative anxiety, and better surgical experiences if given the opportunity preoperatively to discuss all aspects of the surgery, including realistic postoperative expectations (Newell et al, 2020).*
- Teach imagery and encourage distraction for children for postsurgical pain relief. **EBN:** *Distraction decreases pain in children undergoing painful procedures (Al-Yateem et al, 2016).* **EBN:** *Active distraction strategies, such as use of distraction cards or viewing a kaleidoscope, resulted in significant decreases in pain and anxiety among children, as compared with passive distraction techniques (Hussein, 2015).*

Geriatric

- Clients over age 65 should undergo a comprehensive geriatric assessment before surgery. **EB:** *Older clients have higher rates of surgical complications and mortality than younger clients. Studies show postoperative outcomes can be improved through the use of geriatric collaborative models (Zietlow et al, 2021).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- The condition of the client' skin should be noted and fully documented. **EB:** *Using an objective evaluation tool, such as the Braden scale, allows for early identification of older clients at higher risk for developing skin breakdown (Aloweni et al, 2019).*
- Routinely assess pain using a pain scale appropriate for clients with impaired cognition or inability to verbalize. **EBN:** *Self-report should be the first-line approach when possible, with observational assessment used as a supplementary tool, when warranted. The Pain Assessment in Advanced Dementia (PAINAD) and Pain Assessment Checklist for Seniors With Limited Ability to Communicate (PACSLAC) have been validated for reliability (Chow et al, 2016).*
- Serially evaluate the client's vital signs, including temperature. Check baseline vital signs and monitor trends. **CEB:** *Physiological changes of aging often result in lower baseline body temperatures and decreased heart rates, and prevent the older client from developing fever. Medications, such as blood pressure agents, may prevent the client from having an increased heart rate (Chester & Rudolph, 2011).*
- The older client should be evaluated for signs and symptoms of delirium. Ensure that hearing aids and glasses are also available as needed. **EB:** *The older client is at increased risk of postoperative delirium. The Confusion Assessment Method screening tool is a validated instrument widely used to screen for postoperative delirium (Hebert, 2018).* **EB:** *Nonpharmacological interventions for delirium include orienting to surroundings, adequate oxygen, optimizing nutrition and mobility, sleep hygiene strategies, and avoidance of restraints. Any medications known to precipitate delirium should also be avoided (Hebert, 2018).*
- Offer spiritual support. **EB:** *A meta-analysis found that overall religion/spirituality was associated with overall physical health, physical and functional well-being, and physical symptoms (Jim et al, 2015).*

Home Care

- The preceding interventions may be adapted for the home setting.
- Provide supportive telephone calls from nurse to client as a means of decreasing anxiety and providing the psychosocial support necessary for recovery from surgery. **EBN:** *A systematic review of qualitative studies found that clients report being motivated to participate in recovery but face challenges with symptoms (e.g., pain, nausea, weakness). Postoperative follow-up and phone calls provide much needed encouragement and additional assistance to facilitate recovery (Sibbern et al, 2017).*

Client/Family Teaching and Discharge Planning

- Provide discharge planning and teaching in a language that is appropriate to the client and caregiver's education and literacy level. **EBN:** *Do not use technical or medical jargon, and be aware that clients and caregivers may be reluctant to ask for explanation or clarification because of embarrassment and may dishonestly verbalize understanding. Allow the client to repeat their understanding of the discharge plan (Polster, 2015).*
- Create a discharge plan that includes measurable functional goals, expectations for recovery, and signs and symptoms of postoperative complications. **EBN:** *Client-specific discharge education equips the client with the necessary knowledge and skills to engage in their care after discharge and increases client satisfaction with the hospital experience (Kang et al, 2020).*

S

Risk for Delayed Surgical Recovery

Domain 11 Safety/protection Class 2 Physical injury

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to an extension of the number of postoperative days required to initiate and perform activities that maintain life, health, and well-being, which may compromise health.

Risk Factors

Delirium; impaired physical mobility; increased blood glucose level; malnutrition; negative emotional response to surgical outcome; obesity; persistent nausea; persistent pain; persistent vomiting; smoking

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

At-Risk Population

Individuals aged ≥80 years; individuals experiencing intraoperative hypothermia; individuals requiring emergency surgery; individuals requiring perioperative blood transfusion; individuals with American Society of Anesthesiologists (ASA) Physical Status classification score ≥3; individuals with history of myocardial infarction; individuals with low functional capacity; individuals with preoperative weight loss >5%

Associated Conditions

Anemia; diabetes mellitus; extensive surgical procedures; pharmaceutical preparations; prolonged duration of perioperative surgical wound infection; psychological disorder in postoperative period; surgical wound infection

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

See the care plan for Delayed **Surgical** Recovery.

Impaired Swallowing Domain 2 Nutrition Class 1 Ingestion

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Abnormal functioning of the swallowing mechanism associated with deficits in oral, pharyngeal, or esophageal structure or function.

Defining Characteristics

First Stage: Oral

Abnormal oral phase of swallow study; bruxism; choking prior to swallowing; choking when swallowing cold water; coughing prior to swallowing; drooling; food falls from mouth; food pushed out of mouth; gagging prior to swallowing; impaired ability to clear oral cavity; inadequate consumption during prolonged meal time; inadequate lip closure; inadequate mastication; incidence of wet hoarseness twice within 30 seconds; inefficient nippling; inefficient suck; nasal reflux; piecemeal deglutition; pooling of bolus in lateral sulci; premature entry of bolus; prolonged bolus formation; tongue action ineffective in forming bolus

Second Stage: Pharyngeal

Abnormal pharyngeal phase of swallow study; altered head position; choking; coughing; delayed swallowing; fevers of unknown etiology; food refusal; gagging sensation; gurgly voice quality; inadequate laryngeal elevation; nasal reflux; recurrent pulmonary infection; repetitive swallowing

Third Stage: Esophageal

Abnormal esophageal phase of swallow study; acidic-smelling breath; difficulty swallowing; epigastric pain; food refusal; heartburn; hematemesis; hyperextension of head; nighttime awakening; nighttime coughing; odynophagia; regurgitation; repetitive swallowing; reports "something stuck"; unexplained irritability surrounding mealtimes; volume limiting; vomiting; vomitus on pillow

Related Factors

Altered attention; behavioral feeding problem; protein-energy malnutrition; self-injurious behavior

At-Risk Population

Individuals with history of enteral nutrition; older adults; premature infants

Associated Conditions

Acquired anatomic defects; brain injuries; cerebral palsy; conditions with significant muscle hypotonia; congenital heart disease; cranial nerve involvement; developmental disabilities; esophageal achalasia; gastroesophageal reflux disease; laryngeal diseases; mechanical obstruction; nasal defect; nasopharyngeal cavity defect; neurological problems; neuromuscular diseases; oropharynx abnormality; pharmaceutical preparations; prolonged intubation; respiratory condition; tracheal defect; trauma; upper airway anomaly; vocal cord dysfunction

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Swallowing Status: Esophageal Phase, Oral Phase, Pharyngeal Phase

Example NOC Outcome with Indicators

Swallowing Status as evidenced by the following indicators: Delivery of bolus to hypopharynx is timed with swallow reflex/Ability to clear oral cavity/Number of swallows appropriate for bolus size and texture/Voice quality/Choking, coughing, gagging/Normal swallow effort. (Rate the outcome and indicators of **Swallowing Status:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate effective swallowing without signs of aspiration (see the section Defining Characteristics)
- Remain free from aspiration (e.g., lungs clear, temperature within normal range)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Aspiration Precautions; Swallowing Therapy

Example NIC Activities—Swallowing Therapy

Assist client to sit in erect position (as close to 90 degrees as possible) for feeding/exercise; Instruct client not to talk during eating, if appropriate

Nursing Interventions and *Rationales*

- Assess for risk factors associated with impaired swallowing. **EB:** *A systematic review identified the prevalence of dysphagia as 15% of community-dwelling older adults with risk factors that included advanced age; history of clinical disease; physical frailty; and reduced ability to carry out activities of daily living (Madhaven et al, 2016).*
- Complete swallow screen per facility protocol. **EBN:** *Bedside nurse-initiated dysphagia screening with formal guidelines for the identification and management of dysphagia may have a significant effect on serious adverse outcomes such as chest infections and death (Hines, Kynoch, & Munday, 2016).*

▲ Do not feed clients with impaired swallowing orally until an appropriate diagnostic workup is completed. **EBN:** *Impaired swallow function or dysphagia places a client at greater risk for dehydration and malnutrition. Dehydration thickens secretions, increasing the risk for certain respiratory problems, and aspiration may lead to pneumonia and death (Mauk, 2017).*

▲ Ensure proper nutrition by consulting with a health care provider regarding alternative nutrition and hydration when oral nutrition is not safe/adequate. **EBN:** *A timely decision to proceed with tube feeding should be made in collaboration with the client, family (or substitute decision maker), and interprofessional team. Enteral nutrition via intravenous, nasogastric, or percutaneous endoscopic gastrostomy (PEG) tube could substantially reduce risks of aspiration and choking while providing clients with needed hydration and nutrients (Coltman, 2019).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ Refer to a speech-language pathologist for evaluation and diagnostic evaluation of swallowing to determine swallowing problems and solutions as soon as oral and/or pharyngeal dysphagia is suspected. **EBN:** *Safe nursing care includes a consultation with a speech-language pathologist whenever doubts arise regarding a client's ability to tolerate oral-supported nutrition in any form (Teasell et al, 2018). Video fluoroscopic swallow study (VSS, VFSS, or MBS), or fiberoptic endoscopic examination of swallowing (FEES), should be performed on all clients considered at risk for pharyngeal dysphagia or poor airway protection based on results from the bedside swallowing assessment (McGinnis et al, 2019).*

▲ To manage impaired swallowing, use a multiprofessional dysphagia team composed of a speech pathologist, dietitian, nursing, health care provider, and medical staff. A comprehensive assessment from a multiprofessional dysphagia team can lead to personalized therapeutic interventions that can help the client learn to swallow safely and maintain a good nutritional status. **EBN:** *Elderly clients with dysphagia require a multiprofessional team working closely together to perform feeding management. Nurses have more opportunities to contact clients in clinical work, so they must learn the correct guidance of safe eating and feeding for elderly clients with dysphagia (Li et al, 2015).*

▲ Observe the following feeding guidelines:
- ❍ Before giving oral feedings, determine the client's readiness to eat (e.g., alert, able to hold head erect, follow instructions, move tongue in mouth, and manage oral secretions). If one of these elements is missing, it may be advisable to withhold oral feeding and use enteral feeding for nourishment.
- ❍ Monitor client during oral feedings and provide cueing as needed to ensure client follows swallowing guidelines/aspiration precautions recommended by speech-language pathologist or dysphagia specialist. Note: General aspiration precautions include the following: sit at 90 degrees for all oral feedings; take small bites/sips; eat at a slow rate; if client is being fed, position the feeder at eye level with the client; and no straws. However, client-specific strategies will be determined via bedside and/or instrumental swallowing evaluation performed by dysphagia specialist. **EBN:** *Postural changes, sensory enhancements, swallow maneuvers, or voluntary controls exerted over the swallow can improve swallow, but the use and effectiveness of these treatments will vary systematically with the client's medical diagnosis (Atkinson, 2019).*
- ❍ Keep bolus size to 5 mL or smaller. **EB:** *Evidence gathered from the appraised studies generally supports the clinical hypothesis that a small bolus size (5 mL or smaller) decreases the risk of penetration or aspiration of liquids during swallowing events (Rizzo et al, 2016).*
- ❍ During feeding, adapt environment to decrease noise and distractions. **EBN:** *Reducing environmental distractions will assist the client to focus on eating (Atkinson, 2019).*
- ❍ If the client is older or has gastroesophageal reflux disease, ensure the client is kept in an upright posture for an hour after eating. **EBN:** *An upright position after eating is associated with decreased incidence of pneumonia in older adults (Commisso & Lim, 2019).*

● Monitor client during feeding for coughing or choking when eating and drinking, being unable to chew food properly, and losing food and drink from the front of the mouth. **EBN:** *These are common signs of dysphagia (Atkinson, 2019).*

● Use standardized diet and fluid descriptors such as the International Dysphagia Diet Standardisation Initiative (IDDSI) for diet and fluid modification. **EB:** *The IDDSI framework consists of a continuum of 8 levels (0–7), where drinks are measured from Levels 0 to 4, and foods are measured from Levels 3 to 7. The IDDSI framework provides a common terminology to describe food textures and drink thickness (Steele et al, 2018).*

● During meals and all oral intake, observe for wet voice, dysarthria (slurred speech), drooling, inability to cough on command, and an absent gag reflex as an indication of silent aspiration. **EBN:** *Silent aspiration is common in people with dysphagia (Atkinson, 2019).*

▲ If signs of aspiration or pneumonia are present, auscultate lung sounds after feeding. Note new onset of crackles or wheezing, or elevated temperature. **EB:** *Bronchial auscultation of lung sounds was shown to be specific in identifying clients at risk for aspiration (Sanivarapu & Gibson, 2021).*

▲ Assess for signs of malnutrition and dehydration and keep a record of food intake. **EB:** *A study showed that clients with diagnosed high-risk dysphagia had significantly lower scores on the geriatric nutritional risk index (Saito et al, 2018).*

▲ Evaluate nutritional status daily. Weigh the client weekly to help evaluate nutritional status. If the client is not adequately nourished, work with the dysphagia team to determine whether the client needs therapeutic feeding only or needs enteral feedings until the client can swallow adequately. **EB:** *An interprofessional approach is necessary to maintain the client's nutritional status (McGinnis et al, 2019).*

S

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

▲ Assist client in following dysphagia specialist's recommendations and provide open, accurate, and effective communication with dysphagia team regarding client's diet tolerance. **EB:** *Understanding and following the dysphagia specialist's recommendations is a pivotal role that nurses play in helping ensure positive dysphagia management outcomes (McGinnis et al, 2019).*

▲ Document and notify the provider and dysphagia team of changes in medical, nutritional, or swallowing status. **EB:** *Many negative dysphagia management outcomes can be avoided by ensuring dysphagia communication is accurate, complete, and disseminated among and between health care professionals; nurses are pivotal in this process (McGinnis et al, 2019).*

▲ Work with the client on swallowing exercises prescribed by the dysphagia team. **EB:** *Exercise programs can improve airway closure, the range of oral or pharyngeal structure movement during swallow, cricopharyngeal opening, and tongue strength (McGinnis et al, 2019).*

▲ Recognize that the client can aspirate oral feedings, even if there are no symptoms of coughing or distress. This phenomenon is called silent aspiration and is common. **EB:** *In a study of elderly long-term residents, dementia was the best predictor of silent aspiration (Sakai et al, 2016).*

▲ Ensure oral hygiene is maintained. **EB:** *Oral health care including toothbrushing after each meal, cleaning dentures once a day, and consistent professional oral health care reduces the incidence of aspiration pneumonia that can occur due to bacteria associated with the oral cavity (Müller, 2015).*

▲ For clients receiving mechanical ventilation with a tracheostomy tube or after postextubation, request a referral to a speech-language pathologist or dysphagia specialist for an instrumental swallowing evaluation before beginning oral diet. **EB:** *Objective swallowing studies and early intervention are the best ways to determine the safest oral intake and rule out silent aspiration in these clients (Alonso Rodrigues et al, 2015).*

Pediatric

▲ Refer children and infants who have difficulty swallowing, difficulty manipulating food, or delayed swallowing to a speech-language pathologist or dysphagia specialist for further assessment and testing. **EB:** *Assessment of dysphagia requires specialized training. Speech-language pathologists are trained to evaluate and treat pediatric dysphagia (Reynolds, 2020).*

▲ Consult with occupational therapy to evaluate positioning for pediatric clients related to feeding. **EB:** *Efficient oral motor movements depend on the steadiness or stability of the trunk, neck, and head (Mitchell & Paluszak, 2018).*

▲ For at-risk infants, consult with a feeding specialist regarding nipple selection to address sucking and swallowing coordination before bottle feeding. **EB:** *Selection of the nipple will consider the attributes of the nipple, viscosity of the fluid, and the skills and coordination of the infant (Mitchell & Paluszak, 2018).*

● For at-risk infants, provide external pacing by lowering the bottle to remove milk from the nipple or removing the nipple from the mouth entirely. **EB:** *External pacing is a technique in which breaks are imposed after a certain number of sucks to address suck-swallow-breathe incoordination, which may lead to apnea (Mitchell & Paluszak, 2018).*

● For a preterm infant, provide opportunities for patterned nonnutritive sucking (NNS) or oral stimulation. **EB:** *NNS or oral stimulation can be used to normalize responses to sensory input and to facilitate oral-motor coordination without the use of food for infants at risk for choking and aspiration (Mitchell & Paluszak, 2018).*

Geriatric

▲ Recognize that age-related changes can affect swallowing and these changes have a more pronounced effect when superimposed on neurological disease and other chronic problems. **EB:** *Age-related changes can contribute to less efficient and effective swallowing in older adults (McGinnis et al, 2019).*

● Assess for difficulty swallowing medications and modify medication administration as needed. **EB:** *A systematic research review suggested that approximately 14% of community-dwelling older clients have trouble swallowing medicines (Mc Gillicuddy, Crean, & Sahm, 2016).*

▲ Evaluate the medications the client is taking and collaborate with pharmacists and other appropriate professionals for assistance with modifications, correct dosages, and drug interactions. **EB:** *As most older adults take multiple medications, the need for enhanced knowledge in this area emphasizes the importance of interprofessional collaboration (McGinnis et al, 2019).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Home Care

▲ Refer to speech therapy. Speech-language pathologists can work with clients to enhance swallowing ability and teach compensatory strategies.

Client/Family Teaching and Discharge Planning

▲ Teach the client and family restorative and rehabilitative techniques prescribed by the dysphagia team. **EB:** *Restorative and rehabilitative techniques are aimed at improving physiological swallow function (McGinnis et al, 2019).*

- Teach the client, family, and caregivers about standardized diet and fluid descriptors such as the International Dysphagia Diet Standardisation Initiative (IDDSI) for diet and fluid modification. **EB:** *The IDDSI framework consists of a continuum of 8 levels (0–7), where drinks are measured from Levels 0 to 4 and foods are measured from Levels 3 to 7. The IDDSI framework provides a common terminology to describe food textures and drink thickness (Steele et al, 2018).*
- Teach the family and caregivers how to monitor the client to prevent and detect aspiration during eating. **EB:** *Client's family and caregivers should be taught to monitor client during feeding for coughing or choking when eating and drinking, being unable to chew food properly, and losing food and drink from the front of the mouth as these are common signs of dysphagia (Atkinson, 2019).*

S

Risk for Thermal Injury

Domain 11 Safety/protection Class 2 Physical injury

Wendie A. Howland, MN, RN-BC, CRRN, CCM, CNLCP, LNCC

NANDA-I

Definition

Susceptible to extreme temperature damage to skin and mucous membranes, which may compromise health.

Risk Factors

Fatigue; inadequate caregiver knowledge of safety precautions; inadequate knowledge of safety precautions; inadequate protective clothing; inadequate supervision; inattentiveness; smoking; unsafe environment

At-Risk Population

Individuals exposed to environmental temperature extremes

Associated Conditions

Alcoholic intoxication; drug intoxication; neuromuscular diseases; neuropathy; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Safe Home Environment; Parenting: Early/Middle/Adolescent; Physical Safety

Client Outcomes

Client Will (Specify Time Frame)

- Be free of thermal injury to skin or tissue
- Explain actions can take to protect self and others from thermal injury

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Environmental Management: Safety

Example NIC Activities—Environmental Management: Safety

Identify safety hazards in the environment; Modify the environment to minimize hazards and risk

Nursing Interventions and *Rationales*

- Teach the following interventions to prevent fires in the home, to handle any possible fire, and to have a readily available exit from the home:
  - Avoid plugging several appliance cords into the same electrical socket.
  - Do not use open candles or allow smoking in the home.
  - Keep a fire extinguisher within reach in case a fire should occur.
  - Install smoke alarms on every level of the home and in every sleeping area.
  - Keep furniture and other heavy objects out of the way of doors and windows.
  - Develop a fire escape plan that includes two ways out of every room and an outside meeting place. Practice the escape plan at least twice a year.
- Teach clients about home fire safety to prevent thermal injury and prevention. **EB:** *The National Fire Protection Association (NFPA) has teaching materials and other information for this purpose (NFPA, 2021).*
- Apply sunscreen as directed on the container when out in the sun. Also use sun-blocking clothing, and stay in the shade if possible. **EB:** *Sunburn is a clear indicator of overexposure to ultraviolet (UV) radiation and increases the risk of skin cancer. The estimated prevalence of sunburn in the United States is high; 34% of a survey of 31,162 U.S. adults reported one or more sunburns in the past 12 months (Guerra, Urban, & Crane, 2021).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Teach clients safety measures to prevent fires in the home in which medical oxygen is in use:
  - **Never smoke** in a home in which medical oxygen is in use. "No smoking" signs should be posted inside and outside the home. **EB:** *There is considerable morbidity and mortality from burns secondary to smoking while using home oxygen. Ongoing education and careful consideration of prescribing home oxygen therapy for known smokers are highly encouraged (Fields, Whitney, & Bell, 2020).*
  - Do not wear oxygen near an ignition source (e.g., open flame, gas stove, fireplace, candles, cigarettes, matches, lighters) (Fields, Whitney, & Bell, 2020). Note that petroleum jelly, lip balm, skin lotion, or the like will **not** spontaneously combust in the presence of supplemental oxygen without an ignition source (e.g., flame or spark) and are safe to use on the face and in bed in the presence of oxygen (Winslow & Jacobsen, 1998).
  - Homes with medical oxygen must have working smoke alarms that are tested monthly (Fields, Whitney, & Bell, 2020).
  - Test fire extinguishers every 3 to 6 months. Keep a fire extinguisher within reach. If a fire occurs, turn off the oxygen, leave the home, and summon the fire department (NFPA, 2021).
  - Develop a fire escape plan that includes two ways out of every room and an outside meeting place. Practice the escape plan at least twice a year (NFPA, 2021).
- Be aware that thermal injury also includes injury from cold materials and environmental conditions, including freezing injury, nonfreezing injury, and hypothermia. **EB:** *Frostbite causes tissue destruction similar to burns; damage may not be evident for 10 to 15 days (Basit, Wallen, & Dudley, 2021).*
- Provide adequate environmental temperatures. Older clients and others at risk for temperature dysregulation can easily become hypothermic in air-conditioned environments (e.g., a surgical suite), with inadequate clothing, inhaling cold gases, or when exposed to room temperature or chilled fluids (e.g., intravenous, gastric lavage, bowel prep, continuous renal replacement therapy [CRRT], dialysis). **EB:** *Inadvertent hypothermia is a common and preventable condition in surgical procedures and can predispose to infection, blood loss, pressure injury, cardiac events, and shivering that increases metabolic demands, hospital days, and costs (Conway et al, 2019).*
- Be aware that fine motor coordination decreases as a very early sign of hypothermia. Preventing progression of thermal injury is critical to client outcomes. Shivering is the body's attempt to generate heat through muscle activity; it consumes considerable metabolic energy, and is a **late** sign of hypothermia.
- Monitor temperature in vulnerable clients. Core temperature is the best measure to assess for hypothermia. If a pulmonary artery catheter is not available, use a thermometer calibrated for lower body temperature such as a distal esophageal, rectal, temporal artery, or bladder temperature probe.
- Use active warming measures to help clients maintain body temperature (e.g., warming blankets, warmed fluids, forced warm air warming devices, foil wraps, radiant warmers) as indicated. Be aware that passive devices (e.g., clothing items or blankets) do not add heat to body tissues.
- Ensure that exposed skin is protected from cold:
  - From environment, with adequate clothing
  - From cold topical applications (e.g., ice packs or circulating cold water therapy systems), with padding
- Monitor for developing cold thermal injury by checking skin color, peripheral circulation, temperature, and sensation. Be aware that fine motor coordination decreases as a very early sign of hypothermia. Shivering, the body's attempt to generate heat through muscle activity, is a late sign of hypothermia.
- Check the temperature of all equipment and other materials before allowing them to contact client skin, especially if client has increased risk factors for thermal injury.

Pediatric

- Teach the following activities to clients with young children:
  - Lock up matches and lighters out of sight and reach.
  - Never leave a hot stove unattended.
  - Do not allow small children to use the microwave until they are at least 7 or 8 years of age.
  - Keep all portable heaters out of children's reach and at least 3 feet away from anything that can burn.
  - Teach fire prevention and safety to older children.
- Install thermostatic mixer valves in a hot water system to prevent extreme hot water causing scalding burns. **EB:** *Scald injuries from tap water >120°F (48.9°C) are common in urban pediatric emergency department clients (Bentivigna et al, 2020; NFPA, 2021).*

Ineffective Thermoregulation

Domain 11 Safety/protection Class 6 Thermoregulation

Rosemary Timmerman, DNP, APRN, CCNS, CCRN-CSC-CMC

NANDA-I

Definition

Temperature fluctuation between hypothermia and hyperthermia.

Defining Characteristics

Cyanotic nail beds; flushed skin; hypertension; increased body temperature above normal range; increased respiratory rate; mild shivering; moderate pallor; piloerection; reduction in body temperature below normal range; seizure; skin cool to touch; skin warm to touch; slow capillary refill; tachycardia

Related Factors

Dehydration; environmental temperature fluctuations; inactivity; inappropriate clothing for environmental temperature; increased oxygen demand; vigorous activity

At-Risk Population

Individuals at extremes of weight; individuals exposed to environmental temperature extremes; individuals with inadequate supply of subcutaneous fat; individuals with increased body surface area to weight ratio

Associated Conditions

Altered metabolic rate; brain injury; condition affecting temperature regulation; decreased sweat response; impaired health status; inefficient nonshivering thermogenesis; pharmaceutical preparations; sedation; sepsis; trauma

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Thermoregulation; Thermoregulation: Newborn

Example NOC Outcome with Indicators

Thermoregulation as evidenced by the following indicators: Body temperature/Skin temperature/Skin color changes/Hydration/Reported thermal comfort. (Rate the outcome and indicators of **Thermoregulation:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain temperature within normal range
- Explain measures needed to maintain normal temperature

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Describe two to four symptoms of hypothermia or hyperthermia
- List two or three self-care measures to treat hypothermia or hyperthermia

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Temperature Regulation; Temperature Regulation: Inoperative

Example NIC Activities—Temperature Regulation

Institute use of a continuous core temperature-monitoring device, as appropriate; Promote adequate fluid and nutritional intake

Nursing Interventions and *Rationales*

Temperature Measurement

- Measure and record the client's temperature using a consistent method of temperature measurement every 1 to 4 hours depending on the severity of the situation or whenever a change in condition occurs (e.g., chills, change in mental status). **CEB:** *Errors in accurate temperature measurement are most often associated with instrument-related errors, choice of temperature site chosen for monitoring, and operator error (Makic et al, 2011).* **CEB:** *A consistent mode of temperature measurement for accurate trending of body temperature is important for accurate treatment decisions; if different devices are used to obtain temperature measurements, the results should not vary more than 0.3°C to 0.5°C (Makic et al, 2011).*
- Select core, near core, or peripheral temperature monitoring mode based on ability to obtain an accurate temperature from that site and clinical situation, dictating the need for mode of temperature monitoring required for clinical treatment decisions. **CEB/EB:** *Core temperature is obtained by pulmonary artery catheter and distal esophagus; near core temperature measurements include oral, bladder, rectal, tympanic membrane, and temporal artery; and peripheral measurements are obtained by skin surface measurements such as measurement in the axilla (Niven et al, 2015; Chen, 2019).*
- Caution should be taken in interpreting extreme values of temperature (less than 35°C [95°F] or greater than 39°C [102.2°F]) from a near core temperature site device. **CEB:** *Accurate oral temperature measurement requires the probe to be placed in the posterior sublingual pocket to provide a reliable near core temperature measurement (Makic et al, 2011).* **EBP:** *Research has demonstrated that the accuracy of temperature measurement from most accurate to least accurate are intravascular (pulmonary artery), distal esophageal, bladder thermistor, rectal, and oral (Niven & Laupland, 2016); axillary temperature is accurate in neonates but is not well supported in adults (Cheshire, 2016; Barbi et al, 2017).* **EB/EBN:** *Tympanic membrane and temporal artery measurements and chemical dot thermometers are least accurate and should be avoided in caring for the acutely ill adult client. Evidence is limited in testing the accuracy of temperature measurement devices outside of normal temperature ranges (Bijur, Shah, & Esses, 2016; Kiekkas et al, 2016).*
- Evaluate the significance of a decreased or increased temperature. **EB:** *Normal adult temperature is usually identified as 98.6°F (37°C), but in actuality the normal temperature fluctuates by up to 1°C; disease, injury, or pharmacological agents may cause an adaptive increase in the hypothalamic set point resulting in fever (Niven & Laupland, 2016; Chen, 2019).*
- ▲ Notify the health care provider of temperature according to institutional standards or written orders, or when temperature reaches 100.5°F (38.3°C) and above; use a lower threshold for immunocompromised clients who will be less likely to exhibit a fever when seriously ill (Niven & Laupland, 2016). Also notify the health care provider of the presence of a change in mental status and temperature greater than 100.5°F (38.3°C) or less than 96.8°F (36°C). **EB:** *A change in mental status may indicate the onset of septic shock (Rhodes et al, 2017).*

Fever (Pyrexia)

- Recognize that fever is characterized as a temporary elevation in internal body temperature 1°C to 2°C higher than the client's normal body temperature. **EB:** *A rise in body temperature is an innate immune response to a perceived threat and is regulated by the hypothalamus. Hyperthermia may occur when a client gains heat through either an increase in the body's heat production or is unable to effectively dissipate heat,*

and hypothermia occurs when a client loses heat or cannot generate heat (Niven & Laupland, 2016; Walter et al, 2016).

- Recognize that fever is a normal physiological response to a perceived threat by the body, frequently in response to an infection. **EB:** *Fever is a deliberate, active thermoregulatory defense action by the body; metabolic heat accelerates the body's antibody production to defend the body and assists the body's cellular repair processes (nursing care should focus on supporting the body's normal physiological response [fever], locating the cause for the fever, and providing comfort) (Niven & Laupland, 2016; Chiappini et al, 2017).*

▲ Review client history, including current medical diagnosis, medications, recent procedures/interventions, recent travel, environmental exposure to infectious agents, recent blood product administration, and review of laboratory analysis for cause of ineffective thermoregulation. **EB:** *Changes in body temperature (fever) should be explored for possible problems associated with a client's health status (Barbi et al, 2017; Niven & Laupland, 2016).*

- Recognize that fever may be low grade (96.8°F–100.4°F [36°C–38°C]) in response to an inflammatory process such as infection, allergy, trauma, illness, or surgery; moderate to high-grade fever (100.4°F–104°F [38°C–40°C]) indicates a more concerted inflammatory response from a systemic infection; hyperpyrexia (40°C and higher) occurs as a result of damage of the hypothalamus, bacteremia, or an extremely overheated room (Niven & Laupland, 2016; Walter et al, 2016). **EB:** *Interventions to treat fever focus on client comfort, allowing the body to progress through the natural course of fever; exceptions may exist for the client with hyperpyrexia or when oxygen consumption threatens to exhaust metabolic reserves (Chiappini et al, 2017; Young et al, 2019).*

▲ Monitor and intervene to provide comfort during a fever by
- ❍ Obtaining vital signs and accurate intake and output
- ❍ Checking laboratory analysis trends of white blood cell counts and other markers of infection
- ❍ Providing blankets when the client complains of being cold but removing surplus of blankets when the client is too warm
- ❍ Encouraging fluid and nutrition
- ❍ Limiting activity to conserve energy
- ❍ Providing frequent oral care
- ❍ Adjusting room temperature for client comfort

EBN/EB: *Current evidence that examined the evidence of antipyretic therapies used to treat fever, such as administration of antipyretic medications, cooling blankets, and sponge baths, found that these therapies did not reduce the duration of illness or the mortality rate (Chiappini et al, 2017; Young et al, 2019).*

Hypothermia

- Take vital signs frequently, noting changes associated with hypothermia, such as increased blood pressure, pulse, and respirations, that then advance to decreased values as hypothermia progresses. **EB:** *Mild hypothermia activates the sympathetic nervous system, which can increase the levels of vital signs; as hypothermia progresses, the heart becomes suppressed, with decreased cardiac output, heart rate, blood pressure, and respiratory rate (Paal et al, 2016; Zafren, 2017).*
- Monitor the client for signs of hypothermia (e.g., shivering, cool skin, piloerection, pallor, slow capillary refill, cyanotic nail beds, decreased mentation, dysrhythmias) (Paal et al, 2016; Zafren, 2017).
- See the care plan for **Hypothermia** as appropriate.

Hyperthermia

- Recognize that hyperthermia is a different etiology than fever, so the cause of the elevated body temperature should be explored for definitive treatment. **EB:** *Hyperthermia is a condition in which an environmental (e.g., heat stroke), pharmacological (malignant hyperthermia), or endocrine (e.g., thyrotoxicosis) stimulus results in an increase in body temperature without a corresponding increase in the hypothalamic set point (Niven & Laupland, 2016; Lipman et al, 2019).*
- Note changes in vital signs associated with hyperthermia, such as rapid, bounding pulse; increased respiratory rate; and decreased blood pressure, accompanied by orthostatic hypotension; and signs and symptoms of dehydration (Niven & Laupland, 2016; Gaudio & Grissom, 2016). **EB:** *Consistent monitoring promotes prevention and early intervention in clients with altered cardiopulmonary status associated with hyperthermia (Gaudio & Grissom, 2016; Lipman et al, 2019).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Monitor the client for signs of hyperthermia (e.g., headache, nausea and vomiting, weakness, extreme fatigue, delirium, coma). **EB:** *Monitoring for the defining characteristics of hyperthermia allows for early intervention* (*Cheshire, 2016*).
- Adjust clothing to facilitate passive warming or cooling as appropriate.
- See the care plan for **Hyperthermia** as appropriate.

Pediatric

- For routine measurement of temperature, use an electronic thermometer in the axilla in infants younger than 4 weeks; for a child up to 5 years of age, use an electronic thermometer in the axilla or an infrared temporal artery thermometer. **EB:** *Oral and rectal routes should not be used routinely to measure the temperature of infants to children of 5 years of age (Barbi et al, 2017; National Institute for Health and Clinical Excellence [NICE], 2019). Tympanic thermometers often provide inaccurate temperature from incorrect placement in the ear canal and presence of cerumen adversely affecting temperature reading (Niven et al, 2015; Oguz et al, 2018).*
- Recognize that pediatric clients have a decreased ability to adapt to temperature extremes. Take the following actions to maintain body temperature in the infant/child:
  - Keep the head covered.
  - Use blankets to keep the client warm.
  - Keep the client covered during procedures, transport, and diagnostic testing.
  - Keep the room temperature at 72°F (22.2°C).

  EB: The combination of a relatively smaller body surface area, smaller body fluid volume, less well-developed temperature control mechanisms, and smaller amount of protective body fat limits the ability of the infant and child to maintain normal temperatures (NICE, 2019).
- Recognize that the infant and small child are both vulnerable to developing heat stroke in hot weather; ensure that they receive sufficient fluids and are protected from hot environments. **EB:** *Infants and young children are at risk for heat stroke for many reasons, including a decreased thermoregulatory ability in the young body and the inability to obtain their own fluids (Leon & Bouchama, 2015).*
- Antipyretic treatments typically are not indicated unless the child's temperature is higher than 38.3°C [100.4°F] and may be given to provide comfort. **EB:** *The use of antipyretics in febrile children should be examined in light of the therapeutic goal for treatment, which may be primarily to improve the child's discomfort; acetaminophen and ibuprofen are the only antipyretic medications recommended for pediatric clients; both agents should not be administered simultaneously because of concern for inaccurate dosing; alternating doses may be considered only if client distress is not relieved before the next dose is due (Chiappini et al, 2017; NICE, 2019).*

Geriatric

- Do not allow an older client to become chilled; keep the client covered when giving a bath and offer socks to wear in bed; be aware of factors such as room temperature (heating/air conditioning), clothing (layered/loose), and fluid intake. **EB:** *Older adults have a decreased ability to adapt to temperature extremes and need protection from extreme environmental temperatures; the response to cold environment is also compromised with the cutaneous vasoconstrictor response, the shivering process being less effective, decreased ability to feel cold, and medications commonly used to treat chronic age-associated diseases (Jain et al, 2018; Leyk et al, 2019).*
- Recognize that the older client may have an infection without a significant rise in body temperature. **EB:** *Febrile response to infection was found to be reduced with increasing age, and baseline temperatures were generally lower in older clients; therefore this blunted febrile response may lead to delayed diagnosis and treatment necessitating review of all data, including a change in temperature, rather than fever (Limpawattana et al, 2016).*
- Fever from infection in older adults does not confer a higher mortality risk; thus, fever should not be treated with antipyretic agents or other cooling methods unless the client is demonstrating limited cardiorespiratory reserves (Young et al, 2019).
- Ensure that older clients receive sufficient fluids during hot days and stay out of the sun. **EB:** *Older adults may have trouble walking independently to obtain fluids, have decreased thirst sensation, and have chronic illnesses that predispose them to heat stroke, which is a hyperthermic condition (Leon & Bouchama, 2015).*
- Assess the medication profile for the potential risk of drug-related altered body temperature. **EB:** *Anesthetics, barbiturates, salicylates, nonsteroidal antiinflammatory drugs, diuretics, antihistamines, anticholinergics,*

beta-blockers, and thyroid hormones have been linked to decreased body temperature (American Geriatrics Society, 2019).

Home Care

Treating Fever

- Instruct client/parents on the physiological benefits of fever and provide interventions to treat fever symptoms, avoiding antipyretic agents and external cooling interventions.
- Ensure that client/parents know when to contact a health care provider for fever-related concerns.

Client/Family Teaching and Discharge Planning

- Teach the client and family the signs of fever, hypothermia, and hyperthermia and appropriate actions to take if either condition develops.
- Teach the client and family an age-appropriate method for taking the temperature.
- Teach the client to avoid alcohol and medications that depress cerebral function. **EB:** *When the client is sedated or under the influence of alcohol, mentation is depressed, which results in decreased activities to maintain an adequate body temperature (Cheshire, 2016).*

Risk for Ineffective Thermoregulation

Domain 11 Safety/protection Class 6 Thermoregulation

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to temperature fluctuation between hypothermia and hyperthermia, which may compromise health.

Risk Factors

Dehydration; environmental temperature fluctuations; inactivity; inappropriate clothing for environmental temperature; increased oxygen demand; vigorous activity

At-Risk Population

Individuals at extremes of weight; individuals exposed to environmental temperature extremes; individuals with inadequate supply of subcutaneous fat; individuals with increased body surface area to weight ratio

Associated Conditions

Altered metabolic rate; brain injuries; condition affecting temperature regulation; decreased sweat response; impaired health status; inefficient nonshivering thermogenesis; pharmaceutical preparations; sedation; sepsis; trauma

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plans for Ineffective **Thermoregulation, Hyperthermia,** or **Hypothermia.**

Risk for Thrombosis

Domain 4 Activity/rest Class 4 Cardiovascular/pulmonary responses

Dina M. Hewett, PhD, RN, NEA-BC, CCRN-A

NANDA-I

Definition

Susceptible to obstruction of a blood vessel by a thrombus that can break off and lodge in another vessel, which may compromise health.

Risk Factors

Atherogenic diet; dehydration; excessive stress; impaired physical mobility; inadequate knowledge of modifiable factors; ineffective management of preventive measures; ineffective medication self-management; obesity; sedentary lifestyle; smoking

At-Risk Population

Economically disadvantaged individuals; individuals aged ≥ 60 years; individuals with family history of thrombotic disease; individuals with history of thrombotic disease; pregnant women; women < 6 weeks postpartum

Associated Conditions

Atherosclerosis; autoimmune diseases; blood coagulation disorders; chronic inflammation; critical illness; diabetes mellitus; dyslipidemias; endovascular procedures; heart diseases; hematologic diseases; high acuity illness; hormonal therapy; hyperhomocysteinemia; infections; kidney diseases; medical devices; metabolic syndrome; neoplasms; surgical procedures; trauma; vascular diseases

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Perfusion: Peripheral; Tissue Perfusion: Pulmonary Risk Control: Dehydration; Hydration; Knowledge Thrombus Threat Reduction; Risk Control: Thrombus

Example NOC Outcome with Indicators

Risk Control: Thrombus as evidenced by the following indicators: Seeks current information about embolus prevention/Identifies risk factors for thrombus formation/Monitors for warning signs and symptoms of thrombus formation or embolus. (Rate outcome and indicators of **Risk Control: Thrombus:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Not develop a thromboembolism during hospitalization
- State the relevant risk factors associated with the development of a thrombosis
- Engage in behaviors or lifestyle changes to reduce risk of developing a thrombosis

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Embolus Precautions; Embolus Care: Peripheral; Embolus Care: Pulmonary; Lower Extremity Monitoring

Example NIC Activities

Obtain a history of the client's present illness and medical history to evaluate the risk of thrombosis and implement preventative interventions

Nursing Interventions and *Rationales*

- It is estimated that 40% of clients with a deep vein thrombosis (DVT) will progress to postthrombotic syndrome (PTS); therefore, prevention of DVT is a key component. **EB:** *PTS is a chronic disorder characterized by pain, swelling, redness (erythema), and ulcerations. The degree will vary from client to client. Individuals with recurrent ipsilateral DVT are considered the highest risk for PTS (Kvamme & Costanzo, 2015; Lenchus et al, 2017).*
- Assess client's risk factors to develop venous thromboembolism (VTE). **EB:** *There are several factors that may predispose a client to VTE. According to Bruni-Fitzgerald (2015), the strongest risk factors include the following:*
  - Venous stasis as a result of dehydration, immobility, heart failure, or venous compressions from a tumor
  - Hypercoagulable states from disease, obesity, and trauma
  - Immobilization from prolonged bed rest or limb casting
  - Surgery and trauma, especially hip, pelvic, and spinal surgery and leg amputation; several burns also predispose clients to DVT
  - Pregnancy results in a hypercoagulable state placing these clients at risk; although fatal events are rare
  - Oral contraceptives and estrogen replacement may place clients at risk, which is proportional to the estrogen content; postmenopausal women on hormone replacement therapy are considered at risk
  - In malignancy cases 17% of clients with VTE have a neoplasm with the most frequent occurrence in clients with pancreatic cancer
- Use a VTE risk assessment tool to determine individual susceptibility to thrombosis. **EB:** *Determining a client's risk may be guided through the use of an assessment tool such as the Wells Criteria or the Caprini Risk Assessment Model. Assessment tools in the acute care setting are developed based on evidence-based research (Modi et al, 2016). The Wells Criteria was initially developed to assess an individual's risk for VTE in the*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

outpatient setting. Recently, the Center for Evidence-Based Imaging (CEPI) scoring system was developed to more accurately predict the risk for the inpatient setting (Parks & Kohlwes, 2018).

▲ Implement evidence-based prevention methods, both chemical (pharmacological) and/or mechanical. **EB:** *The nurse must be proactive in the assessment of the client for risks for VTE and implementing prophylactic measures as prescribed (Adams, 2015).*

▲ Chemical thromboprophylaxis should be anticipated in the postoperative care of critically ill clients. **EB:** *Research has shown that chemical thromboprophylaxis, when initiated in critically ill and postoperative clients, such as anticoagulants, is not associated with clinically significant bleeding (Bartholomew, 2017). Evidence-based practice guidelines support the use of chemical and mechanical prophylaxis interventions for clients undergoing orthopedic surgery for a minimum of 14 to 35 days to reduce VTE risk (Falck-Ytter et al, 2012).*

- Implement mechanical prophylaxis through use of intermittent pneumatic compression (IPC) devices (Ho & Harahsheh, 2016). **EB:** *IPC is demonstrated to be more effective than no IPC at reducing DVT and is essential when pharmacological therapy is contraindicated because of an increased risk of bleeding (Dunn & Ramos, 2017). IPC devices reduce the risk of venous stasis by increasing the velocity of venous outflow and promoting the emptying of valvular cusps (Muñoz-Figueroa & Ojo, 2015).*
- Ensure proper fit and application of the device. **EB:** *Use a measuring tape to obtain accurate measurements and follow the manufacturer's recommendations for correct sizing. Two fingers should be easily placed between the client's leg and the sleeve. Monitor for edema and resize as needed. (Bartholomew, 2017; Link, 2018).*
- Implement progressive mobility and early ambulation as the client tolerates to reduce risk of VTE. **EB:** *Studies indicate that early mobility may reduce client deconditioning and VTE complications (Booth et al, 2016). One study conducted in a trauma critical care unit revealed a statistically significant (p = .0004) reduced rate of DVT in clients in whom early mobility and ambulation were implemented (Booth et al, 2016). A retrospective study by Cao (2021) confirmed the increased risk of DVT with prolonged bed rest. Clients with additional risk factors of age and smoking had an accumulative increased risk of developing a DVT.*
- Provide education to the client and family about the importance of continued use of IPC after the client is ambulatory. Ensure that IPC is reapplied after ambulation (Hanison & Corbett, 2016; Dunn & Ramos, 2017). **EB:** *IPC should be reapplied after the client ambulates and returns to bed to maintain prevention interventions for VTE (Bartholomew, 2017; Dunn & Ramos, 2017).*
- Perform a skin inspection during bathing. **EB:** *It is important to assess the skin with each application of the IPC and during the bath for signs of skin irritation or breakdown from the device. (Bartholomew, 2017; Dunn & Ramos, 2017).*
- IPC should be applied even when the client is sitting in a chair (Dunn & Ramos, 2017).
- Provide appropriate education or referral to a smoking cessation program. Smoking is a well-established risk factor for atherosclerotic disease that increases the client's risk for VTE (McLendon et al, 2021). **CEB:** *A systematic review and meta-analysis found that smoking increased the risk of VTE and the risk increased by 10.2% for every additional 10 cigarettes smoked per day or by 6.1% for every additional 10 pack-years of smoking. The study also found that smokers who were overweight had a higher risk of VTE (Cheng et al, 2013).*
- Obesity is an independent risk for VTE. **EB:** *A study found a higher incidence of VTE in clients with body mass index (BMI) ≥30 kg/m^2 (Peters et al, 2016). A systematic review of bariatric surgery clients found that male gender, increased BMI, smoking history, and operative procedure and time were risk factors for VTE (Bartlett, Mauck, & Daniels, 2015). Chemical and mechanical preventive interventions should be implemented to reduce the risk of VTE in the bariatric client population (Bartlett, Mauck, & Daniels, 2015).*
- Clients with cancer are at an increased risk of developing DVT mainly because of the release of certain chemicals from the tumor and spread of the tumor into blood vessels. Generally, bloodstream cancers such as leukemia carry the highest risk for development of DVT, followed by solid tumors of the pancreas, stomach, lungs, ovaries, uterus, bladder, and brain (Udoh, 2016).

Pediatric

- The nurse should be alert to certain diagnoses that increase the pediatric client's risk for VTE. **EB:** *Diagnoses associated with increased risk of VTE include mechanical ventilation, pulmonary hypertension, burns, lower extremity or pelvic fracture, spinal cord injury, surgical packing of the abdomen, sepsis, acute infection, oncological malignant growth, surgery/trauma, cardiac disease, obesity, chronic or active inflammatory disease, and immobility (Simmons, 2017).*
- The most frequent diagnosis associated with VTE in the pediatric population is trauma (Yen et al, 2016).

- Incidence of VTE in children is low; however, the rate of VTE in hospitalized children is much higher (Austin, Jenkins, & Hines, 2017).
- Risk factors for pediatric development of VTE include use of central venous access devices (Simmons, 2017). **EB:** *A study by Austin, Jenkins, and Hines (2017) found that pediatric clients are at risk of a catheter-associated DVT because of the size of the device and resulting damage to the fragile intima, leading to clot formation and dislodgement of the clot.*
- Neonatal and adolescent age groups are at higher risk for VTE compared with other pediatric age groups (Monagle et al, 2012). Additional studies are needed to further understand the risks and interventions for this population.

Geriatric

- The risk of VTE increases with age, increasing 90% between the ages of 15 and 80. **EB:** *Many of the risk factors for VTE are commonly seen in the older client with heart failure, chronic obstructive pulmonary disease, and malignancy. VTE is also seen in clients on bed rest and those with implantable devices such as pacemakers and hip/knee replacements (Bruni-Fitzgerald, 2015).*
- It is well established that older clients are at a greater risk of developing atrial fibrillation (Heeringa et al, 2006). **EB:** *The Framingham study indicated increasing risk of developing atrial fibrillation with increasing age (Wolf, Abbott, & Kannel, 1991). Treatment for chronic atrial fibrillation requires the use of anticoagulants to reduce the risk of an embolic event.*

Home Care

- Provide client education on the importance of continued use of compression stockings as directed. **EB:** *Ensuring the client is aware of the benefit of compression stockings reduces the risk of VTE and may facilitate compliance in wearing the compression stocking. The client may only be required to wear stockings during the day and be allowed to remove them at night (Kaur et al, 2016; Pai & Douketis, 2020).*
- Provide education to the client and/or family caregiver about the continued use of anticoagulant pharmacological therapy as directed. The client and/or family caregiver may need instruction on proper injection technique if the client is not discharged on an oral anticoagulant. **EB:** *If the client is discharged home on subcutaneous low-molecular-weight heparin or fondaparinux, the nurse needs to teach the client and/or family caregiver how to properly administer the medication by injection (Pai & Douketis, 2020; Bartholomew, 2017).*
- Clients who take the anticoagulant warfarin should have dietary education. Warfarin's effects may be decreased with a diet rich in vitamin K. **EB:** *Food containing vitamin K includes dark green leafy vegetables such as kale, Brussels sprouts, collard greens, and spinach. Avoid eating large quantities of these vegetables. Cranberry juice and alcohol should be avoided because they enhance the effects of warfarin and may lead to bleeding. (Pai & Douketis, 2020)*
- The newer anticoagulants, such as rivaroxaban, apixaban, and edoxaban, do not have the same medication–food interactions as warfarin.

Disturbed Thought Process

Domain 5 Perception/cognition Class 4 Cognition

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Disruption in cognitive functioning that affects the mental processes involved in developing concepts and categories, reasoning, and problem solving.

Defining Characteristics

Difficulty communicating verbally; difficulty performing instrumental activities of daily living; disorganized thought sequence; expresses unreal thoughts; impaired interpretation of events; impaired judgment; inadequate emotional response to situations; limited ability to find solutions to everyday situations; limited ability to make decisions; limited ability to perform expected social roles; limited ability to plan activities; limited impulse control ability; obsessions; phobic disorders; suspicions

Related Factors

Acute confusion; anxiety; disorientation; fear; grieving; non-psychotic depressive symptoms; pain; stressors; substance misuse; unaddressed trauma

At-Risk Population

Economically disadvantaged individuals; individuals in the early postoperative period; older adults; pregnant women

T

Associated Conditions

Brain injuries; critical illness; hallucinations; mental disorders; neurodegenerative disorders; pharmaceutical preparations

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Distorted Thought Self-Control; Cognition; Cognitive Orientation

Example NOC Outcome with Indicators

Distorted Thought Self-Control as evidenced by the following indicators: Recognizes hallucinations or delusions are occurring/Refrains from attending to hallucinations or delusions/Refrains from responding to hallucinations or delusions. (Rate the outcome and indicators of **Distorted Thought Self-Control:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I.)

Client Outcomes

Client Will (Specify Time Frame)

- Recognize and verbalize that delusions are occurring
- Verbalize reality based thoughts and ideas
- Differentiate between delusions and reality
- Refrain from acting on delusional ideation
- Remain free from injury

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Delusion Management

Example NIC Activities—Delusion Management

Establish a trusting, interpersonal relationship with client; Avoid arguing about false beliefs, state doubt matter-of-factly; Focus discussion on the underlying feelings, rather than the content of delusions

Nursing Interventions and *Rationales*

- Assess client for the presence of delusions with an established tool such as the Positive and Negative Syndrome Scale (PANSS). **EB:** *A systematic narrative review of terminology and assessment tools of psychosis found that the PANSS is a frequent assessment tool for individuals with psychotic disorders, individuals with nonpsychotic mental disorders, the general population, and individuals with medical conditions (Seiler et al, 2020).*
- Assess and monitor the client for suicidal ideation. **EB:** *A study found that suicidal ideation is extremely common in clients with persecutory delusions (Freeman et al, 2019).*
- Assess and monitor how the client copes with delusions and impaired reality testing. **EB:** *Coping may range from avoidance, stalking, and seeking medical care to violence, so nurses must evaluate if the cognitions will translate to action and for the potential for violence (González-Rodríguez & Seeman, 2020).*
- Assess and monitor clients for side effects associated with antipsychotic medications. **EB:** *A study of 679 clients with schizophrenia found that antipsychotics with high D2 receptor antagonism and illness duration were risk factors of extrapyramidal symptoms (Weng et al, 2019).*
- Use active listening to identify the meaning attributed to delusional thoughts. **EB:** *A qualitative study found that grandiose delusions are experienced by clients as highly meaningful. The delusions provide a sense of purpose, belonging, or self-identity or make sense of unusual or difficult events (Isham et al, 2021).*
- Respond to delusional statements with advanced empathy response techniques. Advanced empathy responses include the following:
  - Acknowledge what the person said with a "You say" statement. "You say you have microchips in your brain." Frame the question as exploratory to gain clarification.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- ❍ Acknowledge your understanding with a statement. "I can't see any microchips and the test results do not show microchips in your brain." State your perceptions, what you have seen, heard, or been told.
- ❍ Acknowledge how you imagine the other person feels with a perspective-taking statement such as, "I don't know what it would feel like to have microchips in my brain, but I imagine it might feel scary." Express genuine interest in the client's feelings and ask open-ended questions about their experience.
- ❍ Explore the client's feelings and methods of coping.

EB: *Lakeman (2020) states that a client's thoughts and beliefs may not be grounded in consensual reality, but the feelings associated with those thoughts and beliefs are real and require acknowledgment by professionals.*

- ● Use nursing presence to provide support to clients who experience grandiose or persecutory delusions. **EB:** *Research indicates that people with persecutory or grandiose delusions may report distress associated with their experiences and be willing to engage in treatment (Jacobsen et al, 2019).*
- ● Use asynchronous email as a method to promote engagement with clients who experience psychosis. **EB:** *A study found that asynchronous email support promoted engagement with online interventions for individuals with psychosis, with the potential to enable self-management of illness and improve clinical outcomes (Arnold et al, 2019).*
- ● Assist the client to identify how daily stress can contribute to impaired thinking and cognitive symptoms. **EB:** *A study's results supported the idea that minor daily stress may play an important role in inducing a cascade of effects that may lead to psychotic experiences (Klippel et al, 2018).*
- ● Provide the client with psychoeducation that includes information about their illness, treatment, disease management, problem-solving, coping skills, and how to access community mental health care services. **EB:** *Psychoeducation provides individuals with information so they can actively manage their illness (Morin & Franck, 2017).*
- ▲ Refer the client for cognitive behavioral therapy (CBT). **EB:** *A meta-analysis found that CBT was associated with a higher decrease in positive symptoms for clients with a diagnosis of schizophrenia (Bighelli et al, 2018).*
- ▲ Refer the client for metacognitive training (MCT). MCT is available in a module format, with modules that target common cognitive errors and problem-solving biases. **EB:** *A randomized control trial of Japanese clients diagnosed with schizophrenia found a decrease in delusions and positive symptoms and an increase in general functioning in the MCT group (Ishikawa et al, 2020).*
- ▲ Refer the client for Art Therapy group or services. **EB:** *Practice lessons from Art Therapy recommend encouraging reality orientation through art-based form and content, focusing on environmental understimulation and helping clients gain a sense of control to address poor reality testing symptoms (Shore & Rush, 2019).*

Geriatric

- ● The previous interventions can be adapted for use with geriatric clients.

Multicultural

- ● The previous interventions can be adapted for use with multicultural clients.
- ● Assess for the impact of socioenvironmental risk factors, such as discrimination, on cognitions. **EB:** *A systematic literature review and meta-analysis found a positive association between perceived ethnic discrimination and the occurrence of psychotic symptoms and experiences (Bardol et al, 2020).*

Home Care

- ● The previous interventions can be adapted for use with home care clients.

Client/Family Teaching and Discharge Planning

- ● Assess family reactions to the client's illness. **EB:** *A qualitative study investigated family reactions in 14 families where one family member was experiencing a psychosis for the first time. Results indicated that some responses, such as withdrawal, guilt, fear, and stigma, led to the avoidance of seeking mental health treatment of their ill family member (Connor et al, 2016).*
- ● Provide family and caregivers information about delusions. **EBN:** *Interviews with family caregivers found six themes: caregivers' exposure to symptoms of illness; lack of understanding about their relative's delusional beliefs; concerns about harm from their relative; efforts to conceal their relative's delusional beliefs and their consequences; fractured relationships; and learning how to cope (Onwumere, Learmonth, & Kuipers, 2016).*
- ● Teach family members how to respond to delusions or expressions of impaired thinking. **EBN:** *The process of learning how to cope includes learning effective responses to the family member's expressions of disorganized thinking (Onwumere, Learmonth, & Kuipers, 2016).*

Impaired Tissue Integrity

Domain 11 Safety/protection Class 2 Physical injury

JoAnn Coar, MSN, RN-BC, A-GNP-C, CWOCN

NANDA-I

Definition

Damage to the mucous membrane, cornea, integumentary system, muscular fascia, muscle, tendon, bone, cartilage, joint capsule, and/or ligament.

T

Defining Characteristics

Abscess; acute pain, bleeding, decreased muscle strength; decreased range of motion; difficulty bearing weight; dry eye; hematoma, impaired skin integrity; localized area hot to touch, localized deformity; localized loss of hair; localized numbness; localized swelling; muscle spasms; reports lack of balance; reports tingling sensation; stiffness; tissue exposure below the epidermis redness, tissue damage

Related Factors

External Factors

Excretions; humidity; hyperthermia; hypothermia; inadequate caregiver knowledge about maintaining tissue integrity; inadequate caregiver knowledge about protecting tissue integrity; inadequate use of chemical agent; pressure over bony prominence; psychomotor agitation; secretions; shearing forces; surface friction; use of linen with insufficient moisture wicking property

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Internal Factors

Body mass index above normal range for age and gender; body mass index below normal range for age and gender; decreased blinking frequency; decreased physical activity; fluid imbalance; impaired physical mobility; impaired postural balance; inadequate adherence to incontinence treatment regimen; inadequate blood glucose level management; inadequate knowledge about maintaining tissue integrity; inadequate knowledge about restoring tissue integrity; inadequate ostomy care; malnutrition; psychogenic factor; self mutilation; smoking; substance misuse

At-Risk Population

Homeless individuals; individuals at extremes of age; individuals exposed to environmental temperature extremes; individuals exposed to high-voltage power supply; individuals participating in contact sports; individuals participating in winter sports; individuals with family history of bone fracture; individuals with history of bone fracture

Associated Conditions

Anemia; autism spectrum disorder; cardiovascular diseases; chronic neurological conditions; critical illness; decreased level of consciousness; decreased serum albumin level; decreased tissue oxygenation; decreased tissue perfusion; hemodynamic instability; immobilization; intellectual disability; medical devices; metabolic diseases; peripheral neuropathy; pharmaceutical preparations; sensation disorders; surgical procedures

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Integrity: Skin and Mucous Membranes; Wound Healing: Primary Intention, Secondary Intention

Example NOC Outcome with Indicators

Intact **Tissue Integrity: Skin and Mucous Membranes** as evidenced by the following indicators: Skin intactness/Skin lesions absent/Tissue perfusion/Skin temperature. (Rate the outcome and indicators of **Tissue Integrity: Skin and Mucous Membranes:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Report any altered sensation or pain at site of tissue impairment
- Demonstrate understanding of plan to heal tissue and prevent reinjury
- Describe measures to protect and heal the tissue, including wound care
- Experience a wound that decreases in size and has increased granulation tissue

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Incision Site Care; Pain Management; Pressure Ulcer Care; Risk Identification; Skin Care: Topical Treatments; Skin Surveillance; Wound Care; Wound Irrigation

Example NIC Activities—Pressure Ulcer Care

Monitor color of wound bed, temperature, edema, erythema, moisture, and appearance of surrounding skin; Note characteristics of any drainage

Nursing Interventions and *Rationales*

- The National Pressure Ulcer Advisory Panel (NPUAP) redefined the definition of a pressure ulcer, which is now referred to as a pressure injury, during the NPUAP 2016 Staging Consensus Conference. The new

definitions more accurately define alterations in tissue integrity from pressure as follows: A pressure injury is localized damage to the skin and underlying soft tissue usually over a bony prominence or related to a medical device or another device. The injury can present as intact skin or an open ulcer and may be painful. The injury occurs as a result of intense and/or prolonged pressure or pressure in combination with shear. The tolerance of soft tissue for pressure and shear may also be affected by microclimate, nutrition, perfusion, comorbidities, and condition of the soft tissue (NPUAP, 2016).

- The first step is to identify etiological factors or what is causing the impairment. **EB:** *A thorough assessment of the individual, not only the impairment, is crucial. This includes a comprehensive medical history, current medical status, medications, and family history (Murphree, 2017). Differentiate pressure injuries from other types of wounds such as moisture-associated skin damage (MASD) (Wound, Ostomy and Continence Nurses Society–Wound Guidelines Task Force, 2017). A comprehensive assessment helps identify specific risk factors and systemic factors, which aids the clinician in a more successful wound management approach (Murphree, 2017).*
- Determine the size (length, width) and depth of the wound. **EB:** *Select a uniform, consistent method for measuring wound length, width or wound area, and depth to facilitate meaningful comparisons of wound measurements over time. A careful assessment should be performed to avoid causing injury when probing the depth of a wound bed or determining the extent of undermining or tunneling (National Pressure Injury Advisory Panel [NPIAP], European Pressure Injury Advisory Panel [EPIAP], & Pan Pacific Pressure Injury Alliance [PPPIA], 2019).*

▲ Classify pressure injuries (NPUAP, 2016) using national guidelines and definitions (see http://www.npuap.org/resources/educational-and-clinical-resources/npuap-pressure-injury-stages/).

- **Pressure Injury:** A pressure injury is localized damage to the skin and underlying soft tissue usually over a bony prominence or related to a medical or another device. The injury can present as intact skin or an open ulcer and may be painful. The injury occurs as a result of intense and/or prolonged pressure or pressure in combination with shear. The tolerance of soft tissue for pressure and shear may also be affected by microclimate, nutrition, perfusion, comorbidities, and condition of the soft tissue (NPUAP, 2016).
- **Stage 1 Pressure Injury:** Nonblanchable erythema of intact skin. Area of localized nonblanchable erythema that may appear differently in darkly pigmented skin, and changes in sensation, temperature, or firmness may precede visual changes. Color changes do not include purple or maroon discoloration, which is more likely to indicate deep tissue pressure injury (NPUAP, 2016).
- **Stage 2 Pressure Injury:** Partial-thickness skin loss with exposed dermis. Partial-thickness skin loss with exposed dermis in which the wound bed is pink/red and moist and adipose (fat) and deeper tissues are not visible. Granulation tissue, slough, and eschar are not present. A stage 2 pressure injury may also present as an intact or ruptured blister. These injuries commonly result from adverse microclimate and shear in the skin over the pelvis and shear in the heel. This stage should not be used to describe MASD, including incontinence-associated dermatitis (IAD), intertriginous dermatitis (ITD), medical adhesive–related skin injury (MARSI), or traumatic wounds (skin tears, burns, and abrasions) (NPUAP, 2016).
- **Stage 3 Pressure Injury:** Full-thickness skin loss. Full-thickness loss of skin, in which adipose is visible and granulation tissue and epibole (rolled wound edges) are often present, and undermining/tunneling may occur. Slough and/or eschar may also be visible. Fascia, muscle, tendon, ligament, cartilage, and/or bone are not exposed. The depth of tissue damage varies by anatomical location, and areas of significant adiposity can develop deep wounds. If slough or eschar obscures the extent of tissue loss, this is an unstageable pressure injury (NPUAP, 2016).
- **Stage 4 Pressure Injury:** Full-thickness skin and tissue loss. Full-thickness skin and tissue loss with exposed or directly palpable fascia, muscle, tendon, ligament, cartilage, or bone and slough and/or eschar may be visible. Epibole, undermining, and/or tunneling often occur and depth varies by anatomical location. If slough or eschar obscures the extent of tissue loss, this is an unstageable pressure injury (NPUAP, 2016).
- **Deep Tissue Pressure Injury:** Persistent nonblanchable deep red, maroon, or purple discoloration. Intact or nonintact skin with localized area of persistent nonblanchable deep red, maroon, or purple discoloration or epidermal separation revealing a dark wound bed or blood-filled blister. Pain and temperature change often precede skin color changes. Discoloration may appear differently in darkly pigmented skin. This injury results from intense and/or prolonged pressure and shear forces at the bone–muscle interface. The wound may evolve rapidly to reveal the actual extent of tissue injury, or it may resolve without tissue loss. If necrotic tissue, subcutaneous tissue, granulation tissue, fascia, muscle,

T

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

or other underlying structures are visible, this indicates a full-thickness pressure injury (unstageable, stage 3, or stage 4). Do not use deep tissue pressure injury to describe vascular, traumatic, neuropathic, or dermatological conditions (NPUAP, 2016).
  - ❍ **Unstageable Pressure Injury:** Obscured full-thickness skin and tissue loss. Full-thickness skin and tissue loss in which the extent of tissue damage within the ulcer cannot be confirmed because it is obscured by slough or eschar. If slough or eschar is removed, a stage 3 or stage 4 pressure injury will be revealed. Stable eschar (i.e., dry, adherent, intact without erythema or fluctuance) on the heel or ischemic limb should not be softened or removed (NPUAP, 2016).
  - ❍ **Medical Device–Related Pressure Injury:** This describes an etiology. Medical device–related pressure injuries result from the use of devices designed and applied for diagnostic or therapeutic purposes. The resultant pressure injury generally conforms to the pattern or shape of the device. The injury should be staged using the staging system (NPUAP, 2016).
  - ❍ **Mucosal Membrane Pressure Injury:** Mucosal membrane pressure injury is found on mucous membranes with a history of a medical device in use at the location of the injury. Due to the anatomy of the tissue, these ulcers cannot be staged (NPUAP, 2016).
- ● Inspect and monitor the site of impaired tissue integrity at least once daily for color changes, redness, swelling, warmth, pain, or other signs of infection or per facility/agency policy. Monitor the status of the skin around the wound. Pay special attention to all high-risk areas such as bony prominences, skinfolds, sacrum, and heels. There is evidence that stage 1 pressure injuries are underdetected in individuals with darkly pigmented skin because areas of redness are not easily identified. **EB:** *Systematic inspection can identify impending problems early (NPIAP, EPIAP, & PPPIA, 2019).*
- ● Determine whether the client is experiencing changes in sensation or pain. **EB:** *An initial pain assessment, using a validated tool, should include the following four elements: a detailed pain history including the character, intensity, and duration of pressure ulcer pain; a physical examination that includes a neurological component; a psychosocial assessment; and an appropriate diagnostic workup to determine the type and cause of the pain. Select a wound dressing that requires less frequent changing, is nonadherent, and maintains a moist wound environment (NPIAP, EPIAP, & PPPIA, 2019).*
- ● Individualizing plans for bathing frequency, pH-balanced soaps, and applying moisturizing products while skin is still damp can help improve skin integrity (Murphree, 2017).
- ● Assess for incontinence and implement an individualized plan for management. **EB:** *Differentiate wounds caused by incontinence from other types of wounds. Cleanse the skin promptly after episodes of incontinence and use pH-balanced cleansers avoiding the use of alkaline soaps and cleansers (NPIAP, EPIAP, & PPPIA, 2019). Use incontinence skin barriers including creams, ointments, pastes, or film-forming skin protectants as needed to protect and maintain skin integrity with incontinent individuals (Wound, Ostomy and Continence Nurses Society–Wound Guidelines Task Force, 2017).*
- ● Monitor for correct placement of tubes, catheters, and other devices. Assess the skin and tissue affected by the pressure of the devices and tape used to secure these devices. **EB:** *Reposition the individual and/or the medical device to redistribute pressure and decrease shear forces. Reposition the individual and/or medical device to redistribute pressure and decrease shear forces. Keep skin clean and dry under medical devices. Moisture underneath a medical device can create an environment in which the skin is more vulnerable to alterations in skin integrity (NPIAP, EPIAP, & PPPIA, 2019).*
- ● Medical device–related pressure injury describes an etiology. **EB:** *Medical device–related pressure injuries result from the use of devices designed and applied for diagnostic or therapeutic purposes. The resultant pressure injury generally conforms to the pattern or shape of the device. The injury should be staged using the previously discussed staging system (NPUAP, 2016).*
- ● Assess frequently for correct placement of foot boards, restraints, traction, casts, or other devices, and assess skin and tissue integrity. **EB:** *Frequently assess for signs and symptoms of compartment syndrome (refer to the care plan for Risk for **Peripheral Neurovascular** Dysfunction). Reposition the individual and/or the medical device to redistribute pressure and decrease shear force (NPIAP, EPIAP, & PPPIA, 2019).*
- ▲ Implement and communicate a comprehensive treatment plan for the topical treatment of the skin impairment site. **EB:** *To improve care and outcomes for individuals with or at risk for skin impairments, evidence-based guidelines must be disseminated to ensure that health care providers are making every effort to identify individuals with or at risk for skin alterations and implement appropriate preventive and treatment interventions (Wound, Ostomy and Continence Nurses Society–Wound Guidelines Task Force, 2017).*
- ▲ Identify a plan for debridement if necrotic tissue (eschar or slough) is present and if consistent with overall client management goals (i.e., curative versus palliative care). **EB:** *Debride devitalized tissue within the*

T

wound bed or edge of pressure injuries (NPUAP, 2016) when appropriate to individual's condition and consistent with overall goals of care. Do not debride stable, hard, dry eschar in ischemic limbs or heels (NPIAP, EPIAP, & PPPIA, 2019).

- Select a topical treatment that maintains a moist, wound-healing environment and also allows absorption of exudate and filling of dead space. **EB:** *No single wound care product provides the optimal environment for healing all wounds. Choose dressings that provide a moist healing environment, keep periwound skin dry, and control exudate and eliminate dead space (NPIAP, EPIAP, & PPPIA, 2019).*
- Avoid positioning the client on the site of impaired tissue integrity. **EB:** *If it is consistent with overall client management goals, reposition the client based on level of tissue tolerance and overall condition, and transfer or reposition the client carefully to avoid adverse effects of external mechanical forces (pressure, friction, and shear) (NPIAP, EPIAP, & PPPIA, 2019).*
- Select a support surface that meets the needs of the individual based on the level of immobility/activity, size and weight, need for microclimate management, and history of pressure injuries (*NPIAP, EPIAP, & PPPIA, 2019*). **EB:** *Consider changing to a specialty support surface when an individual cannot be repositioned off of an existing pressure injury or fails to heal with current surface. Continue repositioning of individuals placed on a pressure redistribution support surface (NPIAP, EPIAP, & PPPIA, 2019).*
- If the goal of care is to keep the client comfortable (e.g., for a terminally ill client), repositioning may not be appropriate. **EB:** *Reposition and turn the individual, periodically, in accordance with the individual's wishes, comfort, and tolerance (NPIAP, EPIAP, & PPPIA, 2019). Maintain the head of the bed at the lowest degree of elevation possible to reduce shear and friction and use lift devices, pillows, foam wedges, and pressure-reducing devices in the bed (NPUAP, 2016; Baranoski & Ayello, 2016).*

▲ Assess the client's nutritional status. Refer for a nutritional consultation and/or institute dietary supplements as necessary. **EB:** *Optimizing nutritional intake, including calories, fatty acids, protein, and vitamins, is needed to promote wound healing (O'Hanlon, Dowsett, & Smyth, 2015; NPIAP, EPIAP, & PPPIA, 2019).*

▲ Review client nutrition plan evaluating for the intake of 1.25 to 1.5 g of protein per kilogram body weight daily, unless medically contraindicated, for adults at risk of a pressure injury or with existing pressure injuries. Offer 1 mL of fluid intake per kilocalorie per day, unless medically contraindicated (Wound, Ostomy and Continence Nurses Society–Wound Guidelines Task Force, 2017). Reassess as condition changes (*NPIAP, EPIAP, & PPPIA, 2019*).

▲ Develop a comprehensive plan of care that includes a thorough wound assessment, treatment interventions, support surfaces, nutritional products, adjunctive therapies, and evaluation of the outcome of care. **EB:** *Documentation of these essential elements is paramount to establishing a framework for quality care.*

Home Care

- Some of the interventions previously described may be adapted for home care use.

▲ Assess the client's current phase of wound healing (inflammation, proliferation, or maturation) and stage of injury; initiate appropriate wound management. **EB:** *A holistic assessment is required to guide correct dressing selection. Underlying pathophysiological factors need to be addressed to improve outcomes* (*NPIAP, EPIAP, & PPPIA, 2019*).

- Instruct and assist the client and caregivers in understanding how to change dressings and in the importance of maintaining a clean environment. Provide written instructions and observe them completing the dressing change.

▲ Initiate a consultation in a case assignment with a wound specialist or wound, ostomy, and continence nurse to establish a comprehensive plan as soon as possible. Plan case conferencing to promote optimal wound care. **EB:** *Case conferencing ensures that cases are regularly reviewed to discuss and implement the most effective wound care management to meet client needs* (*NPIAP, EPIAP, & PPPIA, 2019*).

▲ Consult with other health care disciplines to provide a thorough, comprehensive assessment. **EB:** *Consider referring to a dietitian, physical therapist, occupational therapist, and social worker/case manager as needed. Wound care management requires a multiprofessional approach with the frontline nurse as an essential member of this team (Cox, 2019).*

Client/Family Teaching and Discharge Planning

- Teach skin and wound assessment and ways to monitor for signs and symptoms of infection, complications, and healing. **EB:** *Early assessment and intervention help prevent serious problems from developing (Cox, 2019)*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Teach the client why a topical treatment has been selected. Explain wound bed changes that the caregiver can expect to see. Instruct on when the dressing needs to be changed. Assess pressure injuries with each wound dressing change and confirm the appropriateness of the current dressing regimen (NPIAP, EPIAP, & PPPIA, 2019). **EB:** *The type of wound dressing needed may change over time as the wound heals and/or deteriorates (Baranoski & Ayello, 2016; NPIAP, EPIAP, & PPPIA, 2019).*

▲ Teach the use of pillows, foam wedges, and pressure-reducing devices on beds and chairs to prevent pressure injury. **EB:** *Pressure redistributing surfaces serve as adjuncts and not replacements to regular repositioning (Wound, Ostomy and Continence Nurses Society–Wound Guidelines Task Force, 2017).*

Risk for Impaired Tissue Integrity

Domain 11 Safety/protection Class 2 Physical injury

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to damage to the mucous membrane, cornea, integumentary system, muscular fascia, muscle, tendon, bone, cartilage, joint capsule, and/or ligament, which may compromise health.

Risk Factors

External Factors

Excretions; humidity; hyperthermia; hypothermia; inadequate caregiver knowledge about maintaining tissue integrity; inadequate caregiver knowledge about protecting tissue integrity; inadequate use of chemical agent; pressure over bony prominence; psychomotor agitation; secretions; shearing forces; surface friction; use of linen with insufficient moisture wicking property

Internal Factors

Body mass index above normal range for age and gender; body mass index below normal range for age and gender; decreased blinking frequency; decreased physical activity; fluid imbalance; impaired physical mobility; impaired postural balance; inadequate adherence to incontinence treatment regimen; inadequate blood glucose level management; inadequate knowledge about maintaining tissue integrity; inadequate knowledge about restoring tissue integrity; inadequate ostomy care; malnutrition; psychogenic factor; self mutilation; smoking; substance misuse

At-Risk Population

Homeless individuals; individuals at extremes of age; individuals exposed to environmental temperature extremes; individuals exposed to high-voltage power supply; individuals participating in contact sports; individuals participating in winter sports; individuals with family history of bone fracture; individuals with history of bone fracture

Associated Conditions

Anemia; autism spectrum disorder; cardiovascular diseases; chronic neurological conditions; critical illness; decreased level of consciousness; decreased serum albumin level; decreased tissue oxygenation; decreased tissue perfusion; hemodynamic instability; immobilization; intellectual disability; medical devices; metabolic diseases; peripheral neuropathy; pharmaceutical preparations; sensation disorders; surgical procedures

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Impaired **Tissue** Integrity.

Ineffective Peripheral Tissue Perfusion

Domain 4 Activity/rest Class 4 Cardiovascular/pulmonary responses

Susan Bonini, EdD, MSN, RN

NANDA-I

Definition

Decrease in blood circulation to the periphery, which may compromise health.

Defining Characteristics

Absence of peripheral pulses; altered motor function; altered skin characteristics; ankle-brachial index <0.90; capillary refill time >3 seconds; color does not return to lowered limb after 1 minute of leg elevation; decreased blood pressure in extremities; decreased pain-free distances during a 6-minute walk test; decreased peripheral pulses; delayed peripheral wound healing; distance in the 6-minute walk test below normal range; edema; extremity pain; femoral bruit; intermittent claudication; paresthesia; skin color pales with limb elevation

Related Factors

Excessive sodium intake; inadequate knowledge of disease process; inadequate knowledge of modifiable factors; sedentary lifestyle; smoking

Associated Conditions

Diabetes mellitus; endovascular procedure; hypertension; trauma

NOC (Nursing Outcomes Classification)

T

Suggested NOC Outcomes

Circulation Status; Fluid Balance; Hydration; Tissue Perfusion: Peripheral

Example NOC Outcome with Indicators

Demonstrates adequate **Circulation Status** as evidenced by the following indicators: Peripheral pulses strong/Peripheral pulses symmetrical/Skin color and temperature/Peripheral edema not present. (Rate the outcome and indicators of **Circulation Status:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate adequate tissue perfusion as evidenced by palpable peripheral pulses, relief of pain, increased exercise tolerance, warm and dry skin, adequate urine output, and absence of respiratory distress

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Verbalize knowledge of treatment regimen, including appropriate exercise and medications and their actions and possible side effects
- Identify changes in lifestyle needed to increase tissue perfusion

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Circulatory Care: Arterial Insufficiency

Example NIC Activities—Circulatory Care: Arterial Insufficiency

Evaluate peripheral edema and pulses; Inspect skin for arterial ulcers and tissue breakdown

Nursing Interventions and *Rationales*

▲ Assess the brachial, radial, dorsalis pedis, posterior tibial, and popliteal pulses bilaterally. If unable to palpate them, use a handheld Doppler device and notify the health care provider immediately with a decrease in pulse quality or new onset of absence of pulses along with a cold extremity. **EB:** *Audible handheld Doppler ultrasound proved to be a reliable, simple, rapid, and inexpensive bedside test of peripheral arterial disease in clients with or without diabetes (Leers, n.d.; Mitchell et al, 2019).*

- Note skin color; assess skin temperature, sensation and movement, and capillary refill.
- Assess for pain in the extremities, noting severity, quality, timing, and exacerbating and alleviating factors. Differentiate venous from arterial disease. **EB:** *When peripheral artery disease (PAD) involves the lower extremities, it produces signs and symptoms such as claudication, ischemic rest pain, skin ulceration, or gangrene (Berti-Hearn & Elliott, 2018; Berger & Davies, 2021).*
- Note skin texture and the presence of hair, ulcers, or gangrenous areas on the legs or feet. **EB:** *Nonhealing skin ulcerations and gangrene can occur in areas around the toes, boney prominences of the toes, feet, and lower legs. Chronic wounds often develop on the lower limbs as a complication of diabetes, venous insufficiency, or inadequate arterial perfusion.*
- Assess for the presence of edema in the extremities and rate severity on a four-point scale. Measure the circumference of the ankle and calf at the same time each day in the early morning (Busti, 2016).

▲ Prepare for vascular laboratory tests. **EB:** *Evaluation for PAD if signs and symptoms are present frequently involves a noninvasive vascular laboratory assessment as a next step in diagnosis (Mousa et al, 2017; Kremers et al, 2020).*

▲ Prepare for revascularization procedures. **EB:** *From 10% to 15% of clients experiencing PAD with claudication are at risk of progressing to limb ischemia. Revascularization improves claudication symptoms, minimizes tissue loss, and minimizes other lifestyle-limiting impairments (Gerhard-Herman et al, 2017).*

Arterial Insufficiency

▲ Monitor peripheral pulses. If there is new onset of loss of pulses with bluish, purple, or black areas and extreme pain, notify the health care provider immediately. *These are symptoms of arterial obstruction that can result in loss of a limb if not immediately reversed.* **EB:** *New onset of these assessment finding can result in loss of tissue, nerve damage, and loss of limb. Immediate revascularization is required to salvage the limb (Gerhard-Herman et al, 2017).*

▲ Measure ankle-brachial index (ABI) via Doppler imaging. **EB:** *Measurement of the ABI via a palpatory method offers an inexpensive, readily available alternative approach for early disease detection of PAD. Normal ABI is >0.9 (Kinlay & Gerhard-Herman, 2019; Mitchell, 2019).*

- Avoid elevating the legs above the level of the heart. With arterial insufficiency, leg elevation decreases arterial blood supply to the legs.

▲ In clients with intermittent claudication, exercise programs are recommended, such as walking or riding an exercise bicycle from 30 to 45 minutes per day, three times a week as ordered by the health care provider. **EB:** *Supervised or structured exercise programs are more effective and have been shown to improve functional status (Gerhard-Herman et al, 2017; Harding et al, 2020).*

- Keep the client warm and have the client wear clean all-cotton or all-wool socks and rounded-toe shoes or sheepskin-lined slippers when mobile. Clients with arterial insufficiency report being cold; keep extremities warm to maintain vasodilation and blood supply. Do not apply heat. Heat application can easily damage ischemic tissues.

▲ Pay careful attention to foot care. Refer to a podiatrist if the client has thick, overgrown nails or calluses. Ischemic feet are vulnerable to injury; meticulous foot care can prevent further injury. **EB:** *Symptoms or signs of PAD can be observed in up to 50% of the clients with a diabetic foot ulcer, and PAD is a risk factor for poor healing and amputation (Hinchliffe et al, 2020).*

● If the client has ischemic arterial ulcers, refer to the care plan for Impaired **Tissue** Integrity.

▲ If the client smokes, recommend the client stop smoking and offer specific smoking cessation interventions. Refer to the health care provider for medications to support nicotine withdrawal. **EB:** *There is a strong correlation between smoking and the risk of developing PAD. Nurses have professional responsibility to help clients stop smoking, utilizing evidence-based clinical practice guidelines (AHRQ, 2008; Gerhard-Herman et al, 2017; Hinchliffe et al, 2020).*

▲ If the client has diabetes, good glycemic control is recommended. **EB:** *Intensive cardiovascular risk management that includes good glycemic control has been shown to reduce the 5-year mortality rate in clients with PAD and diabetes (Hinchliffe et al, 2020).*

● Educate the client on the use and safety of antiplatelet medications. Encourage the client to wear a medical alert bracelet. **EB:** *Antiplatelet therapy is recommended to reduce the risk of cardiovascular ischemic events (Gerhard-Herman et al, 2017).*

Venous Insufficiency

● Elevate edematous legs as ordered and ensure no pressure under the knee and heels to prevent pressure ulcers. **EB:** *Clients who are inactive (sedentary) for long periods may have leg edema because the calf muscle pump is underused or ineffective. Elevating the ankles above the level of the heart can help relieve this type of swelling (Evans & Ratchford, 2016).*

▲ Apply graduated compression stockings as ordered. Ensure proper fit by measuring accurately. Remove the stockings at least twice a day, in the morning with the bath and in the evening, to assess the condition of the extremity, then reapply. Knee length is preferred rather than thigh length. **EB:** *Compression stockings are indicated for long-term management of chronic venous insufficiency to control edema and reduce the risk of venous ulcers (Berti-Hearn & Elliott, 2019; Youn & Lee, 2019).*

● Encourage the client to walk with compression stockings on and perform toe-up and point-flex exercises. Exercise helps increase venous return, builds up collateral circulation, and strengthens the calf muscles. **EB:** *Physical therapy modalities improve ABI, Doppler flow velocity, and blood parameters in clients with type 2 diabetes (Treat-Jacobson et al, 2019).*

● If the client is overweight, encourage weight loss to decrease venous disease.

● If the client has venous leg ulcers, encourage the client to avoid prolonged sitting, standing, and elevation of the involved leg. Encourage proper use of compression stockings. Pain may prevent compliance. **EB:** *Adherence to the use of compression stockings may be influenced by limited mobility, pain, appearance of stockings, discomfort with wearing, difficulty applying and wearing with shoes, and cost (Ratliff et al, 2016).*

▲ If the client is mostly immobile, consult with the health care provider regarding use of a calf-high intermittent pneumatic compression device for prevention of deep venous thrombosis (DVT). **EB:** *Below-the-knee devices have demonstrated the most efficacy, with multiple guidelines recommending usage (Ratliff et al, 2016; Berti-Hearn & Elliott, 2019).*

● Assess for signs of DVT, including pain, tenderness, dilated superficial veins, a palpable cord indicating a thrombosed vein, swelling in the calf and thigh, and warmth and erythema in the involved extremity. Obtain serial leg measurements of the thigh and calf circumferences. In some clients a tender venous cord can be felt in the popliteal fossa. Do not rely on Homan's sign. **EB:** *Screening and detection of DVT must be as accurate as possible. Consider using the Wells prediction score screening tool. It is critical to diagnose DVT because if left untreated, thrombi in the popliteal vein and above are associated with pulmonary embolism (PE) (Roberts & Lawrence, 2017).*

▲ Note the results of a D-dimer test and ultrasounds. **EB:** *Although a D-dimer test can be used during the initial workup for all clients who present to the emergency department (ED) for suspected DVT, duplex ultrasonography is a more reliable method of diagnosing DVT (Roberts & Lawrence, 2017; Berti-Hearn & Elliott, 2019).*

● If DVT is present, observe for symptoms of a PE. **EB:** *PE is a significant risk of a DVT. Signs and symptoms range from sudden onset, dyspnea, pleuritic chest pain of a sharp stabbing nature, dyspnea, palpitations, wheezing, anxiety, and cough (Roberts & Lawrence, 2017).*

● Educate on use and safety of anticoagulant and antiplatelet medications. **EB:** *DVT and PE are two manifestations of venous thromboembolism (VTE). The mainstay of therapy for DVT is anticoagulation, provided*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

there is no contraindication (Roberts & Lawrence, 2017; Lip & Hull, 2021). Clients need to be aware of adverse effects of anticoagulant medications, wear a medical alert bracelet, and be aware of food–drug interactions (Berti-Hearn & Elliott, 2019).

Geriatric

- Complete a thorough lower extremity assessment, documenting the slightest change from previous assessment, and implement a plan immediately. **EB:** *Complete and accurate assessment is essential to guide health care providers in formulating efficacious plans of care. The prevalence of peripheral arterial disease increases with age. The elevated risk of ulcerations leading to amputation among older adults reflects not only increased rates of PAD and diabetic pathologies but also age-related changes of the vessels (Humphries et al, 2016).*
- Recognize that older adults have an increased risk for development of DVT and PE. **EB:** *Risk for DVT and PE increases with advanced age (age >70) and history of heart disease and/or cancer (Rali et al, 2018).*

Home Care

- The interventions previously described may be adapted for home care use.
- If arterial disease is present and the client smokes, encourage smoking cessation using motivational interviewing techniques and evidenced-based clinical practice guidelines (AHRQ, 2008; AHA, 2021; CDC, n.d.).
- Examine the feet carefully at frequent intervals for changes and new ulcerations. Encourage the client to perform regular assessment of the feet.

▲ Assess the client's nutritional status, paying special attention to obesity, hyperlipidemia, and malnutrition. Refer to a dietitian if appropriate.

- Monitor for development of gangrene, venous ulceration, and symptoms of cellulitis (redness, pain, and increased swelling in an extremity).

Client/Family Teaching and Discharge Planning

- Explain the importance of good foot care. Teach the client and family to wash daily with mild soap and tepid water. Teach the client and family to inspect the feet daily. Recommend that the diabetic client wear properly fitting shoes to prevent the formation of blisters and calluses. Clients with diabetes should be instructed to never walk barefoot (Berti-Hearn & Elliott, 2018).

▲ Teach diabetic clients that they should have a comprehensive foot examination at least annually. The examination should include sensory assessments. If good sensation is not present, refer to a footwear professional for fitting of therapeutic shoes and inserts, the cost of which may be covered by insurance and/or Medicare.

- For arterial disease, stress the importance of not smoking, following a weight loss program (if the client is obese), carefully controlling a diabetic condition, controlling hyperlipidemia, managing hypertension, maintaining intake of antiplatelet therapy, and reducing stress.
- Encourage clients to walk or engage in other forms of physical activity.
- Teach the client to avoid exposure to cold; limit exposure to brief periods if going out in cold weather and wear warm clothing.
- For venous disease, stress the importance of not smoking, and teach the importance of wearing compression stockings as ordered, elevating the legs at intervals (30 minutes, three to four times a day), weight loss if overweight, regular exercise such as walking, and watching for skin breakdown on the legs.
- Educate clients about any medications prescribed to treat their venous disease.
- Educate clients about the importance of taking prescribed medications to achieve therapeutic anticoagulation (Roberts & Lawrence, 2017).
- Teach clients to avoid crossing legs when sitting or standing for prolonged periods (Berti-Hearn & Elliott, 2019).
- Teach client to avoid long periods of sitting or standing to reduce the pooling of blood (D'Alesandro, 2016).
- Teach the client to recognize the signs and symptoms that should be reported to a health care provider (e.g., change in skin temperature, color, or sensation, or the presence of a new lesion on the foot).
- Provide clear, simple instructions about plan of care.

- Instruct and provide emotional support for clients undergoing hyperoxygenation treatment. **EB:** *Hyperbaric oxygen may be used as a treatment option for clients with diabetes suffering from nonhealing or delayed-healing foot ulcers (Huang et al, 2019; Longobardi et al, 2019).*

Risk for Ineffective Peripheral Tissue Perfusion

Domain 4 Activity/rest Class 4

Cardiovascular/pulmonary responses

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to a decrease in blood circulation to the periphery, which may compromise health.

Risk Factors

Excessive sodium intake; inadequate knowledge of disease process; inadequate knowledge of modifiable factors; sedentary lifestyle; smoking

Associated Conditions

Diabetes mellitus; endovascular procedures; hypertension; trauma

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Ineffective Peripheral **Tissue Perfusion.**

Impaired Transfer Ability

Domain 4 Activity/rest Class 2 Activity/exercise

Darcy O'Banion, RN, MS, ACCNS-AG

NANDA-I

Definition

Limitation of independent movement between two nearby surfaces.

Defining Characteristics

Difficulty transferring between bed and chair; difficulty transferring between bed and standing position; difficulty transferring between car and chair; difficulty transferring between chair and floor; difficulty transferring between chair and standing position; difficulty transferring between floor and standing position; difficulty transferring between uneven levels; difficulty transferring in or out of bath tub; difficulty transferring in or out of shower stall; difficulty transferring on or off a bedside commode; difficulty transferring on or off a toilet

Related Factors

Environmental constraints; impaired postural balance; inadequate knowledge of transfer techniques; insufficient muscle strength; neurobehavioral manifestation; obesity; pain; physical deconditioning

Associated Conditions

Musculoskeletal impairment; neuromuscular diseases; vision disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Balance; Body Positioning: Self-Initiated; Transfer Performance

Example NOC Outcome with Indicators

Transfer Performance as evidenced by the following indicators: Transfers from bed to chair and back/Transfers from wheelchair to toilet and back/Transfers from wheelchair to vehicle and back. (Rate the outcome and indicators of **Transfer Performance:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Transfer from bed to chair and back successfully
- Transfer from chair to chair successfully
- Transfer from wheelchair to toilet and back successfully
- Transfer from wheelchair to car and back successfully

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Exercise Promotion: Strength Training; Exercise Therapy: Muscle Control

Example NIC Activities—Exercise Promotion: Strength Training

Obtain medical clearance for initiating a strength-training program, as appropriate; Assist to set realistic short- and long-term goals and to take ownership of the exercise plan

Nursing Interventions and *Rationales*

- Specify level of independence using a standardized functional scale. **EB:** *Use a nurse-driven bedside assessment tool to evaluate the client's mobility status. Regular evaluation of clients' mobility status by nurses using a standardized tool allows more awareness of the skill and equipment needed for safe client handling and mobility, reducing the risk for fall and potential injury to the nursing staff (Boynton et al, 2014; Jones et al, 2020).*
- Assess level of client ability to perform specific tasks before transfer of client. **EB:** *Valid and reliable assessment tools such as the Bedside Mobility Assessment Tool provide assessment of a client to promote safe mobility and reduce injury to staff (Boynton et al, 2014; Teeple et al, 2017; Hillrom Services, Inc., 2019).*
- Assess client's dependence, weight, strength, balance, tolerance to position change, cooperation, fatigue level, and cognition plus available equipment and staff ratio/experience to decide whether to do a manual or device-assisted transfer because devices can reduce staff injury *(American Nurses Association [ANA], 2015; Riccoboni et al, 2021).*
- ▲ Complications associated with immobility and resultant muscle loss begin within 48 hours of onset of injury and are greatest during the first 2 to 3 weeks (Cameron et al, 2015). Request a consultation for a physical therapist (PT) and/or occupational therapist (OT) to develop a plan of care for safe client handling and mobility. **EB:** *Progressive mobility, or mobility that starts earlier and more aggressively during a client's hospital stay, even as early as in the intensive care unit (ICU), decreases mechanical ventilation days and decreases complications such as weakness from prolonged immobilization (Arias-Fernández et al, 2018). Early exercise in the ICU improves clients' muscle strength, reduces activity limitations, and reduces restrictions in participation in activities after discharge (Tipping et al, 2017).*
- ▲ Obtain a consultation for a PT, OT, or orthotist to evaluate and fit clients with proper orthoses, braces, collars, and walking aids before helping them stand. **EB:** *Equipment can help increase clients' independence and decrease the level of assistance needed from caregivers (Romanoski & Swope, 2018).*
- ▲ Help client put on/take off collars, braces, prostheses in bed, and put on/take off antiembolism stockings and abdominal binders. If applying antiembolism stockings is prescribed to reduce the risk of DVT, apply while the client is in bed for ease of application. **EB:** *In clients with diagnosed acute DVT of the leg, compression stockings may not be routinely used to prevent postthrombotic syndrome. Postthrombotic syndrome is a complication that may occur after a DVT develops from venous insufficiency producing symptoms of pain, edema, and venous ulcers. Current guidelines recommend not routinely using compression stockings with clients who have a DVT (Kearon et al, 2016).*
- ▲ Collaborate with PT and OT to use algorithms to identify technological aids to handle and transfer dependent and obese clients. Use assistive mobility devices such as gait belts, lifts, and transport devices to move obese clients to avoid harm to both client and health care professional (Choi & Brings, 2015). **EB:** *Assess the client for appropriate use of assistive devices, such as powered and nonpowered stand-assist devices, mechanical lifts, stretcher-chairs, and friction-reducing devices, to prevent musculoskeletal injuries of staff and allow safe client handling (Centers for Disease Control and Prevention, National Institute for Occupational Safety and Health, 2015; Choi & Brings, 2015; Hallmark et al, 2015).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Implement and document type of transfer (e.g., slide board, pivot), weight-bearing status (non–weight-bearing, partial), equipment (walker, sling lift), and level of assistance (standby, moderate) on care plan, white board in room, and/or electronic medical record.
- Apply a gait belt with handles before transferring clients with partial weight-bearing abilities; keep the belt and client close to provider during the transfer. **EB:** *If used incorrectly, such as at arm's length, it prevents support of client and places staff at risk for back and arm injuries (Choi & Brings, 2015; Hallmark, Meachan, & Shores, 2015).*
- Help clients when wearing shoes with nonskid soles and socks/hose. Proper shoes help prevent slips/pain/pressure and improve balance. **EB:** *Suggest trying a running shoe that is comfortable and lightweight. A study found that there is inconclusive evidence that nonslip socks prevent falls as they do not adequately replace footwear and have the potential to spread infection; instead, clients should use personal footwear to prevent falls (Hartung & Lalonde, 2017).*
- Remove or swivel wheelchair armrests, leg rests, and footplates to the side, especially with squat or slide board transfers. This gives clients and nurses feet space in which to maneuver and provides fewer obstacles to trip over.
- Adjust transfer surfaces so that they are similar in height. For example, lower a hospital bed to about an inch higher than commode height. **EB:** *Similar heights between seat surfaces require less upper extremity muscular effort during transfers (Darragh et al, 2014).*
- Place wheelchair and commode at a slight angle toward the surface onto which the client will transfer. **EB:** *The two surfaces are close together yet allow room for the caregiver to adjust the client's movements during the transfer (Darragh et al, 2014).*
- Teach client to consistently lock brakes on wheelchair/commode/shower chair before transferring. **EB:** *Wheels will roll if not locked, creating risk for falls. Pneumatic wheelchair tires must be adequately inflated for brakes to lock effectively (Darragh et al, 2014; Choi & Brings, 2015).*
- Give clear, simple instructions, allow client time to process information, and let him or her do as much of the transfer as possible. **EB:** *Too much assistance by staff and family may decrease client learning, independence, self-care, and self-esteem (Choi & Brings, 2015).*
- ▲ Remind clients to comply with weight-bearing restrictions ordered by their health care provider. Weight-bearing may retard healing in fractured bones.
- Place client in set position before standing him or her, for example, sitting on edge of surface with bilateral weight-bearing on buttocks and hips, with knees flexed, balls of feet aligned under knees, and head in midline. **EB:** *This position prepares individuals for bearing weight and permits shifting of weight from pelvis to feet as the center of gravity changes while rising (Choi & Brings, 2015).*
- Support and stabilize client's weak knees by placing one or both of your knees next to or encircling client's knees, rather than blocking them. This allows client to flex his or her knees and lean forward to stand and transfer.
  - ❍ Squat transfer: client leans well forward, slightly raises flexed hips off the surface, pivots, and sits down on new surface.
  - ❍ Standing pivot transfer: client leans forward with hips flexed and pushes up with hands from seat surface (or arms of chair), then stands erect, pivots, and sits down on new surface.
  - ❍ Slide board transfer: client should have on pants or have a pillowcase over the board. Remove arm and leg rest from wheelchair on one side, then slightly angle chair toward new surface. Help client lean sideways, shifting his or her weight so the transfer board can be placed well under the upper thigh of the leg next to new surface. Make sure the board is safely angled across both surfaces. Help client to sit upright and place one hand on the board and the other hand on the surface. Remind and help client perform a series of pushups with arms while leaning slightly forward and lifting (not sliding) hips in small increments across the board with each pushup.

  EB: *Using different transfer techniques is necessary to facilitate clients who range from little to no weight-bearing ability (Darragh et al, 2014; Hallmark, Mechan, & Shores, 2015; Cameron et al, 2018).*
- Position walking aids appropriately so a standing client can grasp and use them once he or she is upright. **EB:** *These aids help provide support, balance, and stability to help client stand and step safely and, when used properly, can increase one's level of activity and participation (Bertrand et al, 2017).*
- Reinforce to clients who use walkers to place one hand on walker and push with opposite hand against chair arm or surface from which they are arising to stand up. Placing both hands on the walker may cause it to tip and the client to lose balance and fall.

- Use ceiling-mounted or bedside mechanical bariatric lifts to transfer dependent bariatric (extremely obese) clients. **EB:** *Lifting equipment reduces the risk of client/staff injury and is essential for clients who require a moderate/maximum assist transfer (Choi & Brings, 2015; Lee & Rempel, 2020).*
- Use bariatric devices and use available safe client handling equipment for lifting, transferring, positioning, and sliding client as an effective tool to reduce risk of injury from client handling (Choi & Brings, 2015; Lee & Lee, 2017).
- Place a mechanical lift sling in the wheelchair preventively. Place two transfer sheets or a slide board under the bariatric client. **EB:** *Reinforce that head should be leaning forward and that knees should be level with hips; help hold wheelchair in place as therapist directs/helps client with a scoot transfer. Client may be too fatigued to do a manual transfer back to bed after sitting, so sling/lift can be used (Choi & Brings, 2015; Lee & Lee, 2017).*
- Perform initial and subsequent fall risk assessment. Use standardized tools for fall risk assessment and interdisciplinary multifactorial interventions to reduce falls and risk of falling in hospitals. **EB:** *Best practice in falls reduction occurs when fall risk assessment; visual identification of individuals at high risk for falls; falls risk factor–directed interventions; and standardized multifactorial education, including visual tools for staff, families, and clients, are implemented (Low et al, 2015; Heng et al, 2020).*

▲ Collaborate with PT, OT, and pharmacist for individualized preventive/postfall plans; for example, scheduled toileting, balance and strength training, removal of hazards, chair alarms, call system/phone in reach, and review of medications. **EB:** *A systematic review of the evidence found that low-intensity exercise and incontinence care in residents in nursing homes reduced falls (Low et al, 2015; Hopkins et al, 2016).*

- Coordinate a follow-up encounter within 30 days of discharge from any inpatient facility with a licensed provider to perform a medication reconciliation, including all medications the client has been taking or receiving before the outpatient visit to provide quality care and improve quality of communication related to medications **EB:** *Review of medications, especially new medications added to a client plan of care, can help reduce risk for falls, changes in mentation, or mobility limitations (National Committee for Quality Assurance, 2015b).*
- Encourage an exercise component such as Tai chi, physical therapy, or another exercise for balance, gait, and strength training in group programs or at home.
- Integrate structured, progressive exercise protocols into a client's plan of care and innovative partnerships with other providers to create longer-duration interventions for clients at risk of falling. **EB:** *This promotes strength and aids in increasing confidence, thus reducing the risk of falling (Low et al, 2015).*
- Modify the environment for safety; recommend vision assessment and consideration for cataract removal.
- To reduce the risk of falling, assess the physical environment (e.g., poor lighting, high bed position, improper equipment). **EB:** *Continuous and intentional observational assessment of the environment promotes safety by reducing potential fall hazards (Low et al, 2015).*
- Recommend polypharmacy assessment with special consideration to sedatives, antidepressants, and drugs affecting the central nervous system; recommend evaluation for orthostatic hypotension and irregular heartbeats; and recommend vitamin D supplementation 800 international units/day (National Committee for Quality Assurance, 2015b).

Home Care

▲ Obtain referral for OT and PT to teach home exercises and balance and fall prevention and recovery. They also evaluate for potential modifications such as an entry ramp, elevated toilet seat/toilevator (raised base under toilet), tub seat or shower chair, need for shower stall with built-in seat or wheel-in shower stall without a curb/threshold, handheld flexible shower head, lever-type facets, pull-out drawers with loop handles versus cupboards, and standing lift. **EB:** *Interventions such as environmental modifications and assistive devices can reduce the risk of falling and promote independence by compensating for limitations in functional abilities (Putthinoi, Lersilp, & Chakpitak, 2017).*

- Develop a multifactorial/multicomponent interventions risk strategy to reduce the risk for falls that includes adaptation or modification of the home environment; withdrawal or minimization of psychoactive medications; withdrawal or minimization of other medications; management of postural hypotension; management of foot problems and footwear; and exercise, particularly balance, strength, and gait training (National Committee for Quality Assurance, 2015a).
- Assess for adequate lighting and hazards such as throw/area rugs, clutter, cords, and unfitted bedspreads. Suggest safe floor surfaces, such as use of adhesive nonslip strips in tubs, thresholds, and areas in which floor height changes; removal of wax from slippery floors; and installing low-pile carpet or nonglazed

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

or nonglossy tiles, wood, or linoleum coverings. Encourage relocating commonly used items to shelves/drawers in reach; applying remote controls to appliances; and optimizing furniture placement for function, maneuverability, and stability. **EB:** *Removing potential fall hazards and environmental barriers promotes safety and accessibility; steady furniture can be used to steady or pull oneself up if a fall occurs (Putthinoi, Lersilp, & Chakpitak, 2017; E et al, 2020; Lamb et al, 2020).*

- Assess clients for impairment of vision because this can result in a loss of function in activities of daily living and, consequently, result in impaired functional capacity and is an important risk factor for falls. **EB:** *Possible mechanisms to reduce activity restriction and improve mobility include environmental and behavioral interventions delivered by multiple types of health professionals, including OTs (E et al, 2020).*
- Nurses can provide further safety assessments by suggesting installing hand rails in bathrooms and by stairs, using slip-resistant floor surfaces, ensuring client's slippers and clothes fit properly, and recommending repairing or discarding broken equipment in the home (Keall et al, 2015; E et al, 2020).

▲ Involve social worker or case manager to educate clients about potential assistive technology, financial cost and benefits, regulations of payers, and local resources. **EB:** *Information helps clients understand options and cost of services in order to make informed decisions (Hamadi et al, 2018).*

▲ Implement approaches for home care staff and family to safely handle and transfer clients. Risk of injury is high because people often work alone, without mechanical aids or appropriate equipment such as mechanical beds and in crowded spaces, while providing care (*Hamadi et al, 2018*).

- For further information, refer to care plans for Impaired Physical **Mobility** and Impaired **Walking.**

Client/Family Teaching and Discharge Planning

- Assess for readiness to learn and use teaching modalities conducive to personal learning styles, including written instructions for home use.
- Supervise practice sessions in which client and family apply items such as gait belts, braces, and orthoses. Check skin once aids are removed. **EB:** *Repetition reinforces motor learning for safety and sound skin integrity (Low et al, 2015).*
- Teach and monitor client/family for consistent use of safety precautions for transfers (e.g., nonskid shoes, correctly placed equipment/chairs, locked brakes, leg rests swiveled away) and for correct performance of transfer or use of lifts/slings. *Promotes safety.*
- Teach client/family how to check brakes on chairs to ensure they engage and how to check tires for adequate air pressure; advise routine inspection and annual tune-up of devices. **EB:** *Long-term use may loosen brakes or cause them to slip; brakes work only if they make sound contact with tire or wheel. Pneumatic tires must be adequately inflated (Low et al, 2015).*
- Offer information on safe use of shower and commode chairs to prevent discomfort, pressure, and falls during transfer, transport, care, and hygiene.
- For further information, refer to the care plans for Impaired Physical **Mobility,** Impaired **Walking,** and Impaired Wheelchair **Mobility.**

T

Risk for Physical Trauma

Domain 11 Safety/protection Class 2 Physical injury

Julianne E. Doubet, BSN, RN, EMT-B

NANDA-I

Definition

Vulnerable to accidental tissue injury (e.g., wound, burn, fracture), which may compromise health.

Risk Factors

External

Absence of call for aid device; absence of stairway gate; absence of window guard; access to weapon; bathing in very hot water; bed in high position; children riding in front seat of car; defective appliance; delay in ignition

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

of gas appliance; dysfunctional call for aid device; electrical hazard (e.g., faulty plug, frayed wire, overloaded outlet/fuse box); exposure to corrosive product; exposure to dangerous machinery; exposure to radiation; exposure to toxic chemical; extremes of environmental temperature; flammable object (e.g., clothing, toys); gas leak; grease on stove; high-crime neighborhood; icicles hanging from roof; inadequate stair rails; inadequately stored combustible (e.g., matches, oily rags); inadequately stored corrosive (e.g., lye); insufficient lighting; insufficient protection from heat source; misuse of headgear (e.g., hard hat, motorcycle helmet); misuse of seat restraint; insufficient antislip material in bathroom; nonuse of seat restraints; obstructed passageway; playing with dangerous object; playing with explosive; pot handle facing front of stove; proximity to vehicle pathway (e.g., driveway, railroad track); slippery floor; smoking in bed; smoking near oxygen; struggling with restraints; unanchored electric wires; unsafe operation of heavy equipment (e.g., excessive speed while intoxicated with required eyewear); unsafe road; unsafe walkway; use of cracked dishware; use of throw rugs; use of unstable chair; use of unstable ladder; wearing loose clothing around open flame

Internal

Alteration in cognitive functioning; alteration in sensation (e.g., resulting from spinal cord injury, diabetes mellitus); decrease in eye–hand coordination; decrease in muscle coordination; economically disadvantaged; emotional disturbance; history of trauma (e.g., physical, psychological, sexual); impaired balance; insufficient knowledge of safety precautions; insufficient vision; weakness

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Risk Control; Fall Prevention Behavior

Example NOC Outcome with Indicators

Accomplishes **Risk Control** as evidenced by the following indicators: Acknowledges risk/Develops effective risk-control strategies/Follows selected risk control strategies. (Rate the outcome and indicators of **Risk Control:** 1 = never demonstrated; 2 = rarely demonstrated; 3 = sometimes demonstrated; 4 = often demonstrated; 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free from trauma
- Explain actions that can be taken to prevent trauma

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Environmental Management: Safety; Skin Surveillance

Example NIC Activities—Environmental Management

Provide family/significant other with information about making home environment safe for client; Remove harmful objects from the environment

T

Nursing Interventions and *Rationales*

- Provide vision aids for visually impaired clients. **EB:** *Low-vision rehabilitation enables people to restart and/or maintain the capability of performing the tasks of daily living (Virgili et al, 2013).* **EB:** *Electronic low vision aids have been linked to an improvement in the visually impaired client's psychological health and welfare (Garcia et al, 2017).*
- Assist the client with ambulation. Encourage the client to use assistive devices in activities of daily living (ADLs) as needed. **EB:** *Studies reviewed by Edelstein (2013) have shown the advantages, if used correctly, of using time-honored assistive devices (e.g., crutches, walker).* **EBN:** *According to the results of a study by Ali et al (2020), assistive devices can ease the effects of diminished day-to-day capabilities, plus add support for strength and flexibility, enhance motor control, and increase sensory function.*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

- Evaluate client's risk for burn injury. **CEBN:** *Grant (2013) stated that the very young and the elderly are at an increased risk for burn injuries compared with any other age group.* **EBN:** *It is apparent to Goodarzi et al (2014) in their research that there is a continuing need for further safety.* **EBN:** *Comparatively small burns can be a threat to the health status of elderly victims (Sheaffer, 2018).*
- Assess the client for causes of impaired cognition. **EB:** *Adults with intellectual disabilities are likely to have an elevated risk for traumatic injury compared with the general populace (Finlayson et al, 2014).* **EBN:** *The earlier that cognitive problems are recognized, the sooner the client can be referred for advanced evaluation, which will give them the opportunity to review possible reversible causes and the option to discuss their concerns (Scott & Mayo, 2018).*
- Provide assistive devices in the home. **EBN:** *According to Johnston et al (2014), shared conclusions between the health caregiver and the client with disabilities allows the client to choose the best assistive devices and services that are vital to achieving their goals of education, community living, and employment.* **EB:** *Health care professionals who assess for and advocate for assistive devices (ADs) for their clients should promote a mutual decision-making relationship with those same clients (Tuazon et al, 2019).*

▲ Question the client concerning his or her sense of safety. **EBN:** *In their study, Edwards et al (2014) stated that clients who wish to remain at home at the end of life are at increased risk for trauma caused by declining cognitive and/or physical capabilities, environmental dangers, and concerns with caregivers.* **EBN:** *Kenward et al (2017) advocate maintaining consistent quality care for clients so that nurses can be a factor in the decrease of clients' perceptions of being exposed and at risk.*

▲ Assess for a substance abuse problem and refer to appropriate resources for drug and alcohol education. **EB:** *According to Choi, DiNitto, and Marti (2016), older adults who abuse alcohol and/or illicit drugs should be sent to the most appropriate service that meets their needs, both for rehabilitation and for any mental health challenges that may be involved. Although drinking and driving among student drivers has declined in recent years, driving after the use of marijuana has increased; therefore, O'Malley and Johnston (2013) believed that more attention should be focused on preventing those under the influence of illicit drugs from driving.* **EBN:** *"Screening, Brief Intervention, and Referral to Treatment (SBIRT)" is an evidence-based intercession for those with symptoms of substance abuse (Thoele et al, 2020).*

- Review drug profile for potential side effects that may inhibit performance of ADLs. **EB:** *In their study of pain management in the elderly, Veal and Peterson (2015) found that older adults are at increased risk for detrimental medication side effects caused by changes in drug metabolism and due to polypharmacy that may put them at risk for drug interactions. A study by Graziano et al (2018) found that many medications taken by older clients have the potential to interact and may cause an exacerbation of symptoms and side effects.*
- See care plans for Risk for **Aspiration,** Risk for **Falls,** Impaired **Home** Maintenance, Risk for **Injury,** Risk for **Poisoning,** and Risk for **Suffocation.**

Pediatric

- Assess the client's socioeconomic status. **EB:** *The presently used evaluations that measure evidence of adverse childhood experiences may be insufficient to recognize the extent of adversity to which low-income urban children are exposed (Wade et al, 2014).* **EBN:** *As a consequence of children living with the threat of housing uncertainty, there is a good probability that they will have reduced opportunities to utilize the health care system, therefore triggering more emergency department visits and, in addition, impeded awareness of their basic physical and mental health care needs (Parry et al, 2020).*
- Never leave young children unsupervised. **EB:** *According to van Beelen et al (2014), the death, disability, and loss of quality of life among young children is directly related to injuries that occur in the home.* **EBN:** *Homes remain ripe locations for accidental mishaps, as they have numerous high-risk areas that could be lethal for children (e.g., windows, stairs, sharp objects, cleaning supplies) (Soares Silva et al, 2016).*
- Keep flammable and potentially flammable articles out of reach of young children. **EB:** *Infants and toddlers who scald themselves by spilling hot liquids on themselves or touching irons and hair straighteners are a main cause for concern for targeted prevention (Kemp et al, 2014).* **EBN:** *Hollywood and O'Neill (2014) maintained that nurses working with children in hospitals, schools, and the community can connect with parents, families, school staff, and children to offer professional advice and health and safety guidance for burn prevention.* **EB:** *Juškauskienė and Raškelienė (2018), in their review of studies concerning children's burns, found that the lack of supervision is a key issue in childhood thermal injuries and that the danger of injury is strongly associated with a deficiency in parental awareness.*
- Lock up harmful objects such as guns. **EB:** *Easy access to firearms in the home is responsible for injury to thousands of children in the United States (Barton & Kologi, 2015). There is an increased risk for childhood*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

injury when firearms are left loaded and unlocked (Schwebel et al, 2014). **EBN:** *Beal (2019), in her article concerning gun safety for children, states that nurses are essential to the research and prevention of pediatric firearm injuries and deaths.* **EB:** *Evidenced-based firearm restriction programs are necessary to decrease firearm morbidity and mortality in youth (Ngo et al, 2019).*

Geriatric

- Assess the geriatric client's cognitive level of functioning. **EB:** *Patel et al (2015) agreed that the occurrence of neurocognitive disorders can be an obstacle to the capability of older adults to perform ADLs and this deficit will continue to escalate with age.* **EB:** *Early interventions can hold back cognitive deterioration, help maintain functional capacities, and even postpone the need for long-term care (Evans, 2018).*
- Assess for routine eye examinations. **EBN:** *The older client may find it difficult to adjust to vision loss and aging because of the psychological, functional, social, and health implications that play a significant role in the process (Mac Cobb, 2013).* **EB:** *Vision diminishes with age in every racial and ethnic group (Umfress & Brantley, 2016).*
- Perform a home safety assessment and recommend the following preventive measures: keep electrical cords out of the flow of traffic; remove small rugs or make sure they are slip resistant; increase lighting in hallways and other dark areas; place a light in the bathroom; keep towels, curtains, and other items that might catch fire away from the stove; store harmful products away from food products; provide at least one grab bar in tubs and showers; check prescribed medications for appropriate labels; store medications in original containers or in a dispenser of some type (e.g., egg carton, 7-day plastic dispenser). If the client cannot administer medications according to directions, secure someone to administer medications. Mark stove knobs with bright colors (yellow or red) and outline the borders of steps. **CEBN:** *As part of a person-centered, evidence-based approach, a professional case manager/care coordinator can perform a thorough assessment of the client's needs and will design and put into operation an all-inclusive care plan to meet the clinical, psychosocial, and environmental requirements of the client (Johansson & Harkey, 2014).*
- Discourage driving at night. **EB:** *Gruber et al (2013) suggested that there is an increasing number of older adults who continue to drive, and the population of drivers who are affected by deteriorating night vision is increasing.* **EB:** *Early visual assessment may expose conditions that could impair driving skills (Cummings & Fernandez, 2020).*
- Encourage the client to participate in resistance and impact exercise programs as tolerated. **EB:** *In their review of current evidence, Carvalho et al (2014) suggested that physical activity may not only aid in improving cognitive function in older adults but could also play a part in delaying the development of cognitive impairment in the older adult.* **EBN:** *Niebauer et al (2018) noted that when age-adjusted exercise was introduced into geriatric day care, significant improvement was made in the clients' muscle strength and balance.*

Client/Family Teaching and Discharge Planning

- Educate the family regarding age-appropriate child safety precautions, environmental safety precautions, and intervention in an emergency. **EB:** *Safety education for parents of young children is essential in the prevention of accidental injuries in and/or around the home (van Beelen et al, 2013).* **EB:** *In their study, Morrongiello, McArthur, and Bell (2014) found that to decrease a child's risk of harm, the child must first understand the safety issue.* **EBN:** *Pediatric professionals will find it necessary to evaluate, ascertain, and employ interventions to combat the high rate of unintentional injuries that occur within the pediatric population, states Welch (2017).*
- Teach the family to assess the child care provider's knowledge regarding child safety. **EB:** *Home safety interventions not only aid in reducing children's injuries, but they also enhance the general safety of the home (Kendrick et al, 2013).* **EBN:** *Safeguarding and ensuring client safety is a critical component of competent health care delivery and includes both physical and psychosocial protection (Conroy et al, 2017).*
- Educate the client and family regarding helmet use during recreation and sports activities. **EB:** *It has been proven repeatedly that wearing a bicycle helmet has averted or reduced the risk of serious head injuries (Basch et al, 2014).* **EB:** *Opinions about helmet utilization can fluctuate depending on the cyclist and also due to culturally associated dynamics; assessment of attitudes in particular areas and within distinct populations will afford an enhanced basis for designing interventions (Ledesma et al, 2019).*
- Encourage the proper use of car seats and safety belts. **EB:** *Himle and Wright (2014) stated that child passenger safety restraint, when used correctly, can diminish the risk of severe injury and/or death in motor vehicle crashes.* **EB:** *According to Sicinska and Dabrowska-Loranc (2018), vehicle safety restraints for both children and adults are the easiest and most efficient passive safety devices that will significantly reduce injuries during an accident.*

T

- Teach parents to restrict driving for teens. **EB:** *According to Taubman-Ben-Ari et al (2014), research studies have shown that parents are the most important influence on young people's driving conduct.* **EB:** *Findings by Naz and Scott-Parker (2017) imply that parents of teens need to be knowledgeable about the consequences of their involvement in the teen's driver's licensing process, the importance of coaching, and their own driving performance.*
- Teach parents the importance of monitoring children after school. **EB:** *In a study by Freisthler et al (2014), children who are not supervised appropriately, either by inattentive parents and/or caregivers, could be considered neglected.* **EB:** *Smith and Bradshaw (2017) note that afterschool programs are developing into strategic settings for the avoidance of problem conduct for unsupervised youth and that they also play a role in the formation of positive behavior.*
- Teach firearm safety. **EB:** *According to Schwebel et al (2014), firearms in the home that are loaded and unlocked are sources of increased risks for trauma.* **EB:** *Health care professionals must have knowledge and skills to address safe gun ownership in older adults (Pinholt et al, 2014).* **EBN:** *Nurses, no matter what their specialty, can influence others with their competence and concern and help solve the problem of gun safety (Kronebusch, 2020).*
- For further information, refer to care plans for Risk for **Aspiration,** Risk for **Falls,** Impaired **Home** Maintenance, Risk for **Injury,** Risk for **Poisoning,** and Risk for **Suffocation.**

Unilateral Neglect

Domain 5 Perception/cognition Class 1 Attention

Wendy R. Worden, MS, APRN, CNS, CRRN, CWCN

NANDA-I

Definition

Impairment in sensory and motor response, mental representation, and spatial attention of the body, and the corresponding environment, characterized by inattention to one side and overattention to the opposite side. Left-side neglect is more severe and persistent than right-side neglect.

Defining Characteristics

Altered safety behavior on neglected side; disturbed sound lateralization; failure to dress neglected side; failure to eat food from portion of plate on neglected side; failure to groom neglected side; failure to move eyes in the neglected hemisphere; failure to move head in the neglected hemisphere; failure to move limbs in the neglected hemisphere; failure to move trunk in the neglected hemisphere; failure to notice people approaching from the neglected side; hemianopsia; impaired performance on line bisection tests; impaired performance on line cancellation tests; impaired performance on target cancellation tests; left hemiplegia from cerebrovascular accident; marked deviation of the eyes to stimuli on the non-neglected side; marked deviation of the trunk to stimuli on the non-neglected side; omission of drawing on the neglected side; perseveration; representational neglect; substitution of letters to form alternative words when reading; transfer of pain sensation to the non-neglected side; unaware of positioning of neglected limb; unilateral visuospatial neglect; uses vertical half of page only when writing

Related Factors

To be developed

Associated Conditions

Brain injuries

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Body Image; Body Positioning: Self-Initiated; Mobility; Self-Care: Activities of Daily Living (ADLs)

Example NOC Outcome with Indicators

Mobility as evidenced by the following indicators: Balance/Coordination/Gait/Muscle movement. (Rate the outcome and indicators of **Mobility:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Use techniques that can be used to minimize unilateral neglect (UN)
- Care for both sides of the body appropriately and keep affected side free from harm
- Return to the highest functioning level possible based on personal goals and abilities
- Remain free from injury

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Unilateral Neglect Management

Example NIC Activities—Unilateral Neglect Management

Ensure that affected extremities are properly and safely and positioned; Rearrange the environment to use the right or left visual field

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Nursing Interventions and *Rationales*

▲ Assess the client for signs of UN (e.g., not washing, shaving, or dressing one side of the body; sitting or lying inappropriately on affected arm or leg; failing to respond to environmental stimuli contralateral to the side of lesion; eating food on only one side of plate; reading words on one side of the page; or failing to look to one side of the body). **EB:** *Many tests for UN exist, but there is no consensus about which is the most valid. Joint assessments that include clinical observation, behavioral assessment, and precise testing perform better than any used individually (Azouvi, 2017; Grattan & Woodbury, 2017).* **EB:** *Single use of the National Institutes of Health Stroke Scale (NIHSS) led to underdiagnosis of UN in 56% of cases. In one study, 72.8% of clients had UN on admission to inpatient rehabilitation (Puig-Pijoan et al, 2018; Tarvonen-Schröder et al, 2020).*

▲ Collaborate with health care provider for referral to a rehabilitation team (including, but not limited to, rehabilitation clinical nurse specialist, physical medicine and rehabilitation health care provider, neuropsychologist, occupational therapist, physical therapist, and speech and language pathologist) for continued help in dealing with UN. **EB:** *There is some evidence that rehabilitation for unilateral spatial neglect using tools such as visual scanning and prism adaptation improves function, but their effect on disability is not clear (Gillen et al, 2015).* **EB:** *Challenging the client in the complexity of everyday tasks and environments can assist clients in physical and cognitive recovery (Brown & Powell, 2017).*

● Use the principles of rehabilitation to progressively increase the client's ability to compensate for UN by using assistive devices, feedback, and support. **EB:** *Studies demonstrated that recovery from UN generally resolves within 1 month of stroke, but it can still be detectable after 3 months and/or at discharge from inpatient rehabilitation (Chen et al, 2015).*

● Teach the client to be aware of the problem and modify behavior and environment. **EB:** *Awareness of the environment decreases risk of injury. There is some evidence that use of virtual environment therapy aids the client in creating some independence to perform everyday tasks such as crossing the street (Conti & Arnone, 2016).*

● Set up the environment so that essential activity is on the unaffected side:
  ❍ Place the client's personal items within view and on the unaffected side.
  ❍ Position the bed so that client is approached from the unaffected side.
  ❍ Monitor and assist the client to achieve adequate food and fluid intake.

  Helps in focusing attention and aids in maintenance of safety.

● Implement fall prevention interventions as clients with right hemisphere brain damage are twice as likely to fall as those with left hemisphere damage. **EB:** *Clients with impaired balance, decreased mobility, depression, and reduced safety awareness after stroke have higher fall rates than the general population (Xu et al, 2018).*

● Position affected extremity in a safe and functional manner. **EB:** *A study found that poststroke musculoskeletal pain, shoulder subluxation, spasticity, and joint contracture were among the most common complications during the subacute and chronic stages (15 days to >3 months) (Paolucci et al, 2016).* **EB:** *One study found that in stroke survivors with visuospatial neglect or an affected left arm, use of vision as a strategy does not help compensate for impaired position sense (Herter, Scott, & Dukelow, 2019).*

▲ Collaborate closely with rehabilitation professionals to identify and reinforce therapies aimed at reducing neglect symptoms. **EB:** *Techniques such as repeated scanning, visual cuing approaches, virtual reality, limb activation strategies, prisms, mirror therapy, mental imagery, music, neck vibration, and transcranial magnetic stimulation are being used to treat UN (Winstein et al, 2016), but the evidence is limited and inconclusive on the most effective approach (Azouvi, Jacquin-Courtois, & Luauté, 2017).*

Home Care

● Many of the previously listed interventions may be adapted for use in the home care setting.

● Position bed at home so that client gets out of bed on unaffected side. *Positioning the bed so that the client gets out on the unaffected side can increase safety.*

Client/Family Teaching and Discharge Planning

● Engage discharge planning specialists for comprehensive assessment and planning early in the client's stay. **EB:** *Clients with UN have longer lengths of stay and are more disabled due to functional motor and cognitive impairments (Spaccavento et al, 2017).*

● Encourage family participation in care to promote safety. **EB:** *One study found that safety issues (falls, crossing the street, driving) become problematic and related to lower levels of independence (Conti & Arnone, 2016).*

- Explain pathology and symptoms of UN to both the client and family. Family members may not understand that inattention is a complication of the neurological injury.
- Teach the client how to scan regularly to check the position of body parts and to regularly turn head from side to side for safety when ambulating, using a wheelchair, or doing self-care tasks. **EB:** *In one study, incorporating task-specific treatments, such as eating food from a plate and grooming, improved functional outcome and reduced neglect symptoms (Patole et al, 2015).*
- Teach caregivers to cue the client to the environment.

Impaired Urinary Elimination

Domain 3 Elimination and exchange Class 1 Urinary function

Kenneth J. Oja, PhD, RN

U

NANDA-I

Definition

Dysfunction in urine elimination.

Defining Characteristics

Dysuria; frequent voiding; nocturia; urinary hesitancy; urinary incontinence; urinary retention; urinary urgency

Related Factors

Alcohol consumption; altered environmental factor; caffeine consumption; environmental constraints; fecal impaction; improper toileting posture; ineffective toileting habits; insufficient privacy; involuntary sphincter

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

relaxation; obesity; pelvic organ prolapse; smoking; use of aspartame; weakened bladder muscle; weakened supportive pelvic structure

At-Risk Population

Older adults; women

Associated Conditions

Anatomic obstruction; diabetes mellitus; sensory motor impairment; urinary tract infection

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Urinary Elimination

Example NOC Outcome with Indicators

Urinary Elimination as evidenced by the following indicators: Urine clarity/urine odor, fluid intake, pain with urination. (Rate the outcome and indicators of **Urinary Elimination:** 1 = severely compromised 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State absence of pain or excessive urgency during urination
- Demonstrate voiding frequency no more than every 2 hours

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Urinary Elimination Management

Example NIC Activities—Urinary Elimination Management

Monitor urinary elimination, including frequency, consistency, odor, volume, and color, as appropriate; Teach client signs and symptoms of urinary tract infection (UTI)

Nursing Interventions and *Rationales*

- Ask the client about urinary elimination patterns and concerns. **EB:** *Urinary elimination problems have many presenting signs and symptoms. Asking the client questions may help understand the subtle signs and symptoms associated with urinary elimination (Mayo Clinic, 2020).*
- Question the client regarding the following:
  - Presence of symptoms such as incontinence, dribbling, frequency, urgency, dysuria, and nocturia
  - Presence of pain in the area of the bladder
  - Pattern of urination and approximate amount
  - Possible aggravating and alleviating factors for urinary problems
- Ask the client to keep a bladder diary/bladder log. **EB:** *Use of a bladder diary may provide the client with insight into their urinary patterns, afford them the opportunity to participate purposefully in their treatment plan, and assist them in identifying techniques to manage their symptoms (Dixon & Nakib, 2016).*
- For interventions on urinary incontinence, refer to the following nursing diagnosis care plans as appropriate: Stress Urinary **Incontinence,** Urge Urinary **Incontinence,** Reflex Urinary **Incontinence,** Overflow Urinary **Incontinence,** or Functional Urinary **Incontinence.**

▲ Perform a focused physical assessment including inspecting the perineal skin integrity, percussion, and palpation of the lower abdomen looking for obvious bladder distention or an enlarged kidney. **EB:** *A palpable kidney or bladder provides direct evidence of a dilated urinary collection system (Policastro, 2016).*

U

▲ If signs of urinary obstruction are present, refer client to a urologist. **EB:** *Unrelieved obstruction of urine can result in renal damage and, if severe, renal failure (Policastro, 2016). Refer to the nursing care plan for Urinary Retention if retention is present.*

● Check for costovertebral tenderness. **EB:** *Costovertebral tenderness is seen with pyelonephritis and kidney stones (Gupta & Trautner, 2015; Pietrucha-Dilanchian & Hooton, 2016).*

▲ Review results of urinalysis for the presence of urinary infection such as white blood cells, red blood cells, bacteria, and positive nitrites. **EB:** *If urinalysis results are not available, request a midstream specimen of urine (urine obtained during voiding, discarding the first and last portions) for a urinalysis (Pietrucha-Dilanchian & Hooton, 2016).*

▲ If blood or protein is present in the urine, recognize that both hematuria and proteinuria are serious symptoms, and the client should be referred to a urologist to receive a workup to rule out pathology.

● Inquire about the client's history of smoking. **EB:** *Bladder symptoms such as incomplete emptying, frequency, intermittency, urgency, weak stream, straining, and nocturia may be higher among clients who smoke or who have smoked in the past (Pethiyagoda & Pethiyagoda, 2016).*

Urinary Tract Infection

▲ Consult the provider for culture and sensitivity testing and antibiotic treatment in the individual with evidence of a symptomatic UTI. **EB:** *UTI is a transient, reversible condition that is usually associated with urgency or urge urinary incontinence (Nicolle & Norrby, 2016). Eradication of UTI will alleviate or reverse symptoms of suprapubic pressure and discomfort, urgency, daytime voiding frequency, and dysuria (Nicolle & Norrby, 2016).*

▲ Teach the client to recognize symptoms of UTI, such as dysuria that crescendos as the bladder nears complete evacuation; urgency to urinate followed by micturition of only a few drops; suprapubic aching discomfort; malaise; voiding frequency; and sudden exacerbation of urinary incontinence with or without fever, chills, and flank pain. Recognize that cloudy or malodorous urine, in the absence of other lower urinary tract symptoms, may not indicate the presence of a UTI and that asymptomatic bacteriuria in the older adult does not justify a course of antibiotics. **EB:** *Laboratory tests alone cannot distinguish between asymptomatic bacteriuria and infection. Thus, providers need to be cautious in prescribing antibiotics based on nonspecific findings. Recognizing asymptomatic bacteriuria decreases inappropriate administration of antibiotics in the older adult population preventing adverse drug events and polypharmacy (Cortes-Penfield, Trautner, & Jump, 2017).*

▲ Refer the individual with chronic lower urinary tract pain to a urologist or specialist in the management of pelvic pain. **EB:** *Bladder pain and storage symptoms, in the absence of an acute urinary infection, may indicate the presence of interstitial cystitis, which is a chronic condition requiring ongoing treatment (Interstitial Cystitis Association, 2019).*

Pediatric

● Initial management of childhood urinary incontinence: (1) thorough history and physical examination; (2) bladder diary; (3) urinalysis; (4) urinary tract ultrasound; (5) screening for behavioral problems (Maternik, Krzeminska, & Zurowska, 2015).

● Standard practice recommendations when caring for pediatric clients include an aggressive bowel regimen, timed voiding, and escalating urotherapy with biofeedback. Medications may be considered as a secondary measure (Arlen, 2017).

● Encourage children to void on a timed schedule every 2 hours, void two times with every void, drink two bottles of water during and after school, stop drinking 2 hours before bed, and void two times before bed. **EBN:** *Providing children with a simplified approach helps them to better understand, practice, and comply with urotherapy guidelines. With the "Rule of 2," all urotherapy guidelines are presented using the number 2 so that children can easily remember what to do (Marcella, 2019).*

Geriatric

● Evidence for behavioral interventions include the following: (1) Prompted voiding is suitable for older adult clients, with or without cognitive impairment, who have a consistent caregiver; (2) prompted voiding is unsuccessful in clients who require more than one person for transfers, are not able to follow one-step commands, and a successful toileting rate of less than 66% after a 3-day prompted voiding trial; and (3) a key factor in the success of prompted voiding is caregiver education (Newman, 2019).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Encourage older women to consume one to two servings of fresh blueberries and consider drinking at least 10 ounces of cranberry juice daily or supplement the diet with cranberry concentrate capsules as ordered. **EB:** *There is an ongoing debate about the effectiveness of using cranberry products to prevent UTIs (Gupta, Grigoryan, & Trautner, 2017). However, some evidence suggests that cranberry products may have a protective effect against UTIs (Foxman et al, 2015; Luis, Domingues, & Pereira, 2017).*

▲ Refer the older woman with recurrent UTIs to her health care provider for possible use of topical estrogen creams for treatment of atrophic vaginal mucosa from decreased hormonal stimulation, which can predispose to UTIs (Nicolle & Norrby, 2016).

- Postresidual volumes (PRVs) should be assessed in older women with overactive bladder (OAB). A volume of greater than 200 mL is significant. **EB:** *A history of back or pelvic injury or surgery increases the risk of greater PRV (Park & Palmer, 2015; Porritt, 2019).*

▲ Recognize that UTIs in older men are typically associated with prostatic hyperplasia or strictures of the urethra. Refer the client to a urologist (Nicolle & Norrby, 2016).

- Analysis of urinary elimination patterns of clients could help in clinical follow-up of elderly postoperative clients and in the selection of best nursing interventions. **EB:** *A study exploring NOC indictor interrater reliability showed classifications can be useful for monitoring clinical changes related to urinary elimination. High agreements for the indicators of urine odor, leukocytes, nitrates, blood, painful urination, and urinary continence were found (Ribeiro Bitencourt et al, 2016).*
- Frailty, not age, should guide urinary elimination treatment decisions. **EB:** *Caring for individuals with urinary incontinence and cognitive impairment needs to be tailored to the individual's abilities (Newman, 2019).*
- Managing incontinence-associated dermatitis in the geriatric population involves regular, ongoing skin assessments to identify damaged skin as well as areas for potential skin damage. **EBN:** *Cleanse and carefully dry the skin as soon as possible after each episode of incontinence. Use a skin product that is designed to protect against excess moisture and increased damage to the skin. Address causative factors of incontinence before using invasive approaches such as urinary catheters. Educate the client on the care and prevention of incontinence-associated dermatitis (Lumbers, 2019).*

Client/Family Teaching and Discharge Planning

- Teach the client/family methods to keep the urinary tract healthy. Refer to Client/Family Teaching in the care plan for Readiness for Enhanced **Urinary** Elimination.
- Teach the following measures to women to decrease the incidence of UTIs:
  - ❍ Urinate at appropriate intervals. Do not ignore need to void, which can result in stasis of urine.
  - ❍ Drink plenty of liquids, especially water.
  - ❍ Wipe from front to back. This helps prevent bacteria in the anal region from spreading to the vagina and urethra.
  - ❍ Wear underpants that have a cotton crotch. This allows air to circulate in the area and decreases moisture in the area, which predisposes to infection.
  - ❍ Avoid potentially irritating feminine products.

  EB: *Drinking water helps dilute the urine, allowing bacteria to be flushed from the urinary tract before an infection can begin (Nicolle & Norrby, 2016).* **EB:** *Using deodorant sprays, bubble baths, or other feminine products, such as douches and powders, in the genital area can irritate the urethra. There are multiple commonsense measures that can be used to decrease the incidence of UTIs (Gupta & Trautner, 2015; Mayo Clinic, 2020).*
- Teach the sexually active woman with recurrent UTIs prevention measures:
  - ❍ Void after intercourse to flush bacteria out of the urethra and bladder.
  - ❍ Use a lubricating agent as needed during intercourse to protect the vagina from trauma and decrease the incidence of vaginitis.
  - ❍ Watch for signs of vaginitis and seek treatment as needed.
  - ❍ Avoid use of diaphragms with spermicide.

  EB: *Sexually active women have the highest incidence of UTIs (Nicolle & Norrby, 2016). The vagina and periurethral area can become colonized with organisms from the intestinal flora, such as* Escherichia coli, *and increase the risk for UTIs (Gupta & Trautner, 2015; Pietrucha-Dilanchian & Hontoon, 2016).*

U

- Teach clients with spinal cord injury and neurogenic bladder dysfunction to consider adding cranberry extract tablets or cranberry juice or fruits containing D-mannose (e.g., apples, oranges, peaches, blueberries) on a daily basis and to monitor fluid intake. The client is encouraged to discuss the use of probiotics and antibiotic therapy with the provider for frequent recurrent symptomatic UTIs. **EB:** *Limited evidence suggested that clients who regularly consume cranberry extract tablets experience fewer UTIs than clients who do not routinely consume cranberry extract tablets (Foxman et al, 2015; Luis, Domingues, & Pereira, 2017). Additionally, clients with spinal cord injury and neurogenic bladder dysfunction are at higher risk for UTI, and more frequent monitoring of symptomatic infection is necessary (Brusch, 2018; Castle et al, 2018).*
- Teach all persons to recognize hematuria and to promptly seek care if this symptom occurs.

Urinary Retention

Domain 3 Elimination and exchange Class 1 Urinary function

Kenneth J. Oja, PhD, RN

NANDA-I

Definition

Incomplete emptying of the bladder.

Defining Characteristics

Absence of urinary output; bladder distention; dysuria; increased daytime urinary frequency; minimal void volume; overflow incontinence; reports sensation of bladder fullness; reports sensation of residual urine; weak urine stream

Related Factors

Environmental constraints; fecal impaction; improper toileting posture; inadequate relaxation of pelvic floor muscles; insufficient privacy; pelvic organ prolapse; weakened bladder muscle

At-Risk Population

Puerperal women

Associated Conditions

Benign prostatic hyperplasia; diabetes mellitus; nervous system diseases; pharmaceutical preparations; urinary tract obstruction

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Urinary Elimination

Example NOC Outcome with Indicators

Urinary Elimination as evidenced by the following indicators: Empties bladder completely/Absence of urinary leakage/Urine clarity. (Rate the outcome and indicators of **Urinary Elimination:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate consistent ability to urinate when desire to void is perceived
- Have measured urinary residual volume of less than 300 mL
- Experience correction or relief from dysuria, nocturia, postvoid dribbling, and voiding frequently
- Be free of a urinary tract infection

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Urinary Catheterization; Urinary Retention Care

Example NIC Activities—Urinary Retention Care

Perform a comprehensive urinary assessment focusing on incontinence (e.g., urinary output, urinary voiding pattern, cognitive function, and preexistent urinary problems); Use the power of suggestion by running water or flushing toilet

U

Nursing Interventions and *Rationales*

- Obtain a focused urinary history including questioning the client about episodes of acute urinary retention (UR; complete inability to void) or chronic retention (documented elevated postvoid residual volumes), as well as symptoms such as dysuria, nocturia, postvoid dribbling, and voiding frequently. **EB:** *A history of pain, changes in the amount of urine produced, difficulty urinating, blood in the urine, repeated urinary tract infections, or hypertension may be signs of urinary obstruction (Mayo Clinic, 2020).*
- Question the client concerning specific risk factors for UR:
  - Medications, including antispasmodics/parasympatholytics, alpha-adrenergic agonists, antidepressants, sedatives, narcotics, psychotropic medications, illicit drugs
  - Vaginal delivery within the past 48 hours
  - Bowel elimination patterns, history of fecal impaction, encopresis
  - Metabolic disorders such as diabetes mellitus, chronic alcoholism, and related conditions associated with polyuria and peripheral polyneuropathies
  - Spinal cord injuries
  - Ischemic stroke
  - Herpetic infection
  - Heavy-metal poisoning (lead, mercury) causing peripheral polyneuropathies
  - Advanced stage HIV infection
  - Recent surgery requiring general or spinal anesthesia
  - Recent surgical procedures
  - Recent prostatic biopsy

  EB: *UR is related to multiple factors affecting either detrusor contraction strength or urethral resistance to urinary outflow (Policastro, 2016).*
- Complete a pain assessment including pain intensity using a self-report pain tool, such as the 0 to 10 numerical pain rating scale. Also determine location, quality, onset/duration, intensity, aggravating/alleviating factors, and effects of pain on function and quality of life. **EB:** *Acute onset of obstruction with inability to void is associated with significant pain; partial obstruction causes minimal pain, which may delay diagnosis (Policastro, 2016). Symptoms of bladder distention may include difficulty urinating, a constant feeling that the bladder is full, a slow stream of urine, abdominal pain, urinary incontinence, or waking in the night to urinate (Young, 2018).*
- Perform a focused physical assessment including perineal skin integrity and inspection, percussion, and palpation of the lower abdomen, looking for obvious bladder distention or an enlarged kidney. **EB:** *A palpable kidney or bladder provides direct evidence of a dilated urinary collection system (Policastro, 2016).*
- Recognize that unrelieved obstruction of urine can result in kidney damage and, if severe, kidney failure. UR can be a medical emergency and should be reported to the primary provider as soon as possible. **EB:** *As urine backs up in the urinary tract, the pressure increases inside the ureters, which results in pressure on the nephrons, damaging the nephrons and decreasing glomerular blood flow (Policastro, 2016).*
- Review laboratory test results, including serum electrolytes, blood urea nitrogen (BUN), and creatinine, along with calcium, phosphate, magnesium, uric acid, and albumin. **EB:** *Serum electrolytes (sodium, potassium, chloride, bicarbonate, BUN, and creatinine) and calcium, phosphate, magnesium, uric acid, and albumin should be measured. Elevations of BUN and creatinine and changes in electrolytes may be caused by kidney failure secondary to obstruction (Policastro, 2016).*
- Monitor for signs of dehydration, peripheral edema, elevated blood pressure, and heart failure. **EB:** *The kidney can develop concentrating defects associated with partial obstruction of urine flow, resulting in symptoms that indicate kidney insufficiency (Policastro, 2016).*
- Ask the client to complete a bladder diary including patterns of urine elimination, urine loss (if present), nocturia, and volume and type of fluids consumed for a period of 3 to 7 days.
- ▲ Consult with the health care provider concerning eliminating or altering medications suspected of producing or exacerbating UR.
- Both men and women may develop UR from obstruction of the bladder outlet and abnormalities in detrusor contractility. **EB:** *A common cause of bladder outlet obstruction (BOO) is caused by prostate/bladder neck enlargement, urethral stricture, vaginal vault prolapse, obstructing urethral sling, or impacted stool. Long-term use of medications such as alpha-agonists and tricyclic antidepressants contributes to the problem (Stoffel et al, 2016).* **EB:** *Assess for postresidual void (PVR) greater than 300 mL because it is the minimal volume at which a bladder becomes palpable (Stoffel et al, 2016).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- In clients treated with an indwelling urethral catheter (IUC), complications such as catheter-associated urinary tract infections are common, whereas underuse of IUC may cause harmful UR. **EB:** *A quality improvement (QI) program aimed at staff ability to identify and manage client risk, prevention, and treatment of UR optimizes appropriate IUC use (Andersson et al, 2017).*
- Advise the male client with UR related to benign prostatic hyperplasia (BPH) to avoid risk factors associated with acute UR:
  - Avoid over-the-counter (OTC) cold remedies containing a decongestant (alpha-adrenergic agonist) or antihistamine, such as diphenhydramine, which has anticholinergic effects.
  - Avoid taking OTC dietary medications (frequently contain alpha-adrenergic agonists).
  - Discuss voiding problems with a health care provider before beginning new prescription medications.
  - After prolonged exposure to cool weather, warm the body before attempting to urinate.
  - Avoid overfilling the bladder by regular urination patterns and refrain from excessive intake of alcohol.

  EB: *Botulinum toxin injection into the bladder neck is a promising minimally invasive, tolerated, and cost-effective approach for the treatment of UR in clients with benign prostatic obstruction who are not candidates for surgery and for whom medical treatments have failed (Alam et al, 2016). These modifiable factors predispose the client to acute UR by overdistending the bladder and decreasing muscle contraction (Mayo Clinic, 2021).*
- Advise the client who is unable to void of specific strategies to manage this potential medical emergency as follows:
  - Attempt urination in complete privacy.
  - Place the feet solidly on the floor.
  - If unable to void using these strategies, take a warm sitz bath or shower and void (if possible) while still in the tub or shower.
  - Drink a warm cup of caffeinated coffee or tea to stimulate the bladder, which may promote voiding.
  - If unable to void within 6 hours or if bladder distention is producing significant pain, seek urgent or emergency care.

  EB: *Attempting urination in complete privacy and placing the feet solidly on the floor help relax the pelvic muscles and may encourage voiding. Warm water also stimulates the bladder and may produce voiding; the cooling experienced by leaving the tub or shower may again inhibit the bladder (Porritt, 2019).*
- Perform sterile (in acute care) or clean intermittent catheterization at home as ordered for clients with UR. Refer to care plan for Reflex Urinary **Incontinence** for more information about intermittent catheterization.

▲ Insert an indwelling catheter only as ordered by a health care provider. Understand the indication for the urinary catheter to be placed as part of client management. Catheter-associated urinary tract infections (CAUTIs) are among the most common health care–associated infections and result in unnecessary health care costs. A CAUTI also increases the risk of a bloodstream infection. **EB:** *Although certain conditions among hospitalized clients may require the use of a urinary catheter, limiting their use and decreasing the length of use are the most effective methods of reducing clients' exposure to CAUTIs (American Academy of Nursing, 2018).*

- Nurse-led and computer-based reminders are both successful in reducing how long urinary catheters remain in place (Timmons et al, 2017).
- Nurse-driven practice recommendations to reduce CAUTI risk include securing catheters; maintaining drainage bags lower than level of bladder; emptying drainage bags every 8 hours, when two-thirds full, and before any transfer; daily evaluation of catheter indication/need to promote removal; and use of bladder scanner to prevent reinsertion. **EB:** *Incorporating practice policies that use nurse-driven catheter practices appear to have a positive impact on the clinical predictors and prevalence of CAUTIs (Durant, 2017).*
- Current practice recommendations support aseptic catheter insertions, whereas the use of hydrophilic-coated catheters for clean intermittent catheters can reduce the rate of CAUTIs. Suprapubic catheterization is not more effective than urethral catheterization in reducing the incidence of catheter-related bacteremia. **EB:** *Evidence does not support routine use of antimicrobial-impregnated catheters to prevent CAUTIs (Majeed et al, 2019).*
- For the individual with UR who is not a suitable candidate for intermittent catheterization, recognize that the catheter can be a significant cause of harm to the client through development of a CAUTI or through genitourinary trauma when the catheter is pulled. **EB:** *An indwelling catheter provides continuous drainage of urine; however, the risks for serious urinary complications, such as chronic CAUTIs, with prolonged use*

are significant (Porritt, 2019). **EB:** *One study identified that complications associated with urethral catheters can be infectious and noninfectious including UTI, pain or discomfort, trauma to the skin related to catheter securement or placement, and bladder or kidney stones (Saint et al, 2018).* **EBN:** *Indwelling urinary catheters are associated with up to 80% of hospital-acquired CAUTIs. Appropriate use of bladder ultrasonography can reduce the rate of bladder damage and the need to use catheters. Incorporating bladder ultrasonography into the client's assessment can lead to decreased use of urinary catheter and rate of CAUTIs, lower risk for spread of multiresistant gram-negative bacteria, and lower hospital costs (Guadarrama Ortega et al, 2020).*

- Advise clients with indwelling catheters that bacteria in the urine is an almost universal finding after the catheter has remained in place for more than 1 week and that only symptomatic infections warrant treatment. **EB:** *The long-term indwelling catheter is inevitably associated with bacterial colonization, with formation of biofilm on the catheter surfaces (Nicolle & Norrby, 2016).*
- Use the following strategies to reduce the risk for CAUTI whenever feasible:
  - Insert the indwelling catheter with sterile technique, only when insertion is indicated.
  - Remove the indwelling catheter as soon as possible; acute care facilities should institute a policy for regular review of the necessity of an indwelling catheter.
  - Maintain a closed drainage system whenever feasible.
  - Maintain unobstructed urine flow, avoiding kinks in the tubing and keeping the collecting bag below the level of the bladder at all times.
  - Regularly cleanse the urethral meatus with a gentle cleanser to remove apparent soiling.
  - Change the long-term catheter every 4 weeks; more frequent catheter changes should be reserved for clients who experience catheter encrustation and blockage.
- Educate staff about the risks for CAUTI development and specific strategies to reduce these risks. **EB:** *These strategies are supported by sufficient evidence to recommend routine use (Gould et al, 2019). Numerous nursing studies have demonstrated that nurse-controlled methods to decrease the length of catheterization such as chart reminders and computerized interventions lead to decreased incidences of CAUTI (Durant, 2017).*

Postoperative Urinary Retention

- UR is a common complication of surgery, anesthesia, and advancing age. If conservative measures do not help the client pass urine, the bladder needs to be drained using either an intermittent catheter or IUC, which places the client at risk for development of CAUTI (Lee et al, 2017). **EB:** *A study demonstrated decreased risk of UTI and repeat UR episodes after transurethral resection of the prostate in clients with benign prostatic hyperplasia (BPH) (Lin et al, 2018).*
- Remove the IUC at midnight in the hospitalized postoperative client to reduce the risk for acute UR.
- Perform a bladder scan before considering inserting a catheter to determine PVR volume after surgery. **EBN:** *A study in postoperative clients demonstrated a significant decrease in the number of catheterizations when ultrasonic bladder scanning was done to monitor postoperative UR (Daurat et al, 2015).* **EB:** *A retrospective cohort study of 803 clients who underwent unilateral hip or knee arthroplasty were evaluated for postoperative urinary retention (POUR). Following a nurse-led routine bladder scan protocol postoperatively found a 12.9% incidence of POUR that was treated with a nurse-led intervention and reduced recovery room time (Kort et al, 2018).*
- Spinal anesthesia is a risk factor associated with postoperative urinary retention (Bjerregaard et al, 2015).

Geriatric

- Aggressively assess older clients, particularly those with dribbling urinary incontinence, urinary tract infection, and related conditions, for UR. **EB:** *Older women and men may experience UR with few or no apparent symptoms; a urinary residual volume and related assessments are necessary to determine the presence of retention in this population. Providing routine skin care and scheduled voiding can reduce risks of skin breakdown and/or infections associated with urinary incontinence (Podder, 2019).* **EBN:** *A cohort study of 4061 older adults living in nursing homes found that older individuals with involuntary leakage of urine experienced a 24% increased risk of falls and 11% increase risk of mortality associated with urinary incontinence (Damián et al, 2017).*
- Assess older clients for impaction when UR is documented or suspected; monitor older male clients for retention related to BPH or prostate cancer. Prostate enlargement in older men increases the risk for acute and chronic UR.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Home Care

- Encourage the client to report any inability to void.
- Maintain an up-to-date medication list; evaluate side-effect profiles for risk of UR. New medications or changes in dose may cause UR.

▲ Refer the client for health care provider evaluation if UR occurs. Identification of cause is important. Left untreated, UR may lead to urinary tract infection or kidney failure.

Client/Family Teaching and Discharge Planning

- Teach the client with mild to moderate obstructive symptoms to double void by urinating, resting in the bathroom for 3 to 5 minutes, and then trying again to urinate. **EB:** *Double voiding promotes more efficient bladder evacuation by allowing the detrusor to contract initially and then rest and contract again (Mayo Clinic, 2021).*
- Teach the client with UR and infrequent voiding to urinate by the clock. **EB:** *Timed or scheduled voiding may reduce UR by preventing bladder overdistention (Mayo Clinic, 2021).*
- Teach the client with an indwelling catheter to assess the tube for patency, maintain the drainage system below the level of the symphysis pubis, and routinely cleanse the bedside bag as directed.
- Teach the client with an indwelling catheter or undergoing intermittent catheterization the symptoms of a significant urinary infection, including hematuria, acute-onset incontinence, dysuria, flank pain, fever, or acute confusion.

Risk for Urinary Retention

Domain 3 Elimination and exchange Class 1 Urinary function

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to incomplete emptying of the bladder.

Related Factors

Environmental constraints; fecal impaction; improper toileting posture; inadequate relaxation of pelvic floor muscles; insufficient privacy; pelvic organ prolapse; weakened bladder muscle

At-Risk Population

Puerperal women

Associated Conditions

Benign prostatic hyperplasia; diabetes mellitus; nervous system diseases; pharmaceutical preparations; urinary tract obstruction

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching and Discharge Planning, and References

Refer to care plan for **Urinary Retention.**

Risk for Vascular Trauma

Domain 11 Safety/projection Class 2 Physical injury

Elyse Bueno, MS, ACCNS-AG, C NE-BC

NANDA-I

Definition

Susceptible to damage to vein and its surrounding tissues related to the presence of a catheter and/or infusion solutions, which may compromise health.

Risk Factors

Inadequate available insertion site; prolonged period of time catheter is in place

Associated Conditions

Irritating solution; rapid infusion rate

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Risk Control; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Accomplishes **Risk Control** as evidenced by the following indicators: Monitors environmental risk factors/ Develops effective risk control strategies/Modifies lifestyle to reduce risk. (Rate the outcome and indicators of **Risk Control:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free from vascular trauma
- Remain free from signs and symptoms that indicate vascular trauma
- Remain free of signs and symptoms of vascular inflammation or infection
- Remain free from impaired tissue and/or skin
- Maintain skin integrity, tissue perfusion, usual tissue temperature, color, and pigment
- Report any altered sensation or pain
- State site is comfortable

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Intravenous Therapy; Medication Administration: Intravenous

Example NIC Activities—Intravenous Therapy

Monitor intravenous (IV) flow rate and IV site during infusion; Perform IV site care according to agency protocol

Nursing Interventions and *Rationales*

Client Preparation

▲ Verify objective and estimate duration of treatment. Check health care provider's order. **EB:** *Verify if client will remain hospitalized during the entire treatment or will go home with the device (Phillips, 2014).*

● Assess client's clinical situation when venous infusion is indicated. **EB:** *Consider possible clinical conditions that cause changes in temperature, color, and sensitivity of the possible venous access site. Verify situations that alter venous return (e.g., mastectomy, stroke) (Phillips, 2014). The site of catheter insertion influences the risk of infection and phlebitis, such as preexisting catheters, anatomical deformity, and bleeding diathesis (Kaur, 2019).*

● Assess if client is prepared for an intravenous (IV) procedure. Explain the procedure if necessary, to decrease stress. **EB:** *Stress may cause vasoconstriction that can interfere in the visualization of the vein and flow of the infused solution (Kaur, 2019).*

● Provide privacy and make the client comfortable during the IV insertion. **EB:** *Privacy and comfort help decrease stress (Phillips, 2014).*

● Teach the client what symptoms of possible vascular trauma he or she should be alert to and to immediately inform staff if any of these symptoms are noticed. **EB:** *Prompt attention to adverse changes decreases the chance of adverse effects from complications (Phillips, 2014).*

Insertion

● Wash hands before and after touching the client, as well as when inserting, replacing, accessing, repairing, or dressing an intravascular catheter (O'Grady et al, 2011; Infusion Nurses Society [INS], 2016; Kaur, 2019).

- Maintain aseptic technique for the insertion and care of intravascular catheters. **EB:** *Using an approved antiseptic solution, wearing gloves during insertion of an IV catheter, and immediately covering the insertion site with a transparent sterile semipermeable dressing are important interventions to reduce the risk of infection (Kaur, 2019).*
- In preparation, assess the client's medical history for disease processes such as diabetes and hypertension, frequent venipuncture, variations in skin color, skin alteration, age, obesity, fluid volume deficit, and IV drug use; these factors may lead to difficult vascular visualization (INS, 2016).
- When vascular visualization is difficult, consider the use of visible light devices that provide transillumination of the peripheral veins or ultrasonography (INS, 2016). Ultrasonography reduces the number of venipuncture attempts and procedure time.
- Avoid areas of joint flexion or bony prominences. **EB:** *Movement in these sites can cause mechanical trauma in veins (INS, 2016).*
- Avoid the use of the antecubital area, which has high failure rates, and do not use lower extremities unless necessary because of the risk of tissue damage, thrombophlebitis, and ulceration (INS, 2016).
- ▲ Avoid the dorsal hand, radial wrist, and the volar (inner) wrist, if possible. **EB:** *These are high-risk areas for venipuncture-related nerve injury (INS, 2016).*
- ▲ Consider topical anesthetic before IV cannula insertion to reduce pain (Kaur, 2019).
- Choose an appropriate vascular access device (VAD) based on the types and characteristics of the devices and insertion site. Consider the following:
  - ❍ Peripheral cannulae: these are short devices that are placed into a peripheral vein. They can be straight, winged, or ported and winged.
  - ❍ Midline catheters or peripherally inserted central catheters (PICCs) that range from 7.5 to 20 cm.
  - ❍ Central venous access devices (CVADs) are terminated in the central venous circulation and are available in a range of gauge sizes; they can be nontunneled catheters, skin-tunneled catheters, implantable injection ports, or PICCs.
  - ❍ Polyurethane venous devices and silicone rubber may cause less friction and, consequently, may reduce the risk of mechanical phlebitis (Phillips, 2014).
- ▲ Choose a device with consideration of the nature, volume, and flow of prescribed solution. **EBN:** *Choosing the right gauge size reduces the risk of vascular trauma. Verify that the osmolarity of the solution to be infused is compatible with the available access site and device (Phillips, 2014; Loubani & Green, 2015).*
- If possible, choose the venous access site considering the client's preference. Engaging the client in choosing the venous access site, when possible, may facilitate line patency.
- Select the gauge of the venous device according to the duration of treatment, purpose of the procedure, and size of the vein. **EB:** *Emergency situations require short, large-bore cannulae. Hydration fluids and antibiotics can be delivered through much smaller cannulae (Loubani & Green, 2015). Select the smallest gauge necessary to achieve the prescribed flow rate (INS, 2016). The time of infusion of the drug, especially chemotherapy and vasoactive agents, can contribute to the occurrence of phlebitis (Loubani & Green, 2015).*
- Verify whether the client is allergic to fixation or device material.
- Disinfect the venipuncture site. Assess that skin is dry before puncturing to achieve maximal benefit of the disinfection agent.
- Provide a comfortable, safe, hypoallergenic, easily removable stabilization dressing, allowing for visualization of the access site. **EB:** *Catheter stabilization should be used to preserve the integrity of the access device, to minimize catheter movement at the hub, and to prevent catheter migration and loss of access (INS, 2016). Some peripheral cannulae have stabilization wings (which increase the external surface area) and/or ports (which are used to administer bolus medication) incorporated into their design.*
- Use sterile, transparent, semipermeable dressing to cover catheter site. Replace dressing with catheter change, or at a minimum every 7 days for transparent dressings *(INS, 2016).* **EB:** *The use of a transparent occlusive dressing can facilitate regular monitoring by visually inspecting the VAD (Kaur, 2019). Use of gauze may be necessary if the client is diaphoretic, if the site is oozing or bleeding, or if it becomes damp; if gauze is used, it should be changed every 2 days (INS, 2016).*
- Document insertion date, site, type of VAD, number of punctures performed, other occurrences, and measures/arrangements.
- Always decontaminate the device before infusing medication or manipulating IV equipment. **EB:** *Disinfect the hub with an alcohol pad or according to hospital policy for a minimum of 15 seconds. Friction and decontamination before accessing the device port is essential in reducing contamination and/or infections (Helm et al, 2015; Kaur, 2019).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ Verify the sequence of drugs to be administrated. *Vesicants should always be administered first in a sequence of drugs (Loubani & Green, 2015).*

Monitoring Infusion

- Monitor permeability and flow rate at regular intervals.
- Monitor catheter–skin junction and surrounding tissues at regular intervals, observing possible appearance of burning, pain, erythema, altered local temperature, infiltration, extravasation, edema, secretion, tenderness, or induration. Remove promptly. **EB:** *The infusion should be discontinued at the first sign of infiltration or extravasation, the administration set disconnected, and all fluid aspirated from the catheter with a small syringe (INS, 2016).*

▲ Replace device according to institution protocol. **EBN:** *Remove peripheral IV cannula if there are signs of phlebitis or infection or if the cannula is no longer functioning. There is no need to routinely change the catheter every 72 to 96 hours (Webster et al, 2010; Porritt, 2018).*

▲ Flush vascular access according to organizational policies and procedures and as recommended by the manufacturer. *A pulsating flushing technique should be used (Porritt, 2016).* **EB:** *VADs should be flushed after each infusion to clear the infused medication from the catheter lumen, preventing contact between incompatible medications (INS, 2016). Sodium chloride 0.9% or heparinized sodium chloride has been studied to determine optimal solution for catheter patency.* **EB:** *A Cochrane review found little difference in catheter patency between either solution; thus given the cost and possible client risks to heparin exposure, sodium chloride flush solution is recommended (López-Briz et al, 2014).*

- When locking a catheter, use enough fluid to fill the entire catheter and use a positive pressure technique when disconnecting the syringe (Porritt, 2016).
- Remove catheter on suspected contamination, if the client develops signs of phlebitis or infection, the catheter is malfunctioning, or when the catheter is no longer required. **EB:** *VADs should be removed on unresolved complication, on therapy discontinuation, or if deemed unnecessary (INS, 2016). Replace any catheter inserted under emergency conditions within 24 hours because the sterility of the procedure may have been compromised.*
- Encourage clients to report any discomfort such as pain, burning, swelling, or bleeding (Kaur, 2019).

Pediatric

- The preceding interventions may be adapted for the pediatric client. **EB:** *Consider age, culture, development level, health literacy, and language preferences (INS, 2016).*
- Inform the client and family about the IV procedure; obtain permissions, maintain client's comfort, and perform appropriate assessment before venipuncture. Assess the client for any allergies or sensitivities to tape, antiseptics, or latex. **EB:** *Choose a healthy vein and appropriate site for insertion of selected device (Abolfotouh et al, 2014).*
- Consider using a two-dimensional ultrasound for venous cannulation. **EBN:** *Ultrasound has been shown more effective than traditional techniques and should be considered for pediatric clients (Jayasekara, 2017).* **EBN:** *The cephalic vein in the proximal forearm is the best initial site for ultrasound-guided catheterization when veins are not visible or palpable (Jayasekara, 2017).*
- The use of an appropriate device to obtain blood samples reduces discomfort in the pediatric client. **CEB:** *Accessing a pediatric client's vein successfully can be difficult, and measures to optimize the health care provider's skill are important to ensure successful venous cannulation (Goff et al, 2013).*
- Avoid areas of joint flexion or bony prominences. **EB:** *Cannulae inserted away from joints remain patent for longer periods of time (INS, 2016).*
- For insertion in pediatric clients, use upper extremities, lower extremities, or the scalp in neonates or young infants (O'Grady et al, 2011).

▲ Consider whether sedation or the use of local anesthetic is suitable for insertion of a catheter, taking into consideration the age of the pediatric client. **EB:** *The use of effective local anesthetic methods and agents before each painful dermal procedure should be discussed with the health care provider (INS, 2016; Stoltz & Manworren, 2017).*

▲ Use diversion while performing the procedure. **EB:** *Diversion reduces anxiety (Goff et al, 2013).*

Geriatric

- The preceding interventions may be adapted for the geriatric client.
- Consider the physical, emotional, and cognitive changes related to older adults.

- Use strict aseptic technique for venipuncture of older clients. **EB:** *Older adults are at an increased risk of infection because of decreased immunological function (Azar & Ballas, 2020).*

Home Care

- Some devices may remain after discharge. Provide device-specific education to the client and family members about care of the selected device.
- Help in the choice of actions that support self-care. The nurse can provide valuable information that can be used to guide decision-making to maximize the self-care abilities of clients receiving home infusion therapy.
- Select, with the client, the insertion site most compatible with the development of activities of daily living (ADLs).
- Minimize the use of continuous IV therapy whenever possible. **CEBN:** *Clients who received intermittent IV therapy via a saline lock were more independent regarding ability to perform self-care ADLs than those who received continuous IV therapy (O'Halloran, et al, 2008).*

Impaired Spontaneous Ventilation

Domain 4 Activity/rest Class 4 Cardiovascular/pulmonary responses

Debra Siela, PhD, RN, ACNS-BC, CCRN-K, CNE, RRT

V

NANDA-I

Definition

Inability to initiate and/or maintain independent breathing that is adequate to support life.

Defining Characteristics

Apprehensiveness; decreased arterial oxygen saturation; decreased cooperation; decreased partial pressure of oxygen; decreased tidal volume; increased accessory muscle use; increased heart rate; increased metabolic rate; increased partial pressure of carbon dioxide (PCO_2); psychomotor agitation

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Related Factors

Respiratory muscle fatigue

Associated Conditions

Impaired metabolism

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Neurological Status: Central Motor Control; Respiratory Status: Gas Exchange, Ventilation

Example NOC Outcome with Indicators

Achieves appropriate **Respiratory Status: Ventilation** as evidenced by the following indicators: Respiratory rate/Respiratory rhythm/Depth of inspiration/Symmetrical chest expansion/Ease of breathing/Moves sputum out of airway/Accessory muscle use not present/Adventitious breath sounds not present/Chest retraction not present/Tidal volume/Vital capacity. (Rate the outcome and indicators of **Respiratory Status: Ventilation:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain arterial blood gases within safe parameters
- Remain free of dyspnea or restlessness
- Effectively maintain airway
- Effectively mobilize secretions

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Artificial Airway Management; Mechanical Ventilation: Invasive; Respiratory Monitoring; Resuscitation: Neonate; Ventilation Assistance; Mechanical Ventilation Management: Noninvasive

Example NIC Activities—Mechanical Ventilation Management

Invasive
Monitor for conditions indicating a need for ventilation support (e.g., respiratory muscle fatigue, neurological dysfunction second to trauma, anesthesia, drug overdose, refractory respiratory acidosis); Consult with other health care personnel in selection of a ventilator mode

Nursing Interventions and *Rationales*

▲ Collaborate with the client, family, and provider regarding possible intubation and ventilation. Ask whether the client has advance directives and, if so, integrate them into the plan of care with clinical data regarding overall health and reversibility of the medical condition. **EB:** *Client preferences and goals of care need to be acknowledged and discussed when planning care. Advance directives protect client autonomy and help ensure that the client's wishes are respected. Many states now have Physician Orders for Life-Sustaining Treatment (POLST), Medical Orders for Life-Sustaining Treatment (MOLST), Medical Orders for Scope of Treatment (MOST), Physician Order for Scope of Treatment (POST), Do Not Resuscitate Order/Clinician Orders for Life-Sustaining Treatment (DNR/COLST), and Transportable Physician Orders for Patient Preferences (TPOPP) (House & Ogilvie, 2021). Explore the client's wishes, if possible, before requiring mechanical ventilation support.*

- Assess and respond to changes in the client's respiratory status. Monitor the client for dyspnea, increase in respiratory rate, use of accessory muscles, retraction of intercostal muscles, flaring of nostrils, decrease in O_2 saturation, cyanosis, and subjective complaints (Gallagher, 2017; Loscalzo, 2018).

- Have the client use a numerical scale (0–10) or visual analog scale to self-report dyspnea before and after interventions. **EB:** *The numerical rating scale is a valid measure of dyspnea and has been found to be easiest for clients to use. Incorporating client self-report of dyspnea assists with assessment of symptom intensity, distress, progression, impact, and resolution of dyspnea (Mahler & O'Donnell, 2015; Campbell, 2017). Determine intensity, unpleasantness, or distress of dyspnea using a rating scale such as an intensity-focused modified Borg Scale, Respiratory Distress Observation Scale, or visual analog scale (Parshall et al, 2012; Campbell, 2017).*
- Assess for history of chronic respiratory disorders when administering oxygen .**EB:** *When managing acute respiratory failure in clients with chronic obstructive pulmonary disease (COPD), continually assess the client's oxygenation needs. Long-term administration of oxygen (>15 hours per day) has been shown to increase survival in clients with severe, resting hypoxemia (Global Initiative for Chronic Obstructive Lung Disease [GOLD], 2020).*

▲ Collaborate with the health care provider and respiratory therapists in determining the appropriateness of noninvasive positive pressure ventilation/noninvasive ventilation (NPPV/NIV) for the decompensated client with respiratory diseases (including COPD). Ventilatory support during an exacerbation can be provided by either noninvasive or invasive ventilation (GOLD, 2020). NIV improves respiratory acidosis and decreases respiratory rate, severity of breathlessness, incidence of ventilator-associated pneumonia (VAP), and hospital length of stay (American Association of Critical Care Nurses, 2017a; GOLD, 2020).

▲ Assist with implementation, client support, and monitoring if NPPV/NIV is used. **EB:** *In a client with exacerbation of COPD, NPPV/NIV can be as effective as intubation with use of a ventilator (GOLD, 2020). NPPV/NIV has also been found to improve outcomes in clients with acute cardiogenic pulmonary edema (Pierce, 2021; Sauls, 2021). It can also be used in acute respiratory failure causes such as asthma, pneumonia, postextubation failure, and thoracic trauma. The use of continuous positive airway pressure and bilevel positive airway pressure has been shown to improve oxygenation and decrease the rate of endotracheal intubation in clients with acute pulmonary edema (Frazier, 2017; GOLD, 2020).*

- If the client has apnea, respiratory muscle fatigue, somnolence, hypoxemia, and/or acute respiratory acidosis, prepare the client for possible intubation and mechanical ventilation. **EB:** *These indicators may predict the need for invasive mechanical ventilation to support the client's respiratory efforts (Gallagher, 2017). The indications for initiating invasive mechanical ventilation during a COPD exacerbation include a failure of an initial trial of NIV (Gallagher, 2017; GOLD, 2020).*
- If a client with acute respiratory failure (ARF) has a Rapid Shallow Breathing Index (RSBI) >105, endotracheal intubation is likely needed with invasive mechanical ventilation. A client with ARF with an RSBI of <105 may require only noninvasive ventilation (Karthika et al, 2016).

Ventilator Support

▲ Explain the endotracheal intubation and mechanical ventilation process to the client and family as appropriate, and during intubation administer sedation for client comfort according to the health care provider's orders. **EB:** *Explanation of the procedure decreases anxiety and reinforces information; premedication allows for a more controlled intubation with decreased incidence of insertion problems (Gallagher, 2017).*

- Secure the endotracheal tube in place using either tape or a commercially available device, auscultate bilateral breath sounds, use a CO_2 detector, and obtain a chest radiograph to confirm endotracheal tube placement. **EBN:** *Security of the tube is needed to prevent inadvertent extubation. Nursing studies have shown conflicting results regarding the preferable way to secure the endotracheal tube (Goodrich, 2017a).* **EB:** *Auscultation alone is an unreliable method for checking endotracheal tube placement. A CO_2 detector can be used to confirm tube placement in the trachea (Goodrich, 2017b); However, correct position of the endotracheal tube in the trachea (3 to 5 cm above the carina) must be confirmed by chest radiograph (Goodrich, 2017a, 2017b). Calorimetric CO_2 detectors have also been used successfully to detect inadvertent airway intubation during gastric tube placement (Goodrich, 2017a, 2017b).*

▲ Review ventilator settings with the health care provider and respiratory therapy to ensure support is appropriate to meet the client's minute ventilation requirements (Chacko et al, 2015). **EB:** *Ventilator settings should be adjusted to prevent hyperventilation or hypoventilation. A variety of new modes of ventilation are currently available that are responsive to client effort (pressure support) (Gallagher, 2017).*

▲ Suction as needed and hyperoxygenate according to facility policy.

- Check that monitor alarms are set appropriately at the start of each shift. **EB:** *This action helps ensure client safety (Gallagher, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Respond to ventilator alarms promptly. If unable to immediately locate the source/cause of an alarm, use a manual self-inflating resuscitation bag to ventilate the client while waiting for assistance. **EB:** *Common causes of a high-pressure alarm include secretions, condensation in the tubing, biting of the endotracheal tube, decreased compliance of the lungs, and compression of the tubing. Common causes of a low-pressure alarm are ventilator disconnection, leaks in the circuit, and changing compliance. Using a manual self-inflating resuscitation bag with supplemental oxygen, the nurse can provide immediate ventilation and oxygenation as needed (Gallagher, 2017; Pierce, 2021).*
- Prevent unplanned extubation by maintaining stability of endotracheal tube (Goodrich, 2017b). **EB:** *Prevent unplanned extubation with use of weaning protocol (Pierce, 2021).*
- Drain collected fluid from condensation out of ventilator tubing as needed. **EB:** *This action reduces the risk for infection by decreasing inhalation of contaminated water droplets (Gallagher, 2017).*
- Note ventilator settings of flow of inspired oxygen, peak inspiratory pressure, tidal volume, and alarm activation at intervals and when removing the client from the ventilator for any reason. **EB:** *Checking the settings ensures that safety measures are taken and that the client is not left on 100% oxygen after suctioning (Gallagher, 2017).*

▲ Administer analgesics and sedatives as needed to facilitate client comfort and rest. Use behavioral and sedation scales for nonverbal clients to provide a consistent way of monitoring pain and sedation levels and ensuring that therapeutic outcomes are being met. **EB:** *Clients receiving mechanical ventilation frequently require sedation to help attenuate the anxiety, pain, and agitation associated with this intervention. The overall goal of sedation during mechanical ventilation is to provide physiological stability, ventilator synchrony, and comfort for clients (Makic et al, 2015; Devlin et al, 2018).*

- Tools such as the Riker Sedation-Agitation Scale, the Motor Activity Assessment Scale, the Ramsey Scale, or the Richmond Agitation-Sedation Scale may be useful in monitoring levels of sedation. **EB:** *Each of these instruments has established reliability and validity and can be used to monitor the effect of sedative therapy (Devlin et al, 2018).*
- Alternatives to medications for decreasing anxiety should be attempted, such as music therapy with selections of the client's choice played on headphones at intervals. **EBN/EB:** *Music therapy has been reported to decrease anxiety and reduce heart and respiratory rate in critically ill and intubated clients (Ergin et al, 2018).*
- Analyze and respond to arterial blood gas results, end-tidal CO_2 levels, and pulse oximetry values. Ventilatory support must be closely monitored to ensure adequate oxygenation and acid-base balance. **EB:** *End-tidal CO_2 monitoring is best used as an adjunct to direct client observation and is used to monitor a client's ventilatory status and pulmonary blood flow (Gallagher, 2017).*
- Use an effective means of verbal and nonverbal communication with the client. Barriers to communication include endotracheal tubes, sedation, and general weakness associated with a critical illness. **EB:** *Basic technologies should be readily available to the client, including eyeglasses and hearing aids. A variety of communication devices are available, including electronic voice output communication aids, alphabet boards, picture boards, computers, and writing slate. Ask the client for input into their care as appropriate (Vollman et al, 2017; Pierce, 2021).*
- Move the endotracheal tube from side to side at least every 24 hours, and tape it or secure it with a commercially available device. Assess and document client's skin condition, and ensure correct tube placement at lip line (Vollman et al, 2017).
- Implement steps to prevent ventilator-associated events (VAEs), such as ventilator-associated pneumonia (VAP), including continuous removal of subglottic secretions, elevation of the head of bed to 30 to 45 degrees (Hospital Quality Institute, 2015; American Association of Critical Care Nurses, 2017a) unless medically contraindicated, change of the ventilator circuit no more than every 48 hours, and handwashing before and after contact with each client.
- The accumulation of contaminated oropharyngeal secretions above the endotracheal tube may contribute to the risk of aspiration. **EB:** *Use endotracheal tubes that allow for the continuous aspiration of subglottic secretions (Vollman et al, 2017; Pierce, 2021).* **EB:** *Subglottic secretion drainage during mechanical ventilation results in a significant reduction in VAEs, including late-onset VAP (Vollman et al, 2017). Use of continuous subglottic suctioning endotracheal tubes for intubation in clients who are predicted to require more than 48 hours likely results in decreased incidence of VAP (American Association of Critical Care Nurses, 2017a).*

V

- Position the client in a semirecumbent position with the head of the bed at a 30- to 45-degree angle to decrease the aspiration of gastric, oral, and nasal secretions (Hospital Quality Institute, 2015; American Association of Critical Care Nurses, 2017a; Vollman et al, 2017).
- Consider use of kinetic therapy, using a kinetic bed that slowly moves the client with 40-degree turns. **EB:** *Rotational therapy may decrease the incidence of pulmonary complications in high-risk clients with increasing ventilator support requirements, at risk for VAP, and clinical indications for acute lung injury or acute respiratory distress syndrome with worsening PaO_2:FiO_2 ratio, presence of fluffy infiltrates via chest radiograph concomitant with pulmonary edema, and refractory hypoxemia* (*Hanneman et al, 2015*; *St. Clair & MacDermott, 2017*).
- Perform handwashing using both soap and water and alcohol-based solution before and after all mechanically ventilated client contact to prevent spread of infections *(Centers for Disease Control and Prevention, 2019).*
- Provide routine oral care using tooth brushing and oral rinsing with an antimicrobial agent if needed (American Association of Critical Care Nurses, 2017b, 2017b; Vollman et al, 2017). **EB:** *Reducing bacterial colonization of oral cavity includes interventions of daily oral assessment, deep suctioning every 4 hours, tooth brushing twice per day with a plaque reducer, and oral tissue cleaning with peroxide every 4 hours. A Cochrane review found that routine oral care that included chlorhexidine mouthwash or gel resulted in a 40% reduction in development of VAP (Zhao et al, 2020).*
- Maintain proper cuff inflation for both endotracheal tubes and cuffed tracheostomy tubes with minimal leak volume or minimal occlusion volume to decrease risk of aspiration and reduce incidence of VAP (American Association of Critical Care Nurses, 2016; Johnson, 2017).
- Reposition the client as needed. Use rotational bed or kinetic bed therapy in clients for whom side-to-side turning is contraindicated or difficult. **EBN:** *Changing position frequently decreases the incidence of atelectasis, pooling of secretions, and resultant VAP. Continuous, lateral rotational therapy has been shown to improve oxygenation and decrease the incidence of VAP (St. Clair & MacDermott, 2017).*
- ▲ Clients mechanically ventilated for more than 24 hours can benefit from protocolized rehabilitation directed toward early mobilization (Schmidt et al, 2017).
- Assess bilateral anterior and posterior breath sounds every 2 to 4 hours and as needed; respond to any relevant changes (Gallagher, 2017).
- Assess responsiveness to ventilator support; monitor for subjective complaints and sensation of dyspnea (Gallagher, 2017).
- ▲ Collaborate with the interdisciplinary team in treating clients with acute respiratory failure. Collaborate with the health care team to meet the client's ventilator care needs and avoid complications. **EB:** *A collaborative approach to caring for mechanically ventilated clients has been demonstrated to reduce length of time on the ventilator and length of stay in the intensive care unit (Devlin et al, 2018).*
- Document assessments and interventions according to policy.

Geriatric

- Recognize that critically ill older adults have a high rate of morbidity when mechanically ventilated.
- ▲ NPPV may be used during acute treatment of older clients with impaired ventilation. **EB:** *Current standards suggest that the use of NPPV may facilitate either not placing an older client on a mechanical ventilator or assist with preventing reintubation (Ouellette et al, 2017).*

Home Care

- ▲ Some of the interventions listed previously may be adapted for home care use. Begin discharge planning as soon as possible with the case manager or social worker to assess the need for home support systems, assistive devices, and community or home health services.
- ▲ With help from a medical social worker, assist the client and family to determine the fiscal effect of care in the home versus an extended care facility.
- Assess the home setting during the discharge process to ensure the home can safely accommodate ventilator support (e.g., adequate space and electricity).
- Have the family contact the electric company and place the client residence on a high-risk list in case of a power outage. Some home-based care requires special conditions for safe home administration.
- Assess the caregivers for commitment to supporting a ventilator-dependent client in the home.
- Be sure that the client and family or caregivers are familiar with operation of all ventilation devices, know how to suction secretions if needed, are competent in doing tracheostomy care, and know schedules for

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

cleaning equipment. Have the designated caregiver or caregivers demonstrate care before discharge. Some home-based care involves specialized technology and requires specific skills for safe and appropriate care.

- Assess client and caregiver knowledge of the disease, client needs, and medications to be administered via ventilation-assistive devices. Avoid analgesics. Assess knowledge of how to use equipment. Teach as necessary.
- A client receiving ventilation support may not be able to articulate needs. Respiratory medications can have side effects that change the client's respiration or level of consciousness.
- Establish an emergency plan and criteria for use. Identify emergency procedures to be used until medical assistance arrives. Teach and role-play emergency care. A prepared emergency plan reassures the client and family and ensures client safety.

Client/Family Teaching and Discharge Planning

- Explain to the client the potential sensations that will be experienced, including relief of dyspnea, the feeling of lung inflations, the noise of the ventilator, and the reality of alarms. **EB:** *Knowledge of potential sensations and experiences before they are encountered can decrease anxiety. Administration of sedatives and/or narcotics may be needed to provide adequate oxygenation and ventilation in some clients (Baldwin & Cox, 2016; Gallagher, 2017).*
- Explain to the client and family about being unable to speak, and work out an alternative system of communication. See previously mentioned interventions (Gallagher, 2017).
- Demonstrate to the family how to perform simple procedures, such as suctioning secretions in the mouth with a tonsil-tip catheter, providing range-of-motion exercises, and reconnecting the ventilator immediately if it becomes disconnected. **EB:** *Families are a critical part of the client's care, may be present at the bedside for prolonged periods of time, and need information about the plan of care (Gallagher, 2017).*
- Offer both the client and family explanations of how the ventilator works and answer any questions. **EB:** *Having questions answered is often cited as an important need of clients and families when a client is on a ventilator (Gallagher, 2017).*

Dysfunctional Adult Ventilatory Weaning Response

Domain 4 Activity/rest Class 4

Cardiovascular/pulmonary responses

Debra Siela, PhD, RN, ACNS-BC, CCRN-K, CNE, RRT

NANDA-I

Definition

Inability of individuals >18 years of age, who have required mechanical ventilation at least 24 hours, to successfully transition to spontaneous ventilation.

Defining Characteristics

Early Response (30 minutes)

Adventitious breath sounds; audible airway secretions; decreased blood pressure (<90 mm Hg or >20% reduction from baseline); decreased heart rate (>20% reduction from baseline); decreased oxygen saturation (<90% when fraction of inspired oxygen ratio >40%); expresses apprehensiveness; expresses distress; expresses fear of machine malfunction; expresses feeling warm; hyperfocused on activities; increased blood pressure (systolic pressure >180 mm Hg or >20% from baseline); increased in heart rate (>140 bpm or >20% from baseline); increased respiratory rate (>35 rpm or >50% over baseline); nasal flaring; panting; paradoxical abdominal breathing; perceived need for increased oxygen; psychomotor agitation; shallow breathing; uses significant respiratory accessory muscles; wide-eyed appearance

Intermediate Response (30-90 minutes)

Decreased pH (<7.32 or >0.07 reduction from baseline); diaphoresis; difficulty cooperating with instructions; hypercapnia (>50 mm Hg increase in partial pressure of carbon dioxide or >8 mm Hg increase from baseline); hypoxemia (partial pressure of oxygen 50% or oxygen >6 L/min)

Late Response (>90 minutes)

Cardiorespiratory arrest; cyanosis; fatigue; recent onset arrhythmias

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Related Factors

Altered sleep-wake cycle; excessive airway secretions; ineffective cough; malnutrition

At-Risk Population

Individuals with history of failed weaning attempt; individuals with history of lung diseases; individuals with history of prolonged dependence on ventilator; individuals with history of unplanned extubation; individuals with unfavorable pre-extubation indexes; older adults

Associated Conditions

Acid-base imbalance; anemia; cardiogenic shock; decreased level of consciousness; diaphragm dysfunction acquired in the intensive care unit; endocrine system diseases; heart diseases; high acuity illness; hyperthermia; hypoxemia; infections; neuromuscular diseases; pharmaceutical preparations; water-electrolyte imbalance

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Respiratory Status: Gas Exchange; Ventilation

Example NOC Outcome with Indicators

Achieves appropriate **Respiratory Status: Ventilation** as evidenced by the following indicators: Respiratory rate/Respiratory rhythm/Depth of inspiration/Symmetrical chest expansion/Ease of breathing/Moves sputum out of airway/Accessory muscle use not present/Adventitious breath sounds not present/Chest retraction not present/Tidal volume/Vital capacity. (Rate the outcome and indicators of **Respiratory Status: Ventilation:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Wean from ventilator with adequate arterial blood gases
- Remain free of unresolved dyspnea or restlessness
- Effectively clear secretions

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Mechanical Ventilation Management: Invasive; Mechanical Ventilatory Weaning

Example NIC Activities—Mechanical Ventilatory Weaning

Monitor for optimal fluid and electrolyte status; Monitor to ensure client is free of significant infection before weaning

Nursing Interventions and *Rationales*

▲ Assess client's readiness for weaning as evidenced by the following:
- ❍ Physiological and psychological readiness. **CEBN:** *Assess fears and anxieties that can contribute to prolonged and repeated failure of ventilator weaning. Fear and anxiety have been found to correlate with the client's successful weaning (r = 0.77; p <.001) (Chen et al, 2011).*
- ❍ Resolution of initial medical problem that led to ventilator dependence.
- ❍ Hemodynamic stability.
- ❍ Normal hemoglobin levels.
- ❍ Absence of fever.
- ❍ Normal state of consciousness.
- ❍ Metabolic, fluid, and electrolyte balance.
- ❍ Adequate nutritional status with serum albumin levels >2.5 g/dL.

V

- ❍ Adequate sleep.
- ❍ Adequate pain management and minimal sedation.

EB: *The rapid shallow breathing index (RSBI) may predict weaning success (Peñuelas, Thille, & Esteban, 2015; Furqan et al, 2019; Lin et al, 2020). A spontaneous breathing trial (SBT) is often preceded by evaluation of the client's level of consciousness, physiological and hemodynamic stability, adequacy of oxygenation and ventilation, spontaneous breathing capability, and respiratory rate and pattern. Routine weaning predictor parameters include negative inspiratory force (NIF), vital capacity (VC), tidal volume (VT), respiratory rate (RR), minute ventilation (VE), and RSBI (Kacmarek, 2021; Pierce, 2021). However, applying these weaning predictors should not delay extubation decisions (Peñuelas, Thille, & Esteban, 2015; Lin et al, 2020). Decreased heart rate variability and respiratory rate variability are associated with weaning/extubation failure and should be assessed to help predict weaning outcomes (Kacmarek, 2021; Pierce, 2021). Assessment of the percent of change in diaphragm thickness (Δtdi%) between end-expiration and end-inspiration can reflect diaphragm strength. This measurement is analogous to ejection fraction of the heart (Peñuelas, Thille, & Esteban, 2015; Jansson et al, 2019). Neuromuscular weakness related to respiratory muscle strength at time of extubation was common, reinforcing the need for early ambulation while on mechanical ventilation (Ouellette et al, 2017). Predictors of extubation failure include disease severity, secretion burden, higher minute ventilation, and lower oxygenation (Kacmarek, 2021).*

- ▲ Evaluate serum electrolytes, complete blood count, and nutritional status as a measure of client readiness to wean. **EB:** *The integrative index combining serum albumin, hemoglobin, and Glasgow Coma Scale (GCS) can predict extubation outcomes better than RSBI in an adult medical intensive care unit (Wu et al, 2019).* **EB:** *Multiple SBT attempts, weak cough, and low albumin were associated with failed extubation and resulted in increased reintubation in medicalclients (Xiao & Duan, 2018).*
- ▲ Assess arterial blood gas analysis as part of weaning interventions. Monitor pulse oximetry and not correlation of pulse oximeter reading with arterial blood gas results. **EB:** *Arterial blood gases with abnormal values after an SBT may identify clients who will experience extubation failure (Keyal et al, 2020).*
- ▲ If the client has a central venous catheter, monitor changes in values during weaning as a symptom of hemodynamic stability along with changes in blood pressure and heart rate. **EB:** *An early rise in CVP after starting an SBT was associated with an increased risk of extubation failure (Dubo et al, 2019; Mallat et al, 2020).*
- ▲ Monitor respiratory parameters for weaning and extubation determination. Review and collaborate with respiratory therapists and providers to note improvements in NIF. **EB:** *An NIF threshold of ≤–25 cm H_2O was a moderate-to-good predictor for successful ventilator liberation in mechanically ventilated chronic obstructive pulmonary disease (COPD) clients with hypercapnic respiratory failure (Vahedian-Azimi et al, 2020).*
- ▲ Monitor respiratory rate and volume of independent breaths while on mechanical ventilation. Supporting independent breathing strengthens the diaphragm. **EB:** *Loss of force and reduced diaphragm muscle mass can occur from lack of use while a client is supported on mechanical ventilation (MV) (Petrof, 2018). Even brief periods of MV may result in diaphragm weakness (i.e., ventilator-induced diaphragm dysfunction [VIDD]), which may be associated with difficulty weaning from the ventilator, as well as mortality (Peñuelas et al, 2015). Critical illness–associated diaphragm weakness is consistently associated with poor outcomes, including increased intensive care unit (ICU) mortality, difficult weaning, and prolonged duration of mechanical ventilation (Dres et al, 2017).*
- ▲ Collaborate with respiratory therapy and provider tests to evaluate diaphragm strength for readiness to wean. **EB:** *Diaphragmatic excursion (DE,cm) and inspiration time ($TPIA_{dia}$cm/s) and diaphragmatic contraction speed and velocity measured by ultrasonography are good predictors of extubation success (Varón-Vega et al, 2021). A meta-analysis of 436 mechanically ventilated clients found that diaphragmatic excursion (DE) and diaphragmatic thickening fraction (DTF) showed good diagnostic performance to predict weaning success (Qian et al, 2018). Current literature suggests that diaphragmatic ultrasonography can be a useful and accurate tool to detect diaphragmatic dysfunction in critically ill clients to predict extubation success or failure, to monitor respiratory workload, and to assess atrophy in clients who are mechanically ventilated (Zambon et al, 2017).*
- ▲ Assess the presence and strength of the client's gag reflexes. **EB:** *In individuals with prolonged ventilation the presence of one or both gag reflexes could predict a reduction in extubation failure related to aspiration or excessive upper airway secretions (Houzé et al, 2020).*
- ▲ Collaborate with respiratory therapy and providers to review client readiness to wean using a standardized checklist. Checklist may be referred to as mechanical ventilator liberation protocols or spontaneous awakening trails with spontaneous breathing trials (SAT/SBT) protocols. **EB:** *Implementing an extubation checklist is associated with fewer failed extubations (Bobbs et al, 2019; Jansson et al, 2019).* **EB:** *Clients managed with ventilator liberation protocols spent fewer hours on mechanical ventilation and had earlier ICU*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

discharge than did clients managed with without a protocol (Schmidt et al, 2017; Jansson et al, 2019). **EB:** *Goal-directed weaning decreased ventilator days, as well as ICU and hospital length of stay (Zhu et al, 2015). Pairing SAT and SBT interventions has been found to reduce ICU and hospital length of stay, duration of mechanical ventilation, and ventilator-associated events (Klompas et al, 2015; Rose, 2015).*

- ▲ Use evidence-based weaning and extubation protocols as appropriate. **EB:** *The American Thoracic Society recommends use of ventilator liberation protocols to manage clients who have been mechanically ventilated for over 24 hours (Schmidt et al, 2017). Protocol-directed weaning has been demonstrated to be safe and effective allowing for timely and ongoing clinical decision-making by expert nurses and health care providers (Devlin et al, 2018).* **EB:** *The use of lighter sedation resulted in less duration of mechanical ventilation, more ventilator-free days, more ICU-free days, and reduced mortality (Schmidt et al, 2017).*
- ▲ A client may require noninvasive ventilation (NIV) or bilevel positive airway pressure (BiPAP) once extubated from mechanical ventilation to reduce the risk of reintubation. **EB:** *After a spontaneous breathing trial to extubation high-risk clients receiving mechanical ventilation for more than 24 hours should be placed on NIV (Schmidt et al, 2017). Early use of NIV as a prophylactic intervention can be used to prevent reintubation for clients considered at high risk (Bajaj et al, 2015).* **EB:** *The American College of Chest Physicians and American Thoracic Society recommend inspiratory augmentation during an initial SBT, protocols minimizing sedation, and preventive NIV in relation to ventilator liberation (Ouellette et al, 2017).*
- ▲ An early mobility and walking program can promote weaning from a ventilator support as a client's overall strength and endurance improve. Collaborate with respiratory therapy and physical therapy to implement early mobility programs for clients on mechanical ventilation. **EB:** *Acutely hospitalized clients who are mechanically ventilated for greater than 24 hours require early mobilization to build endurance and support successful weaning and extubation (Peñuelas, Thille, & Esteban, 2015; Schmidt et al, 2017).* **EB:** *Early mobility and physical rehabilitation can reduce muscle weakness, mechanical ventilation duration, ICU stay, and hospital stay (Peñuelas, Thille, & Esteban, 2015; Devlin et al, 2018).* **EB:** *The American Thoracic Society/American College of Chest Physicians recommends that acutely hospitalized adults mechanically ventilated for more than 24 hours receive protocolized rehabilitation directed toward early mobilization, and be managed with a ventilator liberation protocol (Girard et al, 2017).*
- ▲ Evaluate client nutritional status as a critical element for successful weaning and ability to be successful with rehabilitation program. **EB:** *When assessing clinical outcomes of survivors of critical illness requiring prolonged mechanic ventilation (PMV), the combination of high protein and a mobility-based rehabilitation program leads to increased rates of discharge home and ventilator weaning success (Wappel et al, 2017).*
- ▲ Provide adequate nutrition to ventilated clients, using enteral feeding when possible. **EB:** *When assessing clinical outcomes of survivors of critical illness requiring PMV, the combination of high protein and a mobility-based rehabilitation program leads to increased rates of discharge home and ventilator weaning success (Wappel et al, 2017).* **EB:** *The Academy of Nutrition and Dietetics strongly recommends that people with COPD have their body weight and medical nutrition therapy be assessed and monitored by a registered dietitian nutritionist (Hanson et al, 2021).*
- ● Identify reasons for previous unsuccessful weaning attempts, and include that information in development of the weaning plan. **EB:** *Pressure support reduces respiratory effort compared with T-piece. Continuous positive airway pressure of 0 cm H_2O and T-piece more accurately reflect the physiological conditions after extubation (Peñuelas, Thille, & Esteban, 2015). For difficult/prolonged weaning clients with COPD, use of a T-piece may be associated with a longer time to ventilator liberation than use of pressure support ventilation (Santos Pellegrini et al, 2018).* **EB:** *A meta-analysis of seven studies involving 634 clients suggested that proportional assist ventilation (PAV) is superior to pressure support ventilation (PSV) in terms of weaning success (Ou-Yang et al, 2020).*
- ▲ Collaborate with respiratory therapy and provide for optimal oxygen delivery plan once the client is successfully weaned from mechanical ventilation. **EB:** *Compared with the Venturi mask, high-flow nasal cannula oxygen use results in better oxygenation for the same set FiO_2 after extubation. Use of high-flow nasal cannula is associated with better comfort, fewer desaturations and interface displacements, and a lower reintubation rate (Peñuelas, Thille, & Esteban, 2015; Zhu et al, 2019). The use of high-flow nasal oxygen with NIV immediately after extubation significantly decreased the risk of reintubation compared with high-flow nasal oxygen alone (HIGH-WEAN Study Group & REVA Research Network, 2019).*
- ▲ Clients with neurological diseases may need special considerations to successfully wean from mechanical ventilation. **EB:** *Extubation failure may be avoided in clients with neurological disease by using protective ventilation, early enteral nutrition, antibiotic therapy standardization, and systematic testing extubation compared with a conventional strategy (Peñuelas, Thille, & Esteban, 2015).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

▲ Collaborate with an interdisciplinary team (provider, nurse, respiratory therapist, physical therapist, and dietitian) to develop a weaning plan with a timeline and goals; revise this plan throughout the weaning period. **EB:** *Decisions related to weaning trials should be made in conjunction with members of the interdisciplinary team (Devlin et al, 2018; Jansson et al, 2019; Pierce, 2021).*

- Assist client to identify personal strategies that result in relaxation and comfort (e.g., music, visualization, relaxation techniques, reading, television, family visits). Support implementation of these strategies. **EBN:** *Evidence supports music as an effective intervention that can lesson symptoms related to mechanical ventilation and promote effective weaning (Hetland, Lindquist, & Chlan, 2015). Music therapy increases weaning duration on daily weaning and also decreases respiratory rate and dyspnea (Hu et al, 2015; Liang et al, 2016). Clients who received a guided imagery intervention had reduced length of hospital stay (1.4 less days) and 4.88 less mechanical ventilation days compared with the comparison group (Spiva et al, 2015).*
- Provide a safe and comfortable environment. Orient the client to the call light button. Ensure that the call light button is readily available, and assure the client that needs will be met responsively. **CEB:** *Reduce fears and anxiety for the client by reinforcing their ability to call for assistance as needed (Chen et al, 2011).*

▲ Coordinate pain and sedation medications to minimize sedative effects while optimizing analgesia needs. **EB:** *Appropriate levels of analgesia and sedation are necessary for successful weaning (Devlin et al, 2018; Pierce, 2021). Daily interruption of sedation (SAT) is safe in mechanically ventilated medical ICU clients. Current practice evidence suggests that sedation should be client specific to avoid overuse of sedating agents (Klompas et al, 2015; Makic et al, 2015; Aitken et al, 2018; Devlin et al, 2018; Pierce, 2021).*

- Administer analgesics and sedatives as needed to facilitate client comfort and rest. Use behavioral and sedation scales for nonverbal clients to provide a consistent way of monitoring pain and sedation levels and ensuring that therapeutic outcomes are being met. **EB:** *Clients receiving mechanical ventilation frequently require sedation to help attenuate the anxiety, pain, and agitation associated with this intervention (Aitken et al, 2018; Devlin et al, 2018; Pierce, 2021).*
- Tools such as the Riker Sedation-Agitation Scale, the Motor Activity Assessment Scale, the Ramsey Scale, or the Richmond Agitation-Sedation Scale may be useful in monitoring levels of sedation (Devlin et al, 2018).
- Schedule weaning periods for the time of day when the client is most rested. Cluster care activities to promote successful weaning. Avoid other procedures during weaning: keep the environment quiet and promote restful activities between weaning periods.
- Promote a normal sleep-wake cycle, allowing uninterrupted periods of nighttime sleep. **EB:** *Limit visitors during weaning to close and supportive persons; ask visitors to leave if they are negatively affecting the weaning process. Communication with a client and/or the client's family is important to assess the client's typical pattern of sleep (Kacmarek, 2021; Pierce, 2021).*
- During weaning, monitor the client's physiological and psychological responses; acknowledge and respond to fears and subjective complaints. Validate the client's efforts during the weaning process.
- Involve the client and family in the weaning plan. Inform them of the weaning plan and possible client responses to the weaning process (e.g., potential feelings of dyspnea). Foster a partnership between clients and nurses in care planning for weaning.
- Coach the client through episodes of increased anxiety. Remain with the client or place a supportive and calm significant other in this role. Give positive reinforcement, and with permission use touch to communicate support and concern. **EB:** *It is not unusual for a client with lung disease to experience self-limiting episodes of increased shortness of breath. Supporting and coaching a client through such episodes allows weaning to continue (Baldwin & Cox, 2016; Campbell, 2017).*
- Terminate weaning when the client demonstrates predetermined criteria or when the following signs of weaning intolerance occur:
  - ❍ Tachypnea, dyspnea, or chest and abdominal asynchrony
  - ❍ Agitation or mental status changes
  - ❍ Decreased oxygen saturation: SaO_2 <90%
  - ❍ Increased $PaCO_2$ or end-tidal CO_2 ($EtCO_2$)
  - ❍ Change in pulse rate or blood pressure or onset of new dysrhythmias

▲ If the dysfunctional weaning response is severe, consider slowing weaning to brief periods. Continue to collaborate with the team to determine whether an untreated physiological cause for the dysfunctional weaning pattern remains. Consult with health care provider regarding use of noninvasive ventilation immediately after discontinuing ventilation. Consider an alternative care setting (subacute, rehabilitation facility, home) for clients with prolonged ventilator dependence as a strategy that can positively affect outcomes.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Geriatric

- Recognize that older clients may require longer periods to wean.
- ▲ NPPV may be used during acute treatment of older clients with impaired ventilation. **EB:** *Current standards suggest that the use of NPPV may facilitate either not placing an older client on a mechanical ventilator or assist with preventing reintubation (Ouellette et al, 2017).*
- Explore the client's wishes, if possible, before requiring mechanical ventilation support. Collaborate with the client, family, and provider regarding possible intubation and ventilation. Ask whether the client has advance directives and, if so, integrate them into the plan of care with clinical data regarding overall health and reversibility of the medical condition. **EB:** *Client preferences and goals of care need to be acknowledged and discussed when planning care. Advance directives protect client autonomy and help ensure that the client's wishes are respected. Many states now have Physician Orders for Life-Sustaining Treatment (POLST), Medical Orders for Life-Sustaining Treatment (MOLST), Medical Orders for Scope of Treatment (MOST), Physician Order for Scope of Treatment (POST), Do Not Resuscitate Order/Clinician Orders for Life-Sustaining Treatment (DNR/COLST), and Transportable Physician Orders for Patient Preferences (TPOPP) (House & Ogilvie, 2020).*

Home Care

- Weaning from a ventilator at home should be based on client stability and comfort of the client and caregivers under an intermittent care plan. Generally the client will be safer weaning in a hospital environment.

Dysfunctional Ventilatory Weaning Response

Domain 4 Activity/rest Class 4

Cardiovascular/pulmonary responses

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

V

NANDA-I

Definition

Inability to adjust to lowered levels of mechanical ventilator support that interrupts and prolongs the weaning process.

Defining Characteristics

Mild

Breathing discomfort; expresses feeling warm; fatigue; fear of machine malfunction; increased focus on breathing; mildly increased respiratory rate over baseline; perceived need for increased oxygen; psychomotor agitation

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Moderate

Abnormal skin color; apprehensiveness; blood pressure increased from baseline (<20 mm Hg); decreased air entry on auscultation; diaphoresis; difficulty cooperating; difficulty responding to coaching; facial expression of fear; heart rate increased from baseline (<20 beats/min); hyperfocused on activities; minimal use of respiratory accessory muscles; moderately increased respiratory rate over baseline

Severe

Adventitious breath sounds; agitation; asynchronized breathing with the ventilator; blood pressure increased from baseline (≥20 mm Hg); deterioration in arterial blood gases from baseline; gasping breaths; heart rate increased from baseline (≥20 beats/min); paradoxical abdominal breathing; profuse diaphoresis; shallow breathing; significantly increased respiratory rate above baseline; use of significant respiratory accessory muscles

Related Factors

Physiological Factors

Altered sleep-wake cycle; ineffective airway clearance; malnutrition; pain

Psychological Factors

Anxiety; decreased motivation; fear; hopelessness; inadequate knowledge of weaning process; inadequate trust in health care professional; low self-esteem; powerlessness; uncertainty about ability to wean

Situational

Environmental disturbances; inappropriate pace of weaning process; uncontrolled episodic energy demands

At-Risk Population

Individuals with history of unsuccessful weaning attempt; individuals with history of ventilator dependence >4 days

Associated Conditions

Decreased level of consciousness

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Dysfunctional Adult **Ventilatory Weaning** Response.

Risk for Other-Directed Violence

Domain 11 Safety/protection Class 3 Violence

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to behaviors in which an individual demonstrates that he or she can be physically, emotionally, and/or sexually harmful to others.

Risk Factors

Easy access to weapon; negative body language; pattern of aggressive anti-social behavior; pattern of indirect violence; pattern of other-directed violence; pattern of threatening violence; suicidal behavior

At-Risk Population

Individuals with history of childhood abuse; individuals with history of cruelty to animals; individuals with history of fire-setting; individuals with history of motor vehicle offense; individuals with history of substance misuse; individuals with history of witnessing family violence

Associated Conditions

Neurological impairment; pathological intoxication; perinatal complications; prenatal complications; psychotic disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Cessation; Abusive Behavior Self-Restraint; Aggression Self-Restraint; Distorted Thought Self-Control; Impulse Self-Control; Risk Detection

Example NOC Outcome with Indicators

Aggression Self-Restraint as evidenced by the following indicators: Refrains from harming others/Expresses/Vents needs and negative feelings in a nondestructive manner/Identifies when angry. (Rate the outcome and indicators of **Aggression Self-Restraint:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Stop all forms of abuse (physical, emotional, sexual; neglect; financial exploitation)
- Display no aggressive activity
- Refrain from verbal outbursts
- Refrain from violating others' personal space
- Refrain from antisocial behaviors
- Maintain relaxed body language and decreased motor activity
- Identify factors contributing to abusive/aggressive behavior
- Demonstrate impulse control or state feelings of control
- Identify impulsive behaviors
- Identify and talk about feelings; express anger appropriately
- Displace anger to meaningful activities
- Communicate needs appropriately
- Identify responsibility to maintain control
- Express empathy for victim
- Obtain no access or yield access to harmful objects
- Use alternative coping mechanisms for stress
- Obtain and follow through with counseling

Victim (and Children if Applicable) Will (Specify Time Frame)

- Have safe plan for leaving situation or avoiding abuse
- Resolve depression or traumatic response

Parent Will (Specify Time Frame)

- Monitor social/play contacts
- Provide supervision and nurturing environment
- Intervene to prevent high-risk social behaviors

V

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Abuse Protection Support; Anger Control Assistance; Behavior Management; Calming Technique; Coping Enhancement; Crisis Intervention; Delusion Management; Dementia Management; Distraction; Environmental Management: Violence Prevention; Mood Management; Physical Restraint; Seclusion; Substance Use Prevention

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NIC Activities—Environmental Management: Violence Prevention

Remove other individuals from the vicinity of a violent or potentially violent client; Provide ongoing surveillance of all client access areas to maintain client safety and therapeutically intervene as needed

Nursing Interventions and *Rationales*

- Aggressive/violent behavior may be impulsive, but more commonly it evolves in reaction to the environment (internal or external). In either case, nursing staff must go through specialized training to be prepared for a quick response. **EBN:** *Aggression management may include the use of physical or chemical restraints (medications), but the former should be used for brief periods only, and the latter should include monitoring for side effects. Music therapy may positively influence the environment (Fong, 2016).*
- Monitor the environment, evaluate situations that could become violent, and intervene early to deescalate the situation. Know and follow institutional policies and procedures concerning violence. Consider that family members or other staff may initiate violence in all settings. Enlist support from other staff rather than attempting to handle situations alone. **EBN:** *American Psychiatric Nurses Association (APNA) guidelines (2020) warn that workplace violence can occur in all settings and from a variety of sources. Nurses need to be aware and informed of department policies and procedures. Policies should be developed and training programs should be provided in proper use and application of restraints. All nursing units should develop a proactive plan for dealing with violent situations.*
- Assessment with tools that measure violence may be useful in predicting or tracking behavior and serving as outcome measures. **EBN:** *The Broset Violence Checklist (BVC) is an appropriate tool for acute psychiatric setting that predicts imminent threats and physical violence throughout hospitalizations (Lockertsen et al, 2021).*
- Identify clients with interpersonal hostile-dominance personality characteristics. **EBN/EB:** *A study found that interpersonal hostile-dominance personality characteristics were most strongly associated with aggression (Podubinski et al, 2017).*
- Assess for the presence of command hallucinations. **EB:** *Command hallucinations may direct the client to behave violently. Command hallucinations were identified as an independent significant risk factor associated with acute severe or fatal violence in clients with serious mental illness (Chan & Shehtman, 2019).*
- Apply verbal deescalation techniques when clients show increased irritability, hostility, or aggression. **EBN:** *A small quality improvement study found a clinically significant reduction in the rate of charted aggressive behavior after educating psychiatric nurses on verbal deescalation skills (Haefner, Dunn, & McFarland, 2021).*
- Apply **STAMPEDAR** as an acronym for assessing the immediate potential for violence. **EB:** *A review of current literature about violence against health care workers identified the following as factors and behaviors indicating the likelihood of a violent episode: staring, tone of voice, anxiety, mumbling, pacing, emotions, disease process, assertive/nonassertive behavior, and access to resources that might be used for violent behavior (STAMPEDAR) (d'Ettore et al, 2018).*
- Determine the presence and degree of homicidal or suicidal risk. **EB:** *Specific questions will elicit the necessary information: "Have you been thinking about harming someone?" "If yes, who?" "How often do you have these thoughts, and how long do they last?" "Do you have a plan"?" "What is it?" "Do you have access to the means to carry out that plan?" "What has kept you from hurting the person until now?" (Gunn, 2019).* Refer to the care plan for Risk for **Suicidal** Behavior.
- Establish trust, listen to client, convey safety, and assist in developing positive goals for the future. **EB:** *Therapeutic alliance is the nature of the relationship between the client and the nurse. A systematic review of therapeutic alliance and treatment outcome found that therapeutic alliance has a positive impact on treatment outcomes among individuals engaging in or at risk for aggressive behaviors (Fahlgren, Berman, & McCloskey, 2020).*
- Review state laws and mental health codes to determine local mandates for threat reporting by specific health care professionals. Many mental health providers are required to report harm or threats of harm to another person, referred to as the "duty to warn." **EB:** *Health care providers must be familiar with the law that applies to where they practice, as the jurisdictional law even in a given state can be dynamic and unpredictable (Felthous et al, 2021).*
- Place the client on the appropriate precaution monitoring and observation protocol. **EBN:** *A nursing study of continuous client monitoring found that the addition of a protocol designed to prevent violent and impulsive behavior significantly reduced the number of continuous monitoring hours (Ray et al, 2017).*
- Monitor the client's behavior closely, using engagement and support as elements of safety checks while avoiding intrusive overstimulation. **EBN:** *When lack of control exists, client safety is an important issue, and close*

observation is essential. Clients may feel overstimulated by intrusive close observation, resulting in agitation (Moola, 2017).

- Offer information about treatment, unit rules, and procedures. **EB:** *A review of the literature found support for interventions targeting improvement of staff communication skills. The improvement of skills included a protocol for talking to clients who exhibited aggressive behavior, discussing treatment goals with the client shortly after admission, explaining why the ward's door was locked and the exit rules, providing a schedule of staff meetings to explain staff members' absence from the ward, and clarifying the procedure for making an appointment with the psychiatrists (D'Ettore & Pellicani, 2017).*
- Implement recovery-focused care interventions. **EBN:** *A study found that the following recovery-focused care interventions could be used to reduce the risk of client aggression: (1) identifying the reason for the behavior before responding; (2) being sensitive to the client's trigger for aggression; (3) focusing on the client's strengths and support, not risks; (4) being attentive to the client's needs; and (5) reconceptualizing aggression as a learning opportunity (Lim, Wynaden, & Heslop, 2019).*

▲ After a violent event on a unit, debriefing and support of both staff and clients should be made available. **EBN:** *Debriefing shortly after a violent episode may restore a sense of control and autonomy. Debriefing can reveal clients' responses to the event and provides the opportunity for staff to offer reassurance and support. The evaluation of past aggression might prevent new aggressive incidents and prevent the use of coercive measures (Vermeulen et al, 2019).*

▲ Initiate and promote staff attendance at aggression management training programs. **EBN:** *Nurses who attended 32 hours of an aggression management training course showed a significant decrease in the mean total score of perceived stress after attending the training (Masa'Deh et al, 2020).*

Pediatric

- Assess for predictors of anger that can lead to violent behavior. **EBN:** *A correlational study of adolescent anger predictors identified trait anger, anxiety, depression, stress, exposure to violence, and parental drinking behaviors as predictors of anger. Frequency of religious participation was associated with decreased anger (Pullen et al, 2015).*

▲ In the case of child abuse or neglect, refer to child protective services. **EB:** *Nurses are mandated reporters and required by law to report suspected abuse of minor children or vulnerable adults (Lavigne et al, 2017).*

▲ Refer the adolescent client to a violence prevention program. **EB:** *Participation in a school-based violence prevention program for youth exposed to violence in their home, school, or community found that boys and girls decreased in reactive and proactive aggression perpetration. Boys also showed a decline in teen dating violence perpetration and victimization (Reidy et al, 2017).*

Geriatric

- Assess for aggressive behavior in clients with a diagnosis of dementia or severe mental illness. **EB:** *In a multivariate study of residents at an assisted living facility, dementia and severe mental illness were significant risk factors for resident aggression and abuse (Gimm, Chowdhury, & Castle, 2018).*
- For clients with dementia, provide music therapy. **EB:** *A systematic review of interventions with aggression in adults with dementia demonstrated significant improvement with music therapy. Person-centered care, communication skills training, and dementia care matching showed reductions in aggression for up to 6 months (Lizarondo, 2016).*
- Document and record suspected elder abuse according to mandated reporter regulations. **EB:** *The risk for elder abuse is increased during times of social isolation. Nurses are mandated reporters and required by law to report suspected abuse of vulnerable adults (Makaroun, Bachrach, & Rosland, 2020).*

Multicultural

- Exercise caution when using violence risk instruments for populations that have not been included in the testing of the instrument. **EB:** *A study to address the cross-cultural disparities in the forensic risk literature found concerns with negative labeling capacity, lack of cultural contextualization, individualized focus, and absence of cultural norms and practices in violence risk instruments (Shepherd & Willis-Esqueda, 2018).*

Home Care

- Be alert to the potential for violent behavior in the home setting. Respond to verbal aggression with interventions to deescalate negative emotional states. Violence is a process that can be recognized early. Deescalation involves reducing client stressors, responding to the client with respect, acknowledging the

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

client's feeling state, and assisting the client to regain control. If deescalation does not work, the nurse should leave the home.

- Assess family members or caregivers for their ability to protect the client and themselves. The safety of the client between home visits is a nursing priority. Caregivers often need assistance with recognizing or admitting fear of or danger from a loved one. **EBN:** *A qualitative study with home care staff and caregivers of clients with dementia advised that staff use a calm, compassionate approach and minimize controlling strategies such as medications or restraints in dealing with aggressive behavior. A person-centered approach was recommended (Lizarondo, 2016).*
- Assess access to lethal means risk factors in the home. **EB:** *A study of lethal means assessment among emergency department (ED) clients with a positive suicide risk screen found that among 545 suicidal clients discharged home from the ED, 85% had no documentation that any provider assessed access to lethal means (Betz et al, 2018).*

▲ For situations of suspected neglect or abuse, assist the client to develop an emergency plan with access to a cell phone. **EB:** *Client safety is a nursing priority. An emergency plan with access to a cell phone should address either immediate removal to a safe environment or identification of appropriate steps to take in the event of abuse and the securing of resources for the anticipated action (e.g., financial resources, packed bag, alternative living arrangements) (Souza Marques et al, 2020).*

- Encourage safe storage of firearms. **EB:** *To prevent firearm injuries, safe storage of firearms needs to be publicized and emphasized for firearm owners. Nurses can watch the following safe storage video with clients:* https://www.facs.org/quality-programs/trauma/advocacy/ipc *(Duncan et al, 2020).*

Client/Family Teaching and Discharge Planning

- Teach relaxation and exercise as ways to release anger and deal with stress. **EB:** *A study of the effect of progressive relaxation therapy found decreased signs and symptom of aggression among clients with risk of violent behavior (Lucya, Hadiyani, & Juniarni, 2019).*
- Teach cognitive-behavioral activities, such as active problem-solving, reframing (reappraising the situation from a different perspective), or thought stopping (in response to a negative thought, picture a large stop sign and replace the image with a prearranged positive alternative). Teach the client to confront his or her own negative thought patterns (or cognitive distortions), such as catastrophizing (expecting the very worst), dichotomous thinking (perceiving events in only one of two opposite categories), magnification (placing distorted emphasis on a single event), or unrealistic expectations (e.g., "should get what I want when I want it"). **EB:** *A study of the effects of Rockwood's prison-based Cognitive Behavioral Therapy/Risk–Needs–Responsivity (CBT/RNR) sex offender program found low rates of violence recidivism when compared with untreated offenders (Olver et al, 2020).*

▲ Refer perpetrators of violence to acceptance and commitment therapy. **EB:** *A study that examined the impact of an Acceptance and Commitment Therapy (ACT)–based program (Achieving Change Through Values-Based Behavior [ACTV]) found that fewer ACTV participants acquired any new criminal charges, domestic assault charges, or violence charges (Zarling, Bannon, & Berta, 2019).*

- Teach clients and families the use of appropriate community resources in emergency situations (e.g., hotline, economic resources access, community mental health agency, ED, 911 in most places in the United States, the toll-free National Domestic Violence Hotline [1-800-799-SAFE]). Virtual resources are increasing and should be made available to clients. **EB:** *The global pandemic has exacerbated the needs of clients and families experiencing violence. A survey of individuals with safety concerns found the need for increased support and economic resource access, coupled with modified safety planning and improved virtual approaches (Wood et al, 2021).*

V

Risk for Self-Directed Violence

Domain 11 Safety/protection Class 3 Violence

Kathleen L. Patusky, PhD, MA, RN, CNS, and Mamilda Robinson, DNP, APN, PMHNP-BC

NANDA-I

Definition

Susceptible to behaviors in which an individual demonstrates that he or she can be physically, emotionally, and/or sexually harmful to self.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Risk Factors

Behavioral cues of suicidal intent; conflict about sexual orientation; conflict in interpersonal relations; employment concern; engagement in autoerotic sexual acts; inadequate personal resources; social isolation; suicidal ideation; suicidal plan; verbal cues of suicidal intent

At-Risk Population

Individuals aged 15-19 years; individuals aged ≥45 years; individuals in occupations with high suicide risk; individuals with history of multiple suicide attempts; individuals with pattern of difficulties in family background

Associated Conditions

Mental health issues; physical health issues; psychological disorder

NOC (Nursing Outcomes Classification)

Refer to care plans for Risk for **Suicide**, **Self-Mutilation,** and Risk for **Self-Mutilation.**

Client Outcomes

Client Will (Specify Time Frame)

- Stop all forms of abuse/violence to self (physical, self-injurious emotional, sexual; neglect)
- Refrain from self-deprecation
- Identify factors contributing to abusive/self-injurious behavior
- Demonstrate impulse control or state feelings of control
- Identify impulsive behaviors
- Identify precursors to impulsive actions
- Identify consequences of impulsive actions to self
- Avoid high-risk environments and situations
- Identify and talk about feelings; express anger appropriately
- Communicate needs appropriately
- Demonstrate self control
- Use alternative coping mechanisms for stress
- Obtain and follow through with counseling

Client (and Children if Applicable) Will

- Have safe plan for leaving situation
- Resolve depression or traumatic response

Parent/Caregiver Will

- Monitor social/play contacts
- Provide supervision and nurturing environment
- Intervene to prevent high-risk social behaviors

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Abuse Protection Support; Anger Control Assistance; Behavior Management; Calming Technique; Coping Enhancement; Crisis Intervention; Mood Management; Dementia Management; Distraction; Environmental Management: Violence Prevention; Physical Restraint; Seclusion; Substance Use Prevention

Example NIC Activities Environmental Management: Violence and Self-Harm Prevention

Remove self from the vicinity of a violent or potentially violent client; Provide ongoing surveillance of all children's access areas to maintain child's safety and therapeutically intervene as needed

V

Nursing Interventions and *Rationales*

- Assess with suicide-screening tools as a part of a comprehensive clinical practice. Such tools can be helpful predictors of future self-harm. **EBN:** *Clients with an increased risk for suicide were 3 to 16 times more likely to attempt suicide and 7 to 25 times more likely to engage in self-directed violence over the next 12 months (Doran et al, 2016).*
- Screen clients for adverse childhood experiences (ACEs) and refer to ACE-informed services. **EB:** *A systematic review and meta-analysis found that risk for self-directed violence was very strong for individuals with at least 4 ACEs. Screening of adult clients for a history of ACEs can help both clients and professionals understand the underlying causes of health problems and enable better-informed treatment options (Hughes et al, 2017).*
- Assess the client's use of substances such as cigarettes, alcohol, and other drugs, and suggest monitoring and/or decreasing usage. **EB:** *Research suggests that substance use correlates to the likelihood of self-harm. There is an association between daily cigarette smoking and increased self-directed violence, therefore strategies should promote smoking cessation as well as the cessation of other substance misuse with the hopes of mitigating the risk of violence (Lewis et al, 2016). "Alcohol use disorder alone and drug use disorder(s) alone were both associated with significantly increased odds of committing self-directed, other-directed, and combined aggression" (Ghossoub et al, 2019).*
- Assess parental mental health history and recommend treatment for parents who suffer from psychiatric disease. Parental history of mental illness is a risk factor for self-harming behaviors, equally for males and females. **EB:** *Research shows that the risks for offspring suicide attempt were elevated across virtually the full spectrum of parental psychiatric disease. Incidence rate ratios were the most elevated for parental diagnoses of antisocial personality disorder, cannabis misuse, and for parental suicide attempt. Parental mood disorders conferred additional modest risk increases. A history of mental illness or suicide attempt in both parents was associated with twice the risks (Mok et al, 2016).*
- Place the client on the appropriate precaution monitoring and observation protocol. **EBN:** *A nursing study of continuous client monitoring found that the addition of a protocol designed to prevent violent and impulsive behavior significantly reduced the number of continuous monitoring hours (Ray et al, 2017).*

▲ Refer the client to dialectical behavior therapy (DBT). **EB:** *A meta-analysis found that DBT reduced self-directed violence ($d = -.324$, 95% CI = $-.471$ to $-.176$), and reduced frequency of psychiatric crisis services (DeCou, Comtois, & Landes, 2019).*

▲ Refer the client to an emergency department for monitoring and/or surveillance. **EB:** *Clients who are prone to self-harm and self-directed violence can be closely monitored in the emergency department for safety (Zwald et al, 2020).*

Pediatric

- Assess levels of violence in the home environment, and if necessary, take steps to decrease aggression in the family. **EBN/EB:** *High levels of self-harm were reported by youth witnessing and experiencing family aggression. (Zhang et al, 2015).*
- Discuss the client's experience in school, as students who feel unconnected to school, are unhappy at school, or feel that teachers are unfair may be more likely to self-harm in the future. **EB:** *Identification of those at risk of self-harm will enable preventive measures (Kidger et al, 2015).*
- Review the client's experience online, because victims—and also, but to a lesser extent, perpetrators—of cyberbullying have a greater incidence of self-harm. **EB:** *Individuals who are cyberbullied are at a greater risk than nonvictims of both self-harm and suicidal behaviors (John et al, 2018).*
- Investigate the use of cell phone applications to address and monitor self-harming tendencies. **EB:** *BlueIce is an app developed specifically for adolescents, and the "outcome data" are "encouraging" as a means to prevent self-harm (Tingley, Greenhalgh, & Stallard, 2020).*

Geriatric

- Conduct a comprehensive assessment, reviewing previous mental and physical disease diagnoses. **EB:** *A study found that previous mental health diagnoses were twice as prevalent and previous physical health conditions were 20% higher in the self-harm cohort compared with the comparison cohort (Morgan et al, 2018).*
- Closely monitor medication prescribing and dosage in this population. Provide medication education and discuss alternatives to avoid potential adverse situations. **EB:** *Older clients are often prescribed antidepressants, and some correlate more closely with self-harm (Morgan et al, 2018).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Client/Family Teaching and Discharge Planning

- Teach clients about healthy sleep patterns. **EB:** *Adequate education on sleep hygiene should be provided to client and family. The COVID-19 pandemic has had an impact on sleep-wake cycles, thus proper hygiene is warranted (Courtet et al, 2020).*
- Involve family members in the care of geriatric clients, whose incidents of self-harm may indicate distress that cannot easily be expressed in words. **EB:** *Research has shown that in individuals 80 years or older, family member's involvement and support is highly significant (Wand et al, 2018).*

Impaired Walking

Domain 4 Activity/rest Class 2 Activity/exercise

Wendie A. Howland, MN, RN-BC, CRRN, CCM, CNLCP, LNCC

NANDA-I

Definition

Limitation of independent movement within the environment on foot.

Defining Characteristics

Difficulty ambulating on decline; difficulty ambulating on incline; difficulty ambulating on uneven surface; difficulty ambulating required distance; difficulty climbing stairs; difficulty navigating curbs

Related Factors

Altered mood; environmental constraints; fear of falling; inadequate knowledge of mobility strategies; insufficient muscle strength; insufficient physical endurance; neurobehavioral manifestations; obesity; pain; physical deconditioning

Associated Conditions

Cerebrovascular disorders; impaired postural balance; musculoskeletal impairment; neuromuscular diseases; vision disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Ambulation, Mobility

Example NOC Outcome with Indicators

Ambulation as evidenced by the following indicators: Walks with effective gait/Walks at moderate pace/Walks up and down steps/Walks moderate distance. (Rate the outcome and indicators of **Ambulation:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes/Goals

Client Will (Specify Time Frame)

- Demonstrate optimal independence and safety in walking
- Demonstrate the ability to direct others on how to assist with walking
- Demonstrate the ability to use and care for assistive walking devices properly and safely

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Exercise Therapy: Ambulation

Example NIC Activities—Exercise Therapy: Ambulation

Assist client to use footwear that facilitates walking and prevents injury; Encourage to sit in bed, on side of bed ("dangle"), or in chair, as tolerated

Nursing Interventions and *Rationales*

- Progressive mobilization as tolerated (gradually raising head of bed [HOB], sitting in reclined chair, standing, with assistance). Progressing mobility gradually from bed rest to increased sit-to-stand times to short-distance walking and timed testing can result in shorter admission stays and time to recovery (Snow, 2019). See also the care plan for Impaired Physical **Mobility.**
- Consider and monitor for side effects of prescribed hydration and medications; medical diagnosis, physical condition; length of immobility contributing to orthostatic hypotension; and/or if lightheadedness, dizziness, syncope, or unexplained falls occur. **EB:** *Orthostatic hypotension is highly prevalent in clients with a number of neurogenic and nonneurogenic conditions, associated medications, and antihypertensive drugs (Biswas, Karabin, & Turner, 2019).*

▲ Assess for orthostatic hypotension if systolic pressure falls 15 mm Hg or diastolic pressure falls 7 mm Hg from sitting to standing within 3 minutes. If this occurs, replace client in bed and notify prescriber. Evaluation of change in heart rate can be useful to determine if orthostatic hypotension could be neurogenic. **EB:** *Orthostatic hypotension increases fall risk (Biswas, Karabin & Turner, 2019).*

- Apply thromboembolic deterrent (TED) stockings and/or elastic leg wraps as prescribed; raise HOB slowly in small increments to sitting, have client move feet/legs up and down, and then stand slowly; avoid prolonged standing. Movement enhances venous return, improving cardiac output and decreasing syncope.
- Assess for cognitive, neuromuscular, and sensory deficits that will affect safety when walking (e.g., stroke, diabetic neuropathy, history of falls).

▲ Take pulse rate/rhythm, respiratory rate, and pulse oximetry before walking clients, and reassess within 5 minutes of walking, then ongoing as needed. If abnormal, have the client sit for 5 minutes, then remeasure. If still abnormal, walk clients more slowly and with more help or for a shorter time, or notify physician. If

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

uncontrolled diabetes/angina/arrhythmias/tachycardia (100 beats per minute or more) or resting systolic blood pressure at or above 200 mm Hg or diastolic blood pressure at or above 110 mm Hg occurs, do not initiate walking exercise. Refer to the care plan Decreased **Activity** Tolerance.

- Assist clients to apply orthosis, immobilizers, splints, braces, and compression stockings as prescribed before walking.
- Eat frequent small, low-carbohydrate meals. Low-carbohydrate meals help prevent postprandial hypotension.
- Reinforce correct use of prescribed mobility devices, and remind clients of weight-bearing restrictions.
- Emphasize the importance of wearing properly fitting, low-heeled shoes with nonskid soles and socks/hose and of seeking medical care for foot pain or problems with abnormal toenails, corns, calluses, or diabetes. Refer to podiatric consultation if indicated.

▲ Use a snug gait belt with handles and assistive devices while walking clients, as recommended by the physical therapist. **EB:** *A gait belt should be applied before and during all ambulation and functional gait activities; it should be applied securely around the waist and held firmly. Do not rely on clothing for a safe grip (Tang et al, 2018).*

- Walk clients frequently with an appropriate number of people; have one team member state short, simple motor instructions. **EB:** *Standing/weight-bearing benefits gut motility, spasticity, and respiratory/bowel/bladder function and promotes muscle stretching (Tang et al, 2018).*
- Cue and manually guide clients with neglect as they walk. *Prevents clients bumping into objects/people.*
- Document the number of helpers, level of assistance (e.g., maximum, standby), type of assistance, and devices needed in communication tools (e.g., plan of care, client room signage, verbal report).

Special Considerations: Lower Extremity Amputation

▲ Consult with physical therapist for best practices for postoperative mobilization for the individual case. In most cases, a prosthesis will not be fitted until wound healing occurs.

- Recognize that ambulation with a prosthesis is more labor-intensive than with a native limb. **EB:** *Allow for slower walking speed and monitor for fatigue with any person with a new or old amputation (Myers & Chauvin, 2021).*
- Teach clients the importance of avoiding prolonged hip and knee flexion. If contractures occur, they will affect prosthesis fit and function and ability to achieve a more normal gait. **EB:** *Limit amount of time the client is permitted to sit to no more than 40 minutes of each hour. Ensure that when client sits, stands, or is recumbent, the hip and knee are in extension and periodic prone lying is recommended (Myers & Chauvin, 2021).*

Geriatric

▲ Assess for swaying, poor balance, weakness, and fear of falling while elders stand/walk using an objective fall-risk tool if possible. If present, implement fall protection precautions and refer for physical therapy evaluation and recommendations (Thiamwong et al, 2020).

▲ Review medications for polypharmacy (more than five drugs) and medications that increase the risk of falls, including sedatives, antidepressants, and drugs affecting the central nervous system. **EB:** *Consult with pharmacist as part of polypharmacy assessment (Nguyen, Wong, & Ciummo, 2020).*

- Encourage tai chi, physical therapy, or another exercise for balance, gait, and strength training in group programs or at home.
- Recommend vision assessment and consideration for cataract removal if needed.

Home Care

✱ Establish a support system for emergency and contingency care (e.g., wearable medical alert alarm, Internet-connected smart speaker; notify local emergency medical services [EMS] of potential need). Impaired walking may be life-threatening during a crisis (e.g., fall, fire, orthostatic episode).

- Assess for and modify any barriers to walking in the home environment.

▲ Use a standardized tool to assess need for referral for occupational therapist (OT) or physical therapist (PT). If indicated, refer to OT/PT for home assessment and evaluation for home assessment for barriers, individualized strength, balance retraining, an exercise plan, and environmental modifications for safety (Tan et al, 2021).

▲ Refer to home health services for support and assistance with activities of daily living (ADLs).

Client/Family Teaching and Discharge Planning

- Teach clients to check ambulation devices weekly for cracks, loose nuts, or worn tips and to clean dust and dirt on tips.
- Teach diabetics that they are at risk for foot ulcers and teach them preventive interventions. See care plan for Risk for Ineffective Peripheral **Tissue Perfusion.**

▲ Instruct clients at risk for osteoporosis or hip fracture to bear weight, walk, engage in resistance exercise (with appropriate adjustments for conditions), ensure good nutrition (especially adequate intake of calcium and vitamin D), drink milk, stop smoking, monitor alcohol intake, and consult a physician for appropriate medications.

Wandering

Domain 4 Activity/rest Class 3 Energy balance

Olga F. Jarrín, PhD, RN, Linda J. Hassler, DNP, RN, GCNS-BC, FGNLA, and Nishat S. Poppy, BSN, RN

NANDA-I

Definition

Meandering, aimless, or repetitive locomotion that exposes the individual to harm; frequently incongruent with boundaries, limits, or obstacles.

Defining Characteristics

Eloping behavior; frequent movement from place to place; fretful locomotion; haphazard locomotion; hyperactivity; locomotion interspersed with nonlocomotion; locomotion into unauthorized spaces; locomotion resulting in getting lost; locomotion that cannot be easily dissuaded; long periods of locomotion without an apparent destination; pacing; periods of locomotion interspersed with periods of nonlocomotion; persistent locomotion in search of something; scanning behavior; searching behavior; shadowing a caregiver's locomotion; trespassing

Related Factors

Altered sleep-wake cycle; desire to go home; environmental overstimulation; neurobehavioral manifestations; physiological state; separation from familiar environment

At-Risk Population

Individuals with premorbid behavior

Associated Conditions

Cortical atrophy; psychological disorder; sedation

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Safe Wandering; Safe Home Environment; Safe Health Care Environment; Surveillance: Safety; Caregiver Emotional Health; Caregiver-Client Relationship; Family Normalization: Autism Spectrum Disorder; Family Normalization: Dementia; Community Competence

Example NOC Outcome with Indicators

Safe Wandering as evidenced by the following indicators: Moves about without harming self or others/Sits for more than five minutes at a time/Paces a given route/Appears content in environment/Distracts easily/Can be redirected from unsafe activities. (Rate the outcome and indicators of **Safe Wandering:**
1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain safe and free from falls
- Maintain psychological well-being and reduce need to wander
- Reduce episodes of wandering in restricted areas/getting lost/elopement
- Maintain appropriate body weight
- Maintain physical activity and remain comfortable and free of pain

Caregiver Will (Specify Time Frame)

- Be able to explain interventions they can use to provide a safe environment for a care receiver who displays wandering behavior
- Develop strategies to reduce caregiver stress levels

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Dementia Management: Wandering; Anxiety Reduction; Area Restriction; Exercise Promotion; Environmental Management; Family Mobilization; Family Support; Normalization Promotion

Example NIC Activities—Dementia Management: Wandering

Include family members in planning, providing, and evaluating care to the extent desired; Identify usual patterns of wandering behavior; Alert neighbors and police about the person's wandering behavior; Provide a secure and safe place for wandering; Encourage physical activity during the daytime; Consider use of electronic devices (i.e., GPS tracking devices, door alarms) to locate person and monitor wandering.

Nursing Interventions and *Rationales*

- Provide safe and secure surroundings that deter and detect accidental elopements, using perimeter control devices (door alarms) or electronic tracking systems (including radiofrequency identification [RFID] tags, global positioning system [GPS] locator, smart watch, or cell phone application). **EB:** *Electronic tracking and tagging can provide a sense of safety for caregivers and encourage individual autonomy (Mangini & Wick, 2017).*
- Assess for physical distress or unmet needs (e.g., hunger, thirst, pain/discomfort, elimination needs). **EBN:** *Behavioral signs of unmet need for bowel movement or urination include anxiety, taking off/putting on clothes, restlessness, attempting to go elsewhere, scratching skin, repetitive behavior, and making strange sounds (Shih et al, 2015).*
- Assess for emotional or psychological distress, such as anxiety, fear, or feeling lost, considering the situated experience of the client. **EB:** *Restlessness and wandering may be understood as expressions of existential needs and feelings of anxiety, loneliness, and separation (Solomon & Lawlor, 2018).*

- Assess and document the pattern, rhythm, and frequency of wandering over time. **EBN:** *Wandering should be assessed with one or more of the following scales: the Revised Algase Wandering Scale (RAWS), or its version for community (RAWS-CV) and long-term care settings (RAWS-LTC) (Graham, 2017).*
- Obtain a psychosocial history from caregivers, including stress-coping behaviors. **EBN:** *A qualitative study of wandering behavior from the perspectives of older adults with mild to moderate dementia in long-term care discovered six themes: Walking as Enjoyable, Walking for Health Benefits, Walking as Purposeful, Walking as a Lifelong Habit, Walking as a Form of Socialization, and Walking to Be With Animals (Adekoya & Guse, 2019).*
- Observe the location and environmental conditions in which wandering is occurring and modify those that appear to provoke boundary transgression or unsafe wandering. **EBN:** *Simple environmental modifications that disguise a doorway to a potentially hazardous area may reduce entry into these spaces (MacAndrew et al, 2019).*
  - Assess the person's environment and advocate for appropriate modifications using a survey such as the Wayfinding Evidence-Based Checklist and Rating (WEBCAR) instrument (Benbow, 2013).
  - Use a full-length mirror in front of exit doors to deter elopement.
  - Use camouflage (a cloth panel, painted mural, or wall hanging) to cover doorknobs or locks (check fire safety code/policy and never obscure an emergency red EXIT sign).
  - Change the floor pattern in front of door that should not be opened to create a visual, subjective barrier (e.g., illusion of a step, black hole, or pit).
- Increase social interaction and offer structured activity and stress-reducing approaches, such as walking, exercise, music, massage, rocking chair, and activities using household methods and a prepared environment (e.g., watering plants, flower arranging, gardening, preparing meals, shining shoes, setting table, wrapping boxes, watercolor painting, sewing buttons, sorting objects, folding laundry, matching socks, stereognostic/mystery bags, doll therapy, puzzles, games, and crafts). **EB:** *Wandering in restricted areas was reduced 50% to 80% by the use of multimodal behavioral approaches and cognitive techniques such as problem-solving, behavioral rehearsal, and relaxation training (Nascimento Dourado & Laks, 2016).* **EBN:** *Low stress and mentally stimulating environments promote psychological well-being among people living with dementia in long-term care settings (Lee et al, 2017).*
- When using electronic tracking technologies, an approach emphasizing relationships, respect, and the individual needs of the person and caretaker is best suited to finding solutions that both protect and empower. **EB:** *Balancing the ethical principles of beneficence and respect in treating cognitively impaired persons goes beyond the necessary step of evaluating decision-making capacity to include partnering with families, caretakers, and cognitively impaired individuals who wander in a collaborative coalition of care (Yang & Kels, 2017).*
- Role model person-centered care and provide appropriate supervision, support, and education of direct-care staff. **EBN:** *Positive work environments for staff are associated with lower prevalence of client elopement, restlessness, and wandering behaviors compared with less positive work environments (Gu, 2015).*
- Help older adults find their rooms by placing signs with their names and portraits of themselves at a younger age next to the doorways. **EB:** *External memory aids in the form of signs with the person's name and portrait photograph can help people with dementia navigate their environment (Jensen & Padilla, 2017).*
- Provide a regularly scheduled and supervised exercise or walking program, particularly if wandering occurs excessively during the night or at times that are dangerous. **EBN:** *A structured physical activity program resulted in a statistically significant reduction in agitation and eloping behavior for individuals living with dementia in care homes (Traynor et al, 2018).*
- Refer to the care plan for **Caregiver** Role Strain. For clients with dementia, also see care plan for Chronic **Confusion.**

Multicultural

- Assess preferences for use of social services and family caregiver availability and willingness to provide care. **EB:** *A qualitative study in North Carolina found that service providers assumed that Latino families did not want to use government services and that they preferred to care for their elders; however, Latino participants expressed the need to work and not depend on family members for caregiving and financial support (Larson et al, 2017).*

Client/Family Teaching and Discharge Planning

- Teach caregivers about missing person resources such AMBER and Silver Alert public safety systems, MedicAlert Safe Return/Safely Home, Project Lifesaver, and related resources from the Alzheimer's

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Association and National Autism Association; for example, the Autism Wandering Awareness Alerts Response and Education (AWAARE) Collaboration's Big Red Safety Box and Digital Toolkits for Caregivers (available in English and Spanish), First Responders, and Teachers. **EB:** *Similar to the AMBER alert emergency response system for missing children, the Silver alert system has been enacted in some but not all states (Gergerich & Davis, 2017).*

Home Care

- The previously mentioned interventions may be adapted for home care use.
- Help the caregiver set up a plan to reduce and manage wandering behavior, including a plan of action to use if the client elopes or is missing:
  - Assist the family to set up a plan of exercise for the client, including safe walking within appropriate geographic boundaries. **EB:** *Welfare concerns arise when freedom to walk outdoors is restricted; however, the risk of getting lost or injured must be minimized (Bantry White & Montgomery, 2016).*
  - Assess the home environment for modifications that will protect the client and prevent elopement. **EB:** *Monitoring and tracking devices are available to notify the caregiver of the client's movements, including door and bed alarms, and GPS locators worn as a necklace, bracelet/watch, shoe tag, and for clients with a cell phone can be supplemented with privacy setting for location sharing (Gu, 2015).*
  - Refer to supportive community and social services, such as an Area Office on Aging, the Alzheimer's Association, National Autism Association, home health care (psychiatric/geriatric nurse, occupational therapist, medical social worker), and companion or respite care to assist with the impact of caregiving for the wandering client.
  - Provide information about therapy dog/assistance dog resources. **EB:** *Therapy dogs provide a calming presence and may be trained to assist with safe walking and boundaries or to keep children with autism or adults with dementia from straying by circling them and barking to alert family members (O'Haire, 2017).*

Trauma syndrome
  post, 98, *752–756*, 752b–753b
    risk for, 98, *756–759*, 757b
  rape, 103, *787–791*, 787b–788b
Traumatic brain injury (TBI), 117
  activity tolerance, decreased, risk for, 131
Traumatic event, 120
Traveler's diarrhea (TD), 120
Treatment regimen
  disturbed body image and, 175
  risk for aspiration and, 152
  risk for bleeding, 167
Trembling of hands, 120
Tricuspid atresia, 120
Trigeminal neuralgia, 120
Truncus arteriosus, 120
TS. *See* Tourette's syndrome
TSE. *See* Testicular self-examination
Tubal ligation, 120
Tube feeding, 120–121
Tuberculosis (TB), 121
  pulmonary, 117
Tumor
  brain, 32–33
  kidney. *See* Wilms' tumor
  Wilms', 123
TURP. *See* Transurethral resection of the prostate
12-lead ECG, risk for decreased cardiac tissue perfusion, 205

U

Ulcer
  duodenal, 121
  gastric, 57, 121
  peptic, 93, 121
  stasis, 121
Ulcerative colitis. *See* Inflammatory bowel disease
Unilateral neglect, 85, *1008–1010*, 1008b
Unilateral neglect, of one side of body, 121
Uninsured/low income, readiness for enhanced religiosity, 802
Unintentional perioperative hypothermia, 534–536
Unsanitary living conditions, 121
Unstable blood glucose level, risk for, *456–462*, 456b–457b
Unstable blood pressure, risk for, 113
Unstageable pressure injury, 767–768, 773, 892
Upper respiratory infection. *See* Cold, viral
Urge suppression, 571
Urge urinary incontinence, *567–572*, 568b
  risk for, *572*
Urgency to urinate, 121
Urinary catheter, 121
Urinary catheterization, 37
  autonomic dysreflexia and, 162
  risk for autonomic dysreflexia and, 166
Urinary diversion. *See* Ileal conduit
Urinary elimination, impaired, 121, *1010–1014*, 1011b
Urinary incontinence, 67, 121
  disability-associated, *555–559*, 555b–556b
  mixed, *559–562*, 559b–560b
  stress urinary incontinence, *563–567*, 563b–564b
  urge urinary incontinence, *567–572*, 568b
    risk for, *572*
Urinary retention, 121, *1015–1020*, 1015b
  postoperative, 1018
  risk for, *1020*
Urinary tract infection (UTI), 121, 1012
  autonomic dysreflexia and, 162
  risk for autonomic dysreflexia and, 166
Urinary tract injury, risk for, *607–610*, 607b–608b
Urolithiasis. *See* Kidney, stone
Uterine atony
  in labor. *See* Dystocia
  in postpartum. *See* Postpartum hemorrhage
Uterine bleeding, 121
UTI. *See* Urinary tract infection

V

VAD. *See* Ventricular assist device
Vaginal hysterectomy, 121–122
Vaginitis, 122
Vagotomy, 122
Value system conflict, 122
Varicose veins, 122
Vascular access devices, damage to, contrast media, 282–283
Vascular dementia. *See* Dementia
Vascular trauma, risk for, *1020–1024*, 1021b
Vein damage, contrast media and, 282–283
Venereal disease. *See* Sexually transmitted disease
Venous insufficiency, 994–995
Venous thromboembolism (VTE), 122–123
  autonomic dysreflexia and, 162
  risk for autonomic dysreflexia and, 166
Ventilated client, mechanically, 122
Ventilation, spontaneous, impaired, *1024–1030*, 1025b
Ventilator support, for impaired spontaneous ventilation, 1026–1028
Ventilatory weaning response, dysfunctional, *1036–1037*
  adult, *1030–1036*, 1031b
Ventricular assist device (VAD), 121
Ventricular fibrillation. *See* Dysrhythmia
Verbal communication, impaired, *237–242*, 238b
  NANDA-I, 237–241
  NIC, 238–241
  NOC, 238
Vertigo. *See* Syncope
Veterans, 122
  readiness for enhanced religiosity, 802
Violence, other-directed, risk for, *1037–1042*, 1038b–1039b
Violence, self-directed, risk for, *1042–1045*, 1043b
Violent behavior, 122
Viral cold, 40
Viral gastroenteritis, 122
Vision impairment, 122–123
Volume
  deficient fluid volume, 55, *431–437*, 432b
  excess fluid volume, 55, *437–441*, 438b
  risk for deficient fluid volume, *442*
  risk for imbalanced fluid volume, *427–431*, 427b–428b
Vomiting, 123

W

Walking, impaired, 123, *1045–1048*, 1046b
Wandering, 123, *1048–1051*, 1049b
Warts, genital. *See* Sexually transmitted disease
Water-electrolyte imbalance, dysfunctional adult ventilatory weaning response and, 1031
Weakness, 123
  muscular, 83
  risk for allergy reaction and, 141
Weaning response, ventilatory, dysfunctional, *1036–1037*
Weight
  gain, 123
  loss, 123
Well-being, spiritual, readiness for enhanced, *924–928*, 925b
Wellness-seeking behavior, 123
Wernicke-Korsakoff syndrome. *See* Korsakoff's syndrome
West Nile virus, 123
Wheelchair mobility, impaired, 81, *659–663*, 659b–660b
Wheelchair use problems, 123
Wheezing, 123
  risk for allergy reaction and, 141
Whooping cough, 94
Will, living, 75
Wilms' tumor, 123
Withdrawal
  from alcohol, 123
  from drugs, 123
Wound. *See also* Lacerations
  debridement, 123
  dehiscence, 123
  disturbed body image and, 175
  infection, 123
  open, 123
