- Maintain the client's core temperature at normal levels, using warming devices as needed. **EB:** *Hypothermia (body temperature <36°C) is present in the postoperative period in 26% to 90% of all clients who have undergone elective surgery. The risk of hypothermia is particularly high in clients over 60 years of age with poor nutritional status and preexisting disease that impairs thermoregulation (e.g., diabetes mellitus with polyneuropathy), and in those who have had major or lengthy surgery. Lower temperatures in the operating room also increase the risk of hypothermia: the lower the temperature, the higher the risk (Torossian et al, 2015).*
- Fluids administration during surgery can increase risk of hypothermia. **EB:** *Research has shown that perioperative hypothermia can adversely affect the cardiopulmonary system (Giuliano & Hendricks, 2017).*

Postoperative

- Continue to monitor fluids postoperatively. **EB:** *Restrictive fluid therapy and liberal conventional therapy were associated with similar rates of overall and cardiopulmonary complications; however, restrictive fluid therapy was associated with a more rapid recovery and a shorter length of hospital stay (Jia et al, 2017). Also, fluid overload is an independent risk factor for the development of acute kidney injury (Salahuddin et al, 2017).*
- Assess the client for development of tissue edema, especially after cataract surgery in clients with comorbidities such as diabetes. **EB:** *A history of diabetes mellitus has been found to be an independent risk factor for the development of postoperative cystoid macular edema in clients undergoing cataract surgery (Ovewole et al, 2017).*
- Recognize that IV fluid replacement decisions incorporate multiple assessment parameters such as hourly urine output, blood pressure, heart rate, respiratory rate, lung sounds, output from drains, and changes in laboratory results (e.g., hemoglobin/hematocrit, serum electrolytes).

Geriatric

- Check skin turgor of older clients on the forehead, subclavian area, or inner thigh; also look for the presence of longitudinal furrows on the tongue and dry mucous membranes. **EB:** *Older people commonly have decreased skin turgor from normal age-related loss of elasticity, and checking skin turgor on the arm is not reflective of fluid volume (Fingerhood, 2021).*
- Closely monitor urine output, concentration of urine, and serum BUN/creatinine results. **EB:** *Reduced renal perfusion and altered renal function as a normal or abnormal change in physiological aging can compromise the client's fluid volume status (Fingerhood, 2021).*
- Monitor older clients for excess fluid volume during the treatment of deficient fluid volume: auscultate lung sounds, assess for edema, and trend vital signs.
- Assess the older client's cognitive status. **EB:** *Cognitive impairment is a risk factor associated with dehydration, especially in the older adult (Fingerhood, 2021).*

Pediatric

- Assess the pediatric client's weight, length of NPO status, and underlying illness, and the surgical procedure to be performed.
- Recognize that newborns require very little fluid replacement when undergoing major surgical procedures during the first few days of life.
- Monitor pediatric surgical clients closely for signs of fluid loss.
- Administer fluids preoperatively until NPO status must be initiated so that fluid deficit is decreased.
- Perform an assessment for signs of fluid responsiveness in the pediatric client. **EB:** *A systematic review found that respiratory variation was the only assessment parameter to most reliably predict a pediatric client's responsiveness for fluid administration (Zeretzke-Bien, 2018).* **EB:** *Rehydration solutions such as low osmolality solutions have been shown to be safe and effective for correcting dehydration in children (Kumar et al, 2015).*

Deficient Fluid Volume

Domain 2 Nutrition Class 5 Hydration

Dina M. Hewett, PhD, RN, NEA-BC

NANDA-I

Definition

Decreased intravascular, interstitial, and/or intracellular fluid. This refers to dehydration, water loss alone without change in sodium.

Defining Characteristics

Altered mental status; altered skin turgor; decreased blood pressure; decreased pulse pressure; decreased pulse volume; decreased tongue turgor; decreased urine output; decreased venous filling; dry mucous membranes; dry skin; increased body temperature; increased heart rate; increased serum hematocrit levels; increased urine concentration; sudden weight loss; thirst; weakness

Related Factors

Difficulty meeting increased fluid volume requirement; inadequate access to fluid; inadequate knowledge about fluid needs; ineffective medication self-management; insufficient fluid intake; insufficient muscle mass; malnutrition

At-Risk Population

Individuals at extremes of weight; individuals with external conditions affecting fluid needs; individuals with internal conditions affecting fluid needs; women

Associated Conditions

Active fluid volume loss; deviations affecting fluid absorption; deviations affecting fluid elimination; deviations affecting fluid intake; excessive fluid loss through normal route; fluid loss through abnormal route; pharmaceutical preparations; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Fluid Balance; Hydration; Nutritional Status: Food and Fluid Intake

Example NOC Outcome with Indicators

Fluid Balance as evidenced by the following indicators: Elastic skin turgor/Moist mucous membranes/Orthostatic hypotension not present/24-hour intake and output balance/Urine specific gravity. (Rate each indicator of **Fluid Balance:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain urine output of 0.5 to 1.5 mL/kg/h or at least more than 1300 mL/day
- Maintain normal blood pressure, heart rate, and body temperature
- Maintain elastic skin turgor; moist tongue and mucous membranes; and orientation to person, place, and time
- Explain measures that can be taken to treat or prevent fluid volume loss
- Describe symptoms that indicate the need to consult with health care provider

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Fluid Management; Hypovolemia Management; Shock Management: Volume

Example NIC Activities—Fluid Management

Monitor hydration status (e.g., moist mucous membranes, adequacy of pulses, and orthostatic blood pressure) as appropriate; Administer intravenous (IV) therapy, as prescribed

Nursing Interventions and *Rationales*

- Watch for early signs of hypovolemia, including thirst, restlessness, headaches, and inability to concentrate. *Thirst is often the first sign of dehydration (Canfield, 2021).* **CEB:** *A study of healthy women showed heart rate was increased by fluid restriction along with increased urine specific gravity, darker urine color, and increased thirst. They also experienced decreased alertness and increased sleepiness, fatigue, and confusion (Pross et al, 2013).* **EB:** *A combination of biochemical markers that include serum osmolality (i.e., blood urea nitrogen and creatinine) and urine osmolality and specific gravity, blood pressure assessment and clinical symptoms such as thirst, dry mouth, lack of tears provide reliable assessment of dehydration (Armstrong et al, 2016).*
- Recognize symptoms of cyanosis, cold clammy skin, weak thready pulse, confusion, and oliguria as late signs of hypovolemia. **EB:** *These symptoms occur after the body has compensated for fluid loss by moving fluid from the interstitial space into the vascular compartment (Canfield, 2021).*
- Monitor pulse, respiration, and blood pressure of clients with deficient fluid volume every 15 minutes to 1 hour for the unstable client and every 4 hours for the stable client. *Vital sign changes seen with fluid volume deficit include tachycardia, tachypnea, decreased pulse pressure first, then hypotension, decreased pulse volume, and increased or decreased body temperature (Canfield, 2021).* **CEB:** *A systematic review demonstrated that hypotension and tachycardia, and occasionally fever, are clinical signs of dehydration (Jéquier & Constant, 2010).*
- Check orthostatic blood pressures with the client lying, sitting, and standing. **EB:** *A decrease in systolic blood pressure of 20 mm Hg or a decrease in diastolic blood pressure of 10 mm Hg within 3 minutes of*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

standing when compared with blood pressure from the sitting position is considered orthostatic hypotension. This can occur with dehydration or cardiovascular disorders (Wedro & Stöppler, 2019).

- Note skin turgor over bony prominences such as the hand or shin.
- Monitor for the existence of factors causing deficient fluid volume (e.g., hypovolemia from vomiting, diarrhea, difficulty maintaining oral intake, fever, uncontrolled type 2 diabetes, diuretic therapy). **EB:** *Early identification of risk factors and early intervention can decrease the occurrence and severity of complications from deficient fluid volume and acute kidney injury (Dean, 2020; Canfield, 2021).*
- Observe for dry tongue and mucous membranes, and longitudinal tongue furrows. **EB:** *These are symptoms of decreased body fluids (Armstrong et al, 2016).*
- Recognize that checking capillary refill is an assessment of peripheral perfusion and may not be helpful in identifying fluid volume deficit. **EB:** *Capillary refill can appear to be normal in clients with sepsis or shock because increased body temperature dilates peripheral blood vessels and capillary return may be immediate (Canfield, 2021). A quick test is compression of the nail bed sufficient to cause blanching. If there is good blood flow to the nail bed, a pink color should return in less than 2 seconds after pressure is removed. Slow return to pink color can indicate dehydration (White, 2012; Bridges, 2017).* **CEB:** *Capillary refill has been shown to be a good clinical indicator to detect poor perfusion with good specificity but poor sensitivity (Shimizu et al, 2012).*
- Weigh client daily and watch for sudden decreases, especially in the presence of decreasing urine output or active fluid loss. **EB:** *Body weight changes of 1 kg (2.2 pounds) represent a fluid loss of 1 L (Canfield, 2021).*
- Monitor total fluid intake and output every 4 hours (or every hour for the unstable client or the client who has urine output equal to or less than 0.5 mL/kg/h). **EB:** *Recognize that urine output is an indicator of fluid balance. However, urine output alone does not differentiate between volume-sensitive reductions in glomerular filtration rate and structural kidney injury (Schrezenmeier et al, 2017).*
- A urine output of less than 0.5 mL/kg/h for more than 6 hours may be indicative of acute kidney injury (Dean, 2020; Molinari et al, 2020). Nevertheless, in any condition of hypovolemia, renal perfusion pressure falls. If it falls below the level of autoregulation (BP <80 mm Hg), renal blood flow and glomerular filtration will fall (Andreucchi et al, 2017). **EB:** *The RIFLE criteria define* oliguria *as urine output less than 0.5 mL/kg/hr for each of six or more consecutive hours, which is thought to confer "risk" of kidney injury; when urine output is less than 0.5 mL/kg/h and persists for 12 or more consecutive hours, the kidneys are considered to be "in injury" (James et al, 2016). The Kidney Disease: Improving Global Outcomes (KDIGO) guidelines indicate that acute kidney injury is an increase in creatinine 1.5 to 1.9 times baseline and urine output <0.5 mL/kg/h for 6 to 12 hours (Alseiari et al, 2016).*
- Note the color of urine, urine osmolality, and specific gravity. **EB:** *Normal urine is straw colored or amber. Dark-colored urine with a specific gravity greater than 1.030 and a high urine osmolality reflects fluid volume deficit (Kerber, 2021). Although these tools for dehydration screening have been advocated for use in the elderly, their diagnostic accuracy is low and may not be useful (Hooper et al, 2016b).*
- Provide fresh water and oral fluids preferred by the client (distribute over 24 hours [e.g., 1200 mL during days, 800 mL during evenings, and 200 mL during nights]), provide prescribed diet, offer snacks (e.g., frequent drinks, fresh fruits, fruit juice), and instruct significant other to assist the client with feedings as appropriate. **EB:** *Distributing the intake over the entire 24-hour period and providing snacks, specifically those with creatine and carnitine, and beverages including caffeine may improve muscular ability, endurance, and alertness (Somes, 2020).*

▲ Provide oral replacement therapy as ordered and tolerated with a hypotonic glucose-electrolyte solution when the client has acute diarrhea or nausea/vomiting. Provide small, frequent quantities of slightly chilled solutions. **EB:** *Maintenance of oral intake stabilizes the ability of the intestines to absorb nutrients and promote gastric emptying (Gaspar & Mentes, 2021); glucose-electrolyte solutions increase net fluid absorption while correcting deficient fluid volume. Use diluted carbohydrate-electrolyte solutions, such as sports replacement drinks, and ginger ale (Lešnik et al, 2017). The use of diluted oral replacement fluids has been found to reduce the need for IV hydration (Lešnik et al, 2017).*

▲ Administer antidiarrheals and antiemetics as ordered and appropriate. Consider what the client is eating to prevent further diarrhea (Bolen, 2020). The goal is to stop the loss that results from vomiting or diarrhea. Refer to care plan for **Diarrhea** or **Nausea.**

- If the client is on enteral feedings, evidence has shown either continuous or intermittent feedings had similar results regarding diarrhea and nausea (Houston & Fuldauer, 2017). **EB:** *Evaluate the rate of enteral feeding formula administration and other medications to address diarrhea and nausea (Houston & Fuldauer, 2017).*

▲ Hydrate the client with isotonic IV solutions as prescribed. **EB:** *For clients with mild to moderate fluid deficit, lactated Ringer's should be used for fluid volume replacement (Canfield, 2021).*

● Assist with ambulation if the client has postural hypotension. **EB:** *Hypovolemia causes orthostatic hypotension, which can result in syncope when the client goes from a sitting to standing position (Canfield, 2021).*

Critically Ill

▲ Monitor stroke volume, passive leg lift, and ultrasound as trends for more accurate fluid volume status. **EB:** *Hemodynamic pressures such as central venous pressure (CVP) and pulmonary artery pressures have been demonstrated to be less predictive and specific of fluid volume responsiveness (Barlow et al, 2020), whereas changes in stroke volume measured by a number of noninvasive methods including passive leg lift may more accurately predict fluid volume responsiveness of a client (Bridges, 2017; Canfield, 2021).*

▲ Monitor serum and urine osmolality blood urea nitrogen (BUN)/creatinine ratio and hematocrit for elevations. **EB:** *These are all measures of concentration and will be elevated with decreased intravascular volume (Armstrong et al, 2016).*

▲ Insert an indwelling urinary catheter if ordered and measure urine output hourly. Notify health care provider if urine output is less than 0.5 mL/kg/h. **EB:** *A decrease in urine output is seen with poorly perfused kidneys and a drop in the glomerular filtration rate in the client with normal kidney function, and action, if taken early, can prevent further deterioration. Intensive monitoring of urine output is associated with increased detection of acute kidney injury and improved outcomes (Jin et al, 2017; Molinari et al, 2020; Kerber, 2021).*

▲ When ordered, initiate a fluid challenge of crystalloids (e.g., lactated Ringer's or 0.9% normal saline) for replacement of intravascular volume. **EB:** *Guidelines for early goal-directed therapy (EGDT) have been developed by the Surviving Sepsis campaign; however, EGDT in one study did not significantly decrease mortality (Zhang et al, 2017). A systematic review of the literature found that the passive leg raise intervention was valid and reliable in evaluating critically ill and mechanically ventilated clients' need for fluid resuscitation compared with IV fluid challenges that may result in fluid overload (Assadi, 2017).*

▲ Monitor the client's response to prescribed fluid therapy and fluid challenge, especially noting vital signs (mean arterial pressure [MAP] >65 mm Hg in the first 6 hours of treatment, systolic blood pressure >100 mm Hg) (Singer, 2016; Rhodes et al, 2017), urine output, blood lactate concentrations, and lung sounds. **EB:** *A fluid challenge can help the client with deficient fluid volume regain intravascular volume quickly, but the client must be carefully observed to ensure that he or she does not go into fluid volume overload because excess fluid volume can lead to organ edema and increased mortality (Assadi, 2017; Canfield, 2021).*

● Position the client flat with legs elevated when hypotensive, if not contraindicated. **EB:** *This position enhances venous return and, coupled with stroke volume measurement, is a simple noninvasive technique to determine fluid responsiveness (Assadi, 2017).*

▲ Monitor trends in serum lactic acid levels and base deficit obtained from blood gases as ordered. **EB:** *A trend of increasing lactic acid levels >2.0 has been shown to increase mortality than levels less than 2.0 (Seymour et al, 2016; Rhodes et al, 2017).*

▲ Consult provider if signs and symptoms of deficient fluid volume persist or worsen. **EB:** *Prolonged deficient fluid volume increases the risk for development of complications, including decrease in cognitive function, weakness, tachycardia, hemodynamic instability, and kidney injury (Singer, 2016).*

Pediatric

● Monitor the child for signs of deficient fluid volume, including sunken eyes, decreased tears, dry mucous membranes, poor skin turgor, and decreased urine output (Hockenberry et al, 2019). **EB:** *These assessment factors are more significant in identifying dehydration, but a combination of physical examination findings is a much better predictor than individual signs (Carson et al, 2017).*

▲ Reinforce the health care provider recommendation for the parents to give the child oral rehydration fluids to drink in the amounts specified, especially during the first 4 to 6 hours to replace fluid losses. Consider using diluted oral rehydration fluids. Once the child is rehydrated, an orally administered maintenance solution should be used along with food. **EB:** *A study demonstrated that treatment with oral rehydration fluids for children was generally as effective as IV fluids, and IV fluids did not shorten the duration of gastroenteritis and are more likely to cause adverse effects than oral rehydration therapy (Carson et al, 2016).* **EB:** *Current clinical practice guidelines have shown that diluted oral replacement fluids and some drugs resulted in reductions in stool output, decreased vomiting, and less need for IV hydration (Carson et al, 2017).*

● Recommend that the mother resume breastfeeding as soon as possible.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Recommend that parents not give the child carbonated soda, fruit juices, gelatin dessert, or instant fruit drink mix; instead, give the child oral rehydration fluids ordered and, when tolerated, food. **EB:** *Rehydration solutions such as low osmolality solutions have been shown to be safe and effective for correcting dehydration in children (Kumar et al, 2015). Antiemetic, antidiarrheal agents and probiotics have been shown to reduce the duration and severity of infectious diarrhea (Hockenberry et al, 2019).*
- Once the child has been rehydrated, begin feeding regular food, but avoid milk products (Guandalini et al, 2020).

Geriatric

- Monitor older clients for deficient fluid volume carefully, noting new onset of headache, weakness, dizziness, and postural hypotension. **EB:** *Older people are thought to be at greater risk of dehydration because thirst sensation and urinary concentrating ability frequently decline with age. Many older people use diuretics or laxatives, which encourage fluid loss, and reduced muscle volume leads to a smaller fluid reserve. Oral fluid intake may fall in older people for a variety of reasons, including reduced enjoyment of drinks, physical limitations, unmet activities of daily living needs, acute and chronic health problems, and decisions aimed at controlling continence (Oates & Price, 2017; Mantantzis et al, 2020). Additionally, those with dementia may forget to drink as daily routines are lost and social contact diminishes.*
- Implement fall precautions for clients experiencing weakness, dizziness, and/or postural hypotension. **EB:** *Falls are a serious risk in the elderly, especially those with hyponatremia (Kuo et al, 2017).*
- Dehydration in the older adult is associated with poor health outcomes, including fractures, heart disease, infections, and drug toxicity (Lešnik et al, 2017).
- Evaluate the risk for dehydration using the Dehydration Risk Appraisal Checklist. **CEB:** *A study demonstrated that the checklist has potential to predict the onset of dehydration in nursing home clients (Mentes & Wang, 2011).*
- Check skin turgor of older clients on the forehead and axilla; check for dry mucous membranes and dry tongue. **EB:** *A Cochrane review recommended in clinical practice to avoid the reliance on one clinical symptom as a sign of water-loss dehydration in older people (Hooper et al, 2016a). Older adults are susceptible to dehydration because of acute and chronic health problems, which impair thirst; reduce the ability to drink sufficiently; and/or increase urinary, skin, and respiratory fluid loss (Hooper et al, 2016b; Oates & Price, 2017). Older adults present with a constellation of signs and symptoms that need to be further evaluated for connection to dehydration. Signs and symptoms include fatigue, pallor, sunken periorbital area, chapped lips, hypotension, tachycardia, fever, orthostatic blood pressure, weight loss >4%, poor skin turgor over the sternum, and change in mental status (Miller, 2015).*
- Encourage fluid intake by offering fluids regularly to cognitively impaired clients. **EB:** *The single most common risk factor reported associated with dehydration in cognitively impaired clients was a worsening or change in mental state (Oates & Price, 2017).*
- Because older clients have low water reserves, they should be encouraged to drink regularly even when not thirsty. Frequent and varied beverage offerings should be made available by hydration assistants to routinely offer increased beverages to clients in extended care. **EB:** *Strategies to improve fluid intake include making healthy drinks and water easily available and accessible at all times and reminding and encouraging older adults to consume these fluids. Older people should not be encouraged to consume large amounts of fluids at once but rather small amounts throughout the day (Oates & Price, 2017).*
- Flag the food tray of clients with chronic dehydration to indicate if the client is identified as having chronic dehydration and indicate that they should finish 75% to 100% of their food and fluids. **EB:** *Offering beverages in brightly colored cups may improve fluid intake. Older clients often have a combination of both malnutrition and fluid deficit and may not have good taste sensation (Gaspar & Mentes, 2021).*
- Recognize that lower blood pressures and monitoring of an intake record over 24 hours are recommended to track oral intake and possible dehydration (Oates & Price, 2017).
- A higher BUN/creatinine ratio can be significant signs of dehydration in older adults. **EB:** *Structural changes of the kidney include alterations of renal blood flow of up to 50% from age 20 to 80. As people age, the kidney undergoes age-related changes, which translate to an inexorable and progressive decline in renal function.*
- In the United States more than 50% of seniors over the age of 75 are believed to have kidney disease (National Kidney Foundation, 2021).
- Monitor older clients for excess fluid volume during the treatment of deficient fluid volume: auscultate lung sounds, assess for edema, and note vital signs. **EB:** *The older client has a decreased ability to adapt to rapid increases in intravascular volume and can quickly develop fluid overload.*

Home Care

- Teach family members how to monitor output in the home (e.g., use of commode "hat" in the toilet, urinal, or bedpan, or use of catheter and closed drainage system). Instruct them to monitor both intake and output. Use common terms such as "cups" or "glasses of water a day" when providing education.
- When weighing the client, use same scale each day. Be sure scale is on a flat, not cushioned, surface. Do not weigh the client with a scale placed on any type of rug because scales provide more accurate readings when used on a hard surface.
- Teach family about complications of deficient fluid volume and when to call the health care provider.
- Teach the family the signs of hypovolemia, especially in older adults, and how to monitor for dizziness or unsteady gait.
- If the client is receiving IV fluids, there must be a responsible caregiver in the home. Teach caregiver about administration of fluids, complications of IV administration (e.g., fluid volume overload, development of phlebitis, speed of medication reactions), and when to call for assistance. Assist caregiver with administration for as long as necessary to maintain client safety. Administration of IV fluids in the home is a high-technology procedure and requires sufficient professional support to ensure safety of the client.
- Identify an emergency plan, including when to call 911. Some complications of deficient fluid volume cannot be reversed in the home and are life-threatening. Clients progressing toward hypovolemic shock will need emergency care.
- Deficient fluid volume may be a symptom of impending death in terminally ill clients. In palliative care situations, treatment of deficient fluid volume should be determined based on client/family goals. Information and support should be provided to assist the client/family in this decision. Support the family/client in a palliative care situation to decide if it is appropriate to intervene for deficient fluid volume or to allow the client to die without fluids. **EB:** *Deficient fluid volume may be a symptom of impending death in terminally ill clients. There is no defined gold standard for hydrating dying clients, and hydration and nutrition are considered basic acts for care of a dying client (Bear et al, 2017).*

Client/Family Teaching and Discharge Planning

- Instruct the client to avoid rapid position changes, especially from supine to sitting or standing.
- Teach the client and family about appropriate diet, fluid intake, and how to weight self weekly.
- Teach the client and family how to measure and record intake and output accurately.
- Teach the client and family about measures instituted to treat hypovolemia and to prevent or treat fluid volume loss.
- Instruct the client and family about signs of deficient fluid volume that indicate they should contact health care provider.

Excess Fluid Volume

Domain 2 Nutrition Class 5 Hydration

Dina Hewett, PhD, RN, NEA-BC

NANDA-I

Definition

Surplus retention of fluid.

Defining Characteristics

Adventitious breath sounds; altered blood pressure; altered mental status; altered pulmonary artery pressure; altered respiratory pattern; altered urine specific gravity; anxiety; azotemia; decreased serum hematocrit

levels; decreased serum hemoglobin level; edema; hepatomegaly; increased central venous pressure; intake exceeds output; jugular vein distention; oliguria; pleural effusion; positive hepatojugular reflex; presence of S3 heart sound; psychomotor agitation; pulmonary congestion; weight gain over short period of time

Related Factors

Excessive fluid intake; excessive sodium intake; ineffective medication self-management

Associated Conditions

Deviations affecting fluid elimination; pharmaceutical preparations

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Electrolyte and Acid-Base Balance; Fluid Balance; Fluid Overload Severity; Hydration

Example NOC Outcome with Indicators

Fluid Balance as evidenced by the following indicators: Peripheral edema/Neck vein distention/Adventitious breath sounds/Body weight increase. (Rate each indicator of **Fluid Balance:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of edema, effusion, and anasarca
- Maintain body weight appropriate for the client
- Maintain clear lung sounds; no evidence of dyspnea or orthopnea
- Remain free of jugular vein distention, positive hepatojugular reflex, and S3 heart sound
- Maintain normal central venous pressure, pulmonary artery pressure, cardiac output, and vital signs
- Maintain urine output of 0.5 mL/kg/h or more with normal urine osmolality and specific gravity
- Explain actions that are needed to treat or prevent excess fluid volume including fluid and dietary restrictions, and medications
- Describe symptoms that indicate the need to consult with health care provider

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Fluid Management; Fluid Monitoring

Example NIC Activities—Fluid Monitoring

Monitor weight; Monitor intake and output

Nursing Interventions and *Rationales*

- Monitor location and extent of edema using the 1+ to 4+ scale to quantify edema; also measure the legs using a millimeter tape in the same area at the same time each day. Note differences in measurement between extremities. **EBN:** *Numerous studies in clients and in experimental models of congestive heart failure (CHF) have established the important role of the renin-angiotensin-aldosterone system (RAAS) and the sympathetic nervous system (SNS) in the progression of cardiovascular and renal dysfunction in CHF. It is now accepted that excessive neurohormonal activation may adversely affect cardiac function and the hemodynamic condition by enhancement of systemic vasoconstriction and promoting salt and water retention by the kidneys (Azzam et al, 2017).*
- Monitor daily weight for sudden increases; use same scale and type of clothing at same time each day, preferably before breakfast. *Body weight changes reflect changes in body fluid volume.* **EB:** *Body weight is commonly used to monitor for fluid overload (Armstrong et al, 2016).*
- Monitor intake and output; note trends reflecting decreasing urine output in relation to fluid intake. **EB:** *Abnormally low urine output (oliguria) is a leading indicator of acute kidney injury (AKI), which increases*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

mortality, cost of care, and length of stay (Robbins, 2018). The volume of all fluids should be measured. If the family is measuring, instruct them on common conversions between household measurements and metric. **EBN:** *Chronic heart failure (HF) is characterized by neurohumoral activation and sodium retention that leads to excessive fluid accumulation in the systemic and pulmonary circulations. Lung congestion increases dyspnea and impairs gas transfer (Melenovsky et al, 2015).*

- Chronic HF is characterized by neurohormonal activation and sodium retention that leads to excessive fluid accumulation in the systemic and pulmonary circulations. **EB:** *Monitor vital signs; note decreasing blood pressure, tachycardia, and tachypnea. Monitor for S3 heart sounds. If signs of HF are present, see the care plan for Decreased* ***Cardiac*** *Output.*
- Auscultate lung sounds for crackles, monitor respiration effort, and determine the presence and severity of orthopnea. **EB:** *The pulmonary system adapts to the increased post–central venous pressure, which is believed to be caused by reduced capillary filtration from pulmonary basal membrane thickening, enhanced alveolar fluid clearance, and increased lymphatic drainage (Melenovsky et al, 2015).*
- Monitor serum and urine osmolality, serum sodium, blood urea nitrogen (BUN)/creatinine ratio, and hematocrit for abnormalities. **EB:** *Fluid overload is a causative factor for the occurrence of AKI. Volume overload leads to organ congestion and a resultant decrease in renal blood flow (Salahuddin et al, 2017).*
- BUN and creatinine are monitored currently as biomarkers of kidney injury and failure. **EB:** *Serum creatinine is an imperfect marker because its levels reflect delayed functional consequences of the injury rather than direct cell injury and are not sensitive and specific in the early diagnosis of AKI (Salahuddin et al, 2017). BUN and creatinine are affected by fluid volume status and medications (Andreucci et al, 2017).*
- With head of bed elevated 30 to 45 degrees, monitor jugular veins for distention with the client in the upright position; assess for positive hepatojugular reflex. *Increased intravascular volume results in jugular vein distention as a result of backflow through the vena cava (Canfield, 2021).*
- Monitor the client's behavior for restlessness, anxiety, or confusion; use safety precautions if symptoms are present. *When excess fluid volume compromises cardiac output, the client may experience confusion, decreased consciousness, delirium, and HF (Canfield, 2021).*

▲ Monitor for the development of conditions that increase the client's risk for excess fluid volume, including HF, kidney failure, and liver failure, all of which result in decreased glomerular filtration rate and fluid retention. **EB:** *Other causes are increased intake of oral or intravenous (IV) fluids in excess of the client's cardiac and renal reserve levels, and increased levels of antidiuretic hormone (Tasler & Bruce, 2018). Many clients with fluid overload have AKI, and fluid balance is an important indicator of outcomes. One study of end-stage renal disease clients with chronic fluid overload showed a strong risk factor for death (Zoccali et al, 2017).*

▲ Provide a restricted-sodium diet as appropriate if ordered. **EB:** *Restricting the sodium in the diet will favor the renal excretion of excess fluid. Take care to avoid hyponatremia, which can cause serious complications, including nausea, seizures, coma, and death (Tasler & Bruce, 2018).*

▲ Monitor serum albumin level and provide protein intake as appropriate. **EB:** *When plasma proteins, especially albumin, no longer sustain sufficient colloid osmotic pressure to counterbalance hydrostatic pressure, edema develops (Canfield, 2021).*

▲ Administer prescribed diuretics as appropriate; ensure adequate blood pressure before administration. If diuretic is administered intravenously, note and record the blood pressure and urine output after the dose. Monitor serum sodium for hyponatremia. **EBN:** *Increased arginine vasopressin (AVP) levels in HF clients lead to fluid retention by its actions on vasopressin receptors. Hyponatremia is one of the commonly encountered clinical problems among HF clients with a prevalence of about 20% on hospitalization and has been associated with increased length of stay and in-hospital and postdischarge mortality rates. Hyponatremia in HF is mainly dilutional secondary to neurohormonal activation, especially AVP resulting in free water retention and volume overload (Vinod et al, 2017).* **EB:** *Clinical practice guidelines on HF state that daily weight along with monitoring input and output is useful for monitoring effects of diuretic therapy (Yancy et al, 2017).*

- Monitor for side effects of diuretic therapy, including orthostatic hypotension (especially if the client is also receiving angiotensin-converting enzyme [ACE] inhibitors), hypovolemia, and electrolyte imbalances (hypokalemia and hyponatremia). **EB:** *Observe for hyperkalemia in clients receiving a potassium-sparing diuretic and in those on beta-blockers and ACE inhibitors (Yancy et al, 2017).*

▲ Implement fluid restriction as ordered, especially when serum sodium is low; include all routes of intake. Schedule limited intake of fluids around the clock, and include the type of fluids preferred by the client. Fluid restriction may decrease intravascular volume and myocardial workload. Overzealous fluid restriction should not be used because hypovolemia can worsen HF. Client involvement in planning will enhance participation in the necessary fluid restriction.

- Maintain the rate of all IV infusions, using an IV pump. *This is done to prevent inadvertent exacerbation of excess fluid volume and to more accurately monitor fluid intake.*
- Turn clients with dependent edema at least every 2 hours and monitor for areas that may develop pressure ulcers. **EB:** *Decreased oncotic pressure caused by low levels of albumin affects distribution of total body fluids. The association between low levels of albumin and increased risk for pressure ulcers may be caused by a change in tissue tolerance, with redistribution of fluid and formation of edema (Saghaleini et al, 2018).*

▲ Provide ordered care for edematous extremities, including compression, elevation, and muscle exercises. **EB:** *Treatments for clients with peripheral edema include elevation of the extremities above heart level, use of a specialty bed, and offloading of the extremity by repositioning or the use of pressure-offloading devices (Bly et al, 2016).*

- Promote a positive body image and good self-esteem. Visible edema may alter the client's body image. Refer to the care plan for Disturbed **Body** Image**.**

▲ Consult with the health care provider if signs and symptoms of excess fluid volume persist or worsen. **EB:** *Pulmonary edema requires prompt treatment such as preload reducers, afterload reducers, and morphine to relieve anxiety (Yancy et al, 2017).*

Critically Ill

- Insert an indwelling urinary catheter if ordered and measure urine output hourly. Notify health care provider if output is less than 0.5 mL/kg/h. **EB:** *Urine output of less than 0.5 mL/kg/h for 6 or more hours is defined as oliguria (Schetz & Hoste, 2017).*

▲ Monitor blood pressure, heart rate, passive leg lift, mean arterial pressure, central venous pressure, pulmonary artery pressure, and cardiac output/index; note and report trends of increasing or decreasing pressures over time. **EB:** *Alterations in these parameters may indicate that the client is going into shock. Hemodynamic criteria for cardiogenic shock are sustained hypotension (systolic blood pressure less than 90 mm Hg for at least 30 minutes) and a reduced cardiac index (less than 2.2 L/min/m^2) in the presence of elevated pulmonary capillary occlusion pressure (greater than 15 mm Hg), pulmonary congestion, dyspnea, and hypoxemia (van Diepen et al, 2017; Walsh-Irwin, 2021).*

▲ Monitor the effects of infusion of diuretic drips. Perform continuous renal replacement therapy (CRRT) as ordered if the client is critically ill and hemodynamically unstable and excessive fluid must be removed. **EBN:** *CRRT is indicated for hypervolemia, metabolic acidosis, and hyperkalemia (Hewett, 2020).*

Geriatric

- Recognize that the presence of fluid volume excess is particularly serious in older adults. **EB:** *The kidney undergoes age-related changes that include structural and functional changes, which may increase the incidence of AKI (Fingerhood, 2021).*
- Monitor electrolyte levels carefully, including sodium levels and potassium levels**,** with both increased and decreased levels possible. **EB:** *Older adults are prone to electrolyte abnormalities caused by aging, decreased muscle mass, and decreased total body water (Fingerhood, 2021). Also, the large number of medications that are taken can affect electrolyte levels. Many older clients receive selective serotonin reuptake inhibitors (SSRIs) for treatment of depression, which can result in hyponatremia (Varela Piñón & Adán-Manes, 2017). SSRIs are also known to be responsible for many sexual side effects such as altered libido, erectile dysfunction, vaginal dryness, ejaculatory disorders, and orgasmic problems, which are frequently reported by clients (Reisman, 2017).*

Home Care

- Assess client and family knowledge of disease processes causing excess fluid volume.

▲ Teach about disease process and complications of excess fluid volume, including when to contact the health care provider.

- Assess client and family knowledge and compliance with medical regimen, including medications, diet, rest, and exercise. Assist family with integrating restrictions into daily living. Assistance with integration of cultural values, especially those related to foods, with medical regimen promotes compliance and decreased risk of complications.

▲ Teach and reinforce knowledge of medications. Instruct the client not to use over-the-counter medications (e.g., diet medications) without first consulting the provider.

▲ Instruct the client to make the primary health care provider aware of medications ordered by other health care providers.

- Identify emergency plan for rapidly developing or critical levels of excess fluid volume when diuresing is not safe at home. Excess fluid volume can be life-threatening.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ Teach about signs and symptoms of both excess and deficient fluid volume, such as darker urine, dry mouth, and peripheral edema, and when to call the health care provider. **EB:** *Urine color may be a simple indicator of hydration (Walsh-Irwin, 2021).*

Client/Family Teaching and Discharge Planning

- Describe signs and symptoms of excess fluid volume and actions to take if they occur.

▲ Teach client on diuretics to weigh self daily in the morning and to notify the health care provider if there is a 2.2 pound (1 kg) or more weight gain (Walsh-Irwin, 2021). **EB:** *Clinical practice guidelines on HF suggest that daily weight monitoring leads to early recognition of excess fluid retention, which, when reported, can be offset with additional medication to avoid hospitalization caused by HF decompensation (Yancy et al, 2017).*

▲ Teach the importance of fluid and sodium restrictions. Help the client and family devise a schedule for intake of fluids throughout the entire day. Refer to a dietitian concerning implementation of a low-sodium diet.

- Teach clients how to measure and document intake and output with common household measurements, such as cups.

▲ Teach how to take diuretics correctly: take one dose in the morning and second dose (if taken) no later than 4 p.m. **EB:** *Adjust potassium intake as appropriate for potassium-losing or potassium-sparing diuretics. Note the appearance of side effects such as weakness, muscle cramps, hypertension, or palpitations (Yancy et al, 2017).*

- For the client undergoing hemodialysis, teach client the required restrictions in dietary electrolytes, protein, and fluid. Spend time with the client to detect any factors that may interfere with the client's compliance with the fluid restriction or restrictive diet. **EBN:** *Nonadherence to fluid restrictions, especially in clients undergoing hemodialysis, has been linked to numerous deleterious outcomes, including client and provider frustration, treatment failure, illness complications and relapse, and mortality (Howren et al, 2016).*

Risk for Deficient Fluid Volume

Domain 2 Nutrition Class 5 Hydration

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to experiencing decreased intravascular, interstitial, and/or intracellular fluid volumes, which may compromise health.

Risk Factors

Difficulty meeting increased fluid volume requirement; inadequate access to fluid; inadequate knowledge about fluid needs; ineffective medication self-management; insufficient fluid intake; insufficient muscle mass; malnutrition

At-Risk Population

Individuals at extremes of weight; individuals with external conditions affecting fluid needs; individuals with internal conditions affecting fluid needs; women

Associated Conditions

Active fluid volume loss; deviations affecting fluid absorption; deviations affecting fluid elimination; deviations affecting fluid intake; excessive fluid loss through normal route; fluid loss through abnormal route; pharmaceutical preparations; treatment regimen

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching, and References

Refer to care plan for Deficient **Fluid** Volume.

Frail Elderly Syndrome

Domain Health promotion Class 2 Health management

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Dynamic state of unstable equilibrium that affects the older individual experiencing deterioration in one or more domains of health (physical, functional, psychological, or social) and leads to increased susceptibility to adverse health effects, in particular disability.

Defining Characteristics

Bathing self-care deficit (00108); decreased activity tolerance (00298); decreased cardiac output (00029); dressing self-care deficit (00109); fatigue (00093); feeding self-care deficit (00102); hopelessness (00124); imbalanced nutrition: less than body requirements (00002); impaired memory (00131); impaired physical mobility (00085); impaired walking (00088); social isolation (00053); toileting self-care deficit (00110)

Related Factors

Anxiety; decreased energy; decreased muscle strength; exhaustion; fear of falling; impaired postural balance; inadequate knowledge of modifiable factors; inadequate social support; malnutrition; neurobehavioral manifestations; obesity; sadness; sedentary lifestyle

At-Risk Population

Economically disadvantaged individuals; individuals aged >70 years; individuals experiencing prolonged hospitalization; individuals for whom walking 15 feet requires >6 seconds (4 meters > 5 seconds); individuals

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

living alone; individuals living in constricted spaces; individuals with history of falls; individuals with low educational level; individuals with unintentional loss of 25% of body weight over one year; individuals with unintentional weight loss >10 pounds (>4.5 kg) in one year; socially vulnerable individuals; women

Associated Conditions

Anorexia; blood coagulation disorders; chronic disease; decreased serum 25-hydroxyvitamin D concentration; depression; endocrine regulatory dysfunction; mental disorders; sarcopenia; sarcopenic obesity; sensation disorders; suppressed inflammatory response

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Activity Tolerance; Balance; Exercise Participation; Hope; Physical Aging; Psychosocial Adjustment: Life Change; Client Satisfaction: Functional Assistance

Example NOC Outcome with Indicators

Client Satisfaction: Functional Assistance as evidenced by the following indicators: Included in planning for optimal mobility and self-care/Encouraged to be as active as possible/Assistance with physical activity/Allowed to choose food for meals. (Rate the outcome and indicators of **Client Satisfaction: Functional Assistance:** 1 = not at all satisfied, 2 = somewhat satisfied, 3 = moderately satisfied, 4 = very satisfied, 5 = completely satisfied [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain living as independently as possible in the home or care setting of his or her choice
- Maintain safety when engaging in activities of daily living and ambulation
- Increase exercise and/or daily physical activity to build muscle strength
- Maintain a healthy weight

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Exercise Promotion; Exercise Promotion: Balance; Exercise Promotion: Strength Training; Hope Inspiration; Nutrition Therapy

Example NIC Activities—Frail Elderly Syndrome

Promote physical activities that build strength and improve balance and endurance

Nursing Interventions and *Rationales*

- Establish a trusting relationship with the client. **EBN:** *A program for severely frail older people found that a person-centered approach with a focus on trust development and relationship building was a critical component of the care provided (Lhussier, Dalkin, & Hetherington, 2019).*
- Assess frailty with a tool such as the Frailty Index or the Edmonton Frail Scale. **EB:** *Apóstolo et al (2017) did a systematic review on diagnostic accuracy and predictive ability of frailty measures and found that the Frailty Index had good predictive reliability.* **EB:** *The Edmonton Frail Scale is a tool designed to identify frail older adults in clinical settings (Perna et al, 2017).*
- Perform a fall risk assessment on frail clients. **EB:** *The frailty group had the highest fall risk in a cohort of older adults living in a community-dwelling facility (Chittrakul et al, 2020).*
- Assess nutritional status using a validated nutritional screening assessment tool such as the Malnutrition Universal Screening Tool (MUST). **EB:** *Nutritional assessments can inform nursing care for frail clients (Murphy, Mayor, & Forde, 2018).*
- Assess for loneliness and implement measures to reduce feelings of loneliness. **EB:** *A prospective interventional study found that interventions to prevent loneliness have a positive effect on the frailty and independent living of the elderly (Ožić et al, 2020).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

- Encourage clients to engage in active lifestyles. **EB:** *The Longitudinal Aging Study Amsterdam (n = 1440) and the InCHIANTI Study (n = 998) found that physical inactivity was a component in the progression of frailty (Stenholm et al, 2019).*
- Recognize that balance and gait impairment are features of frailty and are risk factors for falls. **EB:** *By reversing frailty through exercise interventions that engender fitness, older adults will remain physically independent longer (Bray et al, 2016).*
- Address balance and gait impairments with a resistance based exercise program. **EB:** *A meta-analysis found that resistance-based exercise improved physical performance, improved gait speed, and increased leg strength in adults over the age of 60 (Macdonald et al, 2020).*
- Preserve physical functioning through individualized physical activity plans. **EB:** *Tomita et al (2018) found that frail older women who engaged in a high level of physical activity (>4000 kcal/week) can increase mobility and functional capacity.* **EB:** *de Labra et al (2015) did a systematic review of the literature and found that low physical activity has been shown to be one of the most common components of frailty.*
- Assess risk of fracture using tools such as the Cardiovascular Health Study (CHS) or Study of Osteoporotic Fracture (SOF) indicators. **EBN:** *Chen et al (2017) did a systematic review of the literature and in total five studies included 103,783 older people and recorded 2960 fractures.*
- Evaluate the client's medications to determine whether medications increase the risk of frailty and/or are potentially inappropriate medications (PIMs), and if appropriate, consult with the client's health care provider regarding the client's medications. **EB:** *Polypharmacy is associated with increased risk of mortality in elderly people (Gómez et al, 2015).* **EB:** *The number of medications prescribed can be useful to help physicians be aware of the high risk for PIMs (Tsao et al, 2016).*
- Use the Screening Tool of Older People's Prescriptions (STOPP) and the Screening Tool to Alert Right Treatment (START) to avoid omissions and inappropriateness in prescription. **EB:** *The STOPP criteria for frail older persons (>65 years) is largely associated with adverse drug events and recommends against taking medications to treat symptoms unassociated with selected illnesses (Nwadiugwu, 2020).*
- Assess and monitor vitamin D levels. **EB:** *Research participants with serum 25-hydroxyvitamin D levels less than 50 nmol/L were about two times more likely to be frail compared to participants with serum 25-hydroxyvitamin D levels greater than 50 nmol/L (Vaes et al, 2019).*

▲ Refer client to an exercise-training program. **EB:** *A randomized controlled trial found that participants in a frailty prevention program had a greater reduction in the combined frailty score and greater improvements in muscle endurance and balance than those in the control group (Yu et al, 2020).*

- Monitor weight loss. **EB:** *Weight loss is considered a main component of frailty syndrome (Yannakoulia et al, 2017).*
- Use an multiprofessional and person-centered approach for supporting frail older adults. **EBN:** *Engaging clients, their family members, or caregivers in care planning and goal setting during transitions is essential (Jeffs et al, 2017).*
- Refer to care plan for Readiness for Enhanced **Nutrition** for additional interventions.

Multicultural, Home Care, and Client/Family Teaching

- The previously mentioned interventions may be adapted for multicultural, home care, and client family teaching.
- Provide a home-based exercise-training program. **EB:** *The results of a randomized controlled trial indicate that a home-based physical training intervention conducted by nonprofessionals is feasible and can address frailty in older persons living at home (Luger et al, 2016).*

Risk for Frail Elderly Syndrome

Domain 1 Health promotion Class 2 Health management

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to a dynamic state of unstable equilibrium that affects the older individual experiencing deterioration in one or more domain of health (physical, functional, psychological, or social) and leads to increased susceptibility to adverse health effects, in particular disability.

Risk Factors

Anxiety; decreased energy; decreased muscle strength; exhaustion; fear of falling; impaired postural balance; inadequate knowledge of modifiable factors; inadequate social support; malnutrition; neurobehavioral manifestations; obesity; sadness; sedentary lifestyle

At-Risk Population

Economically disadvantaged individuals; individuals aged >70 years; individuals experiencing prolonged hospitalization; individuals for whom walking 15 feet requires >6 seconds (4 meters > 5 seconds); individuals living alone; individuals living in constricted spaces; individuals with history of falls; individuals with low educational level; individuals with unintentional loss of 25% of body weight over one year; individuals with unintentional weight loss >10 pounds (>4.5 kg) in one year; socially vulnerable individuals; women

Associated Conditions

Anorexia; blood coagulation disorders; chronic disease; decreased serum 25-hydroxyvitamin D concentration; depression; endocrine regulatory dysfunction; mental disorders; sarcopenia; sarcopenic obesity; sensation disorders; suppressed inflammatory response

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* and References

Refer to care plan for **Frail Elderly** Syndrome.

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

Impaired Gas Exchange

Domain 3 Elimination and exchange Class 4 Respiratory function

Debra Siela, PhD, RN, ACNS-BC, CCRN-K, CNE, RRT

NANDA-I

Definition

Excess or deficit in oxygenation and/or carbon dioxide elimination.

Defining Characteristics

Abnormal arterial pH; abnormal skin color; altered respiratory depth; altered respiratory rhythm; bradypnea; confusion; decreased carbon dioxide levels; diaphoresis; headache upon awakening; hypercapnia; hypoxemia; hypoxia; irritable mood; nasal flaring; psychomotor agitation; somnolence; tachycardia; tachypnea; visual disturbances

Related Factors

Ineffective airway clearance; ineffective breathing pattern; pain

At-Risk Population

Premature infants

Associated Conditions

Alveolar-capillary membrane changes; asthma; general anesthesia; heart diseases; ventilation-perfusion imbalance

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Respiratory Status: Gas Exchange, Ventilation

Example NOC Outcome with Indicators

Achieves appropriate **Respiratory Status: Gas Exchange** as evidenced by the following indicators: Cognitive status/Partial pressure of oxygen/Partial pressure of carbon dioxide/Arterial pH/Oxygen saturation. (Rate each indicator of **Respiratory Status: Gas Exchange:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate improved ventilation and adequate oxygenation as evidenced by blood gas levels within normal parameters for that client
- Maintain clear lung fields and remain free of signs of respiratory distress
- Verbalize understanding of oxygen supplementation and other therapeutic interventions

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Acid-Base Management; Airway Management

Example NIC Activities—Acid-Base Management

Monitor for symptoms of respiratory failure (e.g., low Pa_{O_2} and elevated Pa_{CO_2} levels and respiratory muscle fatigue); Monitor determinants of tissue oxygen delivery (e.g., Pa_{O_2}, SaO_2, and hemoglobin levels, and cardiac output) if available

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Nursing Interventions and *Rationales*

- Monitor respiratory rate, depth, and ease of respiration. Watch for use of accessory muscles and nasal flaring. **EB:** *Normal respiratory rate is 14 to 16 breaths per minute in the adult. When the respiratory rate exceeds 26 to 30 breaths per minute, along with other physiological measures, a significant cardiovascular or respiratory alteration exists (Bickley et al, 2020).*
- Auscultate breath sounds every 1 to 2 hours. The presence of crackles and wheezes may alert the nurse to airway obstruction, which may lead to or exacerbate existing hypoxia. **EB:** *In severe exacerbations of chronic obstructive pulmonary disease (COPD), lung sounds may be diminished or distant with air trapping (Bickley et al, 2020).*
- The nurse should consider respiratory rate, work of breathing, and lung sounds along with Pao_2 values, SaO_2, SpO_2, client tidal volume, and minute ventilation. **EB:** *Presence of dyspnea, asynchronous chest and abdominal movements, accessory muscles, and agitation indicate potential oxygenation problems (Barton, Vanderspank-Wright, & Shea, 2016).*
- Monitor the client's behavior and mental status for the onset of restlessness, agitation, confusion, and (in the late stages) extreme lethargy. **EB:** *Changes in behavior and mental status can be early signs of impaired gas exchange. In the late stages the client becomes lethargic and somnolent (Lee, 2017).*

▲ Monitor oxygen saturation continuously using pulse oximetry. Note blood gas results as available to determine correlation of pulse oximetry value with arterial blood gas oxygen saturation. **EB:** *An oxygen saturation of less than 88% (normal: 95%–100%) or a partial pressure of oxygen of less than 55 mm Hg (normal: 80–100 mm Hg) indicates significant oxygenation problems (Bein, Grasso, & Moerer, 2016; Siela & Kidd, 2017). Pulse oximetry is useful for tracking and/or adjusting supplemental oxygen therapy for clients with COPD (GOLD, 2020).*

- Monitor venous oxygen saturation to determine an index of oxygen balance to reflect between oxygen delivery and oxygen consumption (Dirks, 2017).
- Measurements of oxygenation supply in the macrocirculation include those made upstream from the tissue level. The parameters measured are arterial partial pressure of oxygen (Pao_2), arterial oxygen saturation (SaO_2) determined on the basis of arterial blood gas (ABG) analysis and pulse oximetry (SpO_2), and ratio of Pao_2 to fraction of inspired oxygen (FiO_2), or the P:F ratio. Measurements of oxygenation or oxygen extraction or consumption in the macrocirculation made downstream from tissues include tissue oxygen consumption, mixed venous oxygen saturation (SvO_2) or central venous oxygen saturation ($ScvO_2$), and blood levels of lactate (Siela & Kidd, 2017; Şanci, Coşkun, & Bayram, 2020).
- Observe for cyanosis of the skin; especially note color of the tongue and oral mucous membranes. **EB:** *In central cyanosis both the skin and mucous membranes are affected due to seriously impaired pulmonary function from unventilated or underventilated alveoli. Peripheral cyanosis (skin only) usually indicates vasoconstriction or obstruction to blood flow (Loscalzo, 2018). Central cyanosis of the tongue and oral mucosa is indicative of serious hypoxia and is a medical emergency. Peripheral cyanosis in the extremities may be due to activation of the central nervous system or exposure to cold and may or may not be serious (Bickley et al, 2020).*
- Position the client in a semirecumbent position with the head of the bed at a 30- to 45-degree angle to decrease the aspiration of gastric, oral, and nasal secretions. **EB:** *Evidence shows that mechanically ventilated clients have a decreased incidence of aspiration pneumonia if the client is placed in a 30- to 45-degree semirecumbent position as opposed to a supine position (American Association of Critical Care Nurses, 2016, 2017; Vollman, Sole, & Quinn, 2017b).*
- If the client has unilateral lung disease, position with head of bed at 30 to 45 degrees with "good lung down" in a side-lying position and affected lung up (Barton, Vanderspank-Wright, & Shea, 2016).

▲ If the client is acutely dyspneic, consider having the client lean forward over a bedside table, resting elbows on the table if tolerated. **EB:** *Leaning forward can help decrease dyspnea, possibly because gastric pressure allows better contraction of the diaphragm. This is called the tripod position and is used during times of distress, including when walking, leaning forward on the walker (Mahler, 2017).*

- Help the client deep breathe and perform controlled coughing. Have the client inhale deeply, hold the breath for several seconds, and cough two or three times with the mouth open while tightening the upper abdominal muscles as tolerated. Controlled coughing uses the diaphragmatic muscles, which makes the cough more forceful and effective.

▲ If the client has excessive fluid in the respiratory system based on auscultation, inform the prescribing provider to appropriate interventions.

▲ Monitor the effects of sedation and analgesics on the client's respiratory pattern; use judiciously. **EB:** *Both analgesics and medications that cause sedation can depress respiration at times. However, these medications*

can be very helpful for decreasing the sympathetic nervous system discharge that accompanies hypoxia (Barton, Vanderspank-Wright, & Shea, 2016).

- ● Schedule nursing care to provide rest and minimize fatigue. **EB:** *The hypoxic client has limited reserves; inappropriate activity can increase hypoxia (Barton, Vanderspank-Wright, & Shea, 2016; Mahler, 2017).*
- ▲ Administer humidified oxygen through an appropriate device (e.g., nasal cannula or venturi mask per the provider's order); aim for an oxygen (O_2) saturation level of 90% or above. Oxygen should be titrated to target an SpO_2 of >94%, except with carbon monoxide poisoning (100% oxygen), acute respiratory distress syndrome (ARDS) (88%–95%), those at risk for hypercapnia (88%–92%), and premature infants (88%–94%) (Bickley et al, 2020). Watch for onset of hypoventilation as evidenced by increased somnolence. **EB:** *There is a fine line between ideal and excessive oxygen therapy; increasing somnolence is caused by retention of CO_2 leading to CO_2 narcosis (Baldwin & Cox, 2016). Promote oxygen therapy during a COPD exacerbation. Supplemental oxygen should be titrated to improve the client's hypoxemia with a target of 88% to 92% (GOLD, 2020).*
- ● Once oxygen is started, arterial blood gases should be checked 30 to 60 minutes later to ensure satisfactory oxygenation without carbon dioxide retention or acidosis (GOLD, 2020). **EB:** *Use of high-flow nasal cannula oxygen therapy may improve gas exchange and oxygenation in acute hypoxemic respiratory failure (Siela & Kidd, 2017; Drake 2018) and hypercapnic hypoxemic respiratory failure (Şanci, Coşkun, & Bavram, 2020).*
- ● Supplemental oxygen can cause toxicity and should be administered at the lowest level that achieves an arterial saturation appropriate for a given client (Helmerhorst et al, 2015; Drake, 2018). **EB:** *Conservative oxygen strategies that target a goal of 88% to 92% SpO_2 levels in clients receiving invasive mechanical ventilation appear justified (Panwar et al, 2016). High-flow nasal cannula oxygen therapy decreases respiratory rate in acute respiratory failure (Marjanovic et al, 2020).*
- ● Assess nutritional status including serum albumin level and body mass index (BMI). **EB:** *Malnourishment in a client with COPD has a negative effect on the course of the disease; it can result in loss of muscle mass in the respiratory muscles, including the diaphragm, which can lead to respiratory failure (GOLD, 2020).* **EB:** *The Academy of Nutrition and Dietetics strongly recommend that people with COPD have their body weight and medical nutrition therapy be assessed and monitored by a registered dietitian nutritionist (Hanson et al, 2021).*
- ▲ Assist the client to eat small meals frequently and use dietary supplements as necessary. Engage dietary in evaluating and creating an optimal nutrition plan. For some clients, drinking 30 mL of a supplement every hour while awake can be helpful.
- ▲ If the client is severely debilitated from chronic respiratory disease, consider the use of a wheeled walker to help in ambulation. Request a physical therapy consultation to assist with mobility and strength training.
- ● Assess for signs of psychological distress, including anxiety, agitation, and insomnia.
- ▲ Refer the client with respiratory diseases, especially COPD, to a pulmonary rehabilitation program. Pulmonary rehabilitation is now considered a standard of care for the client with respiratory diseases (GOLD, 2020).

Critical Care

- ▲ Assess and monitor oxygen indices such as the P:F ratio (Pao_2 to FiO_2), venous oxygen saturation/oxygen consumption (SvO_2 or $ScvO_2$) (Dirks, 2017; Siela & Kidd, 2017; Lough et al, 2022).
- ▲ Turn the client every 2 hours. Monitor oxygen saturation closely after turning. If it drops by 10% or fails to return to baseline promptly, turn the client back into the supine position and evaluate oxygen status. If the client does not tolerate turning, consider use of a kinetic bed that rotates the client from side to side in a turn of at least 40 degrees (St. Clair & MacDermott, 2017).
- ▲ If the client has ARDS with difficulty maintaining oxygenation, consider positioning the client prone with the upper thorax and pelvis supported. Monitor oxygen saturation and turn the client back to supine position if desaturation occurs. **EB:** *Oxygenation levels have been shown to improve in the prone position, probably due to decreased shunting and better perfusion of the lungs (Drahnak & Custer, 2015; Barton, Vanderspank-Wright, & Shea, 2016; Bein, Grasso, & Moerer, 2016; Vollman, Dickinson, & Powers, 2017a).* **EB:** *A systematic review and meta-analysis found that prone position with mechanical ventilation significantly reduced mortality in clients with severe acute hypoxemic respiratory failure; however, clients should remain in the prone position for 12 hours daily (Munshi et al, 2017).*
- ▲ High levels of positive end-expiratory pressures may be prescribed to improve oxygenation and gas exchange (Barton, Vanderspank-Wright, & Shea, 2016). **EB:** *The delivery of positive end expiratory pressure can be provided through noninvasive or mechanical ventilation mechanisms (Siela & Kidd, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Geriatric

- Use central nervous system depressants and other sedating agents carefully to avoid decreasing respiration rate.
- Teach the client how to cough and perform deep breathing exercises to enhance gas exchange.
- Maintain appropriate levels of supplemental oxygen therapy for clients with impaired gas exchange and hypoxemia (GOLD, 2020).

Home Care

- Work with the client to determine what strategies are most helpful during times of dyspnea. Educate and empower the client to self-manage the disease associated with impaired gas exchange. **EB:** *Use of oxygen, self-use of medication, handheld fan, behavioral modification, and music can assist clients dealing with dyspnea (Baldwin & Cox, 2016; Ergin et al, 2018). Evidence-based reviews have found that self-management offers COPD clients effective options for managing the illness, leading to more positive outcomes (GOLD, 2020).*
- Collaborate with health care providers regarding long-term oxygen administration for chronic respiratory failure clients with severe resting hypoxemia. Administer long-term oxygen therapy for Pa_{O2} less than 55 or SaO_2 at or below 88% (GOLD, 2020).
- Assess the home environment for irritants that impair gas exchange. Help the client adjust the home environment as necessary (e.g., install an air filter to decrease the level of dust).
- ▲ Refer the client to occupational therapy as necessary to assist the client in adapting to the home and environment and in energy conservation (GOLD, 2020).
- Assist the client with identifying and avoiding situations that exacerbate impairment of gas exchange (e.g., stress-related situations, exposure to pollution of any kind, proximity to noxious gas fumes such as chlorine bleach). Irritants in the environment decrease the client's effectiveness in accessing oxygen during breathing.
- Instruct the client to keep the home temperature above 68°F (20°C) and to avoid cold weather. **EB:** *Cold air temperatures cause constriction of the blood vessels, which impairs the client's ability to absorb oxygen (Bickley et al, 2020).*
- Instruct the client to limit exposure to persons with respiratory infections. **EB:** *Viruses, bacteria, and environmental pollutants are the main causes of exacerbations of COPD (GOLD, 2020).*
- Instruct the family on the complications of the disease and the importance of maintaining the medical regimen, including when to call a health care provider.
- ▲ Refer the client for home health aide services as necessary for assistance with activities of daily living. **EB:** *Clients with decreased oxygenation have decreased energy to carry out personal and role-related activities.*
- When respiratory procedures are being implemented, explain equipment and procedures to family members, and provide needed emotional support. Family members assuming responsibility for respiratory monitoring often find this stressful.
- When electrically based equipment for respiratory support is being implemented, evaluate home environment for electrical safety, proper grounding, and so on. Ensure that notification is sent to the local utility company, the emergency medical team, and police and fire departments. Notification is important to provide for priority service. Work with the family to have an emergency plan and ensure all individuals in the home are aware of the plan.
- ▲ Assess family role changes and coping ability. Refer the client to medical social services as appropriate for assistance in adjusting to chronic illness. **EB:** *Inability to maintain the level of social involvement experienced before illness leads to frustration and anger in the client and may create a threat to the family unit (Mahler, 2017).*
- Support the family of the client with chronic illness. **EB:** *Severely compromised respiratory functioning causes fear and anxiety in clients and their families. Reassurance from the nurse can be helpful (Baldwin & Cox, 2016; Mahler, 2017).*

Client/Family Teaching and Discharge Planning

- Teach the client how to perform pursed-lip breathing and inspiratory muscle training, and how to use the tripod position. Have the client watch the pulse oximeter to note improvement in oxygenation with these breathing techniques. **EB:** *Pursed-lip breathing results in increased use of intercostal muscles, decreased respiratory rate, and improved oxygen saturation levels. Pursed-lip breathing may relieve dyspnea in advanced respiratory diseases, such as COPD (Mahler, 2017; Nguyen & Duong, 2020).*
- Teach the client energy conservation techniques and the importance of alternating rest periods with activity. See nursing interventions for **Fatigue.**

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

- ▲ Teach the importance of not smoking. Refer to smoking cessation programs, and encourage clients who relapse to keep trying to quit. Ensure that clients receive appropriate medications to support smoking cessation from the primary health care provider. **EB:** *Clients should be referred to a comprehensive smoking cessation program, incorporating behavior change techniques that focus on enhancing client motivation and confidence, client education, and pharmacological and nonpharmacological interventions (GOLD, 2020).*
- ▲ Instruct the family regarding home oxygen therapy if ordered (e.g., delivery system, liter flow, safety precautions). **EB:** *Long-term oxygen therapy can improve survival, exercise ability, sleep, and ability to think in hypoxemic clients. Client education improves compliance with prescribed use of oxygen (GOLD, 2020).*
- ▲ Teach the client the need to receive a yearly influenza vaccine. Receiving a yearly influenza vaccine is helpful to prevent exacerbations of COPD (GOLD, 2020).
- ● Teach the client relaxation techniques to help reduce stress responses and panic attacks resulting from dyspnea. **EB:** *Relaxation therapy can help reduce dyspnea and anxiety (Baldwin & Cox, 2016; Mahler, 2017).*
- ● Teach the client to use music, along with a rest period, to decrease dyspnea and anxiety (Ergin et al, 2018; Loscalzo, 2018).

Risk for Dysfunctional Gastrointestinal Motility

Domain 3 Elimination and exchange
Class 2 Gastrointestinal function

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to increased, decreased, ineffective, or lack of peristaltic activity within the gastrointestinal tract, which may compromise health.

Risk Factors

Altered water sources; anxiety; eating habit change; impaired physical mobility; malnutrition; sedentary lifestyle; stressors; unsanitary food preparation

At-Risk Population

Individuals who ingested contaminated material; older adults; premature infants

Associated Conditions

Decreased gastrointestinal circulation; diabetes mellitus; enteral nutrition; food intolerance; gastroesophageal reflux disease; infections; pharmaceutical preparations; treatment regimen

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Dysfunctional **Gastrointestinal** Motility.

Dysfunctional Gastrointestinal Motility

Domain 3 Elimination and exchange Class 2 Gastrointestinal function

Rosemary Timmerman, DNP, APRN, CCNS, CCRN-CSC-CMC

NANDA-I

Definition

Increased, decreased, ineffective, or lack of peristaltic activity within the gastrointestinal tract.

Defining Characteristics

Abdominal cramping; abdominal pain; absence of flatus; acceleration of gastric emptying; altered bowel sounds; bile-colored gastric residual; diarrhea; difficulty with defecation; distended abdomen; hard, formed stool; increased gastric residual; nausea; regurgitation; vomiting

Related Factors

Altered water source; anxiety; eating habit change; impaired physical mobility; malnutrition; sedentary lifestyle; stressors; unsanitary food preparation

At-Risk Population

Individuals who ingested contaminated material; older adults; premature infants

Associated Conditions

Decreased gastrointestinal circulation; diabetes mellitus; enteral nutrition; food intolerance; gastroesophageal reflux disease; infections; pharmaceutical preparations; treatment regimen

● = Independent; ▲ = Collaborative; EBN = Evidence-Based Nursing; EB = Evidence-Based; ✱ = QSEN

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Gastrointestinal Function; Electrolyte and Acid-Base Balance; Fluid Balance; Hydration; Nausea and Vomiting Control

Example NOC Outcome with Indicators

Gastrointestinal Function as evidenced by the following indicators: Bowel sounds/Stool soft and formed/Appetite present without evidence of reflux, nausea, or vomiting/Reported normal abdominal comfort/Abdomen soft to palpation without evidence of distention. (Rate the outcome and indicators of **Gastrointestinal Function:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

G

Client Outcomes

Client Will (Specify Time Frame)

- Be free of abdominal distention and pain
- Have normal bowel sounds
- Pass flatus rectally at intervals
- Defecate formed, soft stool every day to every third day
- State has an appetite
- Be able to eat food without nausea and vomiting

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Gastric Motility Management

Example NIC Activities—Gastric Motility Management

Evaluate use of prokinetics for delayed gastric motility; Suggest change in dietary habits to either increase or decrease gastric motility, depending on the presenting complaint

Nursing Interventions and *Rationales*

- Monitor for abdominal distention and presence of abdominal pain, weight loss, nausea, vomiting, obstipation, or diarrhea. **EB:** *The acute onset of abdominal distention in conjunction with symptoms of cramping pain, weight loss, nausea, vomiting, constipation, or diarrhea warrants further evaluation for disorders that cause intestinal obstruction (Nagarwala, Dev, & Markin, 2016).*
- Inspect, auscultate for bowel sounds noting characteristics and frequency; palpate and percuss the abdomen. Hypoactive bowel sounds are found with decreased motility as with peritonitis from paralytic ileus or from late bowel obstruction. **EB:** *Hyperactive bowel sounds are associated with increased motility (Nagarwala, Dev, & Markin, 2016).*
- Review history noting any anorexia or nausea and vomiting. Other symptoms may include relation of symptoms to meals, especially if aggravated by food, satiety, postprandial fullness/bloating, and weight loss or weight loss with severe gastroparesis. **EB:** *These are signs of abnormal gastric motility (Camilleri, 2016).*
- Monitor for fluid deficits by checking skin turgor and moisture of tongue, daily weights, input and output, and electrolyte values. Refer to care plan for Deficient **Fluid** Volume if relevant.

▲ Monitor for nutritional deficits by keeping close track of food intake. Review laboratory studies that affirm nutritional deficits, such as decreased albumin and serum protein levels, liver profile, glucose, fecal analysis, and an electrolyte panel. Refer to care plan for Imbalanced **Nutrition:** Less Than Body Requirements or Risk for **Electrolyte** Imbalance as appropriate.

Slowed Gastric Motility

- Monitor the client for signs and symptoms of decreased gastric motility, which may include nausea after meals, vomiting, early satiety, postprandial fullness, abdominal bloating, and abdominal pain (Grover et al, 2019; Vavricka & Greuter, 2019).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ Monitor daily laboratory studies and point of care testing blood glucose levels, ensuring ordered glucose levels are performed and evaluated. **EB:** *Elevated blood glucose levels can cause delayed gastric emptying; therefore it is important to normalize blood glucose levels (Shen et al, 2019; Sullivan et al, 2020).*

● Obtain a thorough gastrointestinal history if the client has diabetes because he or she is at high risk for gastroparesis and gastric reflux. **EB:** *Gastroparesis with delayed emptying of the stomach is a well-known complication of diabetes but may also be idiopathic or caused by gastric surgery, medications, neurological disorders, connective tissue disorders, and mesenteric ischemia (Grover et al, 2019; Sullivan et al, 2020).*

▲ If client has nausea and vomiting, provide an antiemetic and intravenous fluids as ordered. Offer or perform oral hygiene after vomiting. Refer to the care plan for **Nausea.**

▲ Administer prokinetic, antisecretory, fundic relaxant, and neuromodulator medications as prescribed (Grover et al, 2019; Sullivan et al, 2020).

▲ Evaluate medications the client is taking. Recognize that opioids, calcium channel blockers, GLP-1 analogs, diphenhydramine, and anticholinergic medications can cause gastric slowing (Onyimba & Clarke, 2019; Shen et al, 2019).

▲ Review laboratory and other diagnostic tools, including complete blood count, amylase, and thyroid-stimulating hormone level, glucose with other metabolic studies, upper endoscopy, and gastric-emptying scintigraphy. **EB:** *The diagnosis of diabetic gastroparesis is made when other causes are excluded and postprandial gastric stasis is confirmed by gastric emptying scintigraphy, which is considered the gold standard for diagnosing gastroparesis (Grover et al, 2019; Sullivan et al, 2020).*

▲ Recognize that endoscopic and surgical therapies for severe gastroparesis include pyloric disruption, electrical stimulation, venting or bypass, and gastric resection (Onyimba & Clarke, 2019; Sullivan et al, 2020).

▲ Alternative and complementary therapies such as acupuncture, electroacupuncture, ginger, and massage may offer symptom relief for gastroparesis (Onyimba & Clarke, 2019).

▲ Obtain a nutritional consultation, considering a small particle size diet or diets lower or higher in liquids or solids, depending on gastric motility. **CEB/EB:** *A small (n = 45) randomized controlled trial found that diets with smaller particle size reduced the symptoms of gastroparesis in diabetic clients (Olausson et al, 2014; Grover et al, 2019).*

▲ If the client is unable to eat or retain food, consult with the registered dietitian and health care provider, considering further nutritional support in the form of enteral or parenteral feedings for the client with gastroparesis. **EB:** *Some clients require supplementation with either enteral or parenteral nutrition for survival (Vavricka & Greuter, 2019; Sullivan et al, 2020).*

▲ If the client is receiving gastric enteral nutrition, see the care plan Risk for **Aspiration.**

▲ Administer bulk-forming or osmotic laxative medications that increase gastrointestinal motility as ordered (Nagarwala, Dev, & Markin, 2016; Coutts, 2019).

● Advise client to eat small meals low in fat and fiber four to five times each day to allow for adequate nutritional intake while limiting the sensation of fullness; avoid spicy food, carbonated beverages, alcohol, and acidic foods; avoid smoking (Grover et al, 2019; Sullivan et al, 2020).

Postoperative Ileus

● Observe for complications of delayed intestinal motility. Symptoms include vague abdominal pain and distention, nausea, vomiting, anorexia, sometimes bloating, and tympany to percussion. Clients may or may not pass flatus and some stool (Eamudomkarn et al, 2018; Hedrick et al, 2018).

▲ Encourage the client to drink coffee three times per day postoperatively to decrease the time to first flatus and defecation after abdominal surgery (Eamudomkarn et al, 2018; Hedrick et al, 2018).

▲ Recommend chewing gum for the abdominal surgery client who is not at risk for aspiration and has normal dentition, particularly if oral intake is limited. **EB:** *Gum chewing may decrease postoperative ileus because it mimics dietary intake, potentially stimulating vagal tone and gastric and bowel motility (Eamudomkark et al, 2018; Hedrick et al, 2018).*

▲ Limit preoperative fasting to 6 hours for solid food and 2 hours for liquids; discontinue fasting and reintroduce oral nutrition postoperatively; if the client has difficulty with oral intake or experiences nonbilious emesis postoperatively, provide a clear liquid diet and advance as tolerated (Hedrick et al, 2018; Taurchini et al, 2018).

● A preoperative walking program helps reduce time to first postoperative flatus and defecation for clients undergoing surgery for gynecological cancer (Özdemir et al, 2019).

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

Assist the client with early mobilization after surgery; encourage client to eat all meals in a chair. Exercise may increase gastrointestinal motility.

▲ Minimize the use of opioids and use a multimodal analgesic approach for pain as feasible (Hedrick et al, 2018; Özdemir et al, 2019).

▲ Administer alvimopan, a mu opioid receptor antagonist medication, as prescribed (Venara et al, 2016; Hedrick et al, 2018).

▲ Avoid routine use of prophylactic nasogastric tubes (Hedrick et al, 2018; Taurchini et al, 2018).

▲ Administer an antiemetic for nausea and nonbilious emesis; for clients experiencing bilious emesis with abdominal distention, tympany, and intolerance of oral intake, insert a nasogastric tube as prescribed and consider other etiologies for the symptoms (Hedrick et al, 2018).

▲ Maintain euvolemia and replace electrolytes as needed (Hedrick et al, 2018; Taurchini et al, 2018).

Increased Gastrointestinal Motility

▲ Observe for complications of gastric surgeries such as dumping syndrome. This syndrome is the effect of changes in size and function of the stomach, with rapid dumping of hyperosmolar food into the intestines (Vavricka & Greuter, 2019).

● Watch for signs and symptoms of early dumping syndrome that occur within 15 minutes to 1 hour after a meal, which might include nausea, vomiting, bloating, cramping, abdominal pain, epigastric fullness, borborygmi, diarrhea, dizziness, desire to lie down, palpitations, tachycardia, syncope, perspiration, headache, hypotension, flushing, pallor, and fatigue (Vavricka & Greuter, 2019).

● Monitor for low blood sugar, fatigue, weakness, confusion, hunger, syncope, perspiration, palpitations, tremor, irritability, and dizziness 1 to 3 hours after eating because this is when late rapid gastric emptying may occur; late rapid gastric emptying is associated with low blood sugar (Vavricka & Greuter, 2019).

▲ Order a nutritional consultation to discuss diet changes; the diet may vary depending on the kind of surgery causing dumping syndrome. **EB:** *Encourage small, frequent, high-fiber, high-protein meals; space fluids around meal times by at least 30 minutes (Vavricka & Greuter, 2019).*

● Encourage client to lie down for 30 minutes after a meal to delay gastric emptying (Vavricka & Greuter, 2019).

▲ Administer acarbose to decrease intraluminal digestion of carbohydrates and somatostatin to delay gastric emptying and decrease the release of insulin as prescribed (Vavricka & Greuter, 2019).

▲ Administer antiemetics and antidiarrhea medications as prescribed (Vavricka & Greuter, 2019).

▲ Give intravenous fluids as ordered for the client complaining of diarrhea with weakness and dizziness. Monitor electrolyte panel and acid-base balance. Severe diarrhea can cause deficient fluid volume with extreme weakness and metabolic acidosis.

- ❍ Offer bathroom, commode, or bedpan assistance, depending on frequency, amount of diarrhea, and condition of client.
- ❍ Monitor rectal area for altered skin integrity and apply barrier creams as needed to protect and treat skin.
- ❍ Consider a fecal management system for bedbound clients with frequent loose stools to protect the perineal skin and minimize spread of infection.

● Refer to the care plans for the nursing diagnoses of Deficient **Fluid** Volume, **Nausea,** Impaired **Skin** Integrity, and **Diarrhea** as relevant.

Pediatric

● Assess infants and children with suspected delayed gastric emptying for fullness and vomiting. **EB:** *Babies and children with delayed gastric emptying take longer to get hungry again and throw up undigested or partially digested food several hours after feeding (Westfal & Goldstein, 2017).*

▲ Observe for nutritional and fluid deficits with assessment of skin turgor, mucous membranes, fontanels, furrows of the tongue, electrolyte panel, fluid status, input and output, and daily weights (Islam, 2015).

▲ For pediatric clients age 6 months to 21 years with uncomplicated gastroenteritis, initiate oral rehydration therapy for mild (<5%) and moderate (5%–10%) dehydration with small, frequent volumes replacing ongoing losses with 2 ounces or 8 milliliters per kilogram for each episode of diarrhea or emesis; administer intravenous fluids as prescribed for severe (>10%) dehydration as prescribed; administer ondansetron for vomiting as prescribed (Carson et al, 2017).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ Recommend gentle massage for preterm infants as appropriate and to treat acute diarrhea in children. **CEB/EB:** *With massage, there was increased vagal activity. This was then associated with increased gastric motility and greater weight gain (Field, Diego, & Hernandez-Reif, 2011; Gao et al, 2018).*

Geriatric

- Closely monitor diet and medication use/side effects because they affect the gastrointestinal system; watch for constipation. **EB:** *Many gastrointestinal functions are slowed in older adults (Dumic et al, 2019).*

▲ Watch for symptoms of dysphagia, gastroesophageal reflux disease, dyspepsia, chronic atrophic gastritis, peptic ulcer disease, mesenteric ischemia, irritable bowel syndrome, inflammatory bowel disease, maldigestion, diverticular disease, and reduced absorption of nutrients. **EB:** *These are common gastrointestinal disorders in older adults (Dumic et al, 2019).*

Client/Family Teaching and Discharge Planning

- Teach the client and caregivers about medications, reinforcing side effects as they relate to gastrointestinal function.
- Teach client and caregivers to report signs and symptoms that may indicate further complications, including increased abdominal girth, projectile vomiting, and unrelieved acute cramping pain (bowel obstruction).
- Review signs and symptoms of dehydration with client and caregivers.

Risk for Unstable Blood Glucose Level

Domain 2 Nutrition Class 4 Metabolism

Paula D. Hopper, MSN, RN, CNE

NANDA-I

Definition

Susceptible to variation in serum levels of glucose from the normal range, which may compromise health.

Risk Factors

Excessive stress; excessive weight gain; excessive weight loss; inadequate adherence to treatment regimen; inadequate blood glucose self-monitoring; inadequate diabetes self-management; inadequate dietary intake; inadequate knowledge of disease management; inadequate knowledge of modifiable factors; ineffective medication self-management; sedentary lifestyle

At-Risk Population

Individuals experiencing rapid growth period; individuals in intensive care units; individuals of African descent; individuals with altered mental status; individuals with compromised physical health status; individuals with delayed cognitive development; individuals with family history of diabetes mellitus; individuals with history of autoimmune disorders; individuals with history of gestational diabetes; individuals with history of hypoglycemia; individuals with history of pre-pregnancy overweight; low birth weight infants; Native American individuals; pregnant women >22 years of age; premature infants; women with hormonal shifts indicative of normal life stage changes

Associated Conditions

Cardiogenic shock; Diabetes mellitus; infections; pancreatic diseases; pharmaceutical preparations; polycystic ovary syndrome; pre-eclampsia; pregnancy-induced hypertension; surgical procedures

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Compliance Behavior: Prescribed Diet; Compliance Behavior: Prescribed Medication; Coping; Endurance; Knowledge: Diabetes Management; Knowledge: Treatment Regimen; Nutritional Status; Personal Health Status; Self-Management: Diabetes; Weight Maintenance Behavior

Example NOC Outcome with Indicators

Blood Glucose Level as evidenced by the following indicators: Blood glucose/Glycosylated hemoglobin/Fructosamine/Urine glucose/Urine ketones. (Rate the outcome and indicators of **Blood Glucose Level:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- NOTE: All goals are general recommendations for most clients. Consult health care provider for client-specific goals.
- For most nonpregnant adults, maintain the following blood glucose targets (American Diabetes Association [ADA], 2021):
- A1C less than 7% (normal level <5.7%) or lower if it can be safely achieved
- A1C less than 8% in adults with limited life expectancy, or in those whom harms of treatment outweigh the benefits
- Preprandial glucose between 80 and 130 mg/dL
- Peak postprandial (1–2 hours after beginning of meal) glucose below 180 mg/dL
- For children and adolescents with diabetes, maintain the following blood glucose targets (ADA, 2021):
- A1C less than 6.5% if it can be achieved without excessive hypoglycemia (types 1 and 2)
- A1C less than 7% in most children (types 1 and 2)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- A1C less than 7.5% in children who are at higher risk of hypoglycemia (types 1 and 2)
- A1C less than 8% in children with history of severe life expectancy, short life expectancy, or in those whom harms of treatment outweigh the benefits (type 1)
- In pregnant mothers with gestational or preexisting type 1 or 2 diabetes, maintain blood glucose as follows (ADA, 2021):
- A1C less than 6% for most women, less than 7% if necessary to prevent hypoglycemia
- Fasting <95 mg/dL
- One-hour postprandial ≤140 mg/dL
- Two-hour postprandial ≤120 mg/dL
- In older adults, maintain blood glucose control as follows (ADA, 2021):
- Healthy older adults: A1C < 7 .0 to 7.5; preprandial blood glucose 80 to 130 mg/dL; bedtime 80 to 180 mg/dL
- Older adults with complex coexisting chronic illness, cognitive impairment, or functional dependence: A1C <8.0%, fasting or preprandial 90 to 150 mg/dL; bedtime 100 to 180 mg/dL
- Older adult end-stage chronic illness or moderate to severe cognitive impairment: A1C not pertinent; preprandial 100 to 180 mg/dL; bedtime 110 to 200 mg/dL
- Maintain blood glucose in the majority of hospitalized clients between 140 and 180 mg/dL; more stringent goals may be appropriate if hypoglycemia can be avoided (ADA, 2021)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Hypoglycemia Management; Hyperglycemia Management

Example NIC Activities—Hypoglycemia Management

Monitor blood glucose levels, as indicated; Provide simple carbohydrate, as indicated

Nursing Interventions and *Rationales*

▲ Monitor blood glucose in hospitalized clients with diabetes who are eating, before meals; who are not eating, every 4 to 6 hours; and who are receiving intravenous (IV) insulin, every 30 minutes to 2 hours. **EB:** *Hypoglycemia and hyperglycemia in the hospitalized client are associated with adverse outcomes, including death (ADA, 2021).*

▲ In clients receiving multiple-dose insulin or insulin pump therapy, obtain blood glucose before meals and snacks, at bedtime, occasionally postprandially, before exercise or critical tasks such as driving, if low blood glucose is suspected, and after treatment for low blood glucose until normoglycemic. This may require checking up to 6 to 10 times daily. **EB:** *Self-monitoring of blood glucose (SMBG) helps clients evaluate their response to therapy and guide treatment and self-management decisions (ADA, 2021).*

▲ Consider SMBG in clients with type 2 diabetes not using insulin. **EB:** *SMBG for type 2 diabetes has showed limited improvement in outcomes. However, for some individuals, glucose monitoring can provide insight into the impact of diet, physical activity, and medication management on glucose levels (ADA, 2021).*

▲ Consider continuous glucose monitoring in clients with type 1 diabetes on intensive insulin regimens. **EB:** *When used properly, real-time continuous glucose monitors in conjunction with multiple daily injections and continuous subcutaneous insulin infusion and other forms of insulin therapy are a useful tool to lower and/or maintain A1C levels and/or reduce hypoglycemia in adults and youth with diabetes (ADA, 2021).*

▲ Evaluate A1C level for glucose control over previous 3 months. **EB:** *A1C reflects average glycemia over approximately 3 months and is used as a strong predictive value for diabetes complications (ADA, 2021).*

▲ Consider monitoring 2 hours after the start of meals in individuals who have premeal glucose values within target but have A1C values above target. **EB:** *Measuring postprandial plasma glucose 1–2 h after the start of a meal and using treatments aimed at reducing postprandial plasma glucose values to 180 mg/dL (10.0 mmol/L) may help to lower A1C (ADA, 2021).*

▲ Consult provider for insulin therapy orders for any client whose glucose is consistently above 180 mg/dL. **EB:** *Glucose control in critically and non–critically ill clients can reduce mortality, though very tight glucose control may increase risk of hypoglycemia and slightly increases risk of mortality (ADA, 2021).*

- Monitor for signs and symptoms of hypoglycemia, such as shakiness, irritability, confusion, tachycardia, hunger, headache, loss of consciousness, or seizures. **EB:** *Hypoglycemia may be inconvenient or frightening to clients with diabetes. Severe hypoglycemia can progress to loss of consciousness, seizure, coma, or death (ADA, 2021).*
- Identify level of hypoglycemia. Level 1 hypoglycemia is defined as a measurable glucose concentration <70 mg/dL (3.9 mmol/L) but ≥54 mg/dL (3.0 mmol/L) that can alert a person to take action" (Agiostratidou et al, 2017). Level 2 hypoglycemia is a blood glucose concentration <54 mg/dL (3.0 mmol/L), which is typically the threshold for neuroglycopenic symptoms. Level 3 hypoglycemia is a clinical event characterized by altered mental and/or physical functioning that requires assistance from another person for recovery. Levels 2 and 3 require immediate correction of low blood glucose (ADA, 2021). **EB:** *Hypoglycemia is a significant—and potentially fatal—complication of type 1 diabetes management and has been found to be a barrier to achieving glycemic goals. Repeated exposure to severe hypoglycemic events has been associated with an increased risk of cardiovascular events and all-cause mortality in people with type 1 or type 2 diabetes (Agiostratidou et al, 2017).*

G

▲ Raise glycemic targets in insulin-treated clients with hypoglycemia unawareness, one level 3 hypoglycemic event, or a pattern of unexplained level 2 hypoglycemia to strictly avoid hypoglycemia for at least several weeks. **EB:** *Several weeks of avoidance of hypoglycemia has been demonstrated to improve counterregulation and hypoglycemia awareness in many clients (ADA, 2021).*

- If the client is experiencing signs and symptoms of hypoglycemia, test glucose; if the result is below 70 mg/dL (level 1), administer 15 to 20 g glucose if the client is conscious. Pure glucose (e.g., three to four glucose tablets) is the preferred treatment, but any form of carbohydrate that contains glucose will suffice (a cup of fruit juice or regular [not diet] soda, one cup of milk, a small piece of fruit). Avoid treating with foods that contain fat, or in type 2 diabetes, avoid foods high in protein. Repeat test in 15 minutes and repeat treatment if indicated. Once blood glucose returns to normal, the individual should consume a meal or snack to prevent recurrence of hypoglycemia. **EB:** *Hypoglycemia treatment requires ingestion of glucose-containing or carbohydrate-containing foods. The acute glycemic response correlates better with the glucose content than with the carbohydrate content of the food. Pure glucose is the preferred treatment, but any form of carbohydrate that contains glucose will raise blood glucose. Added fat may slow and prolong the acute glycemic episode. In type 2 diabetes, ingested protein may increase insulin response without increasing plasma glucose concentrations. Carbohydrate sources high in protein should not be used to treat or prevent hypoglycemia (ADA, 2021).*

▲ Treat severe (level 3) hypoglycemia as follows, if client is unable to swallow glucose:

- ❍ If the client has IV access, administer 25 g of 50% glucose IV (check agency protocol).
- ❍ In the absence of IV access, administer 3 mg intranasal or 1 mg intramuscular or subcutaneous glucagon.
- ❍ For the client at home with no IV glucose or glucagon access, contact emergency personnel and administer oral glucose or cake frosting into the buccal space. Tilt client's head to side to avoid aspiration.

EB: *Severe hypoglycemia requires the assistance of another person to actively administer carbohydrate, glucagon, or other resuscitative actions. In a randomized, crossover trial comparing intranasal (3 mg) and intramuscular (1 mg) glucagon in 77 clients with type 1 diabetes and hypoglycemia … successful reversal of hypoglycemia occurred in 98.7 and 100 percent of intranasal glucagon and intramuscular glucagon visits, respectively. There is little evidence to support use of buccal glucose, but in the absence of other options it might be helpful while awaiting emergency personnel (Cryer, 2021).*

▲ Monitor for and report signs and symptoms of hyperglycemia, such as increased thirst or urination, high blood glucose levels, or elevated A1C. **EB:** *Achieving A1C targets of <7% has been shown to reduce microvascular (retinopathy, neuropathy, and diabetic kidney disease) complications of type 1 and type 2 diabetes when instituted early in the course of disease (ADA, 2021).*

▲ Monitor fluid balance and replace fluids in clients with diabetic ketoacidosis. **EB:** *Prompt rehydration is vital to restore circulating volume and tissue perfusion, clear ketones, and correct electrolyte imbalance. Restoring circulatory volume and tissue perfusion through aggressive rehydration improves glycemic control and acid base balance, and reduces counterregulatory hormones (Tran et al, 2017).*

▲ Avoid use of sliding scale insulin alone in hospitalized clients. **EB:** *A randomized controlled trial has shown that basal-bolus treatment improved glycemic control and reduced hospital complications compared with reactive, or sliding scale, insulin regimens (i.e., dosing given in response to elevated glucose rather than preemptively) in general surgery clients with type 2 diabetes (ADA, 2021).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Before administering IV insulin solution using polyethylene-lined tubing, precondition tubing with insulin solution and allow the solution to dwell for 30 minutes before completing a flush. Use an amount of solution equal to the volume of the tubing for the dwell and again for the flush. **EB:** *Adsorption of insulin into the IV bag and tubing can significantly reduce the concentration of delivered insulin. Less variability in insulin concentration is found in conditioned (with dwell time) tubing (Newby & Holmes, 2017).*
- ▲ Evaluate the client's medication regimen for medications that can alter blood glucose. **EB:** *Some asthma medications, some antipsychotic and antidepressant agents, thiazide diuretics, and glucocorticoids, among others, can cause hyperglycemia. Aspirin and beta-blockers are among agents that can cause hypoglycemia (National Prescribing Service Limited [NPS], 2019).*
- ▲ Refer client to a registered dietitian nutritionist (RDN) who is skilled in diabetes medical nutrition therapy (MNT) for individualized instruction. **EB:** *MNT delivered by an RD/RDN is associated with A1C absolute decreases of 1.0–1.9% for people with type 1 diabetes and 0.3%–2.0% for people with type 2 diabetes (ADA, 2021).*
- ▲ Refer people with type 1 diabetes and those with type 2 diabetes who are prescribed a flexible insulin therapy program for education on how to use carbohydrate counting (and in some cases fat and protein gram estimation) to determine mealtime insulin dosing. **EB:** *Education on how to use carbohydrate counting and on dosing for fat and protein content should be used to determine mealtime insulin dosing (ADA, 2021).*
- ▲ Refer overweight and obese clients with diabetes for diet and activity instruction. **EB:** *There is strong and consistent evidence that modest (5%–7%) persistent weight loss can delay the progression from prediabetes to type 2 diabetes (ADA, 2021).*
- Assist clients with periodontal disease to access dental care. **EB:** *Intensive periodontal treatment [is] associated with better glycemic control and reduction in inflammatory markers after 12 months of follow-up" (ADA, 2021).*
- ▲ Assist clients with depression or mental illness to gain access to mental health services, and ensure collaboration with the diabetes treatment team. **EB:** *Elevated depressive symptoms and depressive disorders affect one in four clients with type 1 or type 2 diabetes. Randomized controlled trials have shown improvements in diabetes and depression health outcomes when depression is simultaneously treated (ADA, 2021).*
- ▲ Advise all (clients) to avoid use of cigarettes and other tobacco products or e-cigarettes. **EB:** *Individuals with diabetes who smoke and/or are exposed to second-hand smoke have a heightened risk of cardiovascular disease, premature death, microvascular complications, and worse glycemic control when compared with those who do not smoke. Smoking may have a role in the development of type 2 diabetes (ADA, 2021).*
- For interventions regarding foot care, refer to the care plan Ineffective Peripheral **Tissue Perfusion.**

Geriatric

- Screen for geriatric syndromes (i.e., polypharmacy, cognitive impairment, depression, urinary incontinence, falls, and persistent pain) in older adults **EB:** *Geriatric syndromes may affect diabetes self-management and diminish quality of life (ADA 2021).*
- ▲ In clients with diabetes who require tube feedings, use a diabetes-specific formulation. **EB:** *For enteral nutritional therapy, diabetes-specific formulas appear to be superior to standard formulas in controlling postprandial glucose, A1C, and the insulin response (ADA 2020).*
- ▲ Refer older adults for diabetes self-management education and support. **EB:** *Management of frailty in diabetes includes optimal nutrition with adequate protein intake combined with an exercise program that includes aerobic and resistance training (ADA, 2021).*
- ▲ Collaborate with provider to ensure that diabetes treatment costs are affordable and cost-related nonadherence is avoided. **EB:** *Medication costs can be a major source of stress for clients with diabetes and contribute to worse adherence to medications; cost-reducing strategies may improve adherence in some cases (ADA, 2021).*

Pediatric

- ▲ Treat hypoglycemia in newborn infants with 0.5 mL/kg oral (buccal) dextrose gel. **EB:** *Neonatal hypoglycemia can be associated with brain injury. Treatment of infants with neonatal hypoglycemia with 40% dextrose gel reduces the incidence of mother-infant separation for treatment (Weston et al, 2016).*
- ▲ Teach parents of children with diabetes how to recognize and treat symptoms of hypoglycemia. **EB:** *Symptoms of hypoglycemia in the young result from adrenergic activation (e.g., shakiness, pounding heart, sweatiness) and neuroglycopenia (e.g., headache, drowsiness, difficulty in concentrating). In young children, behavioral changes such as irritability, agitation, quietness, and tantrums may be prominent (Abraham et al, 2018).*

▲ Begin screening youth with type 1 diabetes for eating disorders between 10 and 12 years of age. The Diabetes Eating Problems Survey—Revised (DEPS-R) is a reliable, valid, and brief screening tool for identifying disturbed eating behavior. **EB:** *Early detection of depression, anxiety, eating disorders, and learning disabilities can facilitate effective treatment options and help minimize adverse effects on diabetes management and disease outcomes (ADA, 2021).*

- Teach children and adolescents (and their parents) with type 1 diabetes to self-monitor glucose (with meter or continuous glucose monitoring) multiple times daily: before meals and snacks, at bedtime, before exercise, when they suspect low blood glucose, after treating low blood glucose until they are normoglycemic, and before critical tasks such as driving. **EB:** *A database study of almost 27,000 children and adolescents with type 1 diabetes showed that … increased daily frequency of SMBG was significantly associated with lower A1C (−0.2% per additional test per day) and with fewer acute complications (ADA, 2021).*
- Teach parents and children that children and adolescents with type 1 and 2 diabetes should spend 60 minutes or more per day in moderate to vigorous aerobic activity, and at least 3 days/week in muscle/bone-strengthening activity. **EB:** *The level of physical activity in children and adolescents with [type 1 diabetes] is lower than in their healthy peers (Czenczek-Lewandowska et al, 2019). Youth with type 1 diabetes who engage in more physical activity may have better health outcomes and health-related quality of life (ADA, 2021).*

Home Care

- Teach family and others having close contact with the person with diabetes how to use an emergency glucagon kit (intranasal, injection kit, or autoinjector, as prescribed). **EB:** *Glucagon should be prescribed for all individuals at increased risk of level 2 or 3 hypoglycemia so that it is available should it be needed. Caregivers, school personnel, or family members of these individuals should know where it is and how to administer it (ADA, 2021).* **EB:** *Nasal glucagon (NG) was non-inferior to intramuscular glucagon for successful treatment of insulin-induced hypoglycemia in Japanese clients with [type 1 and type 2 diabetes], supporting use of NG as a rescue treatment for severe hypoglycemia (Matsuhisa et al, 2020). In a validation study, 98.7% successfully administered the rescue injection using the glucagon autoinjector. Overall, there were no patterns of differences between trained versus untrained participants, between caregivers versus first responders or between adults versus adolescents (Valentine et al, 2019).*

Multicultural

▲ Assess social context, including potential food insecurity, housing stability, and financial barriers, and collaborate with provider to apply the information to treatment decisions. **EB:** *Health inequities related to diabetes and its complications are well documented and are heavily influenced by social determinants of health. In those with diabetes and food insecurity, the priority is mitigating the increased risk for uncontrolled hyperglycemia and severe hypoglycemia (ADA, 2021).*

- Provide ethnically and culturally appropriate content that is person centered, considering such things as literacy levels, ethnic foods, and traditional remedies. **EB:** *Culturally tailored diabetes programs are an important strategy to overcome these health inequities, prevent diabetes complications, and improve care for ethnic minorities (Joo & Liu, 2021).*

Client/Family Teaching and Discharge Planning

- Provide "survival skills" education or review for hospitalized clients before discharge, including information about: (1) identification of the health care provider who will provide diabetes care after discharge; (2) level of understanding related to the diabetes diagnosis, self-monitoring of blood glucose, home blood glucose goals, and when to call the provider; (3) definition, recognition, treatment, and prevention of hyperglycemia and hypoglycemia; (4) information on making healthy food choices at home and referral to an outpatient RDN to guide individualization of meal plan, if needed. If relevant, when and how to take glucose-lowering medications, including insulin administration; (5) sick-day management; and (6) proper use and disposal of needles and syringes. Providing a structured discharge plan tailored to the individual client may reduce length of hospital stay and readmission rates and increase client satisfaction (ADA, 2021).
- Evaluate clients' monitoring technique and ability to use results to adjust therapy at regular intervals. **EB:** *Optimal use of SMBG requires proper review and interpretation of the data by both the client and provider, to ensure that data are used in an effective and timely manner (ADA, 2021).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Teach clients with type 2 diabetes the importance of reducing sedentary behavior, and to interrupt prolonged sitting at least every 30 minutes. **EB:** *Avoiding extended sedentary periods may help prevent type 2 diabetes for those at risk and may also aid in glycemic control for those with diabetes (ADA, 2021).*
- Teach adults with type 1 and type 2 diabetes to engage in 150 min or more of moderate to vigorous-intensity aerobic activity per week, spread over at least 3 days/week, with no more than 2 consecutive days without activity. Shorter durations (minimum 75 min/week) of vigorous intensity or interval training may be sufficient for younger and more physically fit individuals … Adults with type 1 and type 2 diabetes should engage in 2–3 sessions/week of resistance exercise on nonconsecutive days. **EB:** *Exercise has been shown to improve blood glucose control, reduce cardiovascular risk factors, contribute to weight loss, and improve well-being (ADA, 2021).*

▲ Discuss recommending resistance training with the client's provider. **EB:** *"Compared with no exercise, resistance training improves HbA1C by 0.34% and may modestly improve cardiorespiratory fitness" (Oyler et al, 2020).*

- Teach clients with type 1 diabetes to test for urine or blood ketones if they are ill, if their blood glucose is >240 mg/dL, and before exercise if blood glucose is >250 mg/dL. Advise to increase fluid intake and contact provider at first detection of ketones. **EB:** *Exercise should be postponed or suspended if blood ketone levels are elevated (≥1.5 mmol/L) as blood glucose levels and ketones may rise further with even mild activity (Colberg et al, 2016). Diabetic ketoacidosis onset and recurrence can largely be prevented through client education (Kreider, 2018).*

▲ Teach clients taking insulin or secretagogue medication to check blood glucose before and after exercise. Blood glucose levels before exercise should ideally be >90 mg/dL. Discuss carbohydrate use in relation to exercise with provider. **EB:** *Because of the variation in glycemic response to exercise bouts, clients need to be educated to check blood glucose levels before and after periods of exercise (ADA, 2021).*

- Teach clients to use alcohol with caution. **EB:** *Alcohol consumption may place people with diabetes at increased risk for delayed hypoglycemia, especially if taking insulin or insulin secretagogues (ADA, 2021).*
- Inform clients that use of smartphone applications may help them manage their diabetes care and glucose control. **CEB/EB:** *In adjunct to usual care, the use of a diabetes-related smartphone application combined with weekly text-message support from a health care professional can significantly improve glycemic control in adults with type 1 diabetes (Kirwan et al, 2013). Clients that used mobile platforms were found to test their blood glucose more often and demonstrated greater improvement in blood glucose compared to users who did not use the mobile platform (Offringa et al, 2018).*

G

Maladaptive Grieving

Domain 9 Coping/stress response Class 2 Coping responses

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CNEcl, CHSE, ANEF, FAAN

NANDA-I

Definition

A disorder that occurs after the death of a significant other, in which the experience of distress accompanying bereavement fails to follow sociocultural expectations.

Defining Characteristics

Anxiety; decreased life role performance; depressive symptoms; diminished intimacy levels; disbelief; excessive stress; experiencing symptoms the deceased experienced; expresses anger; expresses being overwhelmed; expresses distress about the deceased person; expresses feeling detached from others; expresses feeling of emptiness; expresses feeling stunned; expresses shock; fatigue; gastrointestinal symptoms; grief avoidance; increased morbidity; longing for the deceased person; mistrust of others; nonacceptance of a death; persistent painful memories; preoccupation with thoughts about a deceased person; rumination about deceased person; searching for a deceased person; self-blame

Related Factors

Difficulty dealing with concurrent crises; excessive emotional disturbance; high attachment anxiety; inadequate social support; low attachment avoidance

At-Risk Population

Economically disadvantaged individuals; individuals experiencing socially unacceptable loss; individuals experiencing unexpected sudden death of significant other; individuals experiencing violent death of significant other; individuals unsatisfied with death notification; individuals who witnessed uncontrolled symptoms of the deceased

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Anxiety Level; Coping; Depression; Grief Resolution; Mood Equilibrium; Personal Well-Being; Psychosocial Adjustment: Life Change; Sleep

Example NOC Outcome with Indicators

Grief Resolution as evidenced by the following indicators: Resolves feelings/Verbalizes reality and acceptance of loss/Maintains living environment/Seeks Social support. (Rate the outcome and indicators of **Grief Resolution:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I]).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Client Outcomes

Client Will (Specify Time Frame)

- Express appropriate feelings of guilt, fear, anger, or sadness
- Identify somatic distress associated with grief (e.g., anxiety, changes in appetite, insomnia, nightmares, loss of libido, decreased energy, altered activity levels)
- Seek support in dealing with grief-associated issues
- Identify personal strengths and effective coping strategies
- Function at a normal developmental level and begin to successfully and increasingly perform activities of daily living

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Grief Work Facilitation; Grief Work Facilitation: Perinatal Death; Guilt Work Facilitation; Hope Installation

Example NIC Activities—Grief Work Facilitation

Identify the loss; Encourage expression of feelings about the loss; Assist to identify personal coping strategies; Identify sources of community support

Nursing Interventions and *Rationales*

- Assess for signs of maladaptive grieving that include symptoms that persist at least 6 months after the death and are experienced at least daily or to a disabling degree. Symptoms include feeling emotionally numb, stunned, shocked, and that life is meaningless; dysfunctional thoughts and maladaptive behaviors; experiencing mistrust and estrangement from others; anger and bitterness over the loss; identity confusion; avoidance of the reality of the loss, or excessive proximity seeking to try to feel closer to the deceased, sometimes focused on wishes to die or suicidal statements and behavior; or difficulty moving on with life. Symptoms must be associated with psychosocial and physical impairments. **EB:** *Brown (2016) studied the recurrent grief in mothers caring for a child with intellectual disability and found that recurrent grief is correlated with coping and challenging behaviors of the child.* **EB:** *Buck et al (2020) studied complicated grieving and the effects of accelerated resolution therapy (ART) (a mind-body therapy). In a random control trial, one group of participants received four ART sessions, and the results demonstrated that the intervention group had decreased complicated grief and better grief resolution.*

▲ Determine the client's state of grieving. Use a tool such as the Prolonged Grief Disorder (PGD) scale (Jordan & Litz, 2014), the Grief Support in Health Care Scale (Anderson et al, 2010), the Hogan Grief Reaction Checklist (Hogan, Worden, & Schmidt, 2004), and the Beck Depression Inventory. **EBN:** *Researchers studied the grief of mothers (n = 130) and fathers (n = 52) after infant or child neonatal or pediatric intensive care unit death by completing the Hogan Grief Reaction Checklist at 1, 3, 6, and 13 months after the death, and found initial grief reactions decreased from 3 to 13 months for mothers and from 3 to 6 months for fathers (Youngblut et al, 2017).*

▲ Determine whether the client is experiencing depression, suicidal tendencies, or other emotional disorders. Refer the client for counseling or therapy as appropriate. **EB:** *The study also found that participants experiencing depression and maladaptive grief used grief services at a more frequent rate than participants who were not clinically depressed (Banyasz et al, 2017).* **EB:** *In a qualitative study (Titlestad et al, 2020) of Norwegian parents who experienced a drug-related death of a child, the researchers identified three salient themes. The first theme was processing grief emotions from the incident, the second theme was proactive coping, and the third theme was giving and receiving support and assistance from others and to others.*

- Educate the client and his or her support systems that grief resolution is not a sequential process and that the positive outcome of grief resolution is the integration of the deceased into the ongoing life of the griever. **EB:** *Mowll (2017) studied ways to support family members (n = 48) who needed to view the body of their relative after a traumatic death. Things that assisted the family members included support during interactions, giving permissions and possibilities, providing information and preparation, being caring, timing experiences appropriately, and tuning in to family needs.* **EB:** *Hanish, Margulies, and Cogan (2019) quantitatively studied the outcome of a residential retreat for women (n = 141) who experienced pregnancy or infant loss. The retreat included group discussions, yoga, meditation, crafts, and activities to facilitate grieving and healing. The study demonstrated statistically significant post-test improvements in participations' depression, self-compassion, and perceived social support.*

▲ Assess caregivers, particularly younger caregivers, for pessimistic thinking and additional stressful life events. Refer for appropriate support. **EB:** *Researchers studied African American caregivers (family members) (N = 108) of persons with dementia and found that negative thoughts increase depression and physical suffering (Schulz et al, 2017).* **EB:** *See et al (2020) qualitatively explored women's (N = 22) expectations when they entered an emergency department (ED) for early pregnancy bleeding and impending perinatal loss. Participant interviews revealed four themes: (1) need to inform clients of progress and explain treatments, (2) needing privacy to allow for grieving, (3) decreasing prolonged waiting time, and (4) recommending available services to support clients after they leave the ED.*

- See the interventions and rationales in the care plans for Readiness for Enhanced **Grieving** and Chronic **Sorrow.**

Pediatric/Parent

▲ Refer grieving children and parents to a program to help facilitate grieving if desired, especially if the death was traumatic. **EB:** *Schreiber, Sands, and Jordan (2017) studied children whose parents died of suicide and found that children felt isolated, abandoned, and responsible. Suggestions for nursing included developmentally appropriate education about suicide grief, depression, and normalizing.*

- Encourage grieving parents to take part in activities that are supportive, such as faith-based activities. **EB:** *Nuzum, Meaney, and O'Donoghue (2017) qualitatively studied parents who experienced the loss of a stillborn child, and study results indicated that stillbirth challenges parents' faith, usually one parent more than the other, indicating that all parents should be offered spiritual care after a stillbirth.*
- Encourage grieving parents to seek mental health services as needed. **EBN:** *Morris et al (2017) noted that bereaved parents are an "at-risk" group, and through anecdotal experiences they developed a hospital-wide, preventive model, bereavement program using education, guidance, and support. The model has been received by participants and staff with good results.*
- Help the adolescent determine sources of support and how to use them effectively. If the client is an adolescent exposed to a peer's suicide, watch for symptoms of traumatic grief and posttraumatic stress disorder, which include numbness, preoccupation with the deceased, functional impairment, and poor adjustment to the loss. **EB:** *Woollett et al (2017) qualitatively studied adolescents who were HIV-positive in Africa and their ability to disclose the disease and the bereavement process. The study found that most participants were orphaned and experiencing maladaptive grief that was related negatively to mental health and the ability to accept their HIV status and adhere to treatment.* **EB:** *Praetorius and Rivedal (2020) qualitatively studied stories about suicide survivors (N = 6) and found that stories could be equated to a theme such as sailing down the lazy river, which hit unexpected rapids, then getting to shore before going over a waterfall, waking in the ocean of why, and righting the ship and rescuing others. The story developed in this research project assisted others to understand the feelings of suicide survivors and help friends and family deal with the suicide.*

Geriatric

- Assess for deterioration in bereaved older adults' self-care. **EBN:** *Skritskaya et al (2017) investigated maladaptive cognitions and their relationship to complicated grief by developing a questionnaire called the Typical Beliefs Questionnaire (TBQ) and piloted the tool on bereaved adults (N = 394) with complicated grief. The new tool was effective in identifying specific maladaptive cognitions related to complicated grief.*
- Those who have lived with older adults with dementia and experienced significant feelings of loss before the loved one's death may be at risk for more intense feelings of grief after the death of the client with dementia. **EB:** *Berenbaum, Tziraki, and Cohen-Mansfield (2017) studied how people with dementia are told about the death of a peer. Adult daycare staff (N = 52) was qualitatively interviewed and felt that their clients have the emotional capacity to mourn despite their cognitive impairments.*
- Monitor the older client for complicated grieving manifesting in physical and mental health problems. **EB:** *Boer et al (2014) studied clients with chronic obstructive pulmonary disease (COPD) who have a grieving process because of loss of functioning and found that clients with COPD experience four stages of grief: denial, resistance, sorrow, and acceptance.*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's grief and mourning practices. **EBN:** *Bravo (2017) studied undocumented Latino migrants (N = 12) living in the United States who have*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

experienced coping with deaths of loved ones in their home countries. The participants experienced sadness and guilt, but communication with those in the home country was an important mechanism for coping. **EBN:** *Kongsuwan et al (2019) completed a qualitative study of grieving Thai Buddhist husbands. Interviews revealed five themes: (1) loss of thoughtful focus and energy, (2) attachment to the children, (3) continuing social connections, (4) evaluating lived time, and (5) providing oneself healing time. The study results demonstrate that nurses can develop bereavement care processes by valuing the religious principles integrating social interaction for bereaved husbands.*

- Encourage discussion of the grief process. **EBN:** *Mun and Ow (2017) studied the grief process of mothers who lost a child in Singapore and found that qualitatively four themes were identified: (1) meaning to the child's life and death, (2) quality and assurance of an afterlife, (3) the function of crying, and (4) a continuing bond.*
- Identify whether the client had been notified of the health status of the deceased and was able to be present during illness and death. **EB:** *Young (2017) discussed cases related to people with profound intellectual and multiple disabilities (PIMD) that are bereaved and experience social, emotional, and physical constraints. Young found that people with PIMD are a high-risk group and at greater risk of maladaptive grieving.*

G

Home Care

- Previous interventions can be adapted for home care use.
- Consider providing support via the Internet. **EB:** *Researchers studied an Internet or telephone intervention with caregivers of veterans with dementia and found that in rural populations the Internet was effective if the caregiver was comfortable with technology (Hicken et al, 2017).* **EB:** *Pearce (2020) used the Internet to establish a "Tagboard" after a community crisis in which two people were killed. A content analysis of 493 images was completed and divulged a theme of authentic self in the grief of the community and was effective in promoting grief expression in a complicated situation that affected an entire community.*

Risk for Maladaptive Grieving

Domain 9 Coping/stress tolerance Class 2 Coping responses

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to a disorder that occurs after death of a significant other, in which the experience of distress accompanying bereavement fails to follow sociocultural expectations, which may compromise health.

Risk Factors

Difficulty dealing with concurrent crises; excessive emotional disturbance; high attachment anxiety; inadequate social support; low attachment avoidance

At-Risk Population

Economically disadvantaged individuals; individuals experiencing socially unacceptable loss; individuals experiencing unexpected sudden death of significant other; individuals experiencing violent death of significant other; individuals unsatisfied with death notification; individuals who witnessed uncontrolled symptoms of the deceased; individuals with history of childhood abuse; individuals with history of unresolved grieving; individuals with significant predeath dependency on the deceased; individuals with strong emotional proximity to the deceased; individuals with unresolved conflict with the deceased; individuals without paid employment; women

Associated Conditions

Anxiety disorders; depression

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Maladaptive **Grieving.**

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Readiness for Enhanced Grieving

Domain 9 Coping/stress tolerance Class 2 Coping responses

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CNEcl, CHSE, ANEF, FAAN

NANDA-I

Definition

A pattern of integration of a new functional reality that arises after an actual, anticipated or perceived significant loss, which can be strengthened.

Defining Characteristics

Expresses desire to carry on legacy of the deceased; expresses desire to engage in previous activities; expresses desire to enhance coping with pain; expresses desire to enhance forgiveness; expresses desire to enhance hope; expresses desire to enhance personal growth; expresses desire to enhance sleep-wake cycle; expresses desire to integrate feelings of anger; expresses desire to integrate feelings of despair; expresses desire to integrate feelings of guilt; expresses desire to integrate feelings of remorse; expresses desire to integrate positive feelings; expresses desire to integrate positive memories of deceased; expresses desire to integrate possibilities for a joyful life; expresses desire to integrate possibilities for a meaningful life; expresses desire to integrate possibilities for a purposeful life; expresses desire to integrate possibilities for a satisfactory life; expresses desire to integrate the loss; expresses desire to invest energy in new interpersonal relations

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Grief Resolution; Dignified Life Closure; Hope; Psychosocial Adjustment: Life Change

Example NOC Outcome with Indicators

Grief Resolution as evidenced by the following indicators: Resolves feelings about the loss/Verbalizes reality and acceptance of loss/Maintains living environment/Seeks social support. (Rate the outcome and indicators of **Grief Resolution:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client/Family Outcomes

Client/Family Will (Specify Time Frame)

- Express meaning of the loss to his or her life and the functioning of the family
- Identify ways to support family members and articulate methods of support he or she requires from family and friends
- Accept assistance in meeting the needs of the family from friends and/or extended family

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Grief Work Facilitation; Dying Care; Emotional Support: Perinatal Death; Hope Instillation; Support System Enhancement; Family Support; Family Integrity Promotion

Example NIC Activities—Grief Work Facilitation

Identify the loss; Encourage expression of feelings about the loss; Assist to identify personal coping strategies; Identify sources of community support

Nursing Interventions and *Rationales*

Anticipatory Grieving Interventions

- Acknowledge grieving of a critically ill or dying client and clients' family/relatives for the losses experienced during the deteriorating illness, and the future that will be filled with loss. **EBN:** *Johnson et al (2017)*

qualitatively studied anticipatory grieving associated with clients at the end of life and their families and found that less than 50% of the dying clients and their families were given an anticipatory grieving nursing diagnosis and met the nursing outcomes at the time of death (such as the spiritual health outcome), demonstrating that expected outcomes need additional nursing attention.

- Develop a trusting relationship both with the client and with the family by using presence and therapeutic communication techniques. **EBN:** *Al Mutair et al (2019) explored the impact of cultural diversity on how neonatal and pediatric intensive care nurses care for Muslim families before and after the death of infants. To overcome the challenges there was a commitment to respect everyone and an openness to differences.*
- Keep the family apprised of the client's ongoing condition as much as possible. Consult with the family for decision-making as appropriate. **EB:** *In a study of family caregiving of terminally ill clients, Ullrich et al (2020) found that difficult decision-making was related to moral distress in family members and having path options for choices assisted family caregivers to move toward acceptance.*
- Keep the family informed of client's needs for physical care and support in symptom control, and inform them about health care options at the end of life, including palliative care, hospice care, and home care. **EB:** *Brooks et al (2017) completed a study about communication and shared decision-making about end-of-life care in a 24-bed intensive care unit (ICU) using focus groups with 17 nurses and 11 physicians. Findings indicated that improvement was needed in initiating and communicating end-of-life care among health care professionals and with the families.*
- Ask family members about having adequate resources to care for themselves and the critically ill family member. **EBN:** *Eskola et al (2017) used a mixed-method study on parents' experiences and needs during a child's (*N = *47)* end-*of-life care at home and found that parents created a sense of normality for the child, which caused parental exhaustion. Parents needed practical help with housekeeping and dealing with insurance.*
- Encourage family members to show their caring feelings and talk to the client. **EBN:** *The researchers completed a literature review about using transitional objects with parents for perinatal loss such as taking photographs for parents. The objects provide parents a brief sense of healing (LeDuff et al, 2017).*
- Recognize and respect different feelings and wishes from both the family members and the client. **EB:** *Immigrant families and their grieving related to COVID-19 family deaths were studied by Falicov et al (2020). The study found decreased family stress by providing families resources to Wi-Fi, smartphones, or computers, or sufficient living space.*
- If necessary, refer a family member for counseling or to a minister/priest to help him or her cope with the existential questions and current overwhelming reality. **EB:** *Parente and Ramos (2020) qualitatively studied Brazilian parents (*N = *40) who experienced a death of a child and their spiritual-religious coping. The results demonstrated that spirituality was related to helping others after the death of a child and that 70% of parents reported volunteer work as a method to decrease the grief.* **EB:** *Thompson et al (2020) studied caregiver stress in family members caring for clients with Alzheimer's disease. The researchers examined stress, role strain, self-concept stress, and coping stress in relation to decision-making. The results demonstrated that strong family self-efficacy and high levels of coping skills assisted family members to make critical decisions.*
- Promote mutual goal setting in which decisions are made together that affect the family. **EBN:** *Kim et al (2017) descriptively studied end-of-life care decisions for cancer clients and found that 50% of caregivers did not agree on advance directives, and the overall recommendation is to better include caregivers in end-of-life decisions to decrease disagreement.*

Grieving Interventions When Death of a Loved One Occurs

Use the following activities when interacting with the bereaved person:

- Be present and attentive; use active empathetic listening. **EBN:** *Cheng and Fang (2018) completed a qualitative case study with a dialysis client who experienced the loss of her spouse. The investigators found three trends: dysfunctional grieving, hopelessness, and sleep pattern disturbance. The researchers used caring, active listening, and empathy to promote a positive grieving process by assisting participants to accept the reality of loss, work through the pain of grief, and adjust to an environment without her spouse.*
- Validate the client's feelings of grief and feeling hurt, stressful, anxious, out of control, and further symptoms of grieving with an appropriate tool. **EB:** *The Perinatal Bereavement Care Confidence Scale (PBCCS) has 43 items and is valid to elicit data about care knowledge, bereavement care skills, self-awareness, and*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

organizational support (Kalu et al, 2020). The tool is recommended to be used by practitioners who care for bereaved perinatal parents.

- Provide time and space for the person to tell their story of loss. **EB:** *Lawrence (2017) completed a case study analysis with individuals who experienced catastrophic events as first responders of lost clients or victims. Telling their story assisted in the grieving process.*
- Offer condolences: "I am sorry that you lost your husband." **EB:** *Levi-Belz (2017) investigated the role of the ongoing relationship with the deceased family member comparing 58 suicide-loss survivors and 48 sudden-death and 53 natural-death bereaved individuals, and the suicide-loss family reported a lower positive ongoing relationship with the deceased.*
- Intentionally schedule meetings with family members to provide support during grieving. **EB:** *Parravicini (2017) completed a literature review about the protocols for newborns with life-limiting or life-threatening conditions and concluded that a multiprofessional team is needed to address the infant's needs, parental grieving process, and providers' distress.*
- Help the client use a method to give voice to his or her unique story of loss. Methods include keeping a personal journal to record feelings and insights; retelling of the loss narrative to a caring person; music therapy techniques with a trained therapist or listening to music that has significance to the relationship; and use of the "virtual dream," which is a dreamlike short story written by the grieving person to tell the narrative of the loss. **EBN:** *Beiermann et al (2017) studied families' (n = 50) bereavement reactions related to clients dying in the ICU and found that the majority of families responded positively to receiving an ECG Memento, which is a monitor strip of the clients' heart rhythm.*
- Discuss coping methods with the grieving person. Common coping techniques include exercise, telling the story of grief to a caring person, journaling, pets, and developing a legacy for the deceased. **EB:** *The researchers used kinetic sculpturing as a grief intervention in case studies to create visual examples of family equilibrium before, in the midst of, and after the deaths of family members. Family members found the creative expression beneficial (Brandon & Goldberg, 2017).*
- Encourage the family to create a quiet and comfortable healing environment, and follow comforting grief rituals such as prayer, interacting with nature, or lighting votive candles. **EBN:** *Barrett (2017) reviewed a case study related to how health care professionals provide empathy to grieving parents who lost a child and suggested nursing implications including being present and listening.*
- Help the family determine the best way and place to find social support. Encourage family members to continue to use support for as long as needed. **EB:** *Researchers studied spouses (n = 1224) whose partners died to examine (1) how life satisfaction changed; (2) whether sociodemographic factors and social and health resources moderate the effect on life satisfaction; and (3) whether anticipation, reaction, and adaptation are related to mortality. Life satisfaction decreases for about 2.5 years and older age was associated with more intense declines (Infurna et al, 2017).*
- Identify available community resources, including bereavement groups at local hospitals and hospice centers. Volunteers who provide bereavement support can also be effective. **EB:** *Gibson (2017) investigated the use of Second Life to symbolically bury and memorialize the real-life biological deaths of people. It was shown to not decrease the loss in real life; instead it provides a method to remember the person.*
- ▲ Refer the family members for spiritual counseling as desired. **EB:** *Ortega-Galán et al (2020) qualitatively studied the spiritual and religious beliefs of clients at the end of life by interviews (n = 87). Participants revealed that spirituality was important and that a variety of clergies in health units is needed so all clients and families get support that is comfortable.*
- ▲ Refer to mental health providers as needed. **EB:** *Lenger et al (2020) studied the health of grieving caregivers and its relation to prolonged grief. The researchers described the physical and mental health of people who were caring for clients at the end of life and found that caregivers scored lower on one physical subscale and all mental health measures when compared with the general population.*
- Refer to Maladaptive **Grieving** if the experience of distress accompanying bereavement fails to follow sociocultural expectations.

Pediatric/Parent

- Treat the child/parents with respect, and give them the opportunity to talk about concerns and answer questions honestly. **EB:** *Care providers can give anticipatory guidance to caregivers to support children who are grieving; to assist children to better understand what has happened; and to address any misinformation, misinterpretations, or misconceptions (Schonfeld & Demaria, 2016).*

- Listen to the child's expression of grief. **EBN:** *Schmidt et al (2020) studied 32 children who experienced a loss of a pet. The investigators found that children have continuing bonds with their pets after the loss. The continuing bonds vary depending on the attachment the child had with the pet and the age of the child.*
- Help parents recognize that the grieving child does not have to be "fixed"; instead they need support going through an experience of grieving just like adults. **EB:** *In a study of how bereaved students were perceived in a school setting by adults, the researchers found that 93% of adult participants interacted with bereaved students, provided emotional support, made classroom accommodations, interacted with the family/community, and referred the student for counseling (DeMuth et al, 2020).*
- Consider the use of art for children in hospice care who are dying or dealing with the death of a parent, sibling, or other family member. **EB:** *Hirschon et al (2018) used the "tree of life metaphor" and images to assist adolescents to express their grief. Participants were able to verbalize and share their grief reactions effectively using this technique.*

▲ Refer grieving children and parents to a program to help facilitate grieving if desired, especially if the death was traumatic. **EB:** *Testoni et al (2020) studied the grieving process of Italian mothers (n = 15) after a perinatal loss and identified three main themes during the interviews: continuing bonds between externalized and internalized presence, a difficult guilt to manage, and relationships are crucial support systems. The findings of this study demonstrate that there is a continuing bond after death between mother and the perinatal loss.*

- Help the adolescent determine sources of support and how to use them effectively. **EB:** *DeDiego, Wheat, and Fletcher (2017) explored Adventure Based Counseling (ABC) camps for grieving adolescents and children with positive results.* **EB:** *Dodd et al (2020) studied the Active Inhibition Scale (AIS), an 11-item, self-report measure of emotional suppression. The results revealed that emotional suppression scores were higher among girls compared to boys, Black and Hispanic youth compared to White youth, and older compared to younger age groups.*
- Encourage grieving parents to take good care of their own health. **EB:** *Albuquerque et al (2017) studied parental relationships (n = 17) after the death of a child by grounded theory method and identified three themes: search for meaning, communication with the partner, and care-in-relation that assisted couples to maintain a healthy relationship.*

▲ Refer grieving parents to seek mental health services as needed. The death of a child is regarded as among the most traumatic, incomprehensible, and devastating of losses, with the potential to precipitate a crisis of meaning for the bereaved parent. **EB:** *Researchers studied meaning reconstruction using a life-story interview with a Japanese woman who lost her son to suicide. The analysis revealed three themes: (1) making sense of her son's death and life, (2) relationships with other people, and (3) reconstruction of a bond with the deceased (Kawashima & Kawano, 2017).*

- Recognize that men and women often grieve differently, and explain this to parents as needed. **EB:** *Researchers used a mixed-method approach to investigate mothers' (n = 60) grief after losing a child, forgiveness, and posttraumatic growth. There was a negative correlation between forgiveness and grief and a positive correlation between forgiveness and posttraumatic growth (posttraumatic growth was viewed as changes in life) (Martinčeková & Klatt, 2017).*
- Recognize that mothers who have a miscarriage/stillbirth grieve and experience sorrow because of the loss of the child. **EBN:** *Rocha Catania et al (2017) performed a literature (n = 29) review about prenatal palliative care for parents carrying a fetus with malformations and found no long-term studies about the effects of prenatal palliative care.*

Geriatric

- Monitor an older adult who has been treated for bereavement-related depression for relapse or recurrence. **EB:** *Tanimukai et al (2015) studied the relationship between depression and insomnia in bereaved families and found that insomnia was highly correlated with depression.*
- Provide support for the family when the loss is associated with dementia of the family member. **EB:** *Researchers studied an intervention with caregivers of veterans with dementia. Caregivers were divided into groups of Internet or telephone intervention and found that in rural populations the Internet was effective if the caregiver was comfortable with technology (Hicken et al, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Determine the social supports of older adults. **EBN:** *Dunham, Allmark, and Collins (2017) investigated the experience of cancer pain in elderly clients (n = 9) and identified four themes for nursing consideration: better to be old than to be dying, maintaining independence, grieving for a former self, and denial of pain.*

Multicultural

- See interventions and rationales in care plans for Maladaptive **Grieving** and Chronic **Sorrow.**

Home Care

- The interventions previously described may be adapted for home care use.
- Assessment of activities of daily living (ADLs) and instrumental ADLs is essential as part of comprehensive care after a home care client has suffered the loss of a loved one. **EB:** *Raitio, Kaunonen, and Aho (2015) explored parental grief intervention and its effects on maternal grief with health care provider intervention and found that support from the health care professionals was positively correlated with stronger personal growth at 6 months after the death.*
- Actively listen as the client grieves for his or her own death or for real or perceived loss. Normalize the client's expressions of grief for self. Demonstrate a caring and hopeful approach. **EB:** *Vergo et al (2017) measured the grief reactions of clients (n = 53) with advanced cancer using the Preparatory Grief in Advanced Cancer (PGAC) instrument and found that preparatory grief was common and 25% of participations had significant grief, and all clients demonstrated distress.*

▲ Refer the client to social services as necessary for losses not related to death. Support is helpful to grief work for all types of losses. Social workers can help the client plan for financial changes as a result of job losses and help with community referrals as appropriate. **EB:** *A study by social work researchers about women who experienced a miscarriage, stillbirth, or child's death compared self-esteem to maternal identity and found that stillbirth and death of a child negatively affected self-esteem, and that self-esteem levels were increased by stronger maternal identity (Hill et al, 2017).*

▲ Refer the bereaved to hospice bereavement programs or an Internet self-help group. Relief of the suffering of clients and families (physical, emotional, and spiritual) is the goal of hospice care. **EB:** *An ethnographic study was completed to understand the motivation for grieving mothers to start and maintain a blog. After reviewing 140 blogs the researchers identified themes such as sharing the loss and challenges, creating a network to support and comfort others, guaranteeing a space to express feelings, honoring and perpetuating the image of the child lost, and engaging in social activism (Figueiredo Frizzo et al, 2017).*

Deficient Community Health

Domain 1 Health promotion Class 2 Health management

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Presence of one or more health problems or factors that deter wellness or increase the risk of health problems experienced by a group or population.

Defining Characteristics

Health problem experienced by groups or populations; program unavailable to enhance wellness of a group or population; programs unavailable to eliminate health problems of a group or population; programs unavailable to prevent health problems of a group or population; programs unavailable to reduce health problems of a group or population; risk of hospitalization to a group or population; risk of physiological manifestations to a group or population; risk of psychological manifestations to a group or population

Related Factors

Inadequate access to health care provider; inadequate consumer satisfaction with programs; inadequate expertise within the community; inadequate health resources; inadequate program budget; inadequate program evaluation plan; inadequate program outcome data; inadequate social support for programs; programs incompletely address health problems

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Community Grief Response; Community Health Screening Effectiveness; Community Health Status Community Program Effectiveness; Community Resiliency; Community Risk Control: Obesity; Community Risk Control: Unhealthy Cultural Traditions

Example NOC Outcome with Indicators

Community Health Status as evidenced by the following indicators: Health status of infants/Children/Adolescents/Adults/Elders/Minority populations/Prevalence of health promotion programs. (Rate the outcome and indicators of **Community Health Status:** 1 = poor, 2 = fair, 3 = good, 4 = very good, 5 = excellent, NA [see Section I].)

Client Outcomes

Community/Adolescents/Minority Clients Will (Specify Time Frame)

- Provide programs for healthy behaviors
- Demonstrate goal setting
- Describe and comply with healthy behaviors

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Community health development: Identify health concerns, strengths, and priorities with community partners; Assist community members in raising awareness of health problems and concerns

Nursing Interventions and *Rationales*

- Refer to care plans for Readiness for Enhanced Community **Coping,** Ineffective Community **Coping,** Ineffective **Health** Maintenance Behaviors, Ineffective **Home** Maintenance Behaviors, and Risk for Other-Directed **Violence.**
- Assess for the presence of social determinants associated with community mortality. **EB:** *A study that evaluated associations between social determinants of health and life expectancy suggests that social determinants are associated with population health across the lifespan (Cohen, Broccoli, & Greaney, 2020).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

- Assess for needs related to the community's priority health concerns. **EB:** *In a community-based participatory research study with 3151 respondents, the five most identified health concerns were diabetes, cancer, hypertension, heart problems, and body weight (McElfish et al, 2018).*
- Assess clients accessing health services for a history of military service and provide the necessary referrals and information. **EBN:** *Many veterans eligible for Veterans Administration (VA) health benefits seek health care from community emergency departments and will benefit from information about VA resources (Merkl et al, 2016).*
- Implement community engagement techniques for collaboration with stakeholders to design, develop, and adapt relevant health interventions. **EB:** *In the Hearts of Sonoma County (HSC) initiative, clinical systems and communities worked to reduce cardiovascular disease risk (Cheadle et al, 2019).*
- Encourage attendance at community-based exercise programs. **EBN:** *In this study community-based exercise groups were perceived by pregnant women as a satisfactory and motivating form of exercise engagement (Ette, 2017).*
- Implement community engagement techniques in conjunction with tailored interventions to address health deficiencies. **EB:** *In this study, community engagement techniques were essential in coordinating interventions and engaging clients, the public, and local practitioners in delivery of mental health care (Lamb et al, 2015).*
- Collaborate with other community-based programs to use text messaging to broadcast targeted health messages to reach large numbers of community members. **EB:** *A cluster randomized controlled study showed that mobile text messaging had a positive effect on the gestational weights and hemoglobin levels of expectant mothers (Singh et al, 2020).*

Pediatric

▲ Consider use of a clinical-community collaborative to address health deficiencies in underserved populations with children. **EB:** *Pediatric waiting rooms were redesigned to enhance families' engagement and connection to community resources. Caregivers were significantly more likely to perceive the redesigned waiting rooms as places to obtain help with connecting to community resources and clinical and educational information (Henize et al, 2018).*

▲ Screen at-risk pediatric populations for lead exposure. **EB:** *This study showed undertesting for lead exposure and no mandatory lead test screening in one-third of eligible children during the study period (Knighton, Payne, & Speedie, 2016).*

Geriatric

▲ Assess community-dwelling older individuals for cognitive impairment using the Brief Cognitive Assessment Tool-Short Form (BCAT-SF). **EBN:** *In this study, the BCAT-SF demonstrated sensitivity in differentiating between dementia and nondementia (Mace, Mansbach, & Clark, 2016).*

▲ Refer older clients with a diagnosis of dementia to a home-based missing incident prevention program (HMIPP). **EB:** *An HMIPP program was effective in reducing the number of missing incidents, searching time, and caregivers' stress at 3 months and 1 year (Lau, Chan, & Szeto, 2019).*

▲ Assess community-dwelling older individuals with the Identification of Seniors at Risk (ISAR) screening tool when they present for treatment in the emergency department. **EB:** *A systematic review and meta-analysis found the ISAR had modest predictive accuracy and may serve as a decision-making adjunct when determining which older adults can be safely discharged (Galvin et al, 2017).*

▲ Screen community-dwelling older individuals for fall risk with the Timed Up and Go Test (TUG) or the Functional Gait Assessment (FGA) and refer to a fall prevention program. **EB:** *A clinical review of research recommended the use of the TUG and FGA to identify fall risk in community-dwelling older individuals (Lee, Geller, & Strasser, 2013).* **EBN:** *A nurse practitioner–led fall prevention program was successful at reducing fall risk among older adults (Harrison, 2017).*

Multicultural

- Assess for the impact of race/ethnic-based segregation on health outcomes. **EB:** *Race-based residential segregation was associated with an increase in all-cause mortality that was mediated by education, income inequality, and exposure to air pollution (Schulz et al, 2020).*
- Provide culturally and linguistically appropriate community health programs. **EB:** *A systematic review found that culturally appropriate community-based physical activity programs appear to support and encourage engagement among culturally and linguistically diverse older adults (Montayre et al, 2020).*
- Use decision aids (DAs) (personal counseling, multimedia, and print materials) to facilitate communication between clients and health care providers to determine a plan for health care. **EB:** *A systematic review*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

found 18 studies illustrating the effectiveness of DAs in improving client–provider communication and decision quality outcomes in minority populations (Nathan et al, 2016).

Home Care and Client/Family Teaching and Discharge Planning

- The previously mentioned interventions may be adapted for home care and client/family teaching.

H

Risk-Prone Health Behavior

Domain 1 Health promotion Class 2 Health management

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Impaired ability to modify lifestyle and/or actions in a manner that improves the level of wellness.

Defining Characteristics

Failure to achieve optimal sense of control; failure to take action that prevents health problem; minimizes health status change; nonacceptance of health status change; smoking; substance misuse

Related Factors

Inadequate social support; inadequate understanding of health information; low self efficacy; negative perception of health care provider; negative perception of recommended health care strategy; social anxiety; stressors

At-Risk Population

Economically disadvantaged individuals; individuals with family history of alcoholism

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Participation in Health Care Decisions; Psychosocial Adjustment: Life Change; Risk Detection

Example NOC Outcome with Indicators

Risk Detection as evidenced by the following indicators: Recognizes signs and symptoms that indicate risks/Identifies potential health risks/Participates in screening at recommended intervals/Obtains information about changes in health recommendations. (Rate the outcome and indicators of **Risk Detection:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State acceptance of change in health status
- Request assistance in altering behaviors to adapt to change
- State personal goals for dealing with change in health status and means to prevent further health problems
- State experience of a period of grief that is proportional to the actual or perceived effect of the loss
- Report and/or demonstrate behavior changes mutually agreed upon with nurse as evidence of positive adaptation

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Self-Efficacy Enhancement

Example NIC Activities—Self-Efficacy Enhancement

Explore individual's perception of his or her capability to perform the desired behavior; Reinforce confidence in making behavior changes and taking action

Nursing Interventions and *Rationales*

- Assess the client's perceptions of health, wellness, disability, and major barriers to health and wellness. **EB:** *Understanding the differences in perceptions can direct how a provider talks to clients about their health, but it could also provide insight into how clients value and perceive their own disability and wellness (Morris et al, 2018).*
- Assess the client for adverse childhood experiences (ACEs) and refer for counseling and follow-up as appropriate. **EB:** *A study reported that an ACE score ≥4 was associated with increased odds for binge drinking, heavy drinking, smoking, behavior that increases the risk of HIV transmission, diabetes, myocardial infarction, coronary heart disease, stroke, and depression (Campbell, Walker, & Egede, 2016).*
- Assess the client for depression and refer for counseling and follow-up as appropriate. **EB:** *A study reported data indicating that depression may be a barrier to health-promoting behavior in middle-aged and older women with hypertension or heart disease (Cramer et al, 2020).*
- Use motivational interviewing to help the client identify and change unhealthy behaviors. **EB:** *Motivational interviewing predicted decreases in emerging adults' health-risk behaviors (DeVargas & Stormshak, 2020).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Encourage mindfulness and meditation to help the client cope with changes in health status. **EB:** *A study found mindfulness training improved levels of mindfulness, acceptance, and emotion regulation, and these increases were correlated with reductions in stress, depression, and overeating (Vieten et al, 2018).*
- Allow the client adequate time to express feelings about the change in health status. **EB:** *A longitudinal study of clients with newly diagnosed diabetes found that there was a perception of time pressure, and considerable time was spent with clients by health professionals repeating information that may not be relevant to client need (Dowell et al, 2018).*
- Encourage participation in work-based wellness programs. **EB:** *A 5-year retrospective study to measure health outcomes changes of wellness program participants found statistically significant improvement for cardiovascular disease risk (Pesis-Katz et al, 2020).*
- Provide the client with positive feedback for accomplishments. **EB:** *A study reported that providing feedback was one strategy that improved hand hygiene compliance in the emergency department (Seo et al, 2019).*
- Promote use of positive spiritual and religious experiences as appropriate. **EB:** *A study reported different dimensions of religiousness and spirituality are associated with positive health behaviors in breast cancer survivors (Park, Waddington, & Abraham, 2018).*
- Discuss the client's current goals and assist in modification as needed. Use a goal attainment scaling (GAS) approach, which is a therapeutic method that refers to the development of a written follow-up guide between the client and the nurse and is used for monitoring client progress. **EB:** *A study of clients enrolled in a geriatric day hospital (GDH) demonstrated short- and long-term effectiveness of GDHs in helping clients achieve individualized outcome measures using GAS (Moorhous et al, 2017).*

▲ Refer to community resources. Provide general and contact information for ease of use. **EBN:** *A study of oncology navigators identified that common barriers for clients obtaining assistance included lack of resources (50%), lack of knowledge about resources (46%), and complex/duplicative paperwork (20%) (Spencer et al, 2018).*

Pediatric

- Include social history in client assessment to help identify past abuse and traumatic experiences. **EBN:** *A systematic review found that only 28% of abuse or neglect cases identified by researchers are found in clients' files. This information is considered essential for developing comprehensive formulations and effective treatment plans (Read et al, 2018).*
- Encourage participation in school-based wellness programs. **EB:** *After a school-based health promotion intervention, participants demonstrated significant improvements in physiological measures and health behaviors (Jamerson et al, 2017).*
- Promote use of positive spiritual experiences and religious attendance, as appropriate. **EB:** *A study reported that high spirituality protects adolescents from health risk behaviors such as smoking and drinking alcohol when combined with religious attendance (Malinakova et al, 2019).*
- Encourage parents to process and express grief, uncertainty, and discouragement after learning about their child's diagnosis, prognosis, and treatments. Provide parents with resources and tools to help further their understanding of the illness. **EB:** *A study assessed the effectiveness of an intervention called the Nurturing Program for Parents and Their Children With Special Needs and Health Challenges (SNHC) and found that after the intervention families showed an increase in empathy toward their children's needs and an increase in empowerment as measured by the family empowerment scale (Burton et al, 2018).*
- Provide parents of critically ill children with individualized coping resources. **EBN:** *Research findings indicated that a range of diverse coping strategies are used by neonatal intensive care unit parents. The most common are acceptance, emotional support, active coping, positive reframing, religion, planning, and instrumental support. Despite this, 91% of participants indicated they would likely attend at least one type of parent support program, if offered according to their preferences (Huenink & Porterfield, 2017).*
- Use distraction with children undergoing procedures or treatment with unpleasant side effects. **EB:** *This review found that there was strong support for the use of distraction techniques with older children (Ali, McGrath, & Drendel, 2016).*

Geriatric

▲ Assess for signs of depression resulting from illness-associated changes and make appropriate referrals. **EB:** *A review of evidence related to depression in older individuals found that major depressive disorder (MDD) is less common in late life, but has a more chronic course compared with younger adults with MDD. A significant finding was that older adults with subclinical forms of depression report functional impairment similar to MDD (Haigh et al, 2018).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

- Support activities that promote a sense of purpose for older adults. **EB:** *Purpose in life (PIL) is strongly associated with improved mental and physical health outcomes among older adults. Thus interventions to improve and/or maintain higher levels of PIL over time may promote successful aging (Musich et al, 2018).*
- Encourage social support. **EB:** *In this study, social support was a prerequisite for success of the health-promoting intervention and perceived well-being in older adults (von Berens et al, 2018).*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's ability to modify health behavior. **CEB:** *What the client considers normal and abnormal health behavior may be based on cultural perceptions (Leininger & McFarland, 2002).*
- Assess the client's readiness for change. **EBN:** *A study reported readiness for change was highly correlated with health promotion behaviors in African American women (Hepburn, 2018).*
- Assess the role of fatalism on the client's ability to modify health behavior. Fatalistic perspectives, which involve the belief that you cannot control your own fate, may influence health behaviors in some cultures. **EB:** *A study found that clients with type 2 diabetes who exhibited more fatalistic attitudes were younger, were of lower education levels, had higher body mass index (BMI), and had fewer diabetes comorbidities. It is crucial for health care practitioners to identify fatalistic clients and to tailor culturally appropriate strategies in diabetes management (Sukkarieh-Haraty et al, 2018).*
- Encourage spirituality as a source of support for coping. **EBN:** *Findings from a study provided data to support an understanding of how African American women define spirituality, the role it plays, the purpose it serves, the function of spirituality in their lives, and the implications for breast health behaviors (Conway-Phillips & Janusek, 2016).*
- Acknowledge client's identified gender and sexual orientation and refer client and family members to support networks that have experience with lesbian, gay, bisexual, or transgender (LGBT) issues, as appropriate. **EBN:** *Disclosure and support systems are associated with better self-help perception; creating safe and accepting environments for LGBT clients has been shown to improve overall care in this underserved population (Kamen et al, 2015).*

Home Care

- The previously mentioned interventions may be adapted for home care use.
- Take the client's perspective into consideration and use a holistic approach in assessing and responding to client planning for the future. **EB:** *A recent qualitative study described the experience of the client with both type 1 diabetes and an eating disorder and that of their health care providers. Results demonstrated the need for multiprofessional, collaborative approaches to treatment (Macdonald et al, 2018).*
- Assist the client/family to adapt to his or her diagnosis and to live with their disease. **EBN:** *Research suggested that time-sensitive interventions directed toward education and psychosocial support for all clients and families dealing with a new diagnosis of chronic illnesses are needed (Gunter & Duke, 2018).*
- Ensure that evaluations of the client's ability to perform activities of daily living are age appropriate and consider existing, as well as new, diagnoses. **EB:** *This study used a geriatric-designed functional evaluation that took into account the age-related decrease in flexibility and strength by identifying additional areas for potential loss of function (Adamo, Talley, & Goldberg, 2015).*
- Refer to care plan for **Powerlessness.**

Client/Family Teaching and Discharge Planning

- Assess family/caregivers for coping and teaching/learning styles. **EBN:** *Recommendations for teaching family or caregivers include providing realistic expectations and nurturing psychological safety so caregivers feel comfortable asking questions, expressing their thoughts, and discussing mistakes (Lindauer, Sexson, & Harvath, 2017).*
- Foster communication between the client/family and medical staff. **EBN:** *A study of caregiver communication indicated that oncology nurses must be able to address questions posed by family caregivers and support family communication challenges (Wittenberg et al, 2017).*
- Educate and prepare families regarding the appearance and function of the client and the environment before initial exposure. **EBN:** *A study of mother-caregivers found that health care providers can help anchor family management by recognizing caregiver expectations and facilitating communication about realistic expectations (Lucas et al, 2016).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Teach clients and their family relaxation techniques (controlled breathing, guided imagery) and help them practice. **EB:** *A randomized controlled study reported a significant reduction in signs and symptoms of compulsive Internet use, anxiety, and depression (Quinones & Griffiths, 2019).*

Ineffective Health Self-Management

Domain 1 Health promotion Class 2 Health management

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CNEcl, CHSE, ANEF, FAAN

NANDA-I

H

Definition

Unsatisfactory management of symptoms, treatment regimen, physical, psychosocial, and spiritual consequences and lifestyle changes inherent in living with a chronic condition.

Defining Characteristics

Difficulty with prescribed regimen; failure to include treatment regimen in daily living; failure to take action to reduce risk factor; ineffective choices in daily living for meeting health goal

Related Factors

Competing demands; competing lifestyle preferences; conflict between cultural beliefs and health practices; conflict between health behaviors and social norms; conflict between spiritual beliefs and treatment regimen; decreased perceived quality of life; depressive symptoms; difficulty accessing community resources; difficulty managing complex treatment regimen; difficulty navigating complex health care systems; difficulty with decision-making; inadequate commitment to a plan of action; inadequate health literacy; inadequate knowledge of treatment regimen; inadequate number of cues to action; inadequate role models; inadequate social support; individuals with limited decision making experience; limited ability to perform aspects of treatment regimen; low self efficacy; negative feelings toward treatment regimen; neurobehavioral manifestations; nonacceptance of condition; perceived barrier to treatment regimen; perceived social stigma associated with condition; substance misuse; unrealistic perception of seriousness of condition; unrealistic perception of susceptibility to sequelae; unrealistic perception of treatment benefit

At-Risk Population

Children; economically disadvantaged individuals; individuals experiencing adverse reactions to medications; individuals with caregiving responsibilities; individuals with history of ineffective health self-management; individuals with low educational level; older adults

Associated Conditions

Asymptomatic disease; developmental disabilities; high acuity illness; neurocognitive disorders; polypharmacy; significant comorbidity

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health Beliefs: Perceived Control, Perceived Threat; Knowledge: Disease Process; Knowledge: Treatment Regimen; Participation in Health Care Decisions

Example NOC Outcome with Indicators

Knowledge: Treatment Regimen as evidenced by the following indicators: Extent of understanding of prescribed medication, activity, exercise, and specific disease process. (Rate the outcome and indicators of **Knowledge: Treatment Regimen:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

● = Independent; ▲ = Collaborative; EBN = Evidence-Based Nursing; EB = Evidence-Based; ✱ = QSEN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Client Outcomes

Client Will (Specify Time Frame)

- Describe daily food and fluid intake that meets therapeutic goals
- Describe activity/exercise patterns that meet therapeutic goals
- Describe scheduling of medications that meets therapeutic goals
- Verbalize ability to manage therapeutic regimens
- Collaborate with health professionals to decide on a therapeutic regimen that is congruent with health goals and lifestyle

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Adherence Behavior; Health Education; Health System Guidance; Learning Facilitation; Learning Readiness Enhancement; Teaching: Prescribed Diet, Prescribed Exercise, Prescribed Medication

Example NIC Activities—Learning Facilitation

Present the information in a stimulating manner; Encourage the client's active participation

Nursing Interventions and *Rationales*

- Establish a collaborative partnership with the client for purposes of meeting health-related goals. **EBN:** *Nurse researchers explored ways that nurses and clients can better understand postoperative pain management needs, and the results of a qualitative study revealed the following helpful interventions: (1) communication and knowledge and the clients' ability to communicate, (2) pain assessment using a numerical rating scale, and (3) client–nurse relationship consisting of frequent and direct contact (Kaptain, Bregnballe, & Dreyer, 2017).*
- Explore the client's perception of their illness experience and identify uncertainties and needs through open-ended questions. **EBN:** *A research team qualitatively explored perceptions and preferences of older adults (n = 13) and their family members about a fall risk assessment system when aging in place and to develop better technology to promote safety. Results demonstrated an acceptance of the technology after participants adapted, and acceptance was a process that grew in stages as the client became used to technology (Galambos et al, 2017).* **EB:** *Hertroijs et al (2020) investigated care preferences and their determinants in clients (n = 288) with type 2 diabetes. Participants were provided a choice of six diabetic care packages and the favorable choice was for the traditional care model because it included the most important issue for them, which was emotional support.*
- Assist the client to enhance self-efficacy or confidence in his or her own ability to manage the illness. **EBN:** *Banman and Sawatzky (2017) completed a literature review on cardiovascular disease prevention and uncovered several reasons women are not as active as men in preventive health management: (1) lower self-efficacy beliefs, (2) lack of social support and confidence in their ability to care for themselves, and (3) any findings of depression negatively correlated with women's self-efficacy beliefs related to health behavior.* **EB:** *Harel-Katz et al (2020) studied the Improving Participation After Stroke Self-Management (IPASS) program's effectiveness for stroke clients (n = 60). The results of the randomized intervention demonstrated that the IPASS was feasible for Israeli clients and had a positive effect on improving quality of life.*
- Review factors of the health belief model (HBM) (individual perceptions of seriousness and susceptibility, demographic and other modifying factors, and perceived benefits and barriers) with the client. **EB:** *Ahlers-Schmidt et al (2020) used the HBM to redesign community baby showers in order to promote infant safe sleep using the American Academy of Pediatrics Safe Sleep Guidelines. The study participants (n = 812) demonstrated positive changes about safe sleep after the community baby shower and better understood many of the safe sleep concepts such as sleeping with infant can cause death, loose blankets can cause death, infants should sleep alone, and infants should be placed on their back to sleep.*
- Help the client identify and modify barriers to effective self-management. **EB:** *Researchers examined clients (n = 14) with type 2 diabetes and severe mental illness because this group of clients experiences significantly poorer health outcomes than type 2 diabetic clients without severe mental illness. Participants were aware of the risks and stated that family and health care provider support was important in their self-maintenance (Mulligan et al, 2017).*
- Help the client self-manage his or her own health through education about strategies for changing habits such as overeating, sedentary lifestyle, and smoking. **EB:** *Pappa et al (2017) investigated activity behavior*

and analyzed the message content participants (n = 107,886) in r/loseit, an online weight management community on the online social network Reddit, over 30 days and found that the most discussed topics were healthy food, clothing, calorie counting, workouts, looks, habits, support, and unhealthy food. **EBN:** *Powell and Deroche (2020) studied variables that predicted clients' (n = 500) use of an electronic portal to assist them in self-managing their health. The nurse researchers found that age, gender, or distance from provider did not make a difference in portal use.*

- Develop a contract with the client to maintain motivation for changes in behavior. **EBN:** *Leine et al (2017) studied clients (n = 6) with chronic obstructive pulmonary disease (COPD) and their understanding and treatment adherence using a partnership-based nursing practice program. Interviews revealed two themes: feeling safe and comforted, and motivation to take better care of themselves.*
- Use focus groups to evaluate the implementation of self-management programs. **EB:** *Serwe et al (2017) used focus groups (n = 4) to study caregivers' implementation of a telehealth self-maintenance program; the themes suggested that it promoted relationships, promoted positive interactions, and better explained the role.*
- Refer to the care plan Ineffective Family **Health** Self-Management.

Geriatric

- Identify the reasons for behaviors that are not therapeutic and discuss alternatives. **EBN:** *Lee et al (2017a) used the Theory of Planned Behavior with older adults to affect diabetes maintenance and found that older adults need adequate social support to sustain diabetes self-management practices.*

Multicultural

- Assess the influence of cultural beliefs, norms, and values on the individual's perceptions of the therapeutic regimen. **EBN:** *Mou (2017) explored traditional Chinese medicine (TCM) as a method for promoting health and found through an online survey in China with 800 responses that cultural orientation and spirituality predicted use of TCM to promote health.* **EB:** *Zuccarino et al (2020) studied older Italian clients' (n = 2486) educational level and how it affected their rehabilitation outcome. The results demonstrated that older adults with less education had poorer rehabilitation and health management outcomes.*
- Provide health information that is consistent with the health literacy of clients. **EB:** *Sainato et al (2017) studied US adolescents with chronic conditions and found that this high-risk group was twice as likely not to receive routine vaccinations, indicating that additional education is needed in families with adolescents 16 to 18 years old with chronic illnesses.*
- Assess for barriers that may interfere with client follow-up of treatment recommendations. **EBN:** *Riley and Krüger (2017) examined the use of inhalers in clients with COPD and found that it is imperative to assess and teach clients about using a correct inhalation technique, assessing adequate dexterity to use the prescribed inhaler, if there is sufficient inspiratory flow rate to achieve adequate lung deposition, and if the inhaler is used by the client at all.*
- Validate the client's feelings regarding the ability to manage his or her own care and the impact on lifestyle. **EBN:** *Lee et al (2017b) qualitatively studied clients' perceptions of brisk walking as a method to reduce chronic disease symptomology in the community. Six focus groups were conducted (n = 48), ages 48 to 81, and five themes were identified: (1) health promotion and maintenance, (2) relationship building and social interactions, (3) leaders' enthusiasm and peer pressure, (4) the nature of brisk walking, and (5) becoming part of one's daily life.*

Home Care

- Prepare and instruct clients and family members in the use of a medication box. Set up an appropriate schedule for filling the medication box, and post medication times and doses in an accessible area (e.g., attached by a magnet to the refrigerator). **EBN:** *Milner and Bonaventura (2017) used self-management for clients on anticoagulants at home and it increased client engagement in anticoagulant management, which resulted in better clinical outcomes.* **EB:** *Safren et al (2020) studied medication adherence in clients (n = 27) with uncontrolled HIV and psychosocial problem using transdiagnostic adherence counseling and cognitive behavioral therapy. The interventions improved self-reported medication adherence and therefore health management.*
- Refer to health care professionals for questions and self-care management. **EB:** *Homsted, Magee, and Nesin (2017) studied the use of a comprehensive, medical-home approach to controlling clients' (n = 1300) use of controlled substances. By using a program researchers decreased the use of controlled substances by 67.2% and 65.6%, with fewer clients receiving benzodiazepines.* **EB:** *Researchers studied the effects of a chronic disease self-management program on empowering hemodialysis clients (n = 53) and their quality of life. Self-management increased the clients' quality of life in 3 months (Ahmadzadeh et al, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Client/Family Teaching and Discharge Planning

- Identify the client's and/or family's current knowledge and adjust teaching accordingly. Teach the client and family about all aspects of the therapeutic regimen, providing as much knowledge as the client and family will accept, in a culturally congruent manner. **EBN:** *Sugiharto et al (2017) studied the client outcome of improving nurses' skills and confidence in delivering diabetes self-management education (DSME) among clients with type 2 diabetes and found that the diabetes training program for community health center nurses increased their skills and confidence in delivering DSME.* **EB:** *Chen, Flaherty, and Threats (2020) qualitatively studied complementary and integrative health (CIH) beliefs in 14 participants. The participants had chronic pain conditions and verbalized three thematic beliefs about CIH: (1) individual's beliefs; (2) approach to CIH, including how people view provider information and personalize their CIH use; and (3) factors that affect trust in the information encountered. The identified factors can be taken into account to improve health management.*
- Teach ways to adjust activities of daily living (ADLs) for inclusion in therapeutic regimens. **EBN:** *Jansons et al (2017) completed a randomized, controlled trial of clients with chronic conditions using a gym-based exercise program for health management and found improved health outcomes in the group that exercised when compared with the control group.* **EBN:** *Nestler et al (2017) performed a literature review (n = 12) related to women's muscle strength and work health issues and found that weight training reduced pain and improved outcomes for women working in strenuous and nonstrenuous environments.*
- Teach safety in taking medications. **EB:** *Kim and Hubert (2017)* studied three groups with different levels of technology knowledge about accessing personal health information management (PHIM) by online survey and found that advanced PHIM users were significantly more likely to engage in emailing with providers, viewing test results online, and receiving summaries of hospital visits, indicating that technology knowledge is important for self-advocating.

Readiness for Enhanced Health Self-Management

Domain 1 Health promotion
Class 2 Health management

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CNEcl, CHSE, ANEF, FAAN

NANDA-I

Definition

A pattern of satisfactory management of symptoms, treatment regimen, physical, psychosocial, and spiritual consequences and lifestyle changes inherent in living with a chronic condition, which can be strengthened.

Defining Characteristics

Expresses desire to enhance choices of daily living for meeting goals; expresses desire to enhance immunization/vaccination status; expresses desire to enhance management of illness; expresses desire to enhance management of prescribed regimens; expresses desire to enhance management of risk factors; expresses desire to enhance management of symptoms

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health-Promoting Behavior; Health-Seeking Behavior; Knowledge: Health Behavior; Health Promotion; Health Resources; Illness Care; Medication; Prescribed Activity; Treatment Regimen

Example NOC Outcome with Indicators

Health-Promoting Behavior as evidenced by the following indicators: Monitors personal behavior for risks/Seeks balance activity and rest/Performs healthy behaviors routinely/Uses financial and social support resources to promote health. (Rate each indicator of **Health-Promoting Behavior:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Client Outcomes

Client Will (Specify Time Frame)

- Describe integration of therapeutic regimen into daily living
- Demonstrate continued commitment to integration of therapeutic regimen into daily living routines

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Anticipatory Guidance; Mutual Goal Setting; Client Contracting; Self-Modification Assistance; Self-Responsibility Facilitation; Support System Enhancement

Example NIC Activities—Mutual Goal Setting

Assist client and significant others to develop realistic expectations of themselves in performance of their roles; Clarify with the client the roles of the health care provider and the client, respectively

Nursing Interventions and *Rationales*

- Acknowledge the expertise that the client and family bring to health management. **EBN:** *Nurse researchers compared hospitalized care need perceptions of clients (n = 50) with nurses (n = 100) and found that surveyed clients and nurses agreed on needed areas such as communication and basic care. Slightly lower agreement scores between nurses and clients were identified for care planning and organization (Fernanades Martins & Galan Perroca, 2017).* **EB:** *Kim et al (2019) studied factors related to health care readiness, including family support and self-management competencies in adults (n = 87) with type 1 diabetes mellitus. A cross-sectional survey found that family involvement in diabetes care enhanced self-management competencies.*
- Review factors that contribute to the likelihood of health promotion and health protection. Use Pender's Health Promotion Model and Becker's Health Belief Model to identify contributing factors (Pender et al, 2015). **EBN:** *Researchers used a quasi-experimental designed study with women (n =108) who were placed in two groups to examine nutritional behavior, and the nurse researchers found that Pender's Health Promotion Model–based nutritional training improved behavior better in the experimental group (Khodaveisi et al, 2017).* **EBN:** *Ali et al (2020) investigated the effect of sexual health education based on Pender and Health Belief on sexual function of females (n = 80) with type 2 diabetes. The researchers used a pre- and post-Rosen's sexual function questionnaire and provided an intervention group with 90-minute weekly educational sessions. The Pender group (interventional group) demonstrated an increase in the mean total score of sexual function and subscales.*
- Further develop and reinforce contributing factors that might change with ongoing self-management of the therapeutic regimen (e.g., knowledge, self-efficacy, self-esteem, and perceived benefits). **EB:** *Jiao et al (2017) studied the relationship between methadone maintenance treatment clients with mental health illnesses and resilience and found resilience to be negatively correlated with depression and anxiety, indicating that resilience in this population is important for mental health.* **EB:** *Ritzert et al (2020) studied the use of acceptance and commitment therapy (ACT) self-help bibliotherapy for anxiety and related problems. The researchers found that the ACT model for self-help supported positive change factors in the intervention group.*
- Review the client's strengths in the management of the therapeutic regimen. **EB:** *Liu et al (2020) researched disparities in access to online health-related technology among older adults (n = 1497). The research results identified social determinants that placed clients at risk for lower use of online health-management tools. The risk factors are (1) being a racial/ethnic minority, (2) being married, (3) being uninsured, (4) having low educational attainment, (5) having low income, and (6) being in poor health.*
- Collaborate with the client to identify strategies to maintain strengths and develop additional strengths as indicated. **EB:** *Researchers studied person-centered care by surveying and interviewing older clients (n = 56) in relation to being malnourished and found themes that affected dietary intake of older adults (>81 years): (1) dietetic follow-up, (2) interdisciplinary coordination, and (3) high-quality hospital food services. The nutritional recommendations from this study may facilitate evidence-based person-centered care for older malnourished clients (Hazzard et al, 2017).*
- Identify contributing factors that may need to be improved now or in the future. **EB:** *Kelsey et al (2020) studied clinical decision support systems (CDSSs) in the electronic medical record (EMR) in a primary care practice to identify and remind clients due for cancer screening tests. The CDSSs were*

piloted with clients (n = 37), and there was an increased cancer screening rate for the participants compared with nonparticipants in the CDSS system. **EBN:** *Schneider and Howard (2017) investigated the differences in discharge readiness and postdischarge coping in stroke clients (n = 128) using education provided via a technology package (including client online portal access, email/secure messaging) compared with current standard discharge teaching methods and found that there was no statistically significant difference between the groups in discharge readiness, but there was a significant increase in coping scores in the technology group.*

- Help the client maintain existing support and seek additional supports as needed. **EBN:** *Westcott and Welding (2017) documented case studies that support continuously reassessing home-bound clients' support surfaces in the house, educating clients, and providing appropriate resources to decrease pressure ulcers in community long-term care clients.* **EB:** *David et al (2019) investigated the relationship between family support, diabetes self-care, and health outcomes in older adults (n = 60). The findings indicated that family support or quality of family relations did not contribute significantly to client self-care.*

Geriatric

- Facilitate the client and family to obtain health insurance and drug payment plans whenever needed and possible. **EBN:** *Researchers used an multiprofessional approach to explore the needs of geriatric clients (n = 293) and found through surveys and interviews that the clients' needs included guidance around falls prevention, improved nutrition, medication management, and referrals to available community and social service supports (Hansen et al, 2017).* **EB:** *Kandagatla et al (2018) studied the effect of a postoperative ileostomy intervention (self-care checklist) on readmission and self-efficacy in older surgical clients (n = 288) compared with younger clients (n = 72). The researchers found that older and younger clients reported similar self-efficacy scores and similar rates of readmission.*

Multicultural

- Assess client's cultural perspectives on health management. **EB:** *Raffaele et al (2018) studied the Self-care Ability Scale for the Elderly (SASE) to assess the perceived self-care ability in older Italian adults (n = 402). The researchers used SASE to assess self-care ability to achieve well-being and to set personal goals and produced a 13-item version of the SASE with good psychometric properties.*
- Assess health literacy in clients of diverse backgrounds. **EBN:** *Lee, Lee, and Chung (2017) investigated the level of health literacy in different age groups of South Koreans (n = 1000) and found that for the 45 through 64 and the 65 and over age groups, education was positively associated with health literacy. Additionally, the oldest age group and gender also had a positive association with health literacy. Depression was negatively associated with health literacy.* **EB:** *Kes and Gökdoğan (2020) developed a Turkish version of the Hypertension Self-care Profile and tested the tool on 200 participants with known hypertension and found that the Turkish version of the Hypertension Self-care Profile had validity and reliability in that population and was successfully translated and cross-culturally adapted.*
- Validate the client's feelings regarding the ability to manage his or her own care and the impact on current lifestyle. **EBN:** *Araújo do Reis and de Oliva Menezes (2017) qualitatively studied religiosity and spirituality as a resilience strategy for improved lifestyles and health in aging clients (n = 14) and found that clients who revealed they participated in religious or spiritual habits achieved increased well-being and resiliency and were better able to cope with health and social problems.*

Client/Family Teaching and Discharge Planning

- Facilitate the client and family to obtain financial assistance in the form of health insurance and drug payment plans whenever needed and possible. **EB:** *Tumin et al (2017) studied the change in health insurance after heart transplants in adolescents (n = 366) and found through statistical analysis that changes in health insurance predicted a greater mortality risk compared with clients with continuous private insurance. Therefore assisting with insurance coverage maintenance may provide better health outcomes.*
- Use electronic monitoring to improve medication adherence. **EB:** *Madrasi et al (2017) studied medication adherence for preexposure prophylaxis for clients (n = 1147) using electronic adherence records recording the date and time of medication bottle cap opening and found that female clients and older clients had better adherence.* **EBN:** *Low et al (2017) studied medication adherence with post–kidney transplant clients (n = 25) in a descriptive exploratory study, and the themes identified were causes of distress and coping resources. Researchers concluded that regular reminders, such as alarms to take medications, will reduce the stress of managing a kidney transplant.*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Review therapeutic regimens and their optimal integration with daily living routines. **EBN:** *Nurse researchers evaluated a family-based heart failure education program and performed a randomized controlled trial with clients* (n = *50) and caretakers* (n = *50) in a rural community and found that clients and family members who received the education program had higher knowledge scores at 3 and 6 months than those who received traditional outpatient education (Srisuk et al, 2017).*
- Teach disease processes and therapeutic regimens to clients and peer supporters for management of disease processes. **EBN:** *Kang et al (2018) investigated discharge information provided to surgical clients that addressed their self-management at home using a mixed method literature search* (n = *7) design. The literature revealed that discharge education was delivered to clients in the studies at various times and most instructions were standardized. The researchers found that the quality of discharge education had a significant influence in the client's self-care management.*

Ineffective Family Health Self-Management

Domain 1 Health promotion Class 2 Health management

Gail B. Ladwig, MSN, RN and Julianne E. Doubet, BSN, RN, EMT-B

NANDA-I

Definition

Unsatisfactory management of symptoms, treatment regimen, physical, psychosocial and spiritual consequences and lifestyle changes inherent in living with one or more family members' chronic condition.

Defining Characteristics

Caregiver strain; decrease in attention to illness in one or more family members; depressive symptoms of caregiver; exacerbation of disease signs of one or more family members; exacerbation of disease symptoms of one or more family members; failure to take action to reduce risk factor in one or more family members; ineffective choices in daily living for meeting health goal of family unit; one or more family members report dissatisfaction with quality of life

Related Factors

Cognitive dysfunction of one or more caregivers; competing demands on family unit; competing lifestyle preferences within family unit; conflict between health behaviors and social norms; conflict between spiritual beliefs and treatment regimen; difficulty accessing community resources; difficulty dealing with role changes associated with condition; difficulty managing complex treatment regimen; difficulty navigating complex health care systems; difficulty with decision-making; family conflict; inadequate commitment to a plan of action; inadequate health literacy of caregiver; inadequate knowledge of treatment regimen; inadequate number of cues to action; inadequate social support; ineffective communication skills; ineffective coping skills; limited ability to perform aspects of treatment regimen; low self efficacy; negative feelings toward treatment regimen; nonacceptance of condition; perceived barrier to treatment regimen; perceived social stigma associated with condition; substance misuse; unrealistic perception of seriousness of condition; unrealistic perception of susceptibility to sequelae; unrealistic perception of treatment benefit; unsupportive family relations

At-Risk Population

Economically disadvantaged families; families with member experiencing delayed diagnosis; families with members experiencing low educational level; families with members who have limited decision-making experience; families with premature infant

Associated Conditions

Chronic disease; mental disorders; neurocognitive disorders; terminal illness

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Family Health-Status; Knowledge: Treatment Regimen; Family Participation in Professional Care

Example NOC Outcome with Indicators

Knowledge: Treatment Regimen as evidenced by the following indicator: Understanding conveyed about prescribed medication, activity, exercise, and specific disease process. (Rate the outcome and indicators of **Knowledge: Treatment Regimen:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Make adjustments in usual activities (e.g., diet, activity, stress management) to incorporate therapeutic regimens of its members

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Reduce illness symptoms of family members
- Express desire to manage therapeutic regimens of its members
- Describe a decrease in the difficulties of managing therapeutic regimens
- Describe actions to reduce risk factors

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Family Involvement Promotion; Family Mobilization; Teaching: Disease Process

Example NIC Activities—Family Involvement Promotion

Identify and respect coping mechanisms used by family members; Provide crucial information to family members about the client in accordance with client's preference

Nursing Interventions and *Rationales*

- Base family interventions on knowledge of the family, family context, family dynamics, family structure, and family function. **EBN:** *A family-centered advance care planning (ACP) information intervention for persons with mild dementia and their family caregivers (FCGs) found significant improvements among persons with dementia and FCGs for knowledge of end-stage dementia treatment, knowledge of ACP, and significant reductions in decisional conflicts (Huang et al, 2020).*
- Use a family approach when helping an individual with a health problem that requires therapeutic management. **EBN:** *According to Nunes de Paiva et al (2018), it is important for hemodialysis clients to contribute to the management of their own health care, but to be successful, they will need the support of family and friends.*
- Review with family members the congruence and incongruence of family behaviors and health-related goals. **EBN:** *Nurses are especially qualified to fill the roles of both mentor and coach, and to work with clients and families toward positive health outcomes (Orchard et al, 2017).*
- Acknowledge the challenge of integrating therapeutic regimens with family behaviors. **EBN:** *A study by McDonnell et al (2019) concerning African American cancer survivors details the stressors that affect family members and highlights their particular health care problems. These stressors compromise their ability to effectively alter health behaviors.*
- Review the symptoms of specific illnesses and work with the family toward development of greater self-efficacy in relation to these symptoms. **EBN:** *Nurses should prioritize family support: involve them in the care of the client by coaching them through the completion of multifaceted medical tasks, reducing the family's need for outside services (Funk et al, 2020).*
- Support family decisions to adjust therapeutic regimens as indicated. **EB:** *The National Institute of Neurological Disorders and Stroke (2018) published findings that concluded a woman suffering from epilepsy can have a healthy pregnancy and deliver a healthy child with planned adjustments in medication and the addition of certain supplements.*
- Help the family mobilize social supports. **EBN:** *Nurses in any capacity may detect a family/individual in crisis and are obliged to provide crisis intervention while connecting the family/individual to other needed support services (Parsons, 2016).*
- Help family members modify perceptions as indicated. **EB:** *Illness perception, family adaptability, and coping mechanisms are key factors for the quality of life of a client with a chronic disease (Postolica et al, 2017).*
- Use one or more theories of family dynamics to describe, explain, or predict family behaviors (e.g., theories of Bowen, Satir, and Minuchin). **EBN:** *Family plays a critical role in health and illness; it is crucial for nurses to evaluate and modify family dynamics by using theoretical framework (Yekatalab et al, 2017).*

▲ Collaborate with expert nurses or other consultants regarding strategies for working with families. **EBN:** *The findings underscore the need for researchers and health care professionals to engage in collaborative discussions and make cooperative efforts to help alleviate treatment burden and tailor treatment regimens to the realities of people's daily lives (Sav et al, 2015).*

- Coaching methods can be used to help families improve their health. **EB:** *Young et al (2020) determined in their controlled trial study that a system employing a health coaching program for those with type 2 diabetes had a positive impact on the "physiological, behavioral, psychological, and social outcomes for clients with chronic health conditions."*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

Pediatric

- Support skin-to-skin care for infants at risk at birth. Keep infants in an upright position in skin-to-skin contact until they no longer tolerate it. **EBN:** *According to ten Ham-Baloyi, Ricks, and van Rooyen (2017), some of the benefits derived from kangaroo mother care (KMC) are improving mother–infant attachment; encouraging the continuance of breastfeeding; and helping to reduce mortality of preterm neonates.*

Geriatric

- Recommend that clients use the "Ask Me 3" program when communicating with their health providers (What is my main problem? What do I need to do? Why is it important for me to do this?). **EBN:** *Organized client education using the Ask Me 3 questions program, produced encouraging results confirmed by a reduction in hospital readmissions and an increase in client satisfaction (Smith, 2020).*

Multicultural

- Acknowledge racial and ethnic differences at the onset of care. **EBN:** *Markey et al (2018) surmised that a significant element in improving culturally sensitive, quality care was to first recognize, and then remedy, the nurse's insecurity and lack of confidence when delivering care for clients from a mixture of cultural and ethnic backgrounds.*
- Ensure that all strategies for working with the family are congruent with the culture of the family. **EBN:** *Cain et al (2018) emphasized that the nurse's obligation is to personalize care without stereotyping the client's—and the family's—principles and traditions; each person is unique, no matter the culture with which they identify.*
- Use the nursing intervention of cultural brokerage to help families deal with the health care system. **EBN:** *In their study of how culture shapes nursing practice, Crawford et al (2017) concluded that parents of pediatric clients count on nurses for cultural brokerage, to support them in bridging the daunting cultural restrictions found on a hospital unit.*

Client/Family Teaching and Discharge Planning

- Teach about all aspects of therapeutic regimens. Provide as much knowledge as family members will accept, adjust instruction to account for what the family already knows, and provide information in a culturally congruent manner. **EBN:** *Use "tailored to the client" instructions, which may include medical and disease education, skills training, and resource connection (Chin et al, 2017).*
- Teach ways to adjust family behaviors to include therapeutic regimens, such as safety in taking medications and teaching family members to act as self-advocates with health providers who prescribe therapeutic regimens. **EBN:** *By using continuous care interventions, a trusting relationship can be established with the FCG (Chin et al, 2017).*

Ineffective Health Maintenance Behaviors

Domain 1 Health promotion Class 2 Health management

Kathaleen C. Bloom, PhD, CNM and Lauren McAlister, MSN, FNP-BC, DNP

NANDA-I

Definition

Management of health knowledge, attitudes, and practices underlying health actions that is unsatisfactory for maintaining or improving well-being, or preventing illness and injury.

Defining Characteristics

Failure to take action that prevents health problem; failure to take action that reduces risk factor; inadequate commitment to a plan of action; inadequate health literacy; inadequate interest in improving health; inadequate knowledge about basic health practices; ineffective choices in daily living for meeting health goal; pattern of lack of health-seeking behavior

Related Factors

Competing demands; competing lifestyle preferences; conflict between cultural beliefs and health practices; conflict between health behaviors and social norms; conflicts between spiritual beliefs and health practices; depressive symptoms; difficulty accessing community resources; difficulty navigating complex health care systems; difficulty with decision-making; inadequate health resources; inadequate social support; inadequate trust in health care professional; individuals with limited decision making experience; ineffective communication skills; ineffective coping strategies; ineffective family coping; low self efficacy; maladaptive grieving; neurobehavioral manifestations; perceived prejudice; perceived victimization; spiritual distress

At-Risk Population

Economically disadvantaged individuals; individuals from families with ineffective family coping; individuals with history of violence; men; older adults; young adult

Associated Conditions

Chronic disease; developmental disabilities; mental disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health Orientation; Health Beliefs: Perceived Resources; Health-Promoting Behavior; Health-Seeking Behavior

Example NOC Outcome with Indicators

Health-Seeking Behavior as evidenced by the following indicators: Completes health-related tasks/Performs self-screening/Obtains assistance from health professional. (Rate the outcome and indicators of **Health-Seeking Behavior:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Discuss fear of or blocks to implementing health regimen
- Follow mutually agreed on health care maintenance plan
- Meet goals for health care maintenance

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Health Education; Health System Guidance; Support System Enhancement

Example NIC Activities—Health Education

Prioritize identified learner needs based on client preference, skills of nurse, resources available, and likelihood of successful goal attainment; Emphasize immediate or short-term positive health benefits to be received by positive lifestyle behaviors, rather than long-term benefits or negative effects of noncompliance

Nursing Interventions and *Rationales*

- Provide support to clients in making their health care decisions and provide information about options and associated benefits/harms. **EB:** *A Cochrane review of 105 studies involving 31,043 clients found that people who used simple decision aids were more knowledgeable about options, less conflicted in making decisions, more accurate in their perception of risk, and more apt to be active in decision-making (Stacey et al, 2017).*
- Assess for family patterns, economic issues, and spiritual and cultural patterns that influence compliance with a given medical regimen. **EBN:** *A systematic review of 42 studies found knowledge, motivation, health and safety concerns, lack of social support, and monetary costs associated with exercise facilities to be among the barriers to physical activity among African American women (Joseph et al, 2015).*
- Involve the client in shared decision-making regarding health maintenance. **CEB:** *A meta-analysis of 32 clinical trials revealed that assessing client preferences and involving them in shared decision-making had higher adherence, higher satisfaction, and better clinical outcomes (Lindhiem et al, 2014).* **EB:** *A study of US veterans with mental illnesses found collaboration in decision-making positively influenced satisfaction with care and that such decision-making is best done by tailoring therapeutic approaches to consumer preferences for shared decision-making (Klingaman et al, 2015).*
- Show genuine interest in the client's individual needs. **EB:** *A systematic review of 10 qualitative studies concluded that clients' perceptions of the health care professional's responsiveness, interest in their individual needs, and shared information positively influence self-care (Fu et al, 2016).*
- Assist the client in finding methods to reduce stress. **EB:** *Analysis of the US National Health Interview data of 1997 to 2016 indicated that those who experience psychological distress were more likely to report high-risk behaviors such as alcohol consumption, physical inactivity, and tobacco use (Jokela et al, 2020).*
- Identify complementary healing modalities, such as herbal remedies, acupuncture, healing touch, yoga, or cultural shamans that the client uses in addition to or instead of the prescribed allopathic regimen along with the client's perception of the complementary healing modalities. **EB:** *Results of a mailed survey of health practices of 1825 US veterans indicated common use of acupuncture, chiropractic, massage, and manual physical therapy for pain as well as yoga, meditation, mindfulness, and exercise for well-being and/or general health (Donaldson et al, 2018).*

▲ Refer the client to appropriate and accessible medical and social services as needed, providing adequate information on details about the service. **EBN:** *A systematic review of 43 studies found that nonparticipation in cardiac rehabilitation (CR) was associated more with logistical and health system factors than with interpersonal or CR program factors (Resurrección et al, 2019).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Identify in-person and teleconferenced support groups related to the disease process. **EB:** *A systematic review of 17 studies concluded that outcomes of professional-led teleconferenced support groups are similar to in-person groups (Banbury et al, 2018).*
- Use social media such as text messaging to remind clients of scheduled appointments. **EB:** *Evaluation of compliance with treatment plans found 59% higher odds of attendance at a scheduled follow-up clinic visit with text message reminders and overall decreased cost as compared with telephone reminders (Anthony et al, 2019).* **CEB:** *A Cochrane review of eight randomized controlled trials concluded that text messaging reminders increase attendance at health care appointments similar to telephone reminders but better than no reminders or postal reminders (Gurol-Urganci et al, 2013).*
- Use telehealth interventions to facilitate self-care. **EB:** *In a study with 641 individuals with cardiovascular risk, telehealth services including telephone calls facilitating self-management through the use of targeted online resources were associated with reductions in blood pressure, weight, and body mass index, as well as improvements in diet, physical activity, drug adherence, and satisfaction (Salisbury et al, 2016).*

Geriatric

- Assess the client's perception of health and health maintenance. **EB:** *In a survey of 828 community-dwelling individuals at risk for cardiovascular disease, slightly more than half had an accurate perception of their risk, with one-third underestimating their risk (Lee et al, 2019).*
- Assist client to identify realistic health-related goals. **EB:** *A systematic review and meta-synthesis of 9 qualitative studies found that engagement in individually tailored goal-setting processes based on client preferences, and in conjunction with knowledgeable and skilled clinicians, facilitated setting of realistic goals and avoidance of disappointment in rehabilitative processes (Plant et al, 2016).*
- Encourage and facilitate informed decision-making. **EB:** *Although physicians generally inform clients and families of the risks and benefits of treatment options, incorporation of client/family preferences in the decision-making process, although essential to shared decision-making, is practiced much less frequently (Holmes-Rovner et al, 2015).*
- Educate the client about the symptoms of life-threatening illness, such as myocardial infarction (MI), and the need for timeliness in seeking care. **EB:** *An Australian mass media campaign focused on warning signs of MI was significantly associated with decreased prehospital delay time from onset of symptoms (Bray et al, 2015).*

Multicultural

- Assess influence of cultural beliefs, norms, and values on the client's ability to modify health behavior. **EB:** *A survey of 1445 young Hispanic adults found the cultural concept of respeto (respect for and deferential treatment of family members based on age and status) to be associated with decreased binge drinking and marijuana and hard drug use and that fatalistic beliefs were associated with alternative tobacco product use (Escobedo et al, 2018).*
- Assess the effect of fatalism on the client's ability to modify health behavior. **EB:** *Analysis of data from a national survey (n = 2657) found a high prevalence of fatalistic beliefs related to cancer: everything causes cancer (66%), thinking about cancer makes you think about death (58%), and there's not much you can do to prevent cancer; such fatalism was associated with lack of information seeking, especially among those with low health literacy (Kobayashi & Smith, 2016).*
- Clarify culturally related health beliefs and practices. **EB:** *A qualitative study with 24 self-employed and uninsured Korean immigrant adults indicated that these individuals sought health information from social networks made up of primarily other Koreans or through organizations exclusively serving Korean immigrants. These individuals felt that non-Koreans would not understand the circumstances of Korean immigrants (Oh & Jeong, 2017).*
- Provide culturally appropriate education and health care services. **EB:** *Culturally tailored educational sessions with 159 culturally and linguistically diverse individuals in Australia were found to be associated with improved knowledge and attitudes about cancer screening as well as increased intention to participate in such screenings (Cullerton et al, 2016).*

Home Care

- The interventions described previously may be adapted for home care use.

▲ Provide nurse-led case management. **EBN:** *A retrospective chart review of 307 clients found that those who utilized a nurse-led community case management system had 55% fewer emergency department visits and 61% fewer hospital admissions than those who did not (Armold, 2017).*

- Provide a health promotion focus for the client with disabilities, with the goals of reducing secondary conditions (e.g., obesity, hypertension, pressure sores), maintaining functional independence, providing opportunities for leisure and enjoyment, and enhancing overall quality of life. **EB:** *A secondary analysis of data from the Medical Expenditure Panel Survey revealed that individuals with cognitive, physical, and multiple disabilities are more likely to have unmet health care needs, including being less likely to receive preventive services, dental care, and cancer screening (Mahmoudi & Meade, 2015).*
- Provide support and individual training for caregivers before the client is discharged from the hospital. **EBN:** *In a study of 138 caregiver–client dyads, caregiver training was found to enhance caregivers' preparedness for caregiving and decrease caregiver stress (Hendrix et al, 2016).*

Client/Family Teaching and Discharge Planning

- Provide the client and family with credible social media sources from which health information can be obtained. **EB:** *In a study with 457 clients, 99.1% reported searching online for health information; there was a significant relationship between the type of health information seeking (online versus non-online) and problem-solving (changing decisions, consulting others, promoting self-efficacy) with the highest correlation with online health information searches (Chen et al, 2018).*

▲ Develop collaborative multiprofessional partnerships. **EBN:** *Multiprofessional and multifactorial interventions are likely to be more effective in achieving desired outcomes. In a retrospective cohort study of readmission rates for 660 clients with pneumonia, clients receiving a postdischarge visit by a multiprofessional team consisting of health care providers, nurses, and social workers had significantly fewer 30-day readmissions (Otsuka et al, 2019).*

- Tailor both the information provided and the method of delivery of information to the specific client and/or family. **EB:** *A structured program for engaging parents of children with chronic conditions in preparation for hospital discharge using an iPad-based intervention found that parents had improved quality of discharge teaching and showed promise in helping parents prepare for transition to home (Lerret et al, 2020).*

Ineffective Home Maintenance Behaviors

Domain 1 Health promotion Class 2 Health management

Kathaleen C. Bloom, PhD, CNM and Lauren McAlister, MSN, FNP-BC, DNP

NANDA-I

Definition

An unsatisfactory pattern of knowledge and activities for the safe upkeep of one's residence.

Defining Characteristics

Cluttered environment; difficulty maintaining a comfortable environment; failure to request assistance with home maintenance; home task-related anxiety; home task-related stress; impaired ability to regulate finances; negative affect toward home maintenance; neglected laundry; pattern of hygiene-related diseases; trash accumulation; unsafe cooking equipment; unsanitary environment

Related Factors

Competing demands; depressive symptoms; difficulty with decision-making; environmental constraints; impaired physical mobility; impaired postural balance; inadequate knowledge of home maintenance; inadequate knowledge of social resources; inadequate organizing skills; inadequate role models; inadequate social support; insufficient physical endurance; neurobehavioral manifestations; powerlessness; psychological distress

At-Risk Population

Economically disadvantaged individuals; individuals living alone; older adult

Associated Conditions

Depression; mental disorders; neoplasms; neurocognitive disorders; sensation disorders; vascular diseases

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Safe Home Environment; Self-Care: Activities of Daily Living (ADLs)

Example NOC Outcome with Indicators

Safe Home Environment as evidenced by the following indicators: Elimination of pests/Smoke detector maintenance/Accessibility of assistive devices/Elimination of tobacco smoke. (Rate the outcome and indicators of **Safe Home Environment:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

H

Client Outcomes

Client Will (Specify Time Frame)

- Maintain a healthy home environment
- Use community resources to assist with home care needs
- Maintain a safe home environment

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Home Maintenance Assistance

Example NIC Activities—Home Maintenance Assistance

Involve client/family in deciding home maintenance requirements; Provide information on how to make home environment safe and clean; Help family use social support network

Nursing Interventions and *Rationales*

- Assess the knowledge and concerns of family members, especially the primary caregiver, about home care maintenance and management. **EBN:** *A qualitative descriptive study of 40 caregivers of clients with heart failure concluded that caregivers contributed to both the self-care maintenance and self-care management of the family member, but sometimes lacked necessary skill and/or confidence in decision-making (Durante et al, 2019).*
- Provide home safety education and safety equipment when possible. **EB:** *A program evaluation of a home safety program found that providing safety devices as well as education strategies, including videos and checklists, significantly decreased injuries in the home (Stewart et al, 2016).*
- Assess injury prevention knowledge and practices of the client and caregivers and provide information as appropriate. **EB:** *An evaluation of parental descriptions of the mechanism and perceived cause of 104 childhood home injuries revealed house features, furnishings, foods and/or beverages, and toys as primary causes of injury; 56% reported making changes in the home environment to prevent further injury, including eliminating or replacing hazardous items and increasing adult supervision (Jones et al, 2018).*

▲ Consider a predischarge home assessment referral to determine the need for accessibility and safety-related environmental changes. **EB:** *A randomized controlled trial (RCT) of 1848 individuals in 842 households found significantly fewer falls and fall-related injuries in those households that had specific low-cost home modifications such as alterations in steps inside and outside the house, grab rails and nonslip bath mats in bathrooms, outside lighting, and alterations in carpeting (Keall et al, 2015).*

- Use an assessment tool to identify environmental safety hazards in the home. **EB:** *A scoping review of 136 articles and 4 environmental hazard checklists highlighted the importance of inclusion of objective measurement of structural hazards in the home (Blanchet & Edwards, 2018).*
- Establish an individualized plan of care for improved home maintenance with the client and family based on the client's needs and the caregiver's capabilities. **EB:** *In a study of 86 low-income older adults with*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

asthma, inclusion of education on asthma, its environmental triggers, and environmental remediation was found to be significantly improve health care visits, asthma control, and quality of life (Turcotte et al, 2019).

- Set up a system of relief for the main caregiver in the home and a plan for sharing household duties and/or outside assistance. **EBN:** *In a qualitative study, parents of children with special health care needs involved in a respite care program underlined the benefits of respite care to the family as a whole, emphasizing the value of tailoring respite care to the specific family (Whitmore & Snethan, 2018).*

▲ Provide a multiprofessional approach to target the home environment and the client's ability to function in the home. **EBN:** *The Community Aging in Place: Advancing Better Living for Elders, a program involving teams of nurses, occupational therapists, and handymen that targets the home environment and individual physical function, found that 75% of the participants significantly improved their performance of ADLs and had improved ability to do their own shopping and manage their medications (Szanton et al, 2016).*

Geriatric

- All of the previously mentioned interventions are applicable for the geriatric population.
- Assess functional ability to manage safely after hospital discharge. **EB:** *A qualitative metasummary of 13 studies exploring the perceptions of older persons as they adapt to life after hospital discharge highlighted the importance of involvement of the client and caregiver in assessment, planning, and preparation of the home environment (Hestevik et al, 2019).*
- Explore community resources to assist with home maintenance (e.g., senior centers, Department of Aging, hospital case managers, friends and relatives, the Internet, or church parish nurse). **CEB:** *In a qualitative study with 43 older adults living at home, participants perceived that they were both capable of and willing to manage many home maintenance tasks using compensatory means, such as tools and technologies, making home maintenance and repairs themselves, hiring someone, or having friends, neighbors, or family do the task (Kelly et al, 2014).*
- Provide education related to home modification. **EB:** *A systematic review of 36 articles examining home modifications of older adults found strong evidence in support of home modifications in reducing both the rate and risk of falls (Stark et al, 2017).*
- Focus on the interaction between the older client and the technology, assisting the client to be an active participant in choices of and uses for technology. **EB:** *A qualitative study with older adults, care professionals, home care or social work managers, and technology designers and suppliers found that all groups believed success was enhanced when the older adult's needs and wishes are prioritized and that the technology is accepted by the older adults and perceived as beneficial (Peek et al, 2016).*
- See the care plans for Risk for **Injury** and Risk for **Falls.**

Multicultural

- Acknowledge the stresses unique to racial/ethnic communities. **EB:** *A systematic review of 36 qualitative and 88 quantitative studies focused on medical mistrust concluded that low trust or distrust in the health care system and/or health care providers is a contributing factor to health-related beliefs, utilization, and outcomes (Benkert et al, 2019).*

Home Care

- The previously mentioned interventions incorporate these resources.
- See care plans **Contamination** and Risk for **Contamination.**

Client/Family Teaching and Discharge Planning

- Identify support groups within the community to assist families in the caregiver role. **EBN:** *A qualitative study with 20 family caregivers of clients with Alzheimer's disease involved in a caregiver support group found positive associations with psychological support from professionals and others in similar situations leading to practical help, a feeling of companionship, and solution-focused optimism (Rosenberg & Tokovská, 2017).*
- Incorporate the perspectives of clients and their caregivers in the definition and description of safety. **EBN:** *In a triangulation study of clients in home care, their caregivers, and case management nurses, clients and caregivers recognized their role in ensuring safety, and tended to focus their definition of safety as it relates to meeting the clients' needs, underlining emphasis on empowerment as a model of case management (Jones, 2016).*

- Focus teaching on environmental hazards identified in the nursing assessment. Areas may include, but are not limited to, the following:
  - **Home Safety.** Identify the need for and use of common safety measures in the home. **EB:** *An RCT of an injury prevention briefing designed to improve fire safety found numerous risk factors for falls, poisonings, and scalds. Families in the intervention arm were less likely to report match play and more likely to report bedtime fire safety routines (Kendrick et al, 2017).*
  - **Food Safety.** Instruct client to avoid microbial foodborne illness by storing and cooking food at the proper temperature; regularly washing hands, food contact surfaces, and fruits and vegetables; and monitoring expiration dates. **EB:** *A cross-sectional study of 725 homebound older adults receiving home-delivered meals identified four potential areas of concern with food safety: lack of understanding of safe food storage times, inadequate freezer and/or refrigerator temperatures, overall poor kitchen conditions, and clients' visual difficulties (McWilliams et al, 2017).*
- Teach clients to assess their homes for potential environmental health hazards in the home, including risks related to structure, moisture/mold, fire, pets, electrical, ventilation, pests, and lifestyle. **EB:** *The results of visual in-home inspections of 106 homes using the Healthy Homes Rating System were compared to existing self-reports using the American Housing Survey. The in-home assessment was found to be more reflective of actual conditions, especially in very low income housing (Sokolowsky et al, 2017).*
- See care plans **Contamination,** Risk for **Contamination,** Risk for Adult **Falls,** Risk for Child **Falls**, Risk for **Infection,** and Risk for **Injury.**

Readiness for Enhanced Home Maintenance Behaviors

Domain 1 Health promotion Class 2 Health management

Kathaleen C. Bloom, PhD, CNM

NANDA-I

Definition

A pattern of knowledge and activities for the safe upkeep of one's residence, which can be strengthened.

Defining Characteristics

Expresses desire to enhance affect toward home tasks; expresses desire to enhance attitude toward home maintenance; expresses desire to enhance comfort of the environment; expresses desire to enhance home safety; expresses desire to enhance household hygiene; expresses desire to enhance laundry management skills; expresses desire to enhance organizational skills; expresses desire to enhance regulation of finances; expresses desire to enhance trash management

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Safe Home Environment; Self-Care: Activities of Daily Living (ADLs)

Example NOC Outcome with Indicators

Safe Home Environment as evidenced by the following indicators: Elimination of pests/Smoke detector maintenance/Accessibility of assistive devices/Elimination of tobacco smoke. (Rate the outcome and indicators of **Safe Home Environment:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain a healthy home environment
- Use community resources to assist with home care needs
- Maintain a safe home environment

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Home Maintenance Assistance

Example NIC Activities—Home Maintenance Assistance

Involve client/family in deciding home maintenance requirements; Provide information on how to make home environment safe and clean; Help family use social support network

Nursing Interventions and *Rationales*

- Assess the client's level of readiness for change in home maintenance. **EB:** *A qualitative study using interview data from 30 participants concluded that assessing readiness to change was key to improving occupational safety and health (Cunningham & Jacobson, 2018).*
- Take the client's age and level of disability into account when determining need for housing adaptations. **EB:** *A qualitative analysis of interview data outlined five client profile clusters based on age and level of disability that can be useful in determining home-based interventions and follow-up processes (Luther et al, 2020). These clusters are (1) older adults with low level of disability, (2) older adults with medium/high level of disability, (3) adults with low level of disability, (4) adults with high level of disability, and (5) older adults with medium level of disability including at least moderate cognitive impairment.*

- Engage the client in decisions related to home modifications. **EB:** *In a qualitative study that included 10 older adults, the client often felt frustrated by the lack of attention to their voice in decisions and the aesthetics of the home environment (Lo Bianco et al, 2020).*
- Consider the expectations of individuals living with/caring for the client in determining home adaptations. **EB:** *Granbom et al (2017) used grounded theory to examine the expectations and experiences of nine partners of older persons and individuals with disabilities and found that the expectations of home adaptation centered around concern for mobility, safety, and independence in activities for their partner, as well as benefits to their own everyday life.*
- Reduce injury hazards for children in the home and implement use of safety devices. **EB:** *A systematic review and meta-analysis of four clinical trials concluded that there is evidence that home inspection, safety education, and safety devices reduce home hazards for children (Bhatta et al, 2020).*
- Encourage home rules regarding a smoke free environment. **EB:** *Data from smokers in the Global Adult Tobacco Survey indicate that there are 29.3% fewer cigarettes per day smoked by individuals who live in homes where smoking is not allowed in the home (Owusu et al, 2020).*

Geriatric

All of the previously mentioned interventions are applicable for the geriatric population.

- Provide information to older adults and their families to promote independent living. **EB:** *A review of 5-year longitudinal data indicates that structured advice and home modifications helped prevent transfer of care from home to long-term care facilities in moderately to severely frail older adults (Hollinghurst et al, 2020).*
- Focus on fall prevention in the home. **EBN:** *A quality improvement project designed to enhance awareness of fall risks in the home focused on promoting exercise, home safety, and regular check-up with the primary care provider. This approach was found to increase safety awareness and knowledge of fall prevention (Minnier et al, 2019).*
- Monitor the ways in which home adaptations and equipment are used in the home to ensure continuing safety. **EB:** *In a qualitative study, six older adults who had received a major home adaptation in the past 24 months wore body cameras for 1 day and participated in an interview. Results indicated that these individuals modified the home adaptations and equipment to fit their individual needs (Wilson et al, 2019).*

Multicultural

- Encourage maintenance of personal and cultural possessions in the home even as adaptations are made to the structure and function of the home. **EB:** *In a phenomenological study, participants described how their interaction with cherished possessions helped them connect with their past selves and cope with present changes and challenges. This has the potential to improve quality of life (Coleman & Wiles, 2020).*

Home Care

- Use principles of client-centeredness in home care. **EBN:** *A thematic analysis from an integrative review of 24 articles on home care approaches found four themes defining client-centered care and service in home care: (1) client involvement, (2) family and caregiver participation, (3) communication and collaboration, and (4) evidence-based service competence (Sanerma et al, 2020).*

Client/Family Teaching and Discharge Planning

- Provide the client and family with sufficient, quality information and resources before discharge to ensure a feeling of confidence in home care. **EBN:** *In a qualitative analysis of 14 clients' perception of the discharge process, clients revealed a desire to be involved in a discharge process that focused on communication, information, and participation (Krook et al, 2020).*
- Promote good communication between older persons, hospital providers, and home care providers to improve coordination of care and a seamless transition to home. **EB:** *A metasummary of qualitative data from 13 studies found that clients' concerns include the transition process, settling in at home, their caretaker, and lack of involvement in the process (Hestevik et al, 2019). This is especially true of communications relative to medication management (Tobiano et al, 2019).*

Risk for Ineffective Home Maintenance Behaviors

Domain 1 Health promotion Class 2 Health management

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to an unsatisfactory pattern of knowledge and activities for the safe upkeep of one's residence, which may compromise health.

Defining Characteristics

Competing demands; depressive symptoms; difficulty with decision-making; environmental constraints; impaired physical mobility; impaired postural balance; inadequate knowledge of home maintenance; inadequate knowledge of social resources; inadequate organizing skills; inadequate role models; inadequate social support; insufficient physical endurance; neurobehavioral manifestations; powerlessness; psychological distress

At-Risk Population

Economically disadvantaged individuals; individuals living alone; older adults

Associated Conditions

Depression; mental disorders; neoplasms; neurocognitive disorders; sensation disorders; vascular disease

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plans for Ineffective **Home** Maintenance Behaviors and Readiness for Enhanced **Home** Maintenance Behaviors.

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

Readiness for Enhanced Hope

Domain 6 Self-perception Class 1 Self-concept

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

A pattern of expectations and desires for mobilizing energy to achieve positive outcomes, or avoid a potentially threatening or negative situation, which can be strengthened.

Defining Characteristics

Expresses desire to enhance ability to set achievable goals; expresses desire to enhance belief in possibilities; expresses desire to enhance congruency of expectation with goal; expresses desire to enhance deep inner strength; expresses desire to enhance giving and receiving of care/love; expresses desire to enhance initiative; expresses desire to enhance involvement with self-care; expresses desire to enhance positive outlook on life; expresses desire to enhance problem-solving to meet goal; expresses desire to enhance sense of meaning in life; expresses desire to enhance spirituality

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Hope; Quality of Life

Example NOC Outcome with Indicators

Hope as evidenced by the following indicators: Expresses expectation of a positive future/Expresses faith/Expresses meaning in life/Exhibits a zest for life/Sets goals. (Rate the outcome and indicators of **Hope:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Describe values, expectations, and meanings
- Set achievable goals that are consistent with values
- Design strategies to achieve goals
- Express belief in possibilities

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Emotional Support; Hope Inspiration; Presence; Support System Enhancement

Example NIC Activities—Hope Inspiration

Assist client and family to identify areas of hope in life; Demonstrate hope by recognizing the client's intrinsic worth; Encourage therapeutic relationships; Help the person expand spiritual self

Nursing Interventions and *Rationales*

- Spend one-on-one time with the client. Use empathy; try to understand what the client is saying and communicate this understanding to the client to create a nonjudgmental trusting environment to develop therapeutic relationships with the client. **EB:** *Client ratings of the therapeutic relationship predicted social inclusion through hopefulness (Berry & Greenwood, 2015).*
- Assist clients to identify sources of gratitude in their lives. **EB:** *A study found that gratitude predicted hope and happiness (vanOyen-Witvliet et al, 2019).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Screen the client for hope using a valid and reliable instrument as indicated. **CEB:** *The Herth Hope Index (HHI) is a brief instrument with good psychometric properties that has been developed for clinical use. It has been designed to facilitate the examination of hope at various intervals so that changes in levels of hope can be identified (Hunsaker et al, 2016).*
- Focus on the positive aspects of hope. **EBN:** *An integrative study found that when an institution provides a positive context, it promotes hope (e.g., sets goals, generates pathways, sustains motivation) in attaining educational objectives for college students (Griggs, 2017).*
- Assist the client to develop positive expectations outcomes and recognize the pathways to achieve the positive outcomes. **EB:** *Research findings suggest that lack of positive expectations account for the relationship between hopelessness and future depression and suicidal behavior among adolescents (Horwitz et al, 2017).*
- Explore the meanings, functions, objects, sources, and nature of hope with clients as they relate to their current situation. **EBN:** *A better understanding of clients' meanings of hope can assist nurses to foster hope and provide better support (Marco, Pérez, & García-Alandete, 2016).*
- Teach individuals how to become aware of attention that is focused on unwanted aspects of life and how to redirect attention toward things that feel more wanted or desired by using a future-directed approach. **EB**: *A study determined that the development of a future orientation led to a decline in hopelessness (Mac Giollabhui et al, 2018).*
- Review the client's strengths and resources in conjunction with the client. **EBN:** *A strengths-based perspective support group intervention reduced the participants' level of depressive symptoms and improved the pathway component of hope (Hou, Ko, & Shu, 2016).*
- Assist the client to consider alternatives and set long- and short-term goals that are important to him or her. **EBN:** *A mixed-method thematic review found that setting and achieving goals was a theme that increased hope (Broadhurst & Harrington, 2016).*
- Encourage engagement in positive and pleasant events. **EB:** *This study found that targeting both hopelessness and engagement in pleasant events may be helpful in improving the quality of life of vulnerable, rural, older adults (Scogin et al, 2016).*
- Facilitate sources of the client's resilience. **EB**: *Resilience has a mediating role in the relationship between risk factors involved in interpersonal functioning and hopelessness (Collazzoni et al, 2020).*
- Implement social supports and reintegration programs for postdeployment soldiers and veterans in a timely fashion. **EB:** *Research determined that hopelessness was moderated by timely implementation of postdeployment support and reintegration programs (Martin et al, 2016).*
- Encourage the client to adopt active coping strategies. **EB:** *In the current study, proactive coping predicted hope regardless of severity of spinal cord injury (Phillips et al, 2016).*
- Identify spiritual beliefs and practices. **CEB:** *Spirituality was identified as a factor in increasing hope in clients with mental illness (Schrank et al, 2012).*

Home Care

- The previously mentioned interventions may be adapted for home care use.

Client/Family Teaching and Discharge Planning

- Assist families to identify sources of gratitude in their lives. **EB**: *A study found that gratitude predicted hope and happiness (vanOyen-Witvliet et al, 2019).*
- Use a family-centered approach to provide information regarding the client's condition, treatment plan, and progress. **EBN:** *Clients reported increased hope after a planned family-centered discharge process (Ingram et al, 2017).*
- Teach alternative coping strategies such as physical activity. **EB:** *In a study of adults with congenital heart disease, regular physical activity was a protective factor against hopelessness (Eslami et al, 2017).*

▲ Refer the client to self-help groups. **EB:** *Support groups provided an experience of community in which hope was encouraged (Behler et al, 2017).*

Hopelessness

Domain 6 Self-perception Class 1 Self-concept

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

The feeling that one will not experience positive emotions, or an improvement in one's condition.

Defining Characteristics

Anorexia; avoidance behaviors; decreased affective display; decreased initiative; decreased response to stimuli; decreased verbalization; depressive symptoms; expresses despondency; expresses diminished hope; expresses feeling of uncertain future; expresses inadequate motivation for the future; expresses negative expectations about self; expresses negative expectations about the future; expresses sense of incompetency in meeting goals; inadequate involvement with self care; overestimates the likelihood of unfortunate events; passivity; reports altered sleep-wake cycle; suicidal behaviors; unable to imagine life in the future; underestimates the occurrence of positive events

Related Factors

Chronic stress; fear; inadequate social support; loss of belief in spiritual power; loss of belief in transcendent values; low self efficacy; prolonged immobility; social isolation; unaddressed violence; uncontrolled severe disease symptoms

At-Risk Population

Adolescents; displaced individuals; economically disadvantaged individuals; individuals experiencing infertility; individuals experiencing significant loss; individuals with history of attempted suicide; individuals with history of being abandoned; older adults; unemployed individuals

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Associated Conditions

Critical illness; depression; deterioration in physiological condition; feeding and eating disorders; mental disorders; neoplasms; terminal illness

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Hope; Mood Equilibrium; Nutritional Status: Food and Fluid Intake; Quality of Life; Sleep

Example NOC Outcome with Indicators

Has a presence of **Hope** as evidenced by the following indicators: Expresses expectation of a positive future/Expresses faith/Expresses will to live. (Rate the outcome and indicators of **Hope:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize feelings
- Participate in care
- Make positive statements (e.g., "I can" or "I will try")
- Set goals
- Make eye contact, focus on speaker
- Maintain appropriate appetite for age and physical health
- Sleep appropriate length of time for age and physical health
- Express concern for another
- Initiate activity

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Hope Inspiration

Example NIC Activities—Hope Inspiration

Assist client/family to identify areas of hope in life; Demonstrate hope by recognizing client's intrinsic worth and viewing client's illness as only one facet of the individual; Expand the client's repertoire of coping mechanisms

Nursing Interventions and *Rationales*

- Assess for, monitor, and document the potential for suicide. (Refer the client for appropriate treatment if a potential for suicide is identified.) Refer to the care plan Risk for **Suicidal** Behavior for specific interventions. **EB:** *A 10-year longitudinal study found that hopelessness predicts suicidal ideation (Qiu, Klonsky, & Klein, 2017).*
- Assess and monitor potential for depression. (Refer the client for appropriate treatment if depression is identified.) **EB:** *Hopelessness is associated with depressive and suicidal symptoms (Hallensleben et al, 2019).*
- Assess for hopelessness with the modified Beck Hopelessness Scale. **CEB:** *The modified Beck Hopelessness Scale is a valid and reliable tool to measure hopelessness (Fisher & Overholser, 2013).*
- Assess and monitor family caregivers for symptoms of hopelessness. **EBN:** *Significant correlations were found between hopelessness and coping strategies with a positive correlation between hopelessness and the helpless approaches (Tokem, Ozcelik, & Cicik, 2015).*
- Assess for pain and respond with appropriate measures for pain relief. **EB:** *In the present study, hopelessness played a central role in the relationship between pain and depression with pain intensity positively related to hopelessness (Hülsebusch, Hasenbring, & Rusu, 2016).*
- Facilitate sources of the client's resilience. **EB:** *Resilience has a mediating role in the relationship between risk factors involved in interpersonal functioning and hopelessness (Collazzoni et al, 2020).*

- Assist the adolescent client to develop positive expectations. **EB:** *Research findings suggest that lack of positive expectations account for the relationship between hopelessness and future depression and suicidal behavior among adolescents (Horwitz et al, 2017).*
- Assist the client to explore the meaning of his or her life, satisfaction with his or her life, and life goals. **EB:** *Research shows that a higher meaning of life buffers the association between suicide risk factors and hopelessness (Marco, Pérez, & García-Alandete, 2016).*
- Encourage adolescent clients to get 9 to 10 hours of sleep nightly. **EB:** *Research shows that among adolescents, as little as 1 hour less of weekday sleep was associated with significantly greater odds of feeling hopeless (Winsler et al, 2015).*
- Assist the client in looking at alternatives and setting long- and short-term goals that are important to him or her. **EBN:** *A mixed-method thematic review found that setting and achieving goals was a theme that increased hope (Broadhurst & Harrington, 2016).*
- Explore the meanings, functions, objects, sources, and nature of hope with clients as they relate to their current situation. **EBN:** *A better understanding of clients' meanings of hope can assist nurses to foster hope and provide better support (Marco, Pérez, & García-Alandete, 2016).*
- Spend one-on-one time with the client. Use empathy; try to understand what the client is saying and communicate this understanding to the client to create a nonjudgmental trusting environment to develop therapeutic relationships with the client. **EB:** *Client ratings of the therapeutic relationship predicted social inclusion through hopefulness (Berry & Greenwood, 2015).*
- Teach alternative coping strategies such as physical activity. **EB**: *In a study of adults with congenital heart disease, regular physical activity was a protective factor against hopelessness (Eslami et al, 2017).*
- Use a future-directed approach that teaches individuals how to become aware of attention that is focused on unwanted aspects of life and how to redirect attention toward things that feel more wanted or desired. **EB:** *A study determined that the development of a future orientation led to a decline in hopelessness (Mac Giollabhui et al, 2018).*
- Review the client's strengths and resources in conjunction with the client. **EBN:** *A strengths-based perspective support group intervention reduced the participants' level of depressive symptoms and improved the pathway component of hope (Hou, Ko, & Shu, 2016).*
- Encourage the client to adopt active coping strategies. **EB:** *In a current study, proactive coping predicted hope regardless of severity of spinal cord injury (Phillips et al, 2016).*
- Implement social supports and reintegration programs for postdeployment soldiers and veterans in a timely fashion. **EB:** *Research determined that hopelessness was moderated by timely implementation of postdeployment support and reintegration programs (Martin et al, 2016).*
- For additional interventions, see the care plans for Readiness for Enhanced **Hope, Spiritual** Distress**,** Readiness for Enhanced **Spiritual** Well-Being**,** and Disturbed **Sleep** Pattern.

Geriatric

- Previous interventions may be adapted for geriatric clients.
- ▲ If depression is suspected, confer with the primary health care provider regarding referral for mental health services. **EB:** *This study of older adults found that hopelessness was a significant predictor of death ideation (Guidry & Cukrowicz, 2016).*
- Take threats of self-harm or suicide seriously and intervene as needed. **EB:** *This study of older adults identified hopelessness as a significant predictor of death ideation (Guidry & Cukrowicz, 2016). Older adults have the highest risk of death by suicide in the United States (Fond et al, 2016).*
- Encourage engagement in positive and pleasant events. **EB:** *This study found that targeting both hopelessness and engagement in pleasant events may be helpful in improving the quality of life of vulnerable, rural older adults (Scogin et al, 2016).*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's feelings of hopelessness. **EB:** *Research found that familial acculturative stress may exacerbate the effect of hopelessness on suicidal ideation (Lane & Miranda, 2018).*
- Assess for the effect of fatalism on the client's expression of hopelessness. **EBN:** *A systemic review of qualitative studies found that fatalistic perspectives were common among the cancer beliefs held by ethnic minority populations (Licqurish et al, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Use caution when highlighting health disparities of multicultural populations through public health campaigns and media broadcasts. **EB:** *This study found that media campaigns that broadcasted health disparities resulted in the targeted population feeling less hopeful about the future (Lee et al, 2017).*
- Encourage spirituality as a source of support for hopelessness. **EB:** *Structural equation modeling indicated that Malaysian adolescent students were high in hopelessness and depression, but were also high in spirituality and had less suicidal behavior than others (Talib & Abdollahi, 2017).*

Home Care

- Previously mentioned interventions may be adapted for home care use.
- Use in-person problem-solving therapy (PST) to address depressive symptoms and hopelessness. **EB:** *In-person PST reduced depressive symptoms and alleviated hopelessness in older homebound adults. PST focused on the participants' appraisal of specific problems, identification of the best possible solutions, and the practical implementation of those solutions (Choi, Marti, & Conwell, 2016).*

Client/Family Teaching and Discharge Planning

- Provide information regarding the client's condition, treatment plan, and progress. **EBN:** *Clients reported increased hope after a planned family-centered discharge process (Ingram et al, 2017).*
- ▲ Refer the client to self-help groups. **EB:** *Support groups provided an experience of community in which hope was encouraged (Behler et al, 2017).*

H

Risk for Compromised Human Dignity

Domain 6 Self-perception Class 1 Self-concept

Mamilda Robinson, DNP, APN, PMHNP-BC and Kathleen L. Patusky, PhD, MA, RN, CNS

NANDA-I

Definition

Susceptible for perceived loss of respect and honor, which may compromise health.

Risk Factors

Dehumanization; disclosure of confidential information; exposure of the body; humiliation; inadequate understanding of health information; insufficient privacy; intrusion by clinician; loss of control over body function; perceived social stigma; values incongruent with cultural norms

At-Risk Population

Individuals with limited decision making experience

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health Beliefs: Perceived Control; Decision-Making; Spiritual Control; Mental Control; Perceived Social Support

Example NOC Outcome with Indicators

Health Beliefs: Perceived Control as evidenced by the following indicators: Perceived responsibility for health decisions/Requested involvement in health decisions/Efforts at gathering information/Belief that own decisions control health outcomes/Willingness to designate surrogate decision maker. (Rate the outcome and indicators of **Health Beliefs: Perceived Control:** 1 = very weak, 2 = weak, 3 = moderate, 4 = strong, 5 = very strong [see Section I].)

Client Outcomes

Client/Caregiver Will (Specify Time Frame)

- Perceive that dignity is maintained throughout hospitalization/encounter
- Consistently call client by name and pronoun of choice
- Maintain client's privacy

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Presence; Decision-Making Support; Spiritual Support; Hope Instillation

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NIC Activities—Presence
Demonstrate accepting attitude; Listen to client's concerns

Nursing Interventions and *Rationales*

- Use the person-centered approach for each client, while listening actively and addressing their individual needs. **EBN:** *It is important that the nurse remain cognizant of each person's health problem and recognizes their unique values. The nurse should determine why the person has developed the problem, what the individual wishes to achieve, and how the goal can best be achieved in a dignified manner (Nazarko, 2015).*
- Encourage client to enter into and stay in communication with others. Encourage connections with the inner life world of meaning and spirit of the other. Join in a mutual search for meaning and wholeness of being and becoming to potentiate comfort measures, pain control, a sense of well-being, wholeness, or even spiritual transcendence of suffering. **EBN:** *Human dignity is a central concept within nursing and the caring professions because it promotes client inclusivity. In a shared humanity, clients are included in professional responsibility and part of their care. Because nurses are eager to actualize the caring relationship with clients, they preserve dignity and respect integrity (Blomberg et al, 2015).*
- Determine the client's perspective about his or her health. Example questions include "Tell me about your health." "What is it like to be in your situation?" "Tell me how you perceive yourself in this situation." "What meaning are you giving to this situation?" "Tell me about your health priorities." "Tell me about the harmony you wish to reach." **EBN:** *Such questions usually contribute to promoting clients' dignity, as dignity has been established as one of the essential needs of those with life-threatening illnesses, as well as a measure to mediate the effect of physical symptoms on demoralization (Dose et al, 2017).*
- Determine the client's preferences for when and how nursing care is needed and follow the client's guidelines if possible. **EBN:** *The client's autonomy must be recognized as part of dignified nursing care. A Canadian study of decision-making during the pregnancy experience found that women reported lower autonomy when there were difficulties in communication with provider, feelings of pressure for certain interventions, and not feeling comfortable to ask the provider questions (Vedum et al, 2019).*
- Maintain the client's privacy at all times. **EBN:** *The results of a qualitative study found that preservation and promotion of the dignity of the client was an outcome of maintaining the privacy of hospitalized clients (Tehrani et al, 2020).*
- Encourage the client to share thoughts about spirituality and mortality as desired. **EB:** *The acceptance of mortality, using spirituality and mindfulness, allows clients to view themselves as mortal human beings who are supported by caring loved ones and health care professionals. When clients are dignified through this process, they gain a sense of spiritual healing despite the physicality of death (Nyatanga, 2018).*
- Use interventions to instill increased hope; see the care plan for Readiness for Enhanced **Hope.** **EB:** *When hope for a cure is no longer possible, clients should be reminded that despite the circumstance, they attain dignity in death that is centered to themselves and their loved ones. While dying cannot be stopped, efforts with support and instillation of hope provide comfort through the process of dying while minimizing distress in order to ensure dignity in death (Nyatanga, 2019).*
- ▲ Refer client for dignity therapy. **EBN:** *A systematic review and meta-analysis found that dignity therapy significantly improved dignity-related distress in existential distress domain and social support domain. The narrative summaries also indicated that dignity therapy exerted positive effects on clients' dignity, psychological well-being, and quality of life (Xiao et al, 2019).*
- See the care plan for Readiness for Enhanced **Spiritual** Well-Being.

Geriatric

- Always ask the client how he or she would like to be addressed. Avoid calling older clients "sweetie," "honey," "Gramps," "mama," or other terms that could be considered as demeaning unless this is acceptable in the client's culture or requested by the client. Appropriate forms of address and person-centered approaches must be used with older adults to maintain dignity. **EB:** *Addressing the client in a respectful manner promotes healthy relationships, which are important for mental well-being; this provides a sense of self-worth and belonging. The Care Act (2015) promotes person-centered outcomes as well as supporting families and older adults in order to maintain dignity along the care continuum (Stuart, 2020).*
- Treat the older client with the utmost respect, even if delirium or dementia is present with confusion. **EB:** *A narrative review found that providing respect to clients with dementia was a dignifying aspect of dementia care (van der Geugten & Goossensen, 2020).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's way of communicating, and follow the client's lead in communicating in matters of eye contact, amount of personal space, voice tones, and amount of touching. If in doubt, ask the client. **EB:** *Client dignity is promoted when staff provide privacy and use interactions that help clients feel comfortable, in control, and valued. When this is achieved, a personalized care plan can be developed with client's input to ensure dignity and support while addressing client's cultural beliefs, norms, and values (Hurtley, 2015).*
- Provide diverse clients with person-centered care that is responsive, respectful, and individualized. **EB:** *An Indonesian study found four major categories that described qualities of nursing care essential for maintaining a client's dignity in clinical care settings: (1) responsiveness; (2) respectful nurse–client relationships; (3) caring characteristics; and (4) personalized service. The researchers concluded that the ability to provide culturally competent care is important for nurses as a strategy to maintain client dignity during hospitalization (Asmaningrum & Tsai, 2018).*

Home Care

- Many of the previous intervention may be adapted for home care use.
- Encourage client participation in self-care and the management of one's own care process. **EB:** *An integrative review of client-centeredness in home care found that clients' involvement is the epicenter of successful home care. The researchers conclude that client-centeredness is supported by respect for individual persons' values, right to self-determination, mutual respect, and understanding (Sanerma et al, 2020).*

Client/Family Teaching and Discharge Planning

- Teach and support family and caregiver actions that maintain the dignity of the client. How an individual cognitively perceives and emotionally deals with the illness can depend on the person's family and social relationships, and ultimately can affect the ability to heal. **EBN:** *A qualitative study found that family members could identify when clients were deprived of dignity. The authors concluded that education, communication, and connections with family could prevent factors that may threaten dignified care (Sagbakken et al, 2017).*

Neonatal Hyperbilirubinemia

Domain 2 Nutrition Class 4 Metabolism

Maria Galletto, MSN, RN, CNL, CPHQ

NANDA-I

Definition

The accumulation of unconjugated bilirubin in the circulation (less than 15 mL/dL) that occurs after 24 hours of life.

Defining Characteristics

Abnormal liver function test results; bruised skin; yellow mucous membranes; yellow sclera; yellow-orange skin color

Related Factors

Delay in meconium passage; inadequate paternal feeding behavior; malnourished infants

At-Risk Population

East Asian neonates; low birth weight neonates; Native American neonates; Neonates aged ≤ 7 days; neonates who are breastfed; neonates whose blood groups are incompatible with mothers'; neonates whose mothers had gestational diabetes; neonates whose sibling had history of jaundice; neonates with significant bruising during birth; populations living at high altitudes; premature neonates

Associated Conditions

Bacterial infections; enzyme deficiency; impaired metabolism; internal bleeding; liver malfunction; prenatal infection; sepsis; viral infection

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Breastfeeding Establishment: Infant; Breastfeeding Maintenance; Bowel Elimination; Parent: Knowledge: Parenting/Infant Care; Risk Detection/Control

Example NOC Outcome with Indicators

Breastfeeding Establishment: Infant as evidenced by the following indicators: Proper alignment and latch-on/Proper areolar grasp/Proper areolar compression/Correct suck and tongue placement/Audible swallow/Minimum eight feedings per day/Urinations per day appropriate for age/Weight gain appropriate for age. (Rate the outcome and indicators of **Breastfeeding Establishment: Infant:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client Outcomes

Client (Infant) Will (Specify Time Frame)

- Establish effective feeding pattern (breast or bottle)
- Receive nursing assessments to determine risk for severity of jaundice
- Receive bilirubin assessment and screening within the first few days of life to identify potentially harmful levels of serum bilirubin
- Receive appropriate therapy to enhance indirect bilirubin excretion
- Maintain hydration: moist buccal membranes, four to six wet diapers in a 24-hour period, weight loss no greater than 10% of birth weight within the first week of life
- Evacuate stool within 48 hours of birth, and pass three or four stools per 24 hours by day 4 of life

Client (Parent[s]) Will (Specify Time Frame)

- Receive information on neonatal jaundice before discharge from birth hospital
- Verbalize understanding of physical signs of jaundice prior to discharge

- Verbalize signs requiring immediate health practitioner notification: sleepy infant who does not awaken easily for feedings, fewer than four to six wet diapers in 24-hour period by day 4, fewer than three to four stools in 24 hours by day 4, breastfeeds fewer than eight times per day
- Demonstrate ability to operate home phototherapy unit if prescribed

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Parent Education: Infant; Phototherapy: Neonate

Example NIC Activities—Phototherapy: Neonate

Review maternal and infant history for risk factors for hyperbilirubinemia (e.g., Rh or ABO incompatibility, polycythemia, sepsis, prematurity, malpresentation); Observe for signs of jaundice

Nursing Interventions and *Rationales*

- Evaluate maternal and delivery history for risk factors for neonatal jaundice (RhD, ABO, G6PD deficiency, direct Coombs). **EB:** *Assessment of maternal and neonatal risk factors that may cause jaundice is important in the detection of neonatal jaundice (Barrington & Sankaran, 2018).*
- Perform neonatal gestational age assessment once the newborn has had an initial period of interaction with mother and father. Gestational age is calculated using completed weeks of age. There are two major categories, preterm and term newborns, with further subdivisions in each category. Infants born before 34 weeks' completed gestation will be admitted to the neonatal intensive care unit (NICU). **EB:** *Infants who are born late preterm (34 to 36{6/7} weeks at birth) and early term (37 and 38{6/7} weeks at birth) are at significantly increased risk for problems related to hyperbilirubinemia, feeding problems, and hospital readmission (Reichman et al, 2015).*

PRETERM CATEGORY	TERM CATEGORY
Extremely preterm <28 weeks' completion	Early term 37 to 38 weeks' completion
Very preterm 28 to <32 weeks' completion	Term >38 to 42 weeks' completion
Late preterm 32 to <37 weeks' completion	Postterm >42 weeks' completion

- Encourage breastfeeding within the first hour (otherwise known as the Golden Hour) of the neonate's life. **EB:** *Early feedings increase neonatal intestinal activity, and infant begins establishing intestinal flora; in addition, early breastfeeding promotes enhanced maternal confidence in breastfeeding (Flaherman & Maisels, 2017).*
- Encourage skin-to-skin mother–newborn contact shortly after delivery to support the Golden Hour after birth. **EB:** *Early skin-to-skin mother–baby contact helps promote maternal confidence in nurturing abilities, and it is correlated with improved milk supply and milk transfer (Flaherman & Maisels, 2017).* **EB:** *The Golden Hour contributes to neonatal thermoregulation, decreased stress levels in a woman and her newborn, and improved mother–newborn bonding. Implementation of these actions is further associated with increased rates and duration of breastfeeding (Neczypor & Holley, 2017).*
- Encourage and assist mother with frequent breastfeeding. **EB:** *Increased frequency of breastfeeding accelerates weight gain and increases defecation frequency, reducing the severity of neonatal hyperbilirubinemia (Hassan & Zakerihamidi, 2018). Exclusive breastfeeding is recommended for neonatal feedings yet is associated with the development of hyperbilirubinemia and not directly as a result of the feeding substrate; perhaps it is caused by decreased caloric intake in the first week of life and a substance in breast milk that may interfere with bilirubin excretion (Flaherman & Maisels, 2017).*
- Assist parents who choose to bottle feed their neonate. **EB:** *Adequate caloric intake is essential for the promotion of stooling and the subsequent elimination of bilirubin from the intestine; bottle-feeding parents must be helped to optimize feedings (Hockenberry & Wilson, 2015).*
- Avoid feeding supplements such as water, dextrose water, or any other milk substitutes in breastfeeding neonate. **EB:** *Supplements may act to decrease the effective establishment of breastfeeding (Flaherman & Maisels, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Assess neonate's stooling pattern in first 48 hours of life. *Delayed stooling may indicate inadequate breast milk intake and may further increase reabsorption of bilirubin from neonate's intestine (Hockenberry, Wilson, & Rodgers, 2017).*
- Monitor infant's neurological status for any signs of emerging bilirubin encephalopathy. **EB:** *Initially, the infant may have lethargy, decreased activity, irritability, or poor feeding. As encephalopathy continues, the infant will develop rigid extension of extremities, fever, irritable cry, opisthotonos, and seizures (Green, 2016).*

▲ Monitor transcutaneous bilirubin level in jaundiced neonate per unit protocol. **CEB/EB:** *Noninvasive bilirubin monitoring is a safe and effective means for monitoring bilirubin levels and determining risk for increasing serum bilirubin levels in infants who are not treated with phototherapy (Bhutani et al, 2014; van den Esker-Jonker et al, 2016; Jain et al, 2017).*

▲ Collect and evaluate laboratory blood specimens as prescribed or per unit protocol. **EB:** *Because visual assessments of skin color alone are inadequate to determine rising levels of bilirubin, serum bilirubin measurement may be gathered to evaluate risk for pathology (Hockenberry, Wilson, & Rodgers, 2017). The purpose of monitoring, evaluating, and implementing treatment in moderate to severe cases of neonatal hyperbilirubinemia is to prevent acute bilirubin encephalopathy, which is an early acute central nervous system bilirubin toxicity that is related to the amount of unbound (indirect) bilirubin (Hockenberry, Wilson, & Rodgers, 2017).*

- Perform hour-specific total serum bilirubin (TSB) risk assessment before discharge from hospital or birth center and document the results. **CEB:** *The use of an hour-specific nomogram for designation of risk in healthy, late preterm, early term, and term infants, as well as clinical risk factors, may be used to determine the relative risk of rapidly increasing bilirubin levels requiring medical intervention such as phototherapy (American Academy of Pediatrics, 2004; Maisels et al, 2009). The hour-specific nomogram estimates the TSB in one of four risk zones: low risk, low intermediate risk, high intermediate risk (75th to 94th percentile), and high risk (95th percentile or greater). Infants with TSB values at or above the 75th percentile in addition to risk factors, such as preterm birth, may require medical intervention such as phototherapy (Maisels et al, 2009).*
- Monitor newborn for signs of inadequate breast milk or formula intake: dry oral mucous membranes, fewer than 4 to 6 wet diapers per 24 hours, no stool in 24 hours, and body weight loss greater than 10%. **EB:** *Inadequate intake of breast milk or formula in the neonatal period has been identified as a risk factor for the development of hyperbilirubinemia (Flaherman & Maisels, 2017).*
- Assess late preterm infant (born between 34 and 37 weeks' gestation) for ability to breastfeed successfully and adequate intake of breast milk. **EB:** *Late preterm infants are at higher risk for difficulty breastfeeding and suboptimal milk intake caused by physiological immaturity; thus such infants are also at a much higher risk for severe jaundice than term counterparts (Reichman et al, 2015; Barrington & Sankaran, 2018).*
- Assist mother with breastfeeding and assess latch-on. **EB:** *Successful breastfeeding in the first few weeks of life is associated with decreased levels of serum bilirubin (Flaherman & Maisels, 2017).* See Readiness for Enhanced **Breastfeeding.**
- Encourage alternate methods for providing expressed breast milk if maternal health status is compromised, such as assisting the mother with collection of breast milk via use of breast pump or hand expression. **EB:** *Alternate feeding methods for the ingestion of breast milk may be used to enhance milk intake necessary to promote stooling and enhance bilirubin excretion (Flaherman & Maisels, 2017).*
- Encourage partner's participation in newborn care by changing diapers, helping position newborn for breastfeeding, and holding newborn while mother rests. **EB:** *Paternal involvement in the care of the newborn helps solidify the father's role as a parent and strengthens the paternal–infant attachment process; paternal participation also helps the mother rest during the recovery from labor and delivery (Hockenberry & Wilson, 2015).*
- Weigh newborn daily. **EB:** *Daily weights assist in the detection of excess weight loss, which is often indicative of inadequate caloric intake (Flaherman & Maisels, 2017).*

▲ When phototherapy is ordered, place seminude infant (diaper only) under prescribed amount of phototherapy lights. **CEB:** *Phototherapy is the primary therapy used to treat mild to moderate neonatal indirect (unconjugated) hyperbilirubinemia; the infant must have a large skin surface area exposed to the light source for optimal effectiveness (Hockenberry, Wilson, & Rodgers, 2017).*

- Protect infant's eyes from phototherapy light source with eye shields; remove eye shields periodically when infant is removed from light source for feeding and parent–infant interaction. **EB:** *There is no evidence that removing the infant for parent–infant interaction during feedings and for brief caregiving activities prevents the effectiveness of phototherapy when the infant has mild to moderate hyperbilirubinemia (Hockenberry, Wilson, & Rodgers, 2017).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

H

- Monitor infant's hydration status, fluid intake, skin status, and body temperature while undergoing phototherapy. **EB:** *Transient side effects of phototherapy include increased body temperature, increased insensible water loss, increased gastrointestinal water loss (loose stools), lethargy, irritability, and poor feeding (Hockenberry, Wilson, & Rodgers, 2017).*

▲ Collect and evaluate laboratory blood specimens (TSB) while infant is undergoing phototherapy. **CEB/EB:** *Transcutaneous bilirubin measurements do not provide an adequate estimate of serum bilirubin level and are not effective once phototherapy has been initiated (American Academy of Pediatrics, 2004; Hockenberry, Wilson, & Rodgers, 2017). All bilirubin levels should be interpreted based on the newborn's age in hours (Hartman et al, 2018).*

- Encourage continuation of breastfeeding and brief infant care activities such as changing diapers while the infant is being treated with phototherapy; phototherapy may be interrupted for breastfeeding. **EB:** *Phototherapy can be used while continuing full breastfeeding, or it can be combined with supplementation of expressed breast milk or infant formula if maternal supply is insufficient. Only in extenuating circumstances is temporary interruption of breastfeeding with replacement feeding necessary (Flaherman & Maisels, 2017).*
- Provide emotional support for parents of infants undergoing phototherapy. **EB:** *Separation of the infant from the mother for phototherapy disrupts parent–infant interaction and may promote parental stress and decrease the effective establishment of breastfeeding (Hockenberry, Wilson, & Rodgers, 2017).* **EBN:** *The nursing staff must be prepared to hear and guide mothers throughout phototherapy, taking into consideration that it is a negative experience during the newborn hospitalization (de Souza Fernandes et al, 2016).*
- Provide for novel therapies that can be used in tandem with phototherapy to support parent–infant interaction during treatment. **EB:** *Massage therapy had significant effects on TSB levels, feeding, breastfeeding, defecation, and urination in newborns who received phototherapy for indirect hyperbilirubinemia (Korkmaz & Esenay, 2020).* **EB:** *Kangaroo Mother Care: Out of five trials, two trials reported a significant reduction in bilirubin and three trials reported a significant reduction in duration of phototherapy (Garg, Bansal, & Kabra, 2020).*

Multicultural

- Assess infants of Southeast Asian or Far East Asian and American Indian ethnicity for early rising bilirubin levels, especially when breastfeeding. **EB:** *Studies have shown Asian and American Indian newborns to have higher peak serum bilirubin levels than Caucasian and African American newborns (Hockenberry, Wilson, & Rodgers, 2017).* **EB:** *Mutations of the* UGT1A1 *gene have been shown to be linked to an increased risk of neonatal hyperbilirubinemia in Asian populations compared with white populations (Bentz et al, 2018).*

Client/Family Teaching and Discharge Planning

- Teach parents the signs of inadequate milk intake: fewer than three to four stools per day by day 4, fewer than four to six wet diapers in 24 hours, and dry oral mucous membranes; additional danger signs include a sleepy baby that does not awaken for breastfeeding or appears lethargic (decreased activity level from usual newborn pattern). **EB:** *Providing information about jaundice and effective breastfeeding may serve to decrease risk factors associated with increasing bilirubin levels (Flaherman & Maisels, 2017).*
- Teach parents about the transition in stool color and consistency starting with meconium, followed by green, seedy stool, to mustard-colored, seedy stool by the fourth day of life. **EB:** *Signs of adequate intake in breastfed infants include a transition to seedy, mustard-colored stools by the third or fourth day of life (Muchowski, 2014).*

▲ Teach parents and support persons about the appearance of jaundice (yellow or orange color of skin) after hospital or birth center discharge. Teach parents about the importance of medical follow-up in the first several days of life for the evaluation of jaundice. **EB:** *Most newborns who are discharged before 72 hours of age should have a follow-up visit in 2 days; a newborn who has a recognized risk factor for a health problem should be seen sooner (Hartman et al, 2018).*

- Teach parent about the use of phototherapy (hospital or home, as prescribed); the proper use of the phototherapy equipment; feedings; and assessment of hydration, body temperature, skin status, and urine and stool output. **EB:** *Provide information to the parents of the infant undergoing phototherapy to prevent misinformation about the infant's condition and treatment and to decrease parental anxiety and stress (Hockenberry & Wilson, 2015).* **EBN:** *Home-based phototherapy was more effective than hospital-based phototherapy in treatment of neonatal hyperbilirubinemia (Chu, Qiao, & Xu, 2020).*

H

Risk for Neonatal Hyperbilirubinemia

Domain 2 Nutrition Class 4 Metabolism

Maria Galletto, MSN, RN, CNL, CPHQ

NANDA-I

Definition

Susceptible to the accumulation of unconjugated bilirubin in the circulation (less than 15 ml/dl) that occurs after 24 hours of life, which may compromise health.

Risk Factors

Delay in meconium passage; inadequate paternal feeding behavior; malnourished infants

At-Risk Population

East Asian neonates; low birth weight neonates; Native American neonates; neonates aged ≤7 days; neonates who are breastfed; neonates whose blood groups are incompatible with mothers'; neonates whose mothers had gestational diabetes; neonates whose sibling had history of jaundice; neonates with significant bruising during birth; populations living at high altitudes; premature neonates

Associated Conditions

Bacterial infections; enzyme deficiency; impaired metabolism; internal bleeding; liver malfunction; prenatal infection; sepsis; viral infection

NOC (Nursing Outcomes Classification)

See care plan for Neonatal **Hyperbilirubinemia** for suggested NOC outcomes.

Client Outcomes

Client Will (Specify Time Frame)

- Neonatal total serum bilirubin (TSB) will be monitored and there will be no undetected TSB values in the high-risk (95th percentile or greater) or high-intermediate risk (75th to 94th percentile) zones (as determined by the hour-specific nomogram)
- Newborn will receive appropriate therapies to enhance bilirubin excretion
- Receive bilirubin assessment and screening within the first 24 hours of life with higher risk infants being reevaluated every 24 hours to detect increasing levels of serum bilirubin
- Receive nursing assessments to determine risk for severity of jaundice prior to discharge from birth hospital and schedule return clinic visit within 2 days of discharge for higher risk neonates
- Establish effective on-demand feeding pattern at least every 2 to 3 hours (breast or bottle)
- Maintain hydration: moist buccal membranes, four to six wet diapers in a 24-hour period, weight loss no greater than 10% of birth weight
- Evacuate stool within 48 hours of birth, and pass three to four stools per 24 hours by day 4 of life

NIC (Nursing Interventions Classification)

- See the care plan for Neonatal **Hyperbilirubinemia** for suggested NIC interventions.

Nursing Interventions and *Rationales*

- Identify clinical risk factors that place the infant at greater risk for development of neonatal jaundice: exclusive breastfeeding, isoimmune or hemolytic disease, preterm birth (37{6/7} weeks' gestation or less), weight loss of 10% or more from birth weight within the first week, neonatal sepsis, maternal diabetes, maternal obesity, previous sibling with jaundice, East Asian ethnicity, and significant bruising or cephalohematoma. **EB:** *Breastfeeding is often associated with a higher bilirubin level than is seen in infants fed formula exclusively; increasing the frequency of feeding usually reduces the bilirubin level (Flaherman & Maisels, 2017;. Hartman et al, 2018). **EB:** Preterm is defined as babies born before 37 weeks of pregnancy are completed. The subcategories of preterm birth are extremely preterm (less than 28 weeks), very preterm (28–32 weeks), and moderate to late preterm (32–37 weeks) (World Health Organization, 2018).*
- Measure transcutaneous bilirubin (TcB) of all newborns in the first 24 to 48 hours of life, using a noninvasive transcutaneous bilirubinometer. Plot TcB on a nomogram standardized for the appropriate client population; determine newborn's risk of subsequent significant hyperbilirubinemia. **EB:** *Transcutaneous measurement of bilirubin, in conjunction with use of a nomogram standardized for the appropriate client population, has been demonstrated to be an accurate predictor of subsequent hyperbilirubinemia (Jain et al, 2017). The use of TcB in jaundiced neonates is safe and results in a significant reduction of phlebotomy for serum bilirubin measurement (van den Esker-Jonker et al, 2016).*
- Refer to care plan for Neonatal **Hyperbilirubinemia** for additional interventions for multicultural and discharge planning.

Client/Family Teaching and Discharge Planning

▲ Teach parents about the importance of medical follow-up in the first several days of life for the evaluation of jaundice, especially in the late preterm infant. **EB:** *Late preterm infants (34–36 weeks' gestation) are at much greater risk for hyperbilirubinemia than infants born at term (37–41 weeks' gestation) and should be followed closely in the first few weeks of life (Reichman et al, 2015).*

- Refer to care plan for Neonatal **Hyperbilirubinemia** for additional interventions.

Hyperthermia

Domain 11 Safety/protection Class 6 Thermoregulation

Rosemary Timmerman, DNP, APRN, CCNS, CCRN-CSC-CMC

NANDA-I

Definition

Core body temperature above the normal diurnal range due to failure of thermoregulation.

Defining Characteristics

Abnormal posturing; apnea; coma; flushed skin; hypotension; infant does not maintain suck; irritable mood; lethargy; seizure; skin warm to touch; stupor; tachycardia; tachypnea; vasodilation

Related Factors

Dehydration; inappropriate clothing; vigorous activity

At-Risk Population

Individuals exposed to high environmental temperature

Associated Conditions

Decreased sweat response; impaired health status; increased metabolic rate; ischemia; pharmaceutical preparations; sepsis; trauma

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Thermoregulation; Thermoregulation: Newborn

Example NOC Outcome with Indicators

Thermoregulation as evidenced by the following indicators: Increased skin temperature/Decreased skin temperature/Skin color changes/Dehydration/Hyperthermia. (Rate the outcome and indicators of **Thermoregulation:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain core body temperature within adaptive levels (<40°C [104°F])
- Remain free of complications of malignant hyperthermia
- Remain free of complication of neuroleptic malignant syndrome
- Remain free of dehydration
- Remain free from infection
- Verbalize signs and symptoms of heat stroke and actions to prevent heat stroke
- Verbalize personal risks for malignant hyperthermia and neuroleptic malignant syndrome to be reported during health history reviews to all health care professionals, including pharmacists

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Fever Treatment; Malignant Hyperthermia Precautions; Temperature Regulation

Example NIC Activities—Hyperthermia Treatment

Monitor core body temperature using appropriate device; Monitor for abnormalities in mental status

Nursing Interventions and *Rationales*

Temperature Measurement

- Recognize that hyperthermia is a rise in body temperature above 40°C (104°F) that is not regulated by the hypothalamus, resulting in an uncontrolled increase in body temperature exceeding the body's ability to lose heat. **EB:** *It is a medical emergency (Gaudio & Grissom, 2016; Nakajima, 2016).*
- Continually measure a client's core temperature with a distal esophageal probe or obtain near core body temperature measurements with a rectal or bladder temperature probe and verify with a second method. **EBN:** *Obtaining an accurate core body temperature is essential for detecting heat stroke and monitoring the client's response to treatment; if a core temperature reading is not available or practical, a rectal or bladder temperature measurement provides a closer approximation of the core body temperature than temporal, axillary, oral, aural, or skin measurements (Lipman et al, 2019).* **CEB:** *Research is limited on the accuracy of temporal artery measurements outside normal ranges; axillary temperature is accurate in neonates but is not well supported in adults, and tympanic membrane measurements and chemical dot thermometers are least accurate and should be avoided in caring for the acutely ill adult client (Niven et al, 2015; Syrkin-Nikolau et al, 2017).*
- Use the same site and method (device) for temperature measurement for a given client so that temperature trends are assessed accurately; record site of temperature measurement. **EBN/CEB:** *There are differences in temperature depending on the site from which temperature measurement is obtained; however, differences between sites should not be greater than 0.3°C to 0.5°C (approximately 0.5°F–0.9°F) (Bridges & Thomas, 2009; Makic et al, 2011).*

▲ Work with the health care provider to help determine the cause of the temperature increase (hyperthermia), which will often help direct appropriate treatment. **EB:** *It is important to treat the underlying cause of the temperature to preserve neurological function of the client as well as implement interventions to rapidly lower the core temperature (Niven et al, 2015; Gaudio & Grissom, 2016).*

- Refer to care plan for Ineffective **Thermoregulation** for interventions managing fever (pyrexia).

Heat Stroke

- Recognize that heat stroke may be separated into two categories: classic and exertional. **EB:** *Classic heat stroke usually involves the very young or older client during environmental heat waves. Exertional heat stroke occurs in young adults performing strenuous physical activity in hot climates (Gaudio & Grissom, 2016; Knapik & Epstein, 2019).*
- Watch for risk factors for classic heat stroke, which include the following (Gaudio & Grissom, 2016; Knapik & Epstein, 2019):
  - ❍ Medications, especially diuretics, anticholinergic agents, beta-blockers, calcium channel blockers, anti-Parkinson's medications, antidepressants, thyroid agonists, and antihistamines
  - ❍ City dwellers who reside on top floors of buildings
  - ❍ Alcoholism
  - ❍ Diabetes mellitus
  - ❍ Mental illness
  - ❍ Obesity
  - ❍ Heart disease
  - ❍ Renal disease

  EB: *Physiologic effects of aging include lower onset of sweating and rate of sweating needed to help with dissipation of body heat; medications can dehydrate the client and blunt the physiologic responses necessary*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

to assist with heat dissipation, increasing the risk of heat stroke in older clients (Gaudio & Grissom, 2016; Lipman et al, 2019).

- Risk factors of exertional heat stroke include the following (Gaudio & Grissom, 2016; Lipman et al, 2019):
  - Preexisting illness
  - Drug use (e.g., alcohol, amphetamines, ecstasy)
  - Wearing protective clothing (uniforms and athletic gear) that limits heat dissipation
  - Obesity
  - Low physical fitness
  - Lack of sleep

  EB: *Recognize signs and symptoms of hyperthermia: core body temperature greater than 40°C (104°F), exercise-associated muscle cramps, tachycardia, tachypnea, orthostatic dizziness, weakness, fatigue, ataxia, vomiting, headache, confusion, delirium, seizures, coma, acute kidney injury (rhabdomyolysis), and hot dry skin (classic heat stroke) (Knapik & Epstein, 2019; Lipman et al, 2019).*
- Recognize that antipyretic agents are of little use in treatment of hyperthermia. **EB:** *Because the cause of the hyperthermia does not involve the hypothalamus, antipyretic agents are ineffective and not indicated in treatment of clients with hyperthermia (Leyk et al, 2019; Lipman et al, 2019).*

▲ Assess fluid loss and facilitate oral intake or administer intravenous fluids as prescribed to accomplish fluid replacement and support the cardiovascular system. **EB:** *Increased metabolic rate, diuresis, and diaphoresis-associated exertional hyperthermia cause loss of body fluids (Leyk et al, 2019; Lipman et al, 2019).* Refer to the care plan for Deficient **Fluid** Volume.

▲ Recognize use of alpha-adrenergic agents should be avoided if possible. **EB:** *Alpha-adrenergic agonist agents cause cutaneous vasoconstriction, which impairs cooling (Gaudio & Grissom, 2016).*

- Remove clothing and immerse young and healthy clients who have suffered exertional heat stroke in a cold water bath ensuring the head does not go underwater, or continuously douse the client with cold water. **EB:** *Cold water immersion rapidly cools the core temperature because of the high thermal conductivity of water but may not be practical because of client agitation and limited access for cardiovascular monitoring (Knapick & Epstein, 2019; Lipman et al, 2019).*
- For clients with classic heat stroke, remove clothes and spray or douse the skin with water and provide continual airflow over the body with a fan. **EB:** *Wetting the skin and directing airflow over the body promotes evaporative and convective cooling; this method is less effective for clients with exertional heat stroke (Cheshire, 2016; Lipman et al, 2019).*

▲ Recognize adjunctive cooling measures include administering cold (4°C [39.2°F]) intravenous fluids, ice sheeting (covering client with bed linens that have been soaked in ice water), water circulating hydrogel coated pads placed over the chest and legs, ice packs over the entire body, intravascular cooling catheter, and cooling blankets. **EB:** *There is insufficient evidence to recommend using adjunctive measures as a primary cooling method (Bursey et al, 2019; Lipman et al, 2019).*

▲ Continuously monitor the effects of cooling measures, stop cooling interventions once the body temperature is less than 39°C [102.2°F] , and benzodiazepines may be administered to control shivering. **EB/EBN:** *Hyperthermia must be treated aggressively to lower the body temperature to below 40°C [104°F] within 30 minutes; however, overshooting of the cooling process with resultant hypothermia must be prevented and avoidance of shivering is essential because of the associated increase in heat production, oxygen consumption, and cardiorespiratory effort (Leyk et al, 2019; Lipman et al, 2019).*

▲ Continually assess the client's neurologic and other organ function, especially kidney function (i.e., signs of rhabdomyolysis), for signs of injury from hyperthermia. **EB/EBN:** *Hyperthermia can cause permanent neurological injury, acute kidney injury, electrolyte imbalances, and coagulation disorders so continuous assessment of neurological and other organ function is essential (Knapik & Epstein, 2019; Lipman et al, 2019).*

Malignant Hyperthermia

▲ If the client has just received general anesthesia, especially halothane, sevoflurane, desflurane, enflurane, isoflurane, or succinylcholine, recognize that the hyperthermia may be caused by malignant hyperthermia and requires immediate treatment to prevent death. **EB:** *Malignant hyperthermia is often a fatal disease and must be treated promptly with rapid administration of the medication dantrolene, increasing oxygenation, assisting ventilation, initiating external cooling measures, and treating acid-base (e.g., metabolic acidosis) and electrolyte disorders (Riazi et al, 2018; Cieniewicz et al, 2019; Malignant Hyperthermia Association of the United States [MHAUS], 2020).*

- Monitor core temperature for all clients receiving general anesthetic agents for longer than 30 minutes. **EB/EBN:** *Hyperthermia typically occurs 30 minutes after induction of anesthesia and is associated with a higher mortality rate (Cieniewicz et al, 2019; MHAUS, 2020).*
- Recognize that signs and symptoms of malignant hyperthermia typically occur suddenly after exposure to the anesthetic agent and include rapid rise in core body temperature (as much as 1°C–2°C every 5 minutes [approximately 1.8°F–3.6°F]), hypercarbia (increase in end tidal carbon dioxide), muscle rigidity, masseter muscle spasm, dysrhythmias, tachycardia, tachypnea, rhabdomyolysis, acute kidney injury, and elevated serum calcium and potassium, progressing to disseminated intravascular coagulation and cardiac arrest (Riazi et al, 2018; Cieniewicz et al, 2019).
- ▲ If the client has malignant hyperthermia, begin treatment as prescribed, including cessation of the anesthetic agent and intravenous administration of dantrolene sodium, STAT, along with cooling measures, core body temperature monitoring, hyperventilation with 100% oxygen, antidysrhythmics, and continued support of the cardiovascular system. **EB:** *Dantrolene helps decrease the increased muscle activity associated with malignant hyperthermia and can be lifesaving (Cieniewicz et al, 2019; Riazi et al, 2018).*
- ▲ Recognize that dysrhythmias must not be treated with calcium channel blockers (e.g., verapamil) when the client has malignant hyperthermia. **EB:** *Calcium channel blockers in combination with dantrolene can lead to cardiac arrest (Riazi et al, 2018; Cieniewicz et al, 2019).*
- ▲ Recognize that antipyretics are not recommended. **EB:** *Antipyretics will not be effective for malignant hyperthermia because the hypothalamic set point is normal (Riazi et al, 2018; Cieniewicz et al, 2019).*
- Monitor for reoccurrence of malignant hyperthermia symptoms that correlates with the half-life of dantrolene, typically within 16 hours (Cieniewicz et al, 2019; MHAUS, 2020).
- Provide client and family education when malignant hyperthermia occurs because it is an inherited muscle disorder. **EB:** *Obtaining a thorough health history, including family history of adverse experiences with anesthesia or muscle disorders, is important in identifying clients at risk for malignant hyperthermia. Genetic counseling may also be indicated (Riazi et al, 2018; MHAUS, 2020).*

Neuroleptic Malignant Syndrome

- ▲ Recognize that neuroleptic malignant syndrome is a rare condition associated with clients who are taking typical and atypical antipsychotic agents or after abrupt discontinuation of dopaminergic agonist agents used for Parkinson's disorder (Pileggi & Cook, 2016; Ware et al, 2018). **EB/EBN:** *The most common agents associated with the condition are dopamine-2 inhibiting antipsychotic agents (e.g., haloperidol, fluphenazine, chlorpromazine, quetiapine, risperidone, olanzapine, aripiprazole, asenapine, clozapine, iloperidone, paliperidone, ziprasidone) and dopamine antagonists (e.g., metoclopramide, promethazine, prochlorperazine, droperidol); sudden cessation of dopamine agonists (amantadine, levodopa, lithium, and bromocriptine) has also been associated with neuroleptic malignant syndrome (Pileggi & Cook, 2016; Ware et al, 2018).*
- Watch for signs and symptoms that can range from mild to severe and include a sudden change in mental status, rapid rise in body temperature, muscle rigidity (lead pipe), tachycardia, tachypnea, elevated or labile blood pressure, diaphoresis, urinary incontinence rhabdomyolysis, and acute kidney injury (Kollmann-Camaiora et al, 2017; van Rensburg & Decloedt, 2019).
- ▲ Begin treatment when diagnosed, including cessation of the neuroleptic or dopamine antagonist agent or resumption of dopamine agonist agent that may have been abruptly discontinued; order administration of dantrolene, bromocriptine, amantadine, or benzodiazepine; initiate cooling measures; continue support of the cardiovascular, pulmonary, and renal systems; and electroconvulsive therapy if drug therapy fails or for severe symptoms (Kollmann-Camaiora et al, 2017; van Rensburg & Decloedt; 2019).
- A client health history that reports extrapyramidal reaction to any medication should be further explored for risk of neuroleptic malignant syndrome because this syndrome can occur at any time during a client's treatment with typical and atypical antipsychotic agents (Kollmann-Camaiora et al, 2017; Ware et al, 2018).
- Recognize that clients receiving rapid dose escalation of antipsychotic agents (e.g., haloperidol) intramuscularly for acute treatment of delirium may be at increased risk for neuroleptic malignant syndrome (Kollmann-Camaiora et al, 2017; Ware et al, 2018).

Drug Fever

- Recognize an elevated body temperature in response to a medication ranges from 37.2°C to 42.2°C [98.7°F–108°F) with a typical onset from 7 to 10 days after initiating the medication (Maddock & Connor, 2020).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Recognize individuals suffering from a drug fever will appear clinically well with a lower heart rate relative to the body temperature (relative bradycardia) but may have a maculopapular rash, headache, myalgias, and an elevated eosinophil count (Maddock & Connor, 2020).

▲ Medications most commonly responsible for a drug fever include antimicrobials, antineoplastic agents, anticonvulsants, antiarrhythmics, and dexmedetomidine. **EB:** *Stopping the responsible medication should result in resolution of the fever within 72 hours; if the offending medication is not readily apparent all nonessential medications should be discontinued (Maddock & Connor, 2020).*

Pediatric

- Assess risk factors of malignant hyperthermia including a personal or family history of anesthesia-related complications or death or a history of muscle disorders. **EB:** *There is an increased prevalence of malignant hyperthermia in the pediatric population, and the administration of inhalation anesthesia and succinylcholine is common in this age group (Riazi et al, 2018; MHAUS, 2020).*

▲ Administer dantrolene, provide oxygen and assist with ventilation, monitor heart rate and rhythm, and treat electrolyte and acid-base disorders (i.e., metabolic acidosis) as ordered if malignant hyperthermia is present. **EB:** *Dantrolene and airway management/support are necessary during emergent treatment of malignant hyperthermia (MHAUS, 2020).*

Geriatric

- Help the client seek medical attention immediately if elevated core temperature is present. To diagnose the hyperthermia, assess for possible precipitating factors, including changes in medication, environmental changes, and recent medical interventions or infectious exposures. **EB:** *Older adults are more susceptible to environmentally and medication-induced hyperthermia because of the greater incidence of underlying chronic medical conditions that impair thermal regulation or prevent removal from a hot environment (Jain et al, 2018; Leyk et al, 2019).*
- In hot weather, encourage the client to wear lightweight cotton clothing (Jain et al, 2018; Leyk et al, 2019).
- Provide education on the importance of drinking eight glasses of fluid per day (within their cardiac and renal reserves) regardless of whether they are thirsty, wearing appropriate clothing for the environmental temperature, keeping the head covered, staying home in the afternoon, and avoiding direct sunlight and sitting in a parked vehicle in the sun; assess for the need for and presence of fans or air conditioning. **EB:** *Older adults are more susceptible to a hot environment than younger adults because of a decreased sensitivity to heat, decreased sweat gland function, decreased thirst, and decreased mobility (Jain et al, 2018; Leyk et al, 2019).*
- In hot weather, monitor the older client for signs of heat stroke such as rising temperature, orthostatic blood pressure drop, weakness, restlessness, mental status changes, faintness, thirst, nausea, and vomiting. If signs are present, move the client to a cool place, have the client lie down, give sips of water, check orthostatic blood pressure, spray with lukewarm water, cool with a fan, and seek medical assistance immediately. **EB:** *Older adults are predisposed to heat exhaustion and should be watched carefully for occurrence; if present, it should be treated promptly (Jain et al, 2018; Lipman et al, 2019).*
- During warm weather, help the client obtain a fan or an air conditioner to increase evaporation, as needed. Help the older client locate a cool environment to which they can go for safety in hot weather.
- Take the temperature of the older client in hot weather. **EB:** *Older clients may not be able to tell that they are hot because of decreased sensation.*

Home Care

- Some of the interventions described previously may be adapted for home care use.
- Determine whether the client or family has a functioning thermometer, and know how to use it. Refer to the previous interventions on taking a temperature.
- Help the client and caregivers prevent and monitor for heat stroke/hyperthermia during times of high outdoor temperatures. **EB:** *Preventive measures include minimizing time spent outdoors, use of air conditioning or fans, increasing fluid intake, and taking frequent rest periods (Centers for Disease Control and Prevention [CDC], 2020).*
- To prevent heat-related injury in athletes, laborers, and military personnel, instruct them to acclimate gradually to the higher temperatures, increase fluid intake, wear vapor-permeable clothing, and take frequent rests (Knapick & Epstein, 2019; CDC, 2020).

- In the event of temperature elevation above the adaptive range, institute measures to decrease temperature (e.g., get the client out of the sun and into a cool place, remove excess clothing, have the client drink fluids, spray the client with lukewarm water, fan with cool air, initiate emergency transport). **EB:** *Hyperthermia is an acute and possibly life-threatening situation (Lipman et al, 2019; CDC, 2020).*

Client/Family Teaching and Discharge Planning

▲ Instruct to increase fluids to prevent heat-induced hyperthermia and dehydration in the presence of fever. **EB:** *Liberal fluid intake replaces fluid lost through perspiration and respiration (Knapick & Epstein, 2019; Lipman et al, 2019).*

- Teach the client to stay in a cooler environment during periods of excessive outdoor heat or humidity. If the client does go out, instruct them to avoid vigorous physical activity; wear lightweight, loose-fitting clothing; and wear a hat to minimize sun exposure. **EB:** *Such methods reduce exposure to high environmental temperatures, which can cause heat stroke and hyperthermia (Jain et al, 2018; CDC, 2020).*

Hypothermia

Domain 11 Safety/protection Class 6 Thermoregulation

Rosemary Timmerman, DNP, APRN, CCNS, CCRN-CSC-CMC

NANDA-I

Definition

Core body temperature below normal diurnal range in individuals > 28 days of life.

Defining Characteristics

Acrocyanosis; bradycardia; cyanotic nail beds; decreased blood glucose level; decreased ventilation; hypertension; hypoglycemia; hypoxia; increased metabolic rate; increased oxygen consumption; peripheral vasoconstriction; piloerection; shivering; skin cool to touch; slow capillary refill; tachycardia

Related Factors

Alcohol consumption; excessive conductive heat transfer; excessive convective heat transfer; excessive evaporative heat transfer; excessive radiative heat transfer; inactivity; inadequate caregiver knowledge of hypothermia prevention; inadequate clothing; low environmental temperature; malnutrition

At-Risk Population

Economically disadvantaged individuals; individuals at extremes of age; individuals at extremes of weight

Associated Conditions

Damage to hypothalamus; decreased metabolic rate; pharmaceutical preparations; radiotherapy; trauma

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Thermoregulation; Thermoregulation: Newborn

Example NOC Outcome with Indicators

Thermoregulation as evidenced by the following indicators: Increased skin temperature/Decreased skin temperature/Skin color changes/Dehydration/Hypothermia. (Rate the outcome and indicators of **Thermoregulation:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain body temperature within normal range
- Identify risk factors of hypothermia
- State measures to prevent hypothermia
- Identify symptoms of hypothermia and actions to take when hypothermia is present
- If hypothermia is medically induced client/family will state goals for hypothermia treatment

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Hypothermia Treatment; Temperature Regulation; Temperature Regulation: Intraoperative; Vital Signs Monitoring

Example NIC Activities—Temperature Regulation

Institute use of a continuous core temperature-monitoring device, as appropriate; Promote adequate fluid and nutritional intake

Nursing Interventions and *Rationales*

Temperature Measurement

- Recognize hypothermia as a drop in core body temperature to 35°C (95°F) or lower (Zafren, 2017; Dow et al, 2019).
- Measure and record the client's temperature hourly or, if the client's temperature is less than 35°C (95°F), continuously. **EB:** *Ongoing temperature measurements are needed for timely treatment decisions (Paal et al, 2016; Zafren, 2017).*
- Select a core or a near core measurement site based on the clinical situation and ability to obtain an accurate measurement; verify the temperature reading with a second monitoring device as needed. **EB:** *Hypothermia can be a life-threatening crisis, and obtaining an accurate temperature measurement is essential for detecting hypothermia and monitoring the client's response to treatment. A core temperature measurement from a pulmonary artery catheter is considered the gold standard, but it is often not practical and may precipitate dysrhythmias in hypothermic clients. A probe placed in the distal esophagus correlates with the pulmonary artery temperature and can be used when the client has a decreased level of consciousness and the upper airway is secured. An indwelling urinary catheter with a temperature probe allows for simultaneous measurement of bladder temperatures and urine output but may not be accurate with a low urine output. Rectal and bladder probes provide near core temperature readings but may lag behind core temperatures during rapid cooling and rewarming. Tympanic measurements may give falsely low readings in clients with unstable or absent circulation; oral, skin, and temporal artery temperatures are inaccurate in hypothermic states (Paal et al, 2016; Zafren, 2017).*
- Use the same site and method (device) for a given client so that temperature trends are accurately assessed. **CEB:** *There are differences in temperature measurements depending on the site from which the temperature measurement is obtained; however, differences between sites should not be more than 0.3°C to 0.5°C (32.5°F–32.9°F)* (*Makic et al, 2011*).
- See the care plan for Ineffective **Thermoregulation** as appropriate.

Accidental Hypothermia

- Recognize that there are three categories of hypothermia based on the core temperature (Dow et al, 2019): mild—35°C to 32°C *(95°F–89.6°F),* where the individual is conscious and shivering; moderate—32°C to 28°C *(89.6°F–82.4°F),* where the individual exhibits altered mental status, paradoxical undressing, and loss of shivering and where thermoregulatory mechanisms are less effective, necessitating the application of exogenous heat; and severe—less than 28°C *(82.4°F),* resulting in unconsciousness, loss of shivering, and increased risk of cardiac arrest.
- Remove the client from the cause of the hypothermic episode (e.g., cold environment, cold or wet clothing), bring into a warm environment, cover the client with warm blankets, and apply a covering to the head and neck to conserve body heat. **EB:** *Layering of dry clothing, including wearing a hat, can be effective in warming a client with mild hypothermia; the goal is also to prevent any further heat loss (Zafren, 2017; Dow et al, 2019).*
- Keep the moderately and severely hypothermic client horizontal, limit limb movement, and handle gently during movements. **EB:** *Because cold myocardial tissue is irritable, rough or sudden movements or movement of the limbs of hypothermic clients can precipitate lethal ventricular dysrhythmias; a vertical position may cause severe cardiovascular stress* (*Zafren, 2017*; *Dow et al, 2019*).
- Monitor the client for signs of hypothermia: shivering, slurred speech, confusion, clumsy movements, fatigue progressing to a further decrease in level of consciousness, bradycardia, hypoventilation, hypotension, ventricular fibrillation, and asystole (Rischall & Rowland-Fisher, 2016; Zafren, 2017).
- Monitor the client's vital signs every hour and as appropriate, noting changes associated with hypothermia such as increased pulse rate, respiratory rate, and blood pressure, as well as diuresis with mild hypothermia, progressing to a decreased pulse rate, respiratory rate, and blood pressure, and oliguria with moderate to severe hypothermia. **EB:** *With mild hypothermia, the sympathetic nervous system is activated, which increases the heart rate and respiratory rate; as hypothermia progresses, decreased circulating volume develops, which results in decreased cardiac output and decreased oxygen delivery. Hypoxia, metabolic acidosis, and intrinsic irritability of a cold myocardium result in dysrhythmias (Zafren, 2017; Dow et al, 2019).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ Attach electrodes and a cardiac monitor, increase the gain (QRS amplitude), and monitor for dysrhythmias. **EB:** *With hypothermia, the client is prone to dysrhythmias because of the cold myocardium; dysrhythmias may include atrial fibrillation, ventricular fibrillation, or asystole (Paal et al, 2016; Zafren, 2017).*

▲ Recognize that clients with a core temperature less than 30°C (86°F) are at a higher risk for cardiac arrest; if the client arrests:
- ❍ Check the pulse for up to 1 minute because the pulse may be slow and weak.
- ❍ Provide chest compressions unless the client has a frozen noncompressible chest.
- ❍ Deliver ventilations at the same rate as recommended for a normothermic client if an advanced airway is not in place. If an advanced airway is in place, use an end-tidal CO_2 monitor to guide ventilations or provide ventilations at half the rate recommended for a normothermic client to avoid hyperventilation.
- ❍ Limit defibrillations to one attempt at maximal power for clients with ventricular fibrillation or pulseless ventricular tachycardia until the client's core temperature is at least 30°C (86°F).
- ❍ Medications may be withheld until the client has a core temperature greater than 30°C (86°F); double the interval between doses once the temperature is above 30°C (86°F); resume normal doses of medications once the temperature reaches 35°C (95°F).
- ❍ Recognize prolonged cardiopulmonary resuscitation may be necessary as the client is rewarmed.

EB: *Defibrillation and medications are less effective in the moderately or severely hypothermic client (Dow et al, 2019). Resuscitative efforts may be withheld if the client's serum potassium is greater than 12 mmol/L (12 mEq/L) from blood drawn from a central vein because a higher serum potassium level indicates that hypoxia and cell lysis preceded hypothermia (Pasquier et al, 2019; Rathjen et al, 2019).*

▲ Monitor for signs of coagulopathy (e.g., oozing of blood from any open areas or from intravascular catheter sites or mucous membranes) and note the results of clotting studies as available. **EB:** *Coagulopathy is a common occurrence during hypothermia because of reduced platelet function and coagulation enzymatic activity (Paal et al, 2016; Rischall & Rowland-Fisher, 2016).*

● Assess for localized cold injuries such as frostbite.

● For mild hypothermia (core temperature of 32.2°C–35°C [90°F–95°F]), rewarm client passively:
- ❍ Set room temperature to 21°C to 24°C (70°F–75°F).
- ❍ Keep the client dry; remove any damp or wet clothing.
- ❍ Layer clothing and blankets and cover the client's head.
- ❍ Offer warm fluids, particularly beverages high in carbohydrates for clients who are shivering and able to safely swallow; avoid alcohol or caffeine; avoid fluids that are so warm they might burn the esophagus (Zafren, 2017; Dow et al, 2019).

● For mild hypothermia, allow the client to rewarm at his or her own pace as heat is generated through the normal metabolism; *warm fluids help reduce further heat loss and carbohydrates help fuel metabolic processes (Rischall & Rowland-Fisher, 2016; Zafren, 2017).*

▲ For moderate hypothermia (core temperature 28°C–32.1°C [82.4°F–90°F]) or any client with a decreased level of consciousness, use active external rewarming methods, not exceeding an increase of more than 1°C to 2°C (approximately 1.8°F–3°F) per hour. **EB:** *Passive rewarming is not recommended for clients with temperatures lower than 32.2°C (90°F) because it is a slow process, requires sufficient glycogen stores to be used by the client's body, and may increase oxygen consumption, increasing the risk of adverse cardiac events (Zafren, 2017; Dow et al, 2019).*

● Methods to rewarm the client include the following (Dow et al, 2019; Rathjen et al, 2019):
- ❍ Forced-air warming blankets
- ❍ Circulation of warm water through external pads
- ❍ Heated and humidified oxygen (42°C–46°C [107.6°F–114.8°F]) through the ventilator circuit as ordered
- ❍ Warmed (40°C–42°C [104°F–107.6°F]) intravenous (IV) normal saline and blood products using a commercial IV fluid warmer (hypothermic clients cannot metabolize lactate so IV lactated Ringer's should not be administered)
- ❍ Radiant heat sources; concentrate heat to axillae and upper torso

▲ For severe hypothermia (core temperature below 28°C [82.4°F]), use active core rewarming techniques as ordered (Dow et al, 2019; Rathjen et al, 2019):
- ❍ Hemodialysis
- ❍ Intravascular temperature management catheter
- ❍ Body cavity (thorax, peritoneal, stomach, and bladder) lavage with warmed fluid

- ❍ Recognize that warming by extracorporeal life support (ECLS) using venoarterial extracorporeal membrane oxygenation (ECMO) or cardiopulmonary bypass is essential for clients experiencing hemodynamic instability or hypothermic cardiac arrest

- ● Rewarm clients slowly, generally at a rate of 1°C to 2°C every hour (approximately 1.8°F–3.6°F). **EB:** *Slow rewarming helps prevent a phenomenon called "afterdrop," in which cold, hyperkalemic blood from the periphery returns to the heart, resulting in a biochemical injury, leading to dysrhythmias and severe hypotension (Zafren, 2017; Dow et al, 2019).*
- ● Measure the blood pressure frequently when rewarming and monitor for hypotension. **EB:** *As the body warms, formerly vasoconstricted vessels dilate, resulting in hypotension; dehydration from cold diuresis worsens hypotension (Zafren, 2017).*
- ● After rewarming, monitor the client for afterdrop, or a decrease in body temperature due to return of colder blood from the periphery to the core.
- ▲ Administer isotonic IV normal saline warmed to 40°C to 42°C [104°F–107.6°F] as prescribed. **EB:** *Significant amounts of IV fluids are often needed to maintain adequate perfusion to vital tissues and organs because of hypovolemia from cold diuresis and vasodilation from rewarming; warmed IV fluid does not significantly raise the body temperature but does help prevent further heat loss (Rischall & Rowland-Fisher, 2016; Zafren, 2017).*
- ● Place a barrier between the client and the heating blanket and monitor the client's skin every 30 minutes. **EB:** *Cold skin is susceptible to pressure and thermal injury (Zafren, 2017; Dow et al, 2019).*
- ● Determine the factors leading to the hypothermic episode, particularly if the client fails to rewarm, and treat the underlying condition; see Related Factors. **EB:** *It is important to assess risk factors and precipitating events to prevent another incident of hypothermia and detect and treat underlying disease processes that impede thermoregulation (Rischall & Rowland-Fisher, 2016).*
- ▲ Request a social service referral to help the client obtain the heat, shelter, and food needed to maintain body temperature. **EB:** *A preventive approach that includes adequate food and fluid intake, shelter, heat, and clothing decreases the risk of hypothermia.*
- ▲ Encourage proper nutrition and hydration. **EB:** *Request a referral to a dietitian to identify appropriate dietary needs; insufficient calorie and fluid intake predisposes the client to hypothermia, especially in older adults (Rischall & Rowland-Fisher, 2016).*

Targeted Temperature Hypothermia

- ● Recognize that targeted temperature management, previously called therapeutic hypothermia, is the active lowering of the client's body temperature, in a controlled manner, to preserve neurological function after a cardiac arrest; targeted temperature management may also be considered for clients who have refractory intracranial hypertension. **EB:** *In the event the client is successfully resuscitated after a cardiac arrest, recognize that medically induced targeted temperature management has been shown to provide neurological protection against ischemic neuronal injury after cardiac arrest (Donnino et al, 2016; Cook, 2017).*
- ● Recognize that controlled cooling of clients should be considered for all unconscious survivors of in-hospital or out-of-hospital cardiac arrest with an initial shockable (ventricular fibrillation or pulseless ventricular tachycardia) or nonshockable (asystole or pulseless electrical activity) rhythm; achieve and maintain a constant target temperature between 32°C and 36°C (89.6°F–96.8°F) for at least 24 hours. **EB:** *The American Heart Association and the International Liaison Committee on Resuscitation have included therapeutic hypothermia as an intervention to be considered in the management of cardiac arrest clients to optimize neurological outcomes after return of spontaneous circulation (Donnino et al, 2016; Geocadin et al, 2017).*
- ● Monitor core or near core temperatures continuously using two methods of temperature monitoring. To ensure that the targeted temperature is achieved and maintained closely within the prescribed temperature range, two methods of core or near core temperature monitoring are recommended (*Cook, 2017*; *Taccone et al, 2020*).
- ● Recognize that cooling may be achieved noninvasively, using fluid-filled cooling pads or with an esophageal cooling catheter, or invasively, with an intravascular cooling catheter. **EB/EBN:** *Invasive cooling and surface cooling devices with temperature feedback mechanisms provide a more predictable and rapid cooling, minimizing adverse electrolyte shifts and shivering. Less optimal methods of cooling include the use of fans, ice packs, or blankets, which do not provide temperature regulation feedback between the machine and client (Calabró et al, 2019; Taccone et al, 2020).*
- ● Monitor for signs of infection and implement measures to prevent hospital-acquired infections. **EB:** *Hypothermia places the client at higher risk for infection because of immunosuppression (Cook, 2017; Wright et al, 2020).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Obtain vital signs hourly (or via continuous monitoring) and include continuous electrocardiogram monitoring, and observe for signs of hypotension, bradycardia, and dysrhythmias. Mechanical ventilation is required to protect the client's airway and breathing during treatment. **EB:** *Diuresis is more pronounced during the induction of hypothermia; hypotension may be more prominent as the client is rewarmed because of vasodilation, requiring close monitoring and interventions to support blood pressure. Bradycardia associated with hypothermia is often not responsive to atropine but does not need to be treated unless the client is hemodynamically unstable. If the client is overcooled (temperature drops below 32°C [89.6°F]), the risk of dysrhythmias will increase and ventricular fibrillation refractory to defibrillation may occur at temperatures below 30°C [86°F] (Cook, 2017; Wright et al, 2020).*
- ▲ Observe for shivering using a tool such as the Bedside Shivering Assessment Scale (BSAS) and implement skin counter-warming with blankets or a forced warm-air device; administer sedatives, opioids, neuromuscular blocking agents, α-agonists, buspirone, acetaminophen, nonsteroidal antiinflammatory agents, or magnesium sulfate as prescribed. **EB:** *Shivering typically occurs as the client transitions between 37°C and 35°C [98.6°F–95°F] and significantly increases the body's metabolic rate and oxygen consumption (Armahizer et al, 2020; Taccone et al, 2020).*
- ▲ Closely inspect the skin before and throughout the cooling intervention and implement frequent turning and other pressure reduction interventions as indicated. **EB:** *Lowering the body temperature causes vasoconstriction and can compromise perfusion to the skin, increasing the client's risk of skin breakdown and impaired wound healing (Cook, 2017; Ahtiala et al, 2018).*
- ▲ Monitor and treat serum electrolytes (e.g., potassium, magnesium, calcium, phosphorus) and serum glucose closely during targeted hypothermia and during rewarming of the client; electrolytes will fluctuate as the client is rewarmed. **EB/EBN:** *Hypokalemia can occur during the induction phase of targeted temperature management as potassium moves intracellularly and is also lost through diuresis; as the client is rewarmed, electrolyte replacements, especially potassium replacements, should be closely monitored to prevent rebound hyperkalemia that may occur as the body temperature rises (Cook, 2017; Wright et al, 2020).*
- ▲ Monitor blood cell counts and observe for signs and symptoms of coagulopathy during targeted hypothermia treatment. **EB:** *For every 1°C (approximately 1.8°F) decline in temperature, the hematocrit may increase by approximately 2%, requiring monitoring but not treatment. Platelet counts decrease during hypothermic states, but research has not found a significant risk of bleeding during targeted hypothermia treatment (Walker & Johnson, 2019; Wright et al, 2020).*
- Rewarming should occur in a controlled manner, with a rise in body temperature no faster than 0.5°C (approximately 0.9°F) per hour and a targeted goal of normothermia, 37°C [98.6°F] for 48 hours. **EB:** *Aggressive rewarming may cause rebound hyperthermia, cerebral edema, seizures, hypotension, and ventricular fibrillation; hyperthermia during the 36 hours after a cardiac arrest is associated with worse neurological outcomes and a higher mortality rate (Taccone et al, 2020; Wright et al, 2020).*
- ▲ Neurological and cognitive function should be assessed during targeted temperature treatment and after rewarming. **EB:** *The goal of targeted temperature treatment is neurological protection; close monitoring of neurological function after intervention and serial assessments are indicated (Donnino et al, 2016; Geocadin et al, 2017).*

Pediatric

- Recognize that pediatric clients have a decreased ability to adapt to temperature extremes; take the following actions to maintain body temperature in the infant/child:
  - ❍ Keep the head covered.
  - ❍ Use blankets to keep the client warm.
  - ❍ Keep the client covered during procedures, transport, and diagnostic testing.
  - ❍ Keep the room temperature at 22.2°C (72°F) for children and between 23°C and 25°C[73.4°F–77°F] for infants less than 32 weeks' gestation.
- The combination of a relatively smaller body surface area, smaller body fluid volume, less well-developed temperature control mechanisms, and smaller amount of protective body fat limits the infant's and child's ability to maintain normal temperatures (Sgro et al, 2016; Shah & Madhok, 2019).
- For the preterm or low-birth-weight newborn, set the room temperature to 25°C (77°F) before the delivery; dry the infant; wrap in prewarmed, dry blankets; cover the infant's head with a wool or polyethylene cap; and use specially designed bags, skin-to-skin care, TransWarmer mattresses, radiant warmers, and thermal blankets to keep the infant warm. **EB/EBN:** *These methods can help keep the vulnerable newborn warm in the delivery room (McCall et al, 2018; Trevisanuto et al, 2018). See care plan for Neonatal* ***Hypothermia****.*

- Avoid bathing neonates for at least 12 to 24 hours after birth when temperature stability is achieved; perform immersion bathing rather than sponge bathing for newborns and swaddled bathing for premature neonates; avoid removing the vernix caseosa and allow it to wear off with normal activity and handling; grossly contaminated vernix caseosa may be gently removed. **EBN:** *Early bathing of a neonate can result in hypothermia; the vernix caseosa protects and moisturizes the skin (Johnson & Hunt, 2019). See care plan for Neonatal* ***Hypothermia****.*
- Targeted hypothermia to 34°C (93.2°F) for 72 hours may be implemented in the treatment of neonates with hypoxic-ischemic encephalopathy (HIE). **EB:** *Cooling may be achieved by selective head cooling or whole body cooling with a cooling blanket (Benedetti & Silverstein, 2018; Schump, 2018). See care plan for Neonatal* ***Hypothermia****.*
- Measure the temperature of the neonate undergoing therapeutic hypothermia for HIE with a rectal or esophageal probe. **EB:** *Although rectal and esophageal temperatures accurately reflect the core body temperature of neonates undergoing targeted hypothermia, axillary temperature measurements do not (Schump, 2018). See care plan for Neonatal* ***Hypothermia****.*

Geriatric

- Normal aging often includes changes in touch-related sensations, making it harder to differentiate cool and cold. *Decreased temperature sensitivity increases the risk of hypothermia in the older adult (Martin, 2016).*
- Recognize that older adults can develop hypothermia even from exposure to mildly cold temperatures of 15.5°C to 18.3°C (60°F–65°F).
  - ❍ Set the room temperature to 20°C to 21.1°C (68°F–70°F).
  - ❍ Instruct client to wear warm clothes as appropriate (long underwear, socks, slippers, and a cap or hat) and to use a blanket to keep shoulders and legs warm while indoors.
  - ❍ Instruct client to dress in loose layers and wear a hat, scarf, and gloves or mittens when going outside during cold weather.
  - ❍ Instruct client to maintain adequate calorie intake.

  EB: *Clients present with vague complaints of mental and/or other skill deterioration (Hypothermia and Older Adults, 2016).*
- Assess neurological signs frequently, watching for confusion and decreased level of consciousness. **CEB:** *Mechanisms to control body temperature decrease with age, coupled with a slower counterregulatory response, lower rate of metabolism, and less effective vascular response, making hypothermia less obvious (Danzl, 2012).*

Home Care

- Hypothermia is not a symptom that appears in the normal course of home care, but when it occurs it is a clinical emergency, and the client/family should access emergency medical services immediately.
- Some of the interventions described earlier may be adapted for home care use.
- Before a medical crisis occurs, confirm that the client or family has a thermometer that registers accurately, and the client or family can read it.
- Instruct the client or family to take the temperature when the client displays cyanosis, pallor, or shivering.

▲ Monitor temperature every hour, as noted previously; if the temperature of the client begins dropping below the normal range, apply layers of clothing or blankets, or adjust environmental heat to the comfort level, being careful to not overheat the client. Passive rewarming is the only method of rewarming that is appropriate for home care under normal circumstances.

▲ If temperature continues to drop, activate the emergency system and notify a health care provider. Hypothermia is a clinically acute condition that cannot be managed safely in the home.

▲ If the client is in hospice care or is terminally ill, follow advance directives, client wishes, and the health care provider's orders; keep the client free of pain. The goal of terminal care is to provide dignity and comfort during the dying process.

Client/Family Teaching and Discharge Planning

- Teach the client and family signs of hypothermia and the method of taking the temperature (age appropriate).
- Teach the client methods to prevent hypothermia: wearing adequate clothing, including a hat and mittens; heating the environment to a minimum of 20°C (68°F); and ingesting adequate food and fluid. **EB:** *Simple*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

measures such as layering clothes, wearing a hat, and avoiding extremes in temperature prevent significant heat loss (Hypothermia and Older Adults, 2016).

- Teach clients who engage in cold weather outdoor activities the importance of appropriate clothing, survival skills, and emergency planning.

▲ Teach the client and family about medications such as sedatives, opioids, and anxiolytics that predispose the client to hypothermia (as appropriate). **EB:** *If the client has had hypothermia in the past, using alternative medications is an option if there is no contraindication (Danzl, 2012).*

Risk for Hypothermia

Domain 11 Safety/protection Class 6 Thermoregulation

Rosemary Timmerman, DNP, APRN, CCNS, CCRN-CSC-CMC

NANDA-I

Definition

Susceptible to a failure of thermoregulation that may result in a core body temperature below the normal diurnal range, in individuals >28 days of life, which may compromise health.

Risk Factors

Alcohol consumption; excessive conductive heat transfer; excessive convective heat transfer; excessive evaporative heat transfer; excessive radiative heat transfer; inactivity; inadequate caregiver knowledge of hypothermia prevention; inadequate clothing; low environmental temperature; malnutrition

At-Risk Population

Economically disadvantaged individuals; individuals at extremes of age; individuals at extremes of weight

Associated Conditions

Damage to hypothalamus; decreased metabolic rate; pharmaceutical preparations; radiotherapy; trauma

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for **Hypothermia**.

Neonatal Hypothermia

Domain 11 Safety/protection Class 6 Thermoregulation

Barbara Reyna, PhD, RN, NNP-BC

Definition

Core body temperature of an infant below the normal diurnal range.

Defining Characteristics

Acrocyanosis; bradycardia; decreased blood glucose level; decreased metabolic rate; decreased peripheral perfusion; decreased ventilation; hypertension; hypoglycemia; hypoxia; increased oxygen demand; insufficient energy to maintain sucking; irritability; metabolic acidosis; pallor; peripheral vasoconstriction; respiratory distress; skin cool to touch; slow capillary refill; tachycardia; weight gain <30 g/day

Related Factors

Delayed breastfeeding; early bathing of newborn; excessive conductive heat transfer; excessive convective heat transfer; excessive evaporative heat transfer; excessive radiative heat transfer; inadequate caregiver knowledge of hypothermia prevention; inadequate clothing; malnutrition

At-Risk Population

Low birth weight neonates; neonates aged 0-28 days; neonates born by cesarean delivery; neonates born to an adolescent mother; neonates born to economically disadvantaged families; Neonates exposed to low environmental temperatures; Neonates with high-risk out-of-hospital birth; neonates with inadequate subcutaneous fat; neonates with increased body surface area to weight ratio; neonates with unplanned out-of-hospital birth; premature neonates

Associated Conditions

Damage to hypothalamus; immature stratum corneum; increased pulmonary vascular resistance; ineffective vascular control; inefficient nonshivering thermogenesis; low Appearance, Pulse, Grimace, Activity, & Respiration (APGAR) scores; pharmaceutical preparations

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Thermoregulation; Thermoregulation: Newborn

Example NOC Outcome with Indicators

Thermoregulation as evidenced by the following indicators: Increased skin temperature/Decreased skin temperature/Skin color changes/Dehydration/Hypothermia. (Rate the outcome and indicators of **Thermoregulation:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none

Client Outcomes

Client Will (Specify Time Frame)

- Maintain a body temperature of 36.5°C to 37.5°C (97.7°F–99.5°F)
- Identify risk factors of hypothermia
- State measures to prevent hypothermia
- Identify symptoms of hypothermia and actions to take when hypothermia is present

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Hypothermia Treatment; Temperature Regulation: Monitor Skin Color and Temperature

Example NIC Activities

Promote delayed bathing; Remove wet clothing; Promote adequate fluid and nutritional intake; Monitor vital signs associated with hypothermia in infants

Nursing Interventions and *Rationales*

- At delivery, neonates should be maintained at a temperature of 36.5°C to 37.5°C (97.7°F–99.5°F). Room temperature should be increased to 23°C to 25°C (74°F–77°F). **EB:** *Increasing the temperature of the delivery room can reduce the incidence of neonatal hypothermia (Duryea, 2016; American Academy of Pediatrics & American Heart Association, 2021).*
- Monitor infants at risk for hypothermia and cold stress. **EB:** *Infants at risk for hypothermia include late preterm and preterm infants and small-for-gestational-age infants (Bartal et al, 2021).* **CEB:** *Late preterm infants are at high risk for developing medical complications during hospitalization (Medoff-Cooper et al, 2012).*
- Monitor temperature by skin or axillary measurements using digital/electronic thermometers. **EB:** *Skin temperature changes are an early indication of cold stress (Fanaroff & Klaus, 2013).*
- Reduce risk of hypothermia by avoiding exposure to sources of heat loss, such as exposing wet skin to the air; direct contact with a cold surface; or placing close to a window or cold wall or near open doors or air conditioner vents. **EB:** *Newborns lose heat from the body surface to the environment through convection, radiation, evaporation, and conduction (Trevisanuto et al, 2018).*
- Infants with mild hypothermia (36°C–36.4°C [96.8°F–97.5°F]) can be warmed by being placed skin-to-skin with mother in a warm room. **EB:** *Infants exposed to early skin-to-skin care have improved temperatures and maintain thermal control (WHO, 1997; Nimbalkar et al, 2014).*
- Infants with moderate (32°C–35.9°C [89.6°F–96.6°F]) or severe (<32°C [<89.6°F]) hypothermia should be placed on a radiant warmer or a preheated, double-walled incubator set at 35°C to 36°C (95°F–96.8°F). **EB:** *Physiological alterations occur that result in adverse metabolic events if hypothermia is not corrected (WHO, 1997).*
- Bathing or weighing the infant should be delayed if evidence of cold stress or hypothermia exists. **EB:** *Bathing can cause a drop in the infant's temperature and should be delayed for at least 6 hours after birth (WHO, 1997).* **EBN:** *Delayed bathing for up to 24 hours after birth can reduce the risk of cold stress and hypoglycemia (Chamberlain et al, 2019).*

- Monitor the cold-stressed or hypothermic infant for respiratory distress (grunting, tachypnea, retractions) and hypoglycemia. **EBN:** *Signs of hypothermia can be nonspecific and affect multiple body systems (Vilinsky & Sheridan, 2014).*

Multicultural

- An occlusive plastic wrap or bag at birth can be used in resource-limited settings. **EB:** *Hypothermia can be reduced as compared with standard thermoregulation care without resulting in hyperthermia (Belsches et al, 2013; Leadford et al, 2013).*

Risk for Perioperative Hypothermia

Domain 11 Safety/protection Class 6 Thermoregulation

Kristen A. Oster, DNP, APRN, ACNS-BC, CNOR, CNS-CP

H

NANDA-I

Definition

Susceptible to an inadvertent drop in core body temperature below 36°C/96.8°F occurring one hour before to 24 hours after surgery, which may compromise health.

Risk Factors

Anxiety; body mass index below normal range for age and gender; environmental temperature <21°C/69.8°F; inadequate availability of appropriate warming equipment; wound area uncovered

At-Risk Population

Individuals aged ≥60 years; individuals in environment with laminar air flow; individuals receiving anesthesia for a period >2 hours; individuals undergoing long induction time; individuals undergoing open surgery; individuals undergoing surgical procedure >2 hours; individuals with American Society of Anesthesiologists (ASA) Physical Status classification score >1; individuals with high Model for End-Stage Liver Disease (MELD) score; individuals with increased intraoperative blood loss; individuals with intraoperative diastolic arterial blood pressure <60 mm Hg; individuals with intraoperative systolic blood pressure <140 mm Hg; individuals with low body surface area; neonates <37 weeks gestational age; women

Associated Conditions

Acute hepatic failure; anemia; burns; cardiovascular complications; chronic renal impairment; combined regional and general anesthesia; neurological disorder; pharmaceutical preparations; trauma

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Thermoregulation

Example NOC Outcome with Indicators

Thermoregulation as evidenced by the following indicators: Increased skin temperature/Decreased skin temperature/Skin color changes/Dehydration/Hypothermia. (Rate the outcome and indicators of **Thermoregulation:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain body temperature within normal range

- Identify risk factors of hypothermia
- State measures to prevent hypothermia
- Identify symptoms of hypothermia and actions to take when hypothermia is present
- Be free of surgical site infection

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Hypothermia Treatment; Temperature Regulation; Temperature Regulation: Intraoperative; Vital Signs Monitoring

Example NIC Activities—Temperature Regulation

Institute use of a continuous core temperature-monitoring device, as appropriate; Promote adequate fluid and nutritional intake

H Nursing Interventions and *Rationales*

Temperature Measurement

* ✱ Recognize perioperative hypothermia as a drop in core body temperature below 36°C (96.8°F). Hypothermia can be divided into mild (36°C–34°C [96.8°F–93.2°F]), moderate (33°C–28°C [91.4°F–82.4°F]), and severe (≤28°C [<82.4°F]) (Granum et al, 2019; Centers for Disease Control and Prevention [CDC], 2020; Nordgren et al, 2020).
- Measure the client's temperature frequently, at least every 15 minutes, while the client is undergoing general anesthesia and with changes in client condition (e.g., chills, change in mental status); if more than mild hypothermia is present (temperature lower than 36°C [96.8°F]), use a continuous temperature-monitoring device. Two modes of temperature monitoring may be indicated. Continuous temperature monitoring using an indwelling method of temperature measurement is usually indicated to monitor effectiveness of treating body alterations in core body temperature. **EBN:** *Hypothermia can be a life-threatening crisis that requires accurate temperature measurement. Core temperature is obtained by a pulmonary artery catheter or less invasively from sublingual, the distal esophagus, nasopharyngeal, or direct tympanic sites (Atallah et al, 2020; Aykanat, Broadbent, & Peyton, 2021). Near core temperature measurement sites include oral, bladder, rectal, and temporal artery, and peripheral measurements are obtained by skin surface measurements and in the axilla (Atallah et al, 2020; Shetti & Singla, 2020; Aykanat, Broadbent, & Peyton, 2021). Research is limited on the accuracy of temporal artery, carotid artery, and "zero heat flux" measurements outside normal ranges; however, recent research is demonstrating improved accuracy and reliability (Evron et al, 2017; Morettini et al, 2020; Shetti & Singla, 2020). Axillary temperature is accurate in neonates, but it is not well supported in adults; tympanic membrane measurements and chemical dot thermometers are least accurate and should be avoided in caring for the acutely ill adult client (Mahmoudi et al, 2020; Olasinde et al, 2020). As technology improves, the accuracy and reliability of noninvasive temperature monitoring will make the use of these measures an acceptable choice.*
- Use the same site and method (device) for temperature measurement for a given client so that temperature trends are assessed accurately, and record site of temperature measurement. **EB:** *There are differences in temperature depending on the site (esophageal, oral, bladder, rectal, axillary, or temporal artery); however, differences should not be greater than half a degree (Torossian et al, 2016).*
- Bladder temperature may be used because an indwelling urinary catheter is often inserted in the management of hypothermia to monitor diuresis. **EBN:** *Bladder temperature probes have been shown to be accurate during states of increased diuresis, but measurements may be less accurate when urine volume is low (low rate of diuresis). Temperatures obtained by this method may lag up to 20 minutes during targeted temperature hypothermia interventions (Burlingame & Conner, 2019).*

Unintentional Perioperative Hypothermia

- Keep the client warm throughout the perioperative period (preoperatively, intraoperatively, and postoperatively) to prevent unintentional perioperative hypothermia. **EB:** *Initiating warming interventions preoperatively has been found to assist with normothermia and client comfort (Grote et al, 2020).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Factors that increase the risk of perioperative hypothermia include anesthetic agents, ambient room air temperature, intravenous (IV) fluid infusion, cavity solution irrigation, blood product administration, duration and type of surgical procedure, anemia, extremes of age, neurological disorders, cachexia, minimal covering during surgery, and preexisting conditions (e.g., peripheral vascular disease, endocrine disease, pregnancy, burns, open wounds) (Brodshaug, Tettum, & Raeder, 2019; Bu et al, 2019; Link, 2020; American Society of PeriAnesthesia Nurses [ASPAN], 2021).
- Closely monitoring and preventing unintentional perioperative hypothermia is necessary to prevent adverse client outcomes. **CEB:** *Adverse outcomes include client discomfort, shivering, cardiac events (e.g., arrhythmias), increased catecholamine release, impaired coagulation, altered drug metabolism, impaired wound healing, and impaired immune function (Collins et al, 2019; Grote et al, 2020; ASPAN, 2021).*
- Several interventions should be implemented to prevent unintentional perioperative hypothermia:
  - Use warming booties perioperatively
  - Use warming blankets over and under the client perioperatively
  - Use warming blankets under the client on the operating table
  - Use of reflective blankets
  - Adjust environmental room controls to maintain ambient room temperature between 20°C (68°F) and 25°C (77°F)
  - Use humidified heated breathing circuit
  - Use warmed forced-air blankets preoperatively, during surgery, and in the postanesthesia care unit
  - Use circulating-water mattress
  - Use warmed IV fluids and irrigation solutions
  - Designate responsibility and accountability for thermoregulation

  EBN/EB: *Maintaining the client's temperature during the surgical procedure has been found to be essential in preventing surgical complications, especially surgical site infections. Maintaining normothermia also enhances client comfort (Institute for Healthcare Improvement [IHI], 2012a; Riley & Andrzejowski, 2018; Bu et al, 2019; CDC, 2020; ASPAN, 2021). Preoperative warming should be initiated for any client with a core temperature below 36°C (96.8°F) before induction of anesthesia, whereas preoperative warming for at least 30 minutes for any client may prevent the client from developing hypothermia and positively affect the client to maintain normothermia (Honkavuo & Koivusalo Loe, 2020; Nordgren et al, 2020). Results from previous investigations have shown that a 2°C decrease (approximately 3.6°F) in core temperature triples the incidence of surgical site infection and increases the length of hospital stay by 20% (de Brito Poveda, Oliviera, & Galvão, 2020).*
- Using warmed IV fluids and irrigation solutions during the operative period may assist with reducing the client's risk of unintentional perioperative hypothermia. **EB:** *Researchers found that warmed IV fluids and irrigation solutions assisted with clients' ability to maintain a higher body temperature and reduced the risk for intraoperative hypothermia and postoperative shivering (Giuliano & Hendricks, 2017; Lindahl, 2020).*
- Active warming interventions include the use of warm blankets and forced-air warming devices. **EBN:** *Blankets used for warming clients quickly lose heat. To prevent rapid heat loss from blankets, warming cabinets should be set at 93.3°C (200°F), and reapply blankets frequently (Kelly et al, 2017).* **EBN:** *Actively warming clients with forced-air warming is the most effective method to prevent hypothermia and offers a clinically important reduction in time to achieve normothermia in postoperative clients (Sumida et al, 2019; Nordgren et al, 2020; Özsaban, & Acaroğlu, 2020).*
- A heated humidified breathing circuit can be used intraoperatively to decrease hypothermia. **EB:** *Heated humidified breathing circuits have decreased the severity of hypothermia in clients undergoing thyroid surgery (Park et al, 2017).*
- Watch the client for signs of hypothermia: shivering, slurred speech, confusion, clumsy movements, fatigue, and dehydration. Shivering increases oxygen consumption by about 40%. As hypothermia progresses, the skin becomes pale, muscles are tense, fatigue and weakness progress, breathing is decreased, and pulmonary congestion is present, compromising oxygenation. Pulses are decreased and blood pressure and heart rate decrease, progressing to lethal arrhythmias (e.g., ventricular fibrillation) (Torossian et al, 2016; Danzl, 2018).

▲ Administer oxygen as ordered. **EB:** *Oxygenation is hampered by the change in the oxyhemoglobin curve caused by hypothermia (Danzl, 2018).*

▲ Attach electrodes and a cardiac monitor. Watch for dysrhythmias. **EB:** *With hypothermia, the client is prone to dysrhythmias because of the cold myocardium; dysrhythmias may include atrial fibrillation, ventricular fibrillation, or asystole (Danzl, 2018; Jandu et al, 2020).*

▲ Monitor for signs of coagulopathy (e.g., oozing of blood from any open areas or from intravascular catheter sites or mucous membranes). Also note results of clotting studies as available. **EB:** *Coagulopathy is a common occurrence during hypothermia (Rösli et al, 2020; ASPAN, 2021).*

▲ Monitor for signs of surgical site infection (e.g., increased incisional pain, drainage, poor healing, poor incision approximation). **EB:** *Unintentional perioperative hypothermia has been associated with increased risk of surgical site infections (IHI, 2012a; CDC, 2020 ASPAN, 2021).*

● See care plans for Ineffective **Thermoregulation** and **Hypothermia** as appropriate.

Pediatric

● Interventions implemented in the care of adult clients are similar when providing care to pediatric clients to prevent hypothermia. **EB:** *Keep the head covered, use warm blankets, or force warm air to keep the client warm; maintain normal ambient room temperature in the perioperative units and use warmed IV fluids (IHI, 2012b).* **EBN:** *Children lose their body core temperature at a faster rate than adults. Children with a lower preoperative body temperature are more likely to develop hypothermia during the intraoperative and postoperative periods (Beedle et al, 2017; Lai et al, 2019).*

Home Care

▲ Hypothermia is not a symptom that appears in the normal course of postoperative home care. If the client continues to complain of chills or feeling cold after discharge home from a surgical procedure, provide the client with warm blankets and, if the client is allowed to drink, provide warm fluids by mouth.

▲ Monitor temperature every hour, as noted previously. If the temperature of the client begins dropping below the normal range, apply layers of clothing or blankets, or adjust environmental heat to the comfort level. Do not overheat. Contact a health care provider. **EB:** *Passive rewarming is the only method of rewarming that is appropriate for home care under normal circumstances (Connelly et al, 2017).*

▲ If temperature continues to drop, activate the emergency system and notify a health care provider. **EB:** *Hypothermia is a clinically acute condition that cannot be managed safely in the home.*

Client/Family Teaching and Discharge Planning

✱ Teach the client/family signs of hypothermia and the method of taking the temperature (age appropriate).

▲ Teach the client and family about medications such as sedatives, opioids, and anxiolytics that predispose the client to hypothermia (as appropriate). If the client has had hypothermia in the past, using alternative medications is an option if there is no contraindication (Danzl, 2018).

Disturbed Family Identity Syndrome

Domain 7 Role relationship Class 2 Family relationships

Stacey M. Carroll, PhD, APRN-BC

NANDA-I

Definition

Inability to maintain an ongoing interactive, communicative process of creating and maintaining a shared collective sense of the meaning of the family.

Defining Characteristics

Decisional conflict (00083); disabled family coping (00073); disturbed personal identity (00121); dysfunctional family processes (00063); impaired resilience (00210); ineffective childbearing process (00221); ineffective relationship (00223); ineffective sexuality pattern (00065); interrupted family processes (00060)

Related Factors

Ambivalent family relations; different coping styles among family members; disrupted family rituals; disrupted family roles; excessive stress; inadequate social support; ineffective coping strategies; ineffective family communication; perceived social discrimination; sexual dysfunction; unaddressed domestic violence; unrealistic expectations; values incongruent with cultural norms

At-Risk Population

Blended families; economically disadvantaged families; families experiencing infertility; families with history of domestic violence; families with incarcerated member; families with member experiencing alteration in health status; families with member experiencing developmental crisis; families with member living far from relatives; families with member with history of adoption; families with member with intimacy dysfunction; families with unemployed member; infertility treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Family Social Climate; Family Integrity; Family Coping; Family Functioning

Example NOC Outcome with Indicators

Family Social Climate as evidenced by the following indicators: Works cooperatively to meet family goals/ Promotes cohesion. (Rate the outcome and indicators of **Family Social Climate:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify communication strategies that family members can use to facilitate an improved sense of family identity
- Express feelings and share collective experiences
- Meet physical, psychosocial, and spiritual needs of members
- Support one another and family goals
- Work cooperatively to solve problems

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Family Integrity Promotion; Family Process Maintenance; Family Support

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NIC Activities—Family Integrity Promotion

Collaborate with family in problem solving and decision-making; Facilitate open communication among family members; Identify typical family coping mechanisms

Nursing Interventions and *Rationales*

- Provide family-centered care in all nursing settings to alleviate disturbed family identity. **EB:** *Family members of clients in the intensive care unit (ICU) had depression, anxiety, and posttraumatic stress during the ICU stay, and many had symptoms persisting months later (Harlan et al, 2020).*
- Include family assessment as part of comprehensive nursing assessment to guide appropriate interventions. **EBN:** *Family assessment was a component of implementing a family-centered care approach in acute care (Eustace et al, 2015).*

✱ Assess for clients' self-reports of family dysfunction, particularly noting any reports of abuse or self-injury. **EB:** *Family dysfunction in a community corrections sample was associated with higher suicide risk (Clark et al, 2016).*

- Apply theoretical models to understand family dynamics and communication patterns. **EB:** *The Family Communication Pattern Theory (FCPT) was used to show that a family climate of free conversation combined with stressing homogeneous beliefs is passed on intergenerationally (Rauscher et al, 2020).* **EB:** *Using the Family Adjustment and Adaptation Model to study home-front mothers in military families showed that finding benefits to service can be a positive factor in improving family functioning (Kritikos et al, 2020).*
- Ascertain client's own meaning of family. **EB:** *Gay adoptive parents view family in a way that is socially and culturally constructed and may not follow heteronormative views of family and parenting (Zhang & Chen, 2020).*
- Use established instruments to assess for family communication and functioning. **EB:** *The Revised Family Communication Patterns Scale (RFCP), with three items omitted, was used to measure family members' perception of their family communication patterns (Rauscher et al, 2020).* **EB:** *The Family Coping Questionnaire for Eating Disorders (FCQ-ED) is brief and has good psychometric qualities (Fiorillo et al, 2015).*

▲ Involve families, with client consent, in decision-making processes to facilitate family harmony. **EBN:** *Supporting family involvement in decision-making in cancer care assisted in the adjustment process for the client (Lim & Shon, 2016).* **EBN:** *Families who were aware of clients' end-of-life wishes experienced less decisional conflict (Jeon et al, 2018).*

▲ Consider novel family therapy interventions aimed at coping and reducing relational conflict during periods of extended isolation. **EB:** *A program called Reaching Up, Down, In, and Around is proposed as a unique way for families to foster coping and resilience during the coronavirus pandemic (Fraenkel & Cho, 2020).*

▲ Include early identification of family dysfunction in a comprehensive chronic pain treatment program. **EB:** *Clients with chronic widespread pain had poorer family functioning than those with chronic localized pain (Hayaki et al, 2016).*

Pediatric

- Encourage families to maintain and develop family rituals and traditions. **EB:** *Research suggests that family rituals have a positive impact on child behaviors (Bao et al, 2019).*
- Encourage and support the family to have frequent and regular family meals. **EB:** *Findings from a systematic review of protective factors for disordered eating suggest that family meals promote a healthy family environment around eating (Langdon-Daly & Serpell, 2017).*

Geriatric

- Encourage intergenerational communication among family members. **EB:** *Shared family identity can be fostered by encouraging grandchild-grandparent interactions (Fowler, 2015).*
- Incorporate family interventions for early-onset Alzheimer's disease. **EB:** *Family satisfaction and communication contributed to increased quality of life in clients with early-onset Alzheimer's disease (Lima et al, 2020).*

- Conduct family life review with older adults as they transition to new environments to enhance family relations. **EB:** *Family life review among older adults relocating to assisted living enhanced family relationships during the transition (O'Hora & Roberto, 2019).*

▲ Explore alternative means for family interaction if in-person visits are restricted or not feasible, to maintain connections. **EB:** *Increased phone and email contact with family members resulted in more positive emotions among clients in long-term care who could not receive in-person visits during the coronavirus pandemic (Monin et al, 2020).*

Multicultural

▲ Incorporate multicultural considerations into family therapy. **EB:** *Among families of incarcerated individuals of color, incorporating multicultural family therapy is essential (Tadros et al, 2019).*

- Consider cultural factors in assessing family identity. **EB:** *Culture influenced family identity in the context of severe mental illness (Acero et al, 2017).* **EB:** *Battered women in Ghana often stayed in relationships because of the importance of preserving family social image (Adjei, 2017).*

▲ Be aware of cultural considerations when using instruments to assess family functioning. **EBN:** *The Decisional Conflict Scale in nursing home placement decisions of Chinese family caregivers may not fully capture cultural considerations (Chang et al, 2017).*

- Incorporate faith tenets, as relevant, to strengthen family dynamics. **EB:** *Accessing spiritual and religious values is proposed as a way for families to cope during the coronavirus pandemic (Fraenkel & Cho, 2020).* **EB:** *Family members of clients who had a stroke experienced less burden when they had higher religious coping scores (Kes & Yildirim, 2020).*
- Encourage cultural rituals to enhance expression of family identity. **EB:** *Quinceanera was theorized as a way for Hispanic families to embrace family identity amidst various social contexts (Verdin & Camacho, 2019).*

Home Care

▲ Refer clients with chronic pain and their families for occupational therapy (OT) interventions. **EB:** *OTs can use assertiveness training and occupation-centered interventions to facilitate family communication (Swift et al, 2019).*

- Be sensitive about timing of a family coping intervention. **EB:** Many families of clients in palliative home care declined a nurse-led family coping home care intervention, citing the intervention as being offered too soon in the process (*Ammari et al, 2015*).

Client/Family Teaching and Discharge Planning

▲ Refer families experiencing substance use disorder for family counseling. **EBN:** *Positive family communication patterns led to reduced drug cravings in the client (Badie et al, 2020).* **EB:** *Family cohesion positively influenced family communication in young adults, even when family opioid misuse was present (Alhussain et al, 2019).*

▲ Refer couples to relationship education that includes family social supports in its curriculum. **EB:** *Social support influenced family functioning outcomes in low-income couples attending relationship education (Carlson et al, 2020).*

▲ Refer couples with infertility for specialist consultation. **EB:** *Decisional conflict scores of couples, individually, decreased after a consultation with an infertility specialist (Anguzu et al, 2020).*

Risk for Disturbed Family Identity Syndrome

Domain 7 Role relationship Class 2 Family relationships

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to an inability to maintain an ongoing interactive, communicative process of creating and maintaining a shared collective sense of the meaning of the family, which may compromise family members' health

Risk Factors

Ambivalent family relations; different coping styles among family members; disrupted family rituals; disrupted family roles; excessive stress; inadequate social support; ineffective coping strategies; ineffective family communication; perceived social discrimination; sexual dysfunction; unaddressed domestic violence; unrealistic expectations; values incongruent with cultural norm

At-Risk Population

Blended families; economically disadvantaged families; families experiencing infertility; families with history of domestic violence; families with incarcerated member; families with member experiencing alteration in health status; families with member experiencing developmental crisis; families with member living far from relatives; families with member with history of adoption; families with member with intimacy dysfunction; families with unemployed member

Associated Conditions

Infertility treatment regimen

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching, and References

Refer to care plan for Disturbed **Family** Identity Syndrome.

Disturbed Personal Identity Domain 6 Self-perception Class 1 Self-concept

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CNEcl, CHSE, ANEF, FAAN

NANDA-I

Definition

Inability to maintain an integrated and complete perception of self.

Defining Characteristics

Altered body image; confusion about cultural values; confusion about goals; confusion about ideological values; delusional description of self; expresses feeling of emptiness; expresses feeling of strangeness; fluctuating feelings about self; impaired ability to distinguish between internal and external stimuli; inadequate interpersonal relations; inadequate role performance; inconsistent behavior; ineffective coping strategies; reports social discrimination

Related Factors

Altered social role; cult indoctrination; dysfunctional family processes; gender conflict; low self-esteem; perceived social discrimination; values incongruent with cultural norms

At-Risk Population

Individuals experiencing developmental transition; individuals experiencing situational crisis; individuals exposed to toxic chemical

Associated Conditions

Dissociative identity disorder; mental disorders; neurocognitive disorders; pharmaceutical preparations

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Anxiety Self-Control; Abuse Recovery (Emotional, Physical, Sexual); Body Image; Decision-Making; Distorted Thought Self-Control; Identity; Mutilation; Suicide/Self-Restraint

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NOC Outcome with Indicators

Identity as evidenced by the following indicators: Verbalizes affirmations of personal identity/Exhibits congruent verbal and nonverbal behavior about self/Differentiates self from environment and other human beings. (Rate the outcome and indicators of **Identity:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate new purposes for life
- Show interests in surroundings
- Perform self-care and self-control activities appropriate for age
- Acknowledge personal strengths
- Engage in interpersonal relationships

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Decision-Making Support; Mutual Goal Setting; Self-Awareness Enhancement; Self-Esteem Enhancement; Sexual Counseling; Substance Use Prevention

Example NIC Activities—Self-Esteem Enhancement

Monitor client's statements of self-worth; Encourage client to identify strengths

Nursing Interventions and *Rationales*

- Assess and support family strengths of commitment, appreciation, and affection toward each other; positive communication; time together; a sense of spiritual well-being; and the ability to cope with stress and crisis. **EB:** *Hayes, Maliski, and Warner (2017) discovered through a qualitative study that family is an important support for clients but found that clients are less likely to disclose sensitive health issues when family members are present.* **EB:** *Jagtiani et al (2019) studied family belonging (family meal frequency, strength of family support, and personal identity) and its relationships between the amount of time spent on social networking sites in young adults (n = 2229) and well-being. Well-being was lower for heavy social networking users and those families who had fewer family meals.*

▲ Assess for suicidal ideation and make appropriate referral for clients dealing with mental illness or other risk factors. **EB:** *Dutta et al (2017) completed a large quantitative study about the genetics of suicidal ideation with twins (n = 3906 twins) and nontwins (n = 2016) and found that suicidal ideation was 13.0% for men, 21.8% for women, and no difference between twins and nontwins.* **EB:** *Eikelenboom et al (2019) completed a 6-year longitudinal study assessing predictors of suicide and found the highest risk was for clients with major depressive disorder (MDD), along with younger age, lower education, unemployment, insomnia, antidepressant use, a previous suicide attempt, and current suicidal thoughts predicted a future suicide attempt.*

▲ Assess clients with mood disorders and make appropriate referrals for treatment. **EB:** *Verhoeven et al (2017) compared the Mini International Neuropsychiatric Interview (MINI) with clinical diagnosis for mood disorders and anxiety differentiation and found that agreement between the MINI and clinical diagnoses was moderate but increased for clients with just one diagnosis.* **EB:** *Researchers (Sumiyana & Sriwidharmanely, 2020) examined how proactive personality (confront and transform) mitigated technostress and found that participants who identified as proactive were better able to endure technostress.*

▲ Assess and make appropriate referrals for clients with physical or mental disabilities. **EB:** *A study compared mental health and physical health participants (n = 701) attending an exercise referral program over a 12-month period and found that the mental health participants were more likely to drop out than those with physical health problems, indicating that better referral decisions can be made (Tobi, Kemp, & Schmidt, 2017).* **EB:** *Sultan et al (2020) examined the effects of personality traits and the relationship between religiosity and mental health of university students (n = 372). The results demonstrated that openness to experience and agreeableness as personal traits moderated the relationship between religiosity and mental health.*

▲ Assess clients for substance misuse or addictive behaviors and make appropriate referrals. **EB:** *Nandrino and Gandolphe (2017) studied clients with alcohol use disorder (n = 27) and their self-defining memories (SDMs). Their SDMs disrupt positive memories and negatively affect personal identity and personal goals.* **EB:** *Fenton-O'Creevy and Furnham (2020) studied the relationship between demographic, personality, and attitude and impulsive buying. Results demonstrated that people who were neurotic and extroverts and had low conscientiousness were more likely to be impulse buyers and materialism was akin to their personal identity.*

● Use empathetic communication and encourage the client and family to verbalize fears, express emotions, and set goals. **EBN:** *Families (n = 612) were provided interventions with emphasis on five positive psychology themes, namely, gratitude, flow, happiness, health, and savoring, in a "kitchen project." Results demonstrated that family communication time and frequency of family meal preparation increased with sustainable effects (Ho et al, 2017).* **EB:** *Szwimer et al (2020) used a phenomenological exploratory approach to study female adolescent clients (n = 8) with chronic pain. The participants reported that having engaging hobbies, accepting the incurability of chronic pain, and envisioning a fulfilling future were factors that improved their quality of life.*

● Be present for clients physically or by telephone. **EBN:** *Barrett (2017) completed a grounded theory study about the use of teleconsultation by nurses (n = 17) and found that nursing presence was the core category identified and subcategories of nursing presence were operational, clinical, therapeutic, and social, indicating that nurses provided presence during teleconsultation.* **EB:** *Lindo and Ceballos (2020) studied children's and adolescents' self-expression and career exploration. Using art interventions in case studies, the researchers spent time with the children to assist them with integration of personal identity and career identity variables.*

● Encourage expression of positive thoughts and emotions. **EBN:** *Hughes, Williams, and Shaw (2017) did a literature review (n = 6) about psychological issues faced by teenagers and young adults during cancer treatment, and analysis identified the following themes: anxieties about treatment, concerns regarding the impact on life (feeling restricted and different, the benefits of being sick, facing uncertainty), and coping strategies (positive thinking and problem-solving, support).* **EB:** *Dang et al (2020) used the Multidimensional Perfectionism Scale, Perfectionistic Self-Presentation Scale, Attitudes Towards Seeking Professional Help Scale, and Thoughts About Psychotherapy Survey on 376 community individuals and university students and found that perfectionistic behavior may be an important factor that interferes with seeking and obtaining psychological help when needed.*

● Encourage the client to use coping mechanisms. **EBN:** *Nursing researchers used a cross-sectional study to better understand family satisfaction with health care of their child by measuring support, family quality of life, expressive family functioning, coping strategies, and health care satisfaction in parents (159 mothers and 60 fathers). Results for mothers demonstrated that satisfaction with health care was predicted by family support and their coping strategies, whereas for fathers, satisfaction was predicted by perceived family support, family quality of life, and whether the child had been hospitalized before (Sigurdardottir, Garwick, & Svavarsdottir, 2017).* **EB:** *Bürger Lazar and Musek (2020) investigated how personal parental identity (n = 99) and coping affected the quality of life of children with cancer. Parents with emotion-focused coping skills had a negative effect on the child's well-being.*

● Help clients with serious and chronic conditions to maintain social support networks or assist in building new ones. **EBN:** *Hagedoorn et al (2017) descriptively studied family caregiving of elderly clients (n = 62) with one or more chronic conditions, and themes identified were addressing the clients' social network, which included "social network structure" and "social network support," and addressing coordination of care issues.* **EB:** *Arroyo-Anlló et al (2020) studied clients with Alzheimer's disease and the effect on self-consciousness, because emotions are an integral part of personal identity and "self." The researchers used sensory stimulation such as familiar smells, taste, music, and visuals to promote recall of autobiographical events with positive effects on memory, affective state, and personal identity.*

▲ Refer women facing diagnostic and curative breast cancer surgery for psychosocial support. **EB:** *A literature review (n = 190) about breast cancer treatment for African women found that breast tumors are diagnosed at earlier ages and later stages than in high-income countries, and there is a higher prevalence of triple-negative cancers. Lack of nursing care, inadequate access to radiotherapy and surgery, and poor availability of systemic therapies produce poor survival rates (Vanderpuye et al, 2017).* **EB:** *Rochefort et al (2019) looked at personal traits and identity associated with health and well-being in women with breast cancer (n = 55). The researchers found that higher conscientiousness and lower neuroticism were associated with better health behaviors and health.*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Refer for cognitive behavioral therapy (CBT). **EBN:** *Choi, Lee, and Cho (2017) used CBT with clients* (n = *76) who had panic disorder and found that it was useful and produced greater positive effects in the acute treatment phase than those they experienced when receiving only routine treatment.* **EB:** *Domhardt et al (2020) completed a meta-analysis of adults with panic attacks or agoraphobia and found 16 studies eligible for evaluation. The conclusion of the meta-analysis lent credence to the use of Internet and mobile-based interventions (IMIs) in adults with diagnosed panic disorder and/or agoraphobia. IMI as a CBT decreased symptoms for clients with panic disorder and/or agoraphobia.*

▲ Refer clients with borderline personality disorder (BPD) and dual-diagnosed BPD and substance misuse for dialectical behavior therapy (DBT) and psychoanalytical-orientated day-hospital therapy. **EB:** *Stepp and Lazarus (2017) did a study to identify dimensions of children* (n = *2450) with temperament and psychopathology symptoms that predict future BPD. Researchers found that parent and teacher ratings of emotionality predicted BPD; therefore early detection may increase care for children with BPD.* **EBN:** *Eckerström et al (2020) competed an interventional qualitative study for clients* (n = *15) diagnosed with BPD. The intervention was a "brief admission" (BA) and provided a timeout, in situations of increased stress and threat, in order to foster self-management in a safe environment. The qualitative interviews of the clients experiencing the BA produced four themes: (1) a timeout when life is tough, (2) it is comforting to know that help exists, (3) encouraged to take personal responsibility, and (4) it is helpful to see the problems from a different perspective.*

▲ Refer to the care plans for Readiness for Enhanced **Communication** and Readiness for Enhanced **Spiritual** Well-Being.

Pediatric

- Encourage adolescents to promote positive self-esteem, to enhance coping, and to prevent behavioral and psychological problems. **EB:** *Zhang, Huebner, and Tian (2020) studied the association of cyberbullying and personality characteristics of early adolescent participants* (n = *3961). The researchers discovered that neuroticism and depression were related personality attributes and that neuroticism predicted cyberbullying victimization and depression predicted both cyberbullying perpetration and victimization.* **EBN:** *Ruhl and Lordly (2017) found that students who are a part of a competitive educational program display a negative effect on personal identity, learning motivation, student collaboration, participation in academic opportunities, and student relationships with faculty.*

▲ Evaluate and refer children and adolescents for eating disorder prevention programs that include medical care, nutritional intervention, and mental health treatment and care coordination. **EBN:** *Kendal et al (2017) qualitatively studied eating disorders and social media (400 messages) and found the following online discussion themes: taking on the role of mentor, the online discussion forum as a safe space, friendship within the online forum, flexible help, and peer support for recovery and relapse prevention.* **EB:** *Tsotsi et al (2019) studied maternal anxiety and stress as related to 4-year-olds' (*n = *391) self-regulation. The researchers found a direct correlation between increased maternal anxiety and external behavioral problems.*

- Use computer-mediated support groups to enhance identity formation. **EBN:** *Jackson and Mixer (2017) used Apple iPads in a pilot study for pediatric clients and families who spoke Spanish and found it assisted in bedside communication, and the results assisted in developing a larger-scale communication interface.* **EB:** *Strøm et al (2019) completed a study that examined Internet support groups (ISGs) for clients who experienced lumbar spine fusion* (n = *48). ISGs qualitative analysis identified the following thematic categories: social recognition, experience of pain, experience of physical activity, psychosocial well-being, exploring the ISG, and employment, which correlated with reports of anxiety and depression.*

Geriatric

- Evaluate the effectiveness of nursing interventions used to promote positive self-identify in older adults. **EBN:** *A descriptive study about applying a therapeutic relationship to people* (n = *112) with a common mental disorder found that the nursing therapeutic relationship in mental health transcends the area of specialty and builds client coping strategies and helps clients make changes in daily life (Nóbrega et al, 2017).* **EB:** *Steenhaut et al (2020) studied psychological flexibility and its relation to well-being in young (less than 60 years old) and older (more than 60 years old) participants. The results demonstrated that psychological flexibility (being open minded and having the ability to make flexible choices) was associated with well-being.*
- Encourage clients to discuss their "life histories." Life history–based interventions and self-esteem and life-satisfaction questionnaires may be used to reinforce personal identity and foster hope. **EBN:** *Tamura-Lis (2017) used reminiscing as an effective evidence-based tool in understanding and treating older adults.*

Reminiscing has demonstrated that it improves communication and socialization. **EB:** *Hausknecht et al (2019) used digital storytelling to provide older adults with an opportunity to tell their life history. Results from the focus group interviews demonstrated social and emotional benefits, including social connectedness through shared experience and story, reminiscence and reflecting on life, and creating a legacy.*

▲ Refer the older client to support groups. **EB:** *Canata Becker et al (2017) studied telephone support for diabetic control in elderly clients compared with clients in a group with written materials and found the telephone group had better metabolic results in glucose level and blood pressure.* **EB:** *Wiles et al (2019) explored qualitatively older adults' (n = 76) experiences of a befriending service, among service users and non–service users, drawing on interviews and focus groups. Results suggest that befriending services helped alleviate social isolation and loneliness and connect them to needed support services.*

▲ Refer the client with Alzheimer's disease who is terminally ill to hospice. **EBN:** *Schaustz Bom, Chaves Sá, and da Silva Serejo Cardoso (2017) studied overload in caregivers (n = 53) of the elderly and found that 45.3% of the caregivers presented with moderate overload, 13.2% presented with moderate to severe overload, 3.8% presented with severe overload, and 32.1% presented with no overload, indicating the need for supportive care.* **EB:** *Saari et al (2020) studied the reporting of memory loss symptoms between clients (n = 3198) with dementia and their informant. The results revealed that informant information only captured the more visible symptoms of Alzheimer's disease and did not often report the hopelessness and worthlessness reported by many Alzheimer clients.*

I

Multicultural

- Assess an individual's sociocultural background in teaching self-management and self-regulation as a means of supporting hope and coping. **EB:** *Meca et al (2017) qualitatively studied recent Hispanic adolescent immigrants (n = 302) in the United States and found that personal identity associated with the United States predicted positivism and decreased antisocial behavior.*
- Decrease discrimination to promote positive ethnic identity. **EB:** *Researchers studied ethnic identity development of East Asian adolescents (n = 13) and found that five themes emerged in their qualitative study: ethnic/cultural identity and socialization, bicultural living, racial context–racism and stereotypes, family context–parental expectation, and peer context–friendship/dating. Participants experienced hurtful racial discrimination but experienced ethnic identity at home (Yoon et al, 2017).*
- Refer to care plan for Ineffective **Coping.**

Home Care

- The interventions described previously may be adapted for home care use.
- Provide an Internet-based health coach to encourage self-management for clients with chronic conditions such as depression, impaired mobility, and chronic pain. Use computer-mediated support groups to enhance identity formation. **EB:** *Researchers studied using the Internet to treat social anxiety disorder (SAD) in participants (n = 42) randomized into two groups. One group had therapy support. Both groups decreased symptoms of SAD, and the group with the therapist interventions had a lower attrition rate (Gershkovich et al, 2017).*

▲ Refer the client to mutual health support groups. Participating in mutual health support groups led to enhanced coping by improving psychological and social functioning. **EB:** *Urbanoski, van Mierlo, and Cunningham (2017) used social network analysis to examine online support groups for clients with drinking addictions (n = 711) and found that active members were older and after 5 years the online support group was cohesive and stable.*

▲ Refer cancer clients and their spouses to family programs that include family-based interventions for communication, hope, coping, uncertainty, and symptom management. **EB:** *A qualitative study explored the role of family members (n = 41) with cancer clients in the communication process, and all clients and family members preferred open communication with physicians. The study discussed the importance of family for physical and psychological care and discovered that there needed to be a balance between client autonomy and relatives' desire to be protective (Datta et al, 2017).* **EB:** *Oyibo and Vassileva (2019) studied personality traits on users' susceptibility to social influence (n = 350). The results demonstrated that neuroticism is the most consistent determinant of users' susceptibility to social influence, followed by openness and conscientiousness.*

- Refer combat veterans and service members directly involved in combat, as well as those providing support to combatants, including nurses, for mental health services. **EB:** *Gould et al (2017) developed*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

a telephone-based program for older veterans to reduce loneliness and qualitatively found that it benefited socialization, which included connectedness, learning from others, being active despite limitations, and distraction from limitations.

Client/Family Teaching and Discharge Planning

- Teach the client about available community resources (e.g., therapists, ministers, counselors, self-help groups, family education groups). **EBN:** *Kangovi et al (2017) examined whether community health worker interventions improved outcomes in a low-income population* (n = *302) with multiple chronic conditions. They found that using a standardized intervention improved chronic disease control, mental health, and quality of care.*
- Teach coping skills to family caregivers of cancer clients. **EB:** *Blanco et al (2017) studied family environment* (n = *50) in relation to childhood and found that families with obese children had higher trait anxiety, criticism and overprotectiveness, and maladaptive coping skills.*

Risk for Disturbed Personal Identity

Domain 6 Self-perception Class 1 Self-concept

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to the inability to maintain an integrated and complete perception of self, which may compromise health.

Risk Factors

Altered social role; cult indoctrination; dysfunctional family processes; gender conflict; low self-esteem; perceived social discrimination; values incongruent with cultural norms

At-Risk Population

Individuals experiencing developmental transition; individuals experiencing situational crisis; individuals exposed to toxic chemicals

Associated Conditions

Dissociative identity disorder; mental disorders; neurocognitive disorders; pharmaceutical preparations

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Disturbed Personal **Identity**.

Risk for Complicated Immigration Transition

Domain 9 Coping/stress tolerance Class 1 Post-trauma responses

Nadia Ali Muhammad Ali Charania, PhD, RN

NANDA-I

Definition

Susceptible to experiencing negative feelings (loneliness, fear, anxiety) in response to unsatisfactory consequences and cultural barriers to one's immigration transition, which may compromise health.

Related Factors

Abusive landlord; available work below educational preparation; communication barriers; cultural barriers; inadequate knowledge about accessing resources; inadequate social support; non-related persons within household; overcrowded housing; overt social discrimination; parent-child conflicts related to enculturation; unsanitary housing

At-Risk Population

Individuals experiencing forced migration; individuals experiencing labor exploitation; individuals experiencing precarious economic situation; individuals exposed to hazardous work conditions with inadequate training; individuals living far from significant others; individuals with undocumented immigration status; individuals with unfulfilled expectations of immigration

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Relocation Adaptation, Anxiety Level; Fear Level; Loneliness Severity; Coping

Example NOC Outcome with Indicators

Relocation Adaptation as evidenced by the following indicators: Participates in decision-making in new environment/Expresses satisfaction with daily routine/Fear/Loneliness/Anxiety. (Rate the outcome and indicators of **Relocation Adaptation:** 1 = never demonstrated; 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Participate in community activities
- State satisfaction with social relationships, living arrangements, and social integration
- State satisfaction with health status and access to health care
- Demonstrate actions that are congruent with expressed feelings and thoughts
- State sense of belonging
- Accept strengths and limitations of new environment

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Support System Enhancement; Socialization Enhancement; Values Clarification

Example NIC Activities—Risk for Complicated Immigration Transition

Encourage patience in developing relationships; Encourage social and community activities

Nursing Interventions and *Rationales*

- Understand immigrants' perspectives/stories about their health maintenance and illness management. **CEB:** *Nurses are concerned with the life experiences of people and how these life experiences may affect their health and responses to illness. Furthermore, to diagnose and treat immigrants who are ill, we must be able to put their responses within the context of their lives; otherwise, our understanding and interpretation of their responses to illness will be limited (Meleis, 2010).*
- Assess for use of acculturation strategies. **EB:** *The Multicultural Adolescents Panel Study identified four acculturation strategies: marginalization, separation, assimilation, and integration. A one-way analysis of variance showed that life satisfaction was highest for integration and decreased for assimilation, separation, and marginalization (Yoo, 2021).*
- Focus on providing holistic (physical, emotional, psychological, social, and spiritual) care while caring for immigrants. When appropriate, integrate the use of complementary and alternative approaches. **EBN:** *A small study of Indian immigrants in the United States found that participants preferred complementary and alternative medicine home remedies to address their health needs (Joseph et al, 2019).*
- Assess for intergenerational conflict and parental stress. **EB:** *A study of older immigrant parents found that higher parental stress was found among those with greater intergenerational conflict (Mitchell, Wister, & Zdaniuk, 2019).*
- Assist clients to identify coping strategies and sources of social support. **EB:** *A study of international students found that social support and coping were partial mediators of the relationship between acculturation and acculturative stress (Ra & Trusty, 2017).*
- Obtain a professional translator to enhance cross-cultural communication. **EB:** *Culturally competent verbal and nonverbal communication skills should also identify the need for interpretation and translation (Purnell, 2018).*
- Demonstrate cultural humility to achieve cultural competence to offer individualized discharge services to immigrant mothers with their preterm babies from the neonatal intensive care unit. **EB:** *Regardless of the number of years of being in the migrated country, at discharge, immigrant mothers tend to have less discharge readiness; have poor perceptions of infant well-being; have less comfort to be able to care for their preterm babies after discharge in areas such as infant development, sleep, nutrition, and meeting overall medical needs; and struggled with their well-being, including mental health (McGowan et al, 2019).*
- Health care professionals need to identify risks and obstacles that migrant women transitioning to motherhood may be faced with, including poverty, language barriers, loneliness, and limited access to health

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

care, which can contribute to mental health concerns such as stress, anxiety, depression, and social isolation. **EB:** *It was argued that the outlined efforts would enhance migrant mothers' engagement in and benefit from health care services (Aydın, Körükcü, & Kabukçuoğlu, 2017).*

- Nurses working with immigrant clients in psychiatric units need to (1) assess for posttraumatic stress syndrome and associated symptoms, (2) employ compassionate and trauma-informed care, (3) educate about early recognition of mental illness, (4) share information about psychiatric services, (5) use family-oriented and interpreter services often and as needed, and (6) create trusting relationship in the psychiatric community care. **EB:** *The finding of the qualitative study involving nurses' experiences of caring for immigrant clients pointed toward the need for integrating areas identified above; suggested determining care-related challenges and their manifestations of working with such populations; and suggested offering support to nurses in their efforts toward maintaining professional well-being to be able to provide compassionate and needed care (Kallakorpi, Haatainen, & Kankkunen, 2018).*
- Actively engage in policy-driven solutions to mitigate structural racism. Such macrolevel factors shape the health of racial and ethnic minorities. **EB:** *The finding of the study that aimed to understand the influence of a transition from unlawful to lawful status on the psychological well-being of Latino immigrant young adults suggests that well-being is linked to positive and complete social integration (Patler & Pirtle, 2018).*
- Explore immigrant women's experience of menopause and self-management strategies for menopausal symptoms to be able to provide culturally relevant care and enhance their satisfaction with the specific care they received. **EB:** *The systematic review of the limited available literature indicated that compared with nonimmigrant women, immigrant women reported more physical symptoms (e.g., vasomotor symptoms) and poorer mental health. Moreover, immigrant women were mostly not satisfied with the menopause-specific care that they had received (Stanzel, Hammarberg, & Fisher, 2018).*

Pediatric

- Promote self-efficacy of the newly migrated adolescents by supporting their effort to learn and use the language of the migrated country. **EB:** *Evidence suggests that newly migrated adolescents initially have lower levels of self-efficacy than more experienced adolescent immigrants. Language use was found to be imperative in the adaptation process of newly migrated adolescents contributing to their self-efficacy (Titzmann & Jugert, 2017).*
- Assess for mental health consequences among youth from the ethnic and racial minorities of trauma experienced across the migration process (including before, during, and after migration) through the use of culturally sensitive diagnostic tools, and offer treatment services to facilitate a positive transition to healthy adulthood. **EB:** *Evidence suggests that the trauma experienced by Latino youth at different migration stages seemed to be linked with their current mental health symptoms, including anxiety, depression, and posttraumatic stress disorder (Cleary et al, 2018).*
- Recognize and address the specific needs of both immigrant youths with disabilities transitioning to adulthood (e.g., autonomy) and their caregivers' needs (e.g., information about their youths' condition and of available health services). **EB:** *The research with immigrant youths with disabilities and caregivers from the Middle East suggests providing culturally sensitive care focused on offering support and health care–and health management–specific information in their language (Björquist et al, 2017).*

Home Care

- Educate and encourage immigrants' family members to use available home care–specific support services as needed. **EB:** *It is critical to recognize that the immigrated family is faced with both health care system barriers (e.g., discrimination within the health care system and complex bureaucracies) and individual barriers (e.g., limited communication ability, lack of financial resources, and the experience of shame or stigma) when in need of accessing care (Hacker et al, 2015).*

Ineffective Impulse Control

Domain 5 Perception/cognition Class 4 Cognition

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

A pattern of performing rapid, unplanned reactions to internal or external stimuli without regard for the negative consequences of these reactions to the impulsive individual or to others.

Defining Characteristics

Acting without thinking; asking personal questions despite discomfort of others; dangerous behavior; gambling addiction; impaired ability to regulate finances; inappropriate sharing of personal details; irritable mood; overly familiar with strangers; sensation seeking; sexual promiscuity; temper outbursts

Related Factors

Hopelessness; mood disorder; neurobehavioral manifestations; smoking; substance misuse

Associated Conditions

Altered development; developmental disabilities; neurocognitive disorders; personality disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Impulse Self-Control

Example NOC Outcome with Indicators

Impulse Self-Control as evidenced by the following indicators: Identifies harmful impulsive behaviors/Identifies feelings that lead to impulsive actions/Avoids high-risk situations/Controls impulses/Maintains self-control without supervision. (Rate the outcome and indicators of **Impulse Self-Control:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = continually demonstrated [see Section I].)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Client Outcomes

Client Will (Specify Time Frame)

- Be free from harm
- Cooperate with behavioral modification plan
- Verbalize adaptive ways to cope with stress by means other than impulsive behaviors
- Delay gratification and use adaptive coping strategies in response to stress
- Verbalize understanding that behavior is unacceptable
- Accept responsibility for own behavior

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Impulse Control Training

Example NIC Activities—Impulse Control Training

Use a behavior modification plan, as appropriate, to reinforce the problem-solving strategy that is being taught; Teach client to cue himself/herself to "stop and think" before acting impulsively

Nursing Interventions and *Rationales*

- Refer to mental health treatment for cognitive behavioral therapy (CBT). **EB:** *A review identified the efficacy of CBT for treatment of impulse control symptoms in Parkinson's disease (Koychev & Okai, 2017).*
- Assess individuals with impulsive behaviors for exposure to trauma and referral for mental health evaluation. **EB:** *Research indicates that impulsivity is associated with trauma exposure and posttraumatic stress disorder (PTSD) (Netto et al, 2016).*
- Implement motivational interviewing for clients with impulse control disorders. **EB:** *This research review found motivational interviewing helps individuals with gambling addictions work through ambivalence and commit to change (Choi et al, 2017).*
- Teach client mindfulness meditation techniques. Mindfulness meditation includes observing experiences in the present moment, describing those experiences without judgments or evaluations, and participating fully in one's current context. **EB:** *This study showed that developing mindfulness was an effective way of diminishing binge eating, eating psychopathology, and depression and increasing quality of life in women with obesity (Pinto-Gouveia et al, 2016).*
- Refer to self-help groups such as Gambler's Anonymous. **EB:** *This research review found that Gambler's Anonymous is helpful as an adjunct therapy for individuals with gambling addictions (Choi et al, 2017).*
- Use a brief intervention model to screen and provide information and referral to services for clients that may experience at-risk gambling. **EB:** *A pilot study found that when trained, primary care staff were able to screen clients at routine visits for at-risk gambling behavior by using the brief intervention model (Nehlin et al, 2016).*
- Teach clients to use urge surfing techniques when impulses or urges are triggered. **EB:** *This study demonstrated that the mindfulness coping skill of urge surfing was an effective intervention when used by teens experiencing urges to use alcohol (Harris, Stewart, & Stanton, 2017).*
- Teach client to use cue avoidance techniques to reduce impulsive behaviors. **EB:** *This study shows that cue avoidance techniques were successful in reducing alcohol consumption (Di Lemma & Field, 2017).*

Pediatric

- Assess children for environmental lead exposure. **EB:** *This research shows that a 1 mcg/dL increase in average childhood blood lead level significantly predicts a 0.37 (95% confidence interval [CI] = 0.11, 0.64) point increase in adolescent impulsivity (Winter & Sampson, 2017).*

▲ Refer to mental health treatment for CBT. **EB:** *CBT has been beneficial in treating impulse control disorders in pediatric populations (Farrell et al, 2016).*

▲ Refer adolescent clients with impulsive symptoms at risk of self-harm to Dialectical Behavioral Therapy for Adolescents (DBT-A). **EB:** *A systematic review found that behavioral impulsivity is related to self-harm and negative affect. DBT-A includes distress tolerance and problem-solving skills directed toward impulsivity and self-harm (Lockwood et al, 2017).*

Geriatric

- Assess for impulsive symptoms and maintain increased surveillance of the client whenever the use of dopamine agonists has been initiated. **EB:** *Dopamine agonist therapy is related to the development of impulse control disorders in clients with Parkinson's disease (Voon et al, 2017).*
- Implement fall risk screening and precautions for geriatric clients with inattention and impulse control symptoms. **EBN:** *The Marianjoy Fall Risk Assessment tool has internal validity and reliability and includes impulsive behavior as one of the fall risk indicators (Ruroede, Pilkington, & Guernon, 2016).*
- Monitor caregivers for evidence of caregiver burden. **EB:** *A study found that mild behavioral impairment was common in memory clinic clients without dementia and was associated with greater caregiver burden (Sheikh et al, 2018).*

Client/Family Teaching and Discharge Planning

- Families should be encouraged to use practical measures to manage behavior such as limiting access to credit cards and restricting and monitoring Internet access gambling and casino websites, checking medication compliance, reporting behavior typical of impulse control disorders, and transferring control of financial affairs to a partner or other family members. **EB:** *This review showed effective management of impulsive behaviors through client and caregiver education (Zhang et al, 2016).*

Disability-Associated Urinary Incontinence

Domain 3 Elimination and exchange Class 1
Urinary function

Amanda Andrews, BSc (Hons), MA and Bernie St Aubyn, BSc (Hons), MSc

NANDA-I

Definition

Involuntary loss of urine not associated with any pathology or problem related to the urinary system.

Defining Characteristics

Adaptive behaviors to avoid others' recognition of urinary incontinence; mapping routes to public bathrooms prior to leaving home; time required to reach toilet is too long after sensation of urge; use of techniques to prevent urination; voiding prior to reaching toilet

Related Factors

Avoidance of non-hygienic toilet use; caregiver inappropriately implements bladder training techniques; difficulty finding the bathroom; difficulty obtaining timely assistance to bathroom; embarrassment regarding toilet use in social situations; environmental constraints that interfere with continence; habitually suppresses urge to urinate; impaired physical mobility; impaired postural balance; inadequate motivation to maintain continence; increased fluid intake; neurobehavioral manifestations; pelvic floor disorders

At-Risk Population

Children; older adults

Associated Conditions

Heart diseases; impaired coordination; impaired hand dexterity; intellectual disability; neuromuscular diseases; osteoarticular diseases; pharmaceutical preparations; psychological disorder; vision disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Urinary Continence; Urinary Elimination

Example NOC Outcome with Indicators

Urinary Continence as evidenced by the following indicators: Recognizes urge to void/Responds to urge in timely manner/Voids in appropriate receptacle/Underclothing remains dry during day/Underclothing or bedding remains dry during night. (Rate the outcome and indicators of **Urinary Continence:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Eliminate or reduce incontinent episodes on a daily basis
- Eliminate or overcome environmental barriers to toileting on a daily basis
- Use adaptive equipment to reduce or eliminate incontinence related to impaired mobility or dexterity on a daily basis
- Use portable urinary collection devices or urine containment devices when access to the toilet is not feasible on a daily basis

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Urinary Habit Training; Urinary Incontinence Care

Example NIC Activities—Urinary Habit Training

Keep a continence-specification record for 3 days to establish voiding pattern; Establish interval for toileting of preferably not less than 2 hours

Nursing Interventions and *Rationales*

- Introduce yourself to the client and anyone accompanying him or her and inform them of your role. **EB:** *Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the basis for building trust on which to base the provision of care (Ellis et al, 2020).*
- Gain consent to provide care before proceeding further with the assessment. For clients unable to give consent, discuss permission with relevant health care professionals and/or family members. **EB:** *Clients have the right of autonomy both legally and morally and therefore should be fully involved in the decision-making process (Griffith & Tengnah, 2020).*
- Wash hands using a recognized technique. **EB:** *Evidence shows that strict hand hygiene regimens significantly reduce the incidence of methicillin-resistant* Staphylococcus aureus *and* Clostridioides (Clostridium) difficile *infection (Goldberg, 2017).*
- Assess usual pattern of bladder management and establish the extent of the problem to include a detailed and accurate assessment of the client.
- Evaluate the client's bladder habits:
  - Episodes of incontinence during the day and night
  - Alleviating and aggravating factors
- Current management strategies include containing/collection devices, restriction of fluid intake, and avoidance of fluid/food groups that cause bladder irritation. **EB:** *Several types of incontinence exist and since the treatments will vary, it is important that the assessment, also known as "diagnostic evaluation," establishes which type is present. The authors recognize that guidelines should be adapted to individual clients' needs (Nambiar et al, 2018).*
- Complete a Lifestyle and Risk Assessment that includes assessment of toilet access and ability to use, including the following:
  - Distance of the toilet from the bed, chair, and living quarters
  - Characteristics of the bed, including presence of side rails and distance of the bed from the floor
  - Characteristics of the pathway to the toilet, including barriers such as stairs, loose rugs on the floor, and inadequate lighting
  - Characteristics of the bathroom, including patterns of use, lighting, height of the toilet from the floor, the presence of handrails to assist transfers to the toilet, and breadth of the door and its accessibility for a wheelchair, walker, or other assistive devices

  EB: *When assessing different client groups, relevant assessment factors should be considered because standard assessment and treatment pathways may not be appropriate. Examples include older people with cognitive impairment (dementia is strongly associated with urinary incontinence), people with reduced mobility, and women who are pregnant, because the standard assessment and treatment pathways might not be appropriate for them (Stewart, 2018).*
- Assess the client's physical and mental abilities:
  - Ability to rise from chair and bed, transfer to the toilet, and ambulate and the need for physical assistive devices such as a cane, walker, or wheelchair. **EB:** *A study carried out in a nursing home care setting identified a significant association between impaired mobility and urinary incontinence in nursing home residents (Jachan et al, 2019).*
  - Ability to manipulate buttons, hooks, and zippers as needed to remove clothing. **EB:** *It is important to ensure the client is assessed for motor capability as this is integral to the client's ability to maintain continence (Keenan et al, 2018).*
  - Functional and cognitive status assessment should be done using a tool such as the Mini-Mental Status Examination for the older client with functional incontinence. **EB:** *A dementia diagnosis (or severe cognitive impairment) is associated with a higher prevalence of incontinence compared with people without such a diagnosis (Gove et al, 2017). An association has also been observed between incontinence and more severe cognitive impairment and mobility problems (Jerez-Roig et al, 2016).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- ❍ Daily fluid intake, including amount and types of fluids consumed.
- ❍ Risk of falls caused by dizziness, impaired vision, and hearing.
- ❍ Functional ability declines secondary to comorbidities (e.g., cerebrovascular incidents, amputation).

● Discuss quality-of-life issues relating to socialization and family events. **EB:** *The impact on the client's quality of life should not be underestimated. One of the key consequences of urinary incontinence is loss of self-confidence and social isolation (Pizzol et al, 2021).*

● Review the client's medical history:
- ❍ Obstetrical/gynecological/urological history and surgeries
- ❍ Relevant comorbidities such as cardiac, respiratory, renal, or neurological
- ❍ Recurrent urinary tract infections

EB: *Reviewing the client's medical history, considering any significant medical, surgical, obstetric, or genitourinary history, is essential as any identified conditions may affect an individual's ability to maintain continence (Bardsley, 2016).*

● Teach the client, the client's care providers, or the family to complete a bladder diary. Each 24-hour period should be subdivided into 1- to 2-hour periods and include number of urinations occurring in the toilet, actual episodes of incontinence and amount of urine leaked, reasons for episode of incontinence, type and amount of liquid intake, number of bowel movements, and incontinence pads or other products used. **EB:** *Bladder diaries provide accurate data and are more reliable than clients recollections of symptoms. In addition to being inexpensive and low risk, clients view diaries as easy to complete and helpful for their care (Dixon & Nakib, 2016).*

● Consult with the health care provider and complete a medication review relating to side effects and contraindications. **EB:** *Health professionals should review the use of any medication that could affect a client's urine production. Side effects for consideration should include sedation, impaired cognition, or a change in sensation and muscle tone (Bardsley, 2016).*

● Ensure that an appropriate, safe urinary receptacle such as a three-in-one commode, female or male handheld urinal, no-spill urinal, or containment device when toileting access is limited by immobility or environmental barriers is available to assist the client with elimination needs while other interventions are being implemented. **EB:** *Containment is important for people with urinary incontinence and should be considered when active treatment does not cure the problem, when it is not available or not possible, or if the risks of treatment outweigh the benefits to the client (Nambiar et al, 2018). A useful resource for health care professionals and clients can be found at www.continenceproductadvisor.org.*

▲ Refer to occupational therapy for help in obtaining assistive devices and adapting the home for optimal toilet accessibility. **EB:** *Occupational therapists are needed to assist clients with dexterity and mobility issues that may be contributing to incontinence (Spencer, McManus, & Sabourin, 2017).*

● Provide advice to clients relating to loose-fitting clothing with stretch waistbands rather than buttoned or zippered waist; minimize buttons, snaps, and multilayered clothing; and substitute a loop-and-pile closure or other easily loosened systems such as Velcro for buttons, hooks, and zippers in existing clothing. **EB:** *Clients with impaired dexterity or weakness may benefit from clothing that has been modified or is without buttons and zippers (Leaver, 2017).*

● Work with the client on retraining the bladder by regularly timed toileting regimens (every 2 hours). For the older client in the home or a long-term care facility who has functional incontinence and dementia:
- ❍ Determine the frequency of current urination using an alarm system or check-and-change device.
- ❍ Record urinary elimination and incontinent patterns in a bladder log to use as a baseline for assessment and evaluation of treatment efficacy.
- ❍ Begin a prompted toileting program based on the results of this program; toileting frequency may vary from every 1.5 to 2 hours to every 4 hours.
- ❍ Provide positive reinforcement.

EB: *Bladder retraining aims to increase the time in between trips to the toilet by encouraging the clients to "hold on" when they need to go. This aims to improve the client's control of their bladder and this can reduce symptoms of urinary frequency, urinary urgency, and nocturia (Stewart, 2018).*

● Monitor older clients in a long-term care facility, acute care facility, or home for dehydration. **EB:** *Clients may have anxiety about incontinence and intentionally reduce fluid intake as a personal strategy to manage the problem. Such clients need to be monitored regularly as the onset of dehydration has the potential to develop slowly over time (Cook et al, 2019).*

● Inspect the perineal and perianal skin for evidence of incontinence-associated dermatitis, including inflammation, vesicles in skin exposed to urinary leakage, and especially skinfolds or denudation of the

skin, particularly when incontinence is managed by absorptive pads or containment briefs. **EB:** *Skinfolds and the perineal skin are at risk for dermatitis and fungal or bacterial infections (Beeckman, 2017).*

- Begin a preventive skin care regimen for all clients with urinary incontinence and treat clients with incontinence-associated dermatitis or related skin damage. **EB:** *Minimizing exposure to urine; gentle cleansing; moisture protection, preferably with an emollient; and application of a skin protectant are the necessary components of a skin protection program (Beeckman, 2017).*
- Advise the client about the advantages of using disposable or reusable insert pads, pad-pant systems, or replacement briefs specifically designed for urinary incontinence as indicated for short-term/long-term use, including social events. **EB:** *A systematic review identified that the use of incontinence pads is the main conservative behavioral approach to managing continence. They are preferred to invasive management strategies (e.g., catheterization) (Roe, Flanagan, & Maden, 2015).*
- Consider the use of an indwelling catheter for continuous drainage in the client who is both homebound and bedbound and is receiving palliative or end-of-life care (requires a health care provider's order). At end of life, they may be the best choice. **EB:** *Catheters provided relief when mobility was a challenge for clients and getting out of bed was painful. The insertion of an indwelling catheter will not cure incontinence but aligns with the objective of managing symptoms at end of life (Smith et al, 2019).*
- When an indwelling urinary catheter is in place, follow prescribed maintenance protocols for managing the catheter, taping and replacing the catheter, the drainage bag, and care of perineal skin and urethral meatus. Teach infection control measures adapted to the home care setting. **EB:** *Proper care reduces the risk of catheter-associated urinary tract infection (Centers for Disease Control and Prevention, 2021).*
- Assist the client in adapting to the catheter. Encourage discussion of the client's response to the catheter. Research has consistently shown that indwelling catheter users need to be given more information, but some clients still feel poorly informed. **EB:** *Nurses are in a good position to find out what people know and what they need and to ensure that clients have contact phone numbers for further information and details of reliable websites and support organizations (Prinjha et al, 2016).*
- Provide clients with comprehensive written information about the management of continence-related problems. **EB:** *Client information materials and decision aids are essential tools for helping clients to make informed decisions and share in the decision-making process about their care (Posch et al, 2020).*
- Document all care and advice given in a factual and comprehensive manner. **EB:** *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (Andrews & St Aubyn, 2015).*

Mixed Urinary Incontinence

Domain 3 Elimination and exchange Class 1 Urinary function

Amanda Andrews, BSc (Hons), MA and Bernie St Aubyn, BSc (Hons), MSc

NANDA-I

Definition

Involuntary loss of urine in combination with or following a strong sensation or urgency to void, and also with activities that increase intra-abdominal pressure.

Defining Characteristics

Expresses incomplete bladder emptying; involuntary loss of urine upon coughing; involuntary loss of urine upon effort; involuntary loss of urine upon laughing; involuntary loss of urine upon physical exertion; involuntary loss of urine upon sneezing; nocturia; urinary urgency

Related Factors

Incompetence of the bladder neck; incompetence of the urethral sphincter; overweight; pelvic organ prolapse; skeletal muscular atrophy; smoking; weak anterior wall of the vagina

At-Risk Population

Individuals with chronic cough; individuals with one type of urinary incontinence; multiparous women; older adults; women experiencing menopause; women giving birth vaginally

Associated Conditions

Diabetes mellitus; estrogen deficiency; motor disorders; pelvic floor disorders; prolonged urinary incontinence; surgery for stress urinary incontinence; urethral sphincter injury

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Urinary Continence; Urinary Elimination

Example NOC Outcome with Indicators

Urinary Continence as evidenced by the following indicators: Absence of urinary leakage between catheterizations or containment of micturition by condom catheter and drainage bag/Absence of symptomatic urinary tract infection (absence of leukocytes and absence of bacterial growth or >100,000 colony-forming units/mL)/Underclothing dry during day/Underclothing or bedding dry during night. (Rate the outcome and indicators of **Urinary Continence:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Follow prescribed schedule for bladder emptying on a daily basis

- Have intact perineal skin on a daily basis
- Remain clear of symptomatic urinary tract infection on a daily basis
- Demonstrate how to apply containment device or insert intermittent catheter or be able to provide caregiver with instructions for performing these procedures as per individual needs on a daily basis

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Urinary Catheterization: Intermittent; Urinary Elimination Management; Urinary Incontinence Care

Example NIC Activities—Urinary Elimination Management

Monitor urinary elimination including frequency, consistency, odor, volume, and color as appropriate; Teach client signs and symptoms of urinary tract infection

Nursing Interventions and *Rationales*

- Introduce yourself to the client and anyone accompanying him or her and inform them of your role. **EB:** *Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the basis for building trust on which to base the provision of care (Ellis et al, 2020).*
- Gain consent to provide care before proceeding further with the assessment. **EB:** *Clients have the right of autonomy both legally and morally and therefore should be fully involved in the decision-making process (Griffith & Tengnah, 2020).*
- Wash hands using a recognized technique. **EB:** *Evidence shows that strict hand hygiene regimens significantly reduce the incidence of methicillin-resistant* Staphylococcus aureus *and* Clostridioides (Clostridium) difficile *infection (Goldberg, 2017).*
- Assess the usual pattern of bladder management and establish the extent of the problem. **EB:** *Several types of incontinence exist and since the treatments will vary, it is important that the assessment, also known as "diagnostic evaluation," establishes which type is present. The authors recognize that guidelines should be adapted to individual clients' needs (Nambiar et al, 2018).*
- Ask the client to complete a bladder diary/log to determine the pattern of urine elimination, any incontinence episodes, and current bladder management program. An electronic voiding diary may be kept whenever feasible. **EB:** *Bladder diaries provide accurate data and are more reliable than clients' recollections of symptoms. In addition to being inexpensive and low risk, clients view diaries as easy to complete and helpful for their care (Dixon & Nakib, 2016).*
- ▲ Consult with the health care provider concerning current bladder function and the potential of the bladder to produce hydronephrosis, vesicoureteral reflux, febrile urinary tract infection, or compromised renal function. **EB:** *Early diagnosis of a urinary tract infection, along with adequate management and new infection prevention, is key to reducing the risk of further compromised renal function leading to hospitalization and increased mortality rates from urinary tracts infections (Gomes De Medeiros Jr et al, 2020).*
- ▲ Consult with the health care provider and physical therapist concerning the neuromuscular ability to perform bladder management. The type of neurological disorder, as well as the level of neurological impairment and the ability to use the hands effectively, determines the method of urine management in reflex incontinence. **EB:** *An individual's function and experience of disability needs to be considered in relation to their underpinning pathology. Any resulting impairment, both personal and environmental, needs to be analyzed and assessed in relation to the implementation of a rehabilitation plan (Stevenson & Playford, 2016).*
- Inspect the perineal and perigenital skin for signs of incontinence-associated dermatitis and pressure ulcers. **EB:** *Standardizing skin care routines and making them an integrated part of essential care for incontinence clients will improve client care in specialized areas, which helps reduce the incidence of incontinence-associated dermatitis (Beeckman, 2017).*
- ▲ In consultation with the rehabilitation team, counsel the client and family concerning the merits and potential risks associated with each possible bladder management program, including spontaneous voiding, intermittent self-catheterization (ISC), and reflex voiding with condom catheter containment and in some cases, indwelling suprapubic catheterization. **EB:** *A systematic review of the literature suggests that indwelling suprapubic catheterization is favorable to indwelling urethral catheterization because there is a reduction in both the rate of recatheterization and asymptomatic infection. However, suprapubic*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

catheterization is also associated with a higher rate of hematuria generally following the catheter's insertion. Intermittent catheterization is favored over indwelling catheterization in relation to a reduction in symptomatic urinary tract infections (Li et al, 2019).

- Ensure the client is aware of when and how to report any problems and/or complications of reflex incontinence care when at home. **EB:** *Clients should be routinely asked about how they are adjusting to and managing ISC. The use of regular reviews provides clients with opportunities to report any problems, complications, or concerns in a timely manner (Lake, 2018).*
- Provide clients with comprehensive written information about the management of continence-related problems. **EB:** *Client information materials and decision aids are essential tools for helping clients to make informed decisions and share in the decision-making process about their care (Posch et al, 2020).*
- Assist the family with arranging care in a way that allows the client to participate in family or favorite activities without embarrassment. Elicit discussion of the client's concerns about the social or emotional burden of incontinence. **EB:** *Urinary incontinence can have a negative effect on the quality of life for clients and their families. Effective communication, support, and reassurance are essential to help clients and families make the lifestyle adjustments required for continence management (Collins, 2019).*
- Teach the client to ensure good hydration. **EB:** *Clients may have anxiety about incontinence and intentionally reduce fluid intake as a personal strategy to manage the problem. Such clients need to be monitored regularly as the onset of dehydration has the potential to develop slowly over time (Cook et al, 2019).*
- Teach the client with a spinal injury the signs of autonomic dysreflexia, its relationship to bladder fullness, and management of the condition. Refer to the care plan for **Autonomic Dysreflexia.**

Intermittent Self-Catheterization

- Begin intermittent catheterization as ordered using sterile technique; the client may be taught to use clean technique in the home situation. **EB:** *Clean ISC has recently been advocated as a safe and simple technique to teach clients who are experiencing voiding dysfunction (Lake, 2018).*
- Adopt a person-centered ISC approach to motivate and schedule the frequency of intermittent catheterization based on the frequency/volume records of previous catheterizations, functional bladder capacity, and the impact of catheterization on the quality of the client's life. **EB:** *Adopting an individualized approach to ISC management should be reflective of the client's lifestyle, fitting ISC into existing routines (Nørager et al, 2019). The use of previous drainage regimens will help develop the client's new individual voiding regimen (Hillery, 2020).*
- Teach the client to recognize signs of symptomatic urinary tract infection and to seek care promptly when these signs occur. The signs of symptomatic infection include the following:
  - Discomfort over the bladder or during urination
  - Acute onset of urinary incontinence
  - Fever
  - Markedly increased spasticity of muscles below the level of the spinal lesion
  - Malaise, lethargy
  - Hematuria
  - Autonomic dysreflexia (hyperreflexia) symptoms

  EB: *Clients need the skills and knowledge to identify signs of symptomatic urinary tract infections. In order for clients to maintain adherence to ISC regimens they need to know how to manage any urinary tract infections by liaising with appropriate health professionals (Nørager et al, 2019).*
- Recognize that intermittent catheterization is typically associated with asymptomatic bacteriuria, and the indwelling catheter is routinely associated with asymptomatic colonization. **EB:** *There is a clinical need to refine the management of asymptomatic infection in association with bacteriuria. Effective strategies should include minimizing inappropriate antimicrobial use unless a symptomatic infection is detected (Nicolle, 2016).*
- Teach intermittent catheterization as the client approaches discharge as per operational guidelines and best practices. Instruct the client and at least one family member in the performance of catheterization. Teach the client with quadriplegia how to instruct others to perform this procedure. **EB:** *Intermittent catheterization is a safe and effective bladder management strategy for persons with reflex urinary incontinence. More and more clients are advised to perform intermittent catheterization. Quality-of-life studies show that intermittent catheterization has a great impact on daily life (Cobussen-Boekhorst et al, 2016).*
- Clients using ISC may experience bladder spasms that hinder the insertion process. **EB:** *Clients need to be educated about the use and side effects (constipation, dry mouth, and dizziness) of antispasmodic*

(parasympathetic) medications as prescribed by the health care provider. Antispasmodic medication is useful when clients are experiencing incomplete emptying, leading to an overactive bladder. In such cases antispasmodic medication can be prescribed to reduce involuntary bladder contractions (Diokno, 2019).

Condom Catheter/Sheath System

- For a male client with reflex incontinence who does not have urinary retention and cannot manage the condition effectively with spontaneous voiding, who does not choose to perform intermittent catheterization, or who cannot perform catheterization, teach the client and his family to obtain, select, and apply an external collective device and urinary drainage system. Assist the client and family to choose a product that adheres to the glans penis or penile shaft without allowing seepage of urine onto surrounding skin or clothing, which avoids provoking hypersensitivity reactions on the skin, and that includes a urinary drainage reservoir that is easily concealed under the clothing and does not cause irritation to the skin of the thigh. **EB:** *When considering the use of an external continence device, it is vital that the correct size is measured and fitted to eliminate many of the problems associated with leakage and the sheath falling off (Woodward, 2015).*
- Teach the client whose incontinence is managed by a condom catheter to routinely inspect the skin with each catheter change for evidence of lesions caused by pressure from the containment device or by exposure to urine, to cleanse the penis thoroughly, and to reapply a new device daily or every other day. **EB:** *A well-fitted sheath reduces the risk of skin irritation or ulceration. The sheath should always be fitted leaving a space between the tip of the penis and the shaft allowing urine to flow without the sheath "ballooning" (Woodward, 2015).*
- Document all care and advice given in a factual and comprehensive manner. **EB:** *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (Andrews & St Aubyn, 2015).*

Stress Urinary Incontinence

Domain 3 Elimination and exchange Class 1 Urinary function

Amanda Andrews, BSc (Hons), MA and Bernie St Aubyn, BSc (Hons), MSc

NANDA-I

Definition

Involuntary loss of urine with activities that increase intra-abdominal pressure, which is not associated with urgency to void.

Defining Characteristics

Involuntary loss of urine in the absence of detrusor contraction; involuntary loss of urine the absence of overdistended bladder; involuntary loss of urine upon coughing; involuntary loss of urine upon effort; involuntary loss of urine upon laughing; involuntary loss of urine upon physical exertion; involuntary loss of urine upon sneezing

Related Factors

Overweight; pelvic floor disorders; pelvic organ prolapse

At-Risk Population

Individuals who perform high-intensity physical exercise; multiparous women; pregnant women; women experiencing menopause; women giving birth vaginally

Associated Conditions

Damaged pelvic floor muscles; degenerative changes in pelvic floor muscles; intrinsic urethral sphincter deficiency; nervous system diseases; prostatectomy; urethral sphincter injury

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Urinary Continence; Urinary Elimination

Example NOC Outcome with Indicators

Urinary Continence as evidenced by the following indicators: Experiences no urine leakage with increased abdominal pressure (e.g., sneezing, laughing, lifting)/Voids in appropriate receptacle/Able to move to toilet after strong desire to urinate is perceived/Underclothing remains dry during day/Underclothing or bedding remains dry during night. (Rate the outcome and indicators of **Urinary Continence:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Report no stress incontinence episodes and/or a decrease in the severity of urine loss over a 24-hour period
- Experience no episodes of urinary incontinence as recorded on voiding diary (bladder log) over a 24-hour period
- Identify containment devices that assist in management of stress incontinence over a 24-hour period

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Pelvic Muscle Exercises; Urinary Incontinence Care

Example NIC Activities—Urinary Incontinence Care

Explain etiology of problem and rationale for actions; Modify clothing and environment to provide easy access to toilet

Nursing Interventions and *Rationales*

- Introduce yourself to the client and anyone accompanying him or her and inform them of your role. **EB:** *Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the basis for building trust on which to base the provision of care (Ellis et al, 2020).*
- Gain consent to provide care before proceeding further with the assessment. For clients unable to give consent, discuss permission with relevant health care professionals and/or family members. **EB:** *Clients have the right of autonomy both legally and morally and therefore should be fully involved in the decision-making process (Griffith & Tengnah, 2020).*
- Wash hands using a recognized technique. **EB:** *Evidence shows that strict hand hygiene regimens significantly reduce the incidence of methicillin-resistant* Staphylococcus aureus *and* Clostridioides (Clostridium) difficile *infection (Goldberg, 2017).*
- Assess usual pattern of bladder management to understand the extent of the problem and establish pattern of bladder management. Explore factors provoking urine loss (diuretics, bladder irritants, alcohol), focusing on the differential diagnosis of stress, urge or mixed stress, and urge urinary symptoms. Consider using a symptom questionnaire that elicits relevant lower urinary tract symptoms and provides differentiation between stress and urge incontinence symptoms. **EB:** *Several types of incontinence exist and since the treatments will vary, it is important that the assessment, also known as "diagnostic evaluation," establishes which type is present. The authors recognize that guidelines should be adapted to individual clients' needs (Nambiar et al, 2018).*
- Review the client's medical history to identify possible risk factors for stress incontinence (i.e., pregnancy, parity, large babies, forceps or breech deliveries, obesity, chronic cough, physical activity, previous urinary tract or gynecological surgery, smoking history). **EB:** *Reviewing the client's medical history, considering any significant medical, surgical, obstetric, or genitourinary history, is essential as any identified conditions may affect an individual's ability to maintain continence (Bardsley, 2016).*
- Review the client's medication list (e.g., diuretics, lithium, adrenergic blockers, diabetes medications) to see what may exacerbate the client's urinary urgency. **EB:** *Health professionals should review the use of any medication that could affect a client's urine production. Side effects for consideration should include sedation, impaired cognition, or a change in sensation and muscle tone (Bardsley, 2016).*
- Review the client's bladder habits:
  - Onset and duration of urinary leakage
  - Related lower urinary tract symptoms, including voiding frequency (day/night) and urgency, severity (small, moderate, large amounts) of urinary leakage
- Assess for mixed urinary incontinence (a combination of stress and urge incontinence) by asking the client:
  - Can you delay urination for a 2-hour movie or car ride?
  - How often do you wake/arise at night to urinate?
  - When you have the urge to urinate, can you reach the toilet without leaking?

  EB: *The assessment is enhanced by the use of a questionnaire. This questionnaire needs to be a validated incontinence-specific quality of life questionnaire (Bardsley, 2016) to capture the possibility of mixed urinary incontinence.*
- Complete a lifestyle assessment to understand the effect of stress urinary incontinence on an individual's lifestyle. Inquire about incontinence pad use and change in daily, social, or recreational activities, as well as emotional impact. **EB:** *The impact of urinary incontinence on the quality of life is well recognized and includes a negative effect on psychological well-being, social interactions and activities, and sexual and interpersonal relationships (Minassian et al, 2015).*
- Inspect the perineal skin for evidence of incontinence-associated dermatitis, including inflammation, vesicles in skin exposed to urinary leakage, and especially skinfolds or denudation of the skin, particularly when incontinence is managed by absorptive pads or containment briefs. **EB:** *Ammonia produced from the breakdown of urea in urine causes an increase in skin pH, which increases the permeability of the skin; excess moisture and damage to the acid mantle further increases permeability and vulnerability to bacterial and*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

fungal infections (Beeckman, 2017). Skin exposed to urine or stool will become bright red, and the surface may appear shiny because of serous exudate; inflamed areas of individuals with darker skin tones may be a duller red or hypopigmented when compared with adjacent skin. Inspect the skin for a maculopapular red rash typical of candidiasis (Beeckman, 2017).

▲ Refer client for specific testing to confirm incontinence etiology and diagnosis. If trained to do so, perform the cough stress test and request a 24-hour pad test (if appropriate) and urodynamic studies (including urine speed and flow, postvoid residual measurement, leak point pressure, and pressure flow study). **EB:** *A greater agreement rating was found between cough stress test and urodynamics than between 24-hour pad test and urodynamics in the assessment of stress incontinence (Minassian et al, 2015).*

● Establish with the client the current use of containment devices, for example, a well-fitted sheath; evaluate the devices for their ability to adequately contain urine loss, protect clothing, and control odor. Assist the client in identifying containment devices specifically designed to contain urinary leakage and not to use sanitary pads. **EB:** *A well-fitted sheath reduces the risk of skin irritation or ulceration. The sheath should always be fitted leaving a space between the tip of the penis and the shaft allowing urine to flow without the sheath "ballooning" (Woodward, 2015).*

● Teach the client to complete a bladder diary by recording voiding frequency, the frequency and degree of urinary incontinence episodes, association with urgency (a sudden and strong desire to urinate that is difficult to defer), fluid intake, and pad usage over a 3- to 7-day period. An electronic voiding diary may be kept whenever feasible. **EB:** *Use of a bladder diary may reduce client discrepancies in recall and is a valuable tool for assessment; the short (24-hour) duration of the bladder diary may yield inadequate data, and excessive diary duration reduces compliance (Dixon & Nakib, 2016).*

▲ With the client and in close consultation with the health care provider, review treatment options, including behavioral management; drug therapy; use of a pessary, vaginal device, or urethral insert; and surgery. Outline the potential benefits, efficacy, and side effects of each treatment option. **CEB:** *A 10-year review of the literature identified that there are two common conservative treatments recommended to treat stress urinary incontinence in women: strengthening pelvic floor muscles including biofeedback and weighted vaginal cones, and the use of intravaginal devices such as pessaries (McIntosh, Andersen, & Reekie, 2015).*

● Teach the client how to carry out pelvic floor muscle training. Teach the client to identify, contract, and relax the pelvic floor muscles without contracting distal muscle groups (e.g., abdominal muscles or gluteus muscles) using verbal feedback based on vaginal or anal palpation, biofeedback, or electrical stimulation and the assistance of an incontinence specialist or health care provider as necessary. **EB:** *A study carried out by Al Belushi et al (2020) concluded that a home-based pelvic floor muscle training program was effective in decreasing the severity of symptoms and improving the quality of life among women with stress urinary incontinence.*

● Incorporate principles of exercise physiology into a pelvic muscle training program using the following strategies:
  ❍ Begin a graded exercise program, usually starting with 5 to 10 repetitions and advancing gradually to no more than 35 to 50 repetitions every day or every other day based on baseline and ongoing evaluation of maximal strength and endurance.
  ❍ Continue exercise sessions over a period of 3 to 6 months.
  ❍ Integrate muscle training into activities of daily living.
  ❍ Assess progress every 2 weeks during the first month and every 4 to 6 weeks thereafter.

  EB: *Pelvic floor muscle exercises are carried out repetitively contracting and relaxing specific pelvic floor muscles. The contraction of the periurethral muscles leads to improved efficiency of the supportive functions for the urethra. Pelvic floor muscle exercises are therefore considered as the first-line intervention of prevention and treatment for stress urinary incontinence (Sangsawang & Sangsawang, 2016).*

● Work with the client on retraining the bladder by regularly timed toileting regimens (every 2 hours). For the older client in the home or a long-term care facility who has functional incontinence and dementia:
  ❍ Determine the frequency of current urination using an alarm system or check-and-change device.
  ❍ Record urinary elimination and incontinent patterns in a bladder log to use as a baseline for assessment and evaluation of treatment efficacy.
  ❍ Begin a prompted toileting program based on the results of this program; toileting frequency may vary from every 1.5 to 2 hours to every 4 hours.
  ❍ Provide positive reinforcement.

  EB: *Bladder retraining aims to increase the time in between trips to the toilet by encouraging the client to "hold on" when they need to go. This aims to improve the client's control of their bladder and this can reduce symptoms of urinary frequency, urinary urgency, and nocturia (Stewart, 2018).*

▲ Teach the client to self-administer duloxetine as ordered by the consulting health care provider and to monitor for adverse side effects. **EB:** *Duloxetine is a serotonin-norepinephrine reuptake inhibitor approved for treatment of stress urinary incontinence. A systematic review carried out by Rodrigues-Amorim et al (2020) identified that in the studies evaluated duloxetine was found to be safe and tolerable in over 70% of clients studied.*

▲ Teach the client to self-administer topical (vaginal) estrogens as directed and to monitor for adverse side effects. **EB:** *The use of local estrogens has been found to be safe and effective in improving the urinary symptoms in postmenopausal clients with urinary incontinence (Bodner-Adler et al, 2020).*

- Refer the female client with stress urinary incontinence and pelvic organ prolapse who wishes to use a pessary to manage stress incontinence to a nurse specialist or gynecologist with expertise in the placement and maintenance of these devices. **EB:** *The use of vaginal pessaries is an effective nonsurgical option for women experiencing stress urinary incontinence. The satisfaction rate with pessary use is high, and vaginal pessaries provide an adequate control of stress urinary incontinence if they are fit properly and managed by frequent replacements and regular checkups (Al-Shaikh et al, 2018).*
- Discuss potentially reversible or controllable risk factors, such as weight loss, with the client with stress incontinence, and assist the client to formulate a strategy to eliminate these conditions. **EB:** *Clinical studies have found that increased intraabdominal pressure due to obesity adversely stresses the pelvic floor and contributes to the development of stress urinary incontinence (Fuselier et al, 2018).*
- Refer the client with persistent stress incontinence to a continence service, health care provider, or nurse who specializes in the management of this condition. **EB:** *All clients presenting with incontinence should be offered an initial assessment by an individual who specializes in management of continence disorders. Continence specialists can provide expert knowledge, for example, around products and management (Kumah & McGlashan, 2019).*
- Teach the client to ensure good hydration. **EB:** *Clients may have anxiety about incontinence and intentionally reduce fluid intake as a personal strategy to manage the problem. Such clients need to be monitored regularly as the onset of dehydration has the potential to develop slowly over time (Cook et al, 2019).*
- Provide client with comprehensive written information about bladder care and how to access relevant support resources (e.g., national associations). **EB:** *Client information materials and decision aids are essential tools for helping clients to make informed decisions and share in the decision-making process about their care (Posch et al, 2020).*
- Encourage a program of self-care management. **EB:** *Addressing self-care activities through exercise, diet, fluid intake, and protective devices helps the client exercise control over incontinence and may reduce the substantial care provider burden affecting a significant proportion of spouse, partner, or familial care providers.*
- Assist the family with arranging care in a way that allows the client to participate in family or favorite activities without embarrassment. Elicit discussion of the client's concerns about the social or emotional burden of incontinence. **EB:** *Urinary incontinence can have a negative effect on the quality of life for clients and their families. Effective communication, support, and reassurance are essential to help clients and families make the lifestyle adjustments required for continence management (Collins, 2019).*
- Document all care and advice given in a factual and comprehensive manner. **EBN:** *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (Andrews & St Aubyn, 2015).*
- Refer to the Disability-Associated Urinary **Incontinence** care plan.

Urge Urinary Incontinence

Domain 3 Elimination and exchange Class 1 Urinary function

Amanda Andrews, BSc (Hons), MA and Bernie St Aubyn, BSc (Hons), MSc

NANDA-I

Definition

Involuntary loss of urine in combination with or following a strong sensation or urgency to void.

Defining Characteristics

Decreased bladder capacity; feeling of urgency with triggered stimulus; increased urinary frequency; involuntary loss of urine before reaching toilet; involuntary loss of urine with bladder contractions; involuntary loss of urine with bladder spasms; involuntary loss of varying volumes of urine between voids, with urgency; nocturia

Related Factors

Alcohol consumption; anxiety; caffeine consumption; carbonated beverage consumption; fecal impaction; ineffective toileting habits; involuntary sphincter relaxation; overweight; pelvic floor disorders; pelvic organ prolapse

At-Risk Population

Individuals exposed to abuse; individuals with history of urinary urgency during childhood; older adults; women; women experiencing menopause

Associated Conditions

Atrophic vaginitis; bladder outlet obstruction; depression; diabetes mellitus; nervous system diseases; nervous system trauma; overactive pelvic floor; pharmaceutical preparations; treatment regimen; urologic diseases

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Integrity: Skin and Mucous Membranes; Urinary Continence; Urinary Elimination

Example NOC Outcome with Indicators

Urinary Continence as evidenced by the following indicators: Responds in timely manner to urge/Voids in appropriate receptacle/Has adequate time to reach toilet between urge and evacuation of urine/Underclothing remains dry during day/Underclothing or bedding remains dry during night. (Rate the outcome and indicators of **Urinary Continence:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Report relief from urge urinary incontinence or a decrease in the frequency of incontinent episodes on a daily basis
- Identify containment devices that assist in the management of urge urinary incontinence on a daily basis

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Urinary Habit Training; Urinary Incontinence Care

Example NIC Activities—Urinary Habit Training

Keep a continence specification record for 3 days to establish voiding pattern; Establish interval for toileting of preferably not less than 2 hours

Nursing Interventions and *Rationales*

- Introduce yourself to the client and anyone accompanying him or her and inform them of your role. **EB:** *Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the basis for building trust on which to base the provision of care (Ellis et al, 2020).*
- Gain consent to perform care before proceeding further with the assessment. **EB:** *Clients have the right of autonomy both legally and morally and therefore should be fully involved in the decision-making process (Griffith & Tengnah, 2020).*
- Wash hands using a recognized technique. **EB:** *Evidence shows that strict hand hygiene regimens significantly reduce the incidence of methicillin-resistant* Staphylococcus aureus *and* Clostridioides (Clostridium) difficile *infection (Goldberg, 2017).*
- Assess the usual pattern of bladder management and establish the pattern of bladder management and extent of the problem. **EB:** *Several types of incontinence exist and since the treatments will vary, it is important that the assessment, also known as "diagnostic evaluation," establishes which type is present. The authors recognize that guidelines should be adapted to individual clients' needs (Nambiar et al, 2018).*
- Assess bladder habits and quality-of-life issues:
  - Diurnal frequency (voiding more than once every 2 hours while awake)
  - Urgency, daytime frequency, and nocturia
  - Involuntary leakage and leakage accompanied by or preceded by urgency
  - Amount of urine loss, moderate or large volume
  - Severity of symptoms
  - Alleviating and aggravating factors
  - Effect on quality of life

  EB: *Incontinence is distressing and may contribute to decreased quality of life. This includes a negative effect on psychological well-being, social interactions and activities, and sexual and interpersonal relationships (Minassian et al, 2015).*
- Ask specific questions relating to urge presentation:
  - Can you delay urination for a 2-hour movie or car ride?
  - How often do you wake at night to urinate?
  - When you have the urge to urinate, can you reach the toilet without leaking?

  EB: *This questionnaire needs to be a validated incontinence-specific quality-of-life questionnaire (Bardsley, 2016) to capture the possibility of mixed urinary incontinence.*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Assess the severity of incontinence and the effect on the individual's lifestyle; inquire about incontinence pad use and change in daily, social, or recreational activities, and emotional impact. **EB:** *Incontinence is distressing and may contribute to decreased quality of life, especially for women with mixed incontinence (Bardsley, 2016).*

▲ Perform a focused physical assessment, in close consultation with a health care practitioner or advanced practice nurse, including the following:
  - ❍ Bladder palpation after voiding to check for retention
  - ❍ Bladder scanning for postvoid residual
  - ❍ Inspection of the perineal skin
  - ❍ Vaginal examination to determine hypoestrogenic changes in the mucosa (may contribute to urge incontinence)
  - ❍ Pelvic examination to determine the presence, location, and severity of vaginal wall prolapse, and reproduction of stress urinary incontinence with the cough test

- Anal tone and constipation should be assessed. **EB:** *A thorough abdominal and pelvic examination must be completed to accurately assess incontinence. Identification of "red flag" symptoms (e.g., nocturia, hematuria) needs referral to the appropriate consultant (NICE, 2015).*
- Inspect the perineal and perianal skin for evidence of incontinence-associated dermatitis, including inflammation, vesicles in skin exposed to urinary leakage, and especially skinfolds or denudation of the skin, particularly when incontinence is managed by absorptive pads or containment briefs. **EB:** *Ammonia produced from the breakdown of urea in urine causes an increase in skin pH, which increases the permeability of the skin; excess moisture and damage to the acid mantle further increase permeability and vulnerability to bacterial and fungal infections (Beeckman, 2017). Skin exposed to urine or stool will become bright red, and the surface may appear shiny because of serous exudate; inflamed areas of individuals with darker skin tones may be a duller red or hypopigmented when compared with adjacent skin. Inspect the skin for a maculopapular red rash typical of candidiasis (Beeckman, 2017).*
- Teach the client to complete a bladder diary by recording voiding frequency, the frequency and degree of urinary incontinence episodes, their association with urgency (a sudden and strong desire to urinate that is difficult to defer), fluid intake, and pad usage over a 3- to 7-day period. An electronic voiding diary may be kept whenever feasible. In addition to these parameters, the client may be asked to record voided volume and fluid intake. **EB:** *Use of a bladder diary may reduce client discrepancies in recall and is a valuable tool for assessment; short (24-hour) duration of the bladder diary may yield inadequate data, and excessive diary duration reduces compliance (Dixon & Nakib, 2016).*
- Review all medications the client is receiving, paying particular attention to sedatives, opioid analgesics, diuretics, antidepressants, psychotropic drugs, and cholinergics. Consult the health care practitioner or nurse practitioner about altering or eliminating these medications if they are suspected of affecting incontinence. **EB:** *Health professionals should review the use of any medication that could affect a client's urine production. Side effects for consideration should include sedation, impaired cognition, or a change in sensation and muscle tone (Bardsley, 2016).*
- Assess the client for urinary retention (see the care plan for **Urinary Retention**).
- Assess the client for functional limitations (environmental barriers, limited mobility or dexterity, and impaired cognitive function). **EB:** *Clients with impaired dexterity or weakness may benefit from clothing that has been modified or is without buttons and zippers (Leaver, 2017).*
- Consult the health care practitioner concerning diabetic management or pharmacotherapy for urinary tract infection when indicated. In specific cases, urgency and an increased risk of urge incontinence may be related to bacteriuria or urinary tract infection. **EB:** *Studies have found that clients with urge incontinence and the coexistence of recurrent urinary tract infections have diverse urinary microbiota. This suggests that persistent bladder colonization augments the pathology of clients' incontinence (Chen et al, 2018).*

▲ Assess for signs and symptoms of atrophic vaginal changes in the perimenopausal or postmenopausal woman, including vaginal dryness, tenderness to touch, mucosal dryness, friability, and discomfort with gentle palpation. Specifically query the woman with atrophic vaginitis concerning associated lower urinary tract symptoms (usually voiding frequency, urgency, and dysuria). Refer the woman with atrophic vaginal changes and bothersome lower urinary tract symptoms to a gynecologist, urologist, or women's health nurse practitioner for further evaluation and management. **EB:** *The use of local estrogens has been found to be safe and effective in improving the urinary symptoms in postmenopausal clients with urinary incontinence (Bodner-Adler et al, 2020).*

Pelvic Floor Training Program

- Teach the client how to carry out pelvic floor muscle training. Teach the client to identify, contract, and relax the pelvic floor muscles without contracting distal muscle groups (e.g., abdominal muscles or gluteus muscles) using verbal feedback based on vaginal or anal palpation, biofeedback, or electrical stimulation and the assistance of an incontinence specialist or health care provider as necessary. **EB:** *A study carried out by Al Belushi et al (2020) concluded that a home-based pelvic floor muscle training program was effective in decreasing the severity of symptoms and improving the quality of life among women with stress urinary incontinence.*
- Incorporate principles of exercise physiology into a pelvic muscle training program using the following strategies:
  - ❍ Begin a graded exercise program, usually starting with 5 to 10 repetitions and advancing gradually to no more than 35 to 50 repetitions every day or every other day based on baseline and ongoing evaluation of maximal strength and endurance.
  - ❍ Continue exercise sessions over a period of 3 to 6 months.
  - ❍ Integrate muscle training into activities of daily living.
  - ❍ Assess progress every 2 weeks during the first month and every 4 to 6 weeks thereafter.

  EB: *Pelvic floor muscle exercises are carried out repetitively contracting and relaxing specific pelvic floor muscles. The contraction of the periurethral muscles leads to improved efficiency of the supportive functions for the urethra. Pelvic floor muscle exercises are therefore considered the first-line intervention of prevention and treatment for stress urinary incontinence (Sangsawang & Sangsawang, 2016).*

I

Bladder Training Program

- Assist the client in completing a voiding diary over a period of a minimum of 3 days or up to 7 days.
- Review the results with the client, determining typical voiding frequency and establishing goals for voiding frequency based on the longest time interval between voids that is comfortable for the client.
- Using baseline voiding frequency, as determined by the diary, teach the client to void first thing in the morning, every time the predetermined voiding interval passes, and before going to bed at night.
- Encourage adherence to the program with timing devices and verbal encouragement and support, and address individual reasons for schedule interruption.
- Teach distraction and urge suppression techniques (see later discussion) to control urgency while the client postpones urination.
- Gradually increase the time between urinations to the negotiated goal. Time intervals between voiding are typically increased in increments of 15 to 30 minutes for clients with a baseline frequency of less than every 60 minutes and increments of 25 to 30 minutes for clients with a baseline frequency of more than every 60 minutes. The voiding interval should be increased by 15 to 30 minutes each week (based on the client's tolerance) until a voiding interval of 3 to 4 hours is achieved. Use a bladder diary to monitor progress. **EB:** *Bladder training involves adjusting your habits and developing a schedule to void even if the client does not have an urge to void. Gradually increase the time intervals between urination, allowing the bladder to fill more fully and providing more control over the urge to urinate (Mayo Clinic Staff, 2020).*
- Review with the client the types of beverages consumed, focusing on the intake of caffeine, which is associated with a transient effect on lower urinary tract symptoms. Advise all clients to reduce or eliminate intake of caffeinated beverages or over-the-counter medications of dietary aids containing caffeine. Identify and counsel the client to eliminate other bladder irritants that may exacerbate incontinence, such as smoking, carbonated beverages, citrus, sugar substitutes, and tomato products. **EB:** *Caffeine is a diuretic and a bladder irritant, increases detrusor pressure, and is a risk factor for detrusor instability; reducing caffeine may decrease both stress and urge incontinence. Decrease caffeine gradually to avoid caffeine withdrawal. Carbonated beverages, citrus fruits, sugar substitutes, and tomato products may be bladder irritants (Mayo Clinic Staff, 2020).*
- Teach the client to ensure good hydration. **EB:** *Clients may have anxiety about incontinence and intentionally reduce fluid intake as a personal strategy to manage the problem. Such clients need to be monitored regularly as the onset of dehydration has the potential to develop slowly over time (Cook et al, 2019).*
- Teach the client methods to avoid constipation such as increasing dietary fiber, moderately increasing fluid intake, exercising, and establishing a routine defecation schedule.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Urge Suppression

- Urge suppression skills are essential in helping clients learn a new way of responding to the sense of urgency. **EB:** *Rushing to the toilet increases physical pressure on the bladder, enhances the sensation of fullness, exposes the client to visual cues that can trigger incontinence, and exacerbates urgency.*
- Teach the client the following techniques:
  - When a strong or precipitous urge to urinate is perceived, teach the client to avoid running to the toilet.
  - Pause, sit down, and relax the entire body.
  - Perform repeated, rapid pelvic muscle contractions until the urge is relieved.
  - Use distraction: count backward from 100 by sevens; recite a poem; write a letter; balance a checkbook; do handwork such as knitting; and take five deep breaths, focusing on breathing.
  - Relief is followed by micturition within 5 to 15 minutes, using nonhurried movements when locating a toilet and voiding.
  - Use urge suppression strategies on waking during the night. If the urge subsides, the client should be encouraged to go back to sleep. If after a minute or two the urge does not subside, clients should be instructed to get up to void to avoid sleep interruption.

  EB: *Behavioral therapy is considered first-line therapy due to its effectiveness and minimal risk to the client. A key factor in bladder training is the use of timed voiding incorporated with pelvic muscle exercises (Raju & Linder, 2020).*
- Teach the client to self-administer antimuscarinic (anticholinergic) drugs as directed. Teach dosage side effects and administration of the medication and the importance of combining pharmacotherapy with scheduled voiding, adequate fluid intake, restriction of bladder irritants, and urge suppression techniques. **EB:** *Numerous antimuscarinic medications are available (e.g., oxybutynin and tolterodine). When adequate symptom control is achieved, an attempt to manage side effects should be made (e.g., the use of oral lubricants to aid dry mouth) (Raju & Linder, 2020).*
- Assist the client in selecting, obtaining, and applying a containment device for urine loss as indicated. **EB:** *Containment is important for people with urinary incontinence and should be considered when active treatment does not cure the problem, when it is not available or not possible, or if the risks of treatment outweigh the benefits to the client. A useful resource for health care professionals and clients can be found at* www.continenceproductadvisor.org *(Nambiar et al, 2018).*
- Provide client with comprehensive written information about bladder care and how to access relevant support resources (e.g., national associations). **EB:** *Client information materials and decision aids are essential tools for helping clients to make informed decisions and share in the decision-making process about their care (Posch et al, 2020).*
- Assess the functional and cognitive status of all clients with urge incontinence; use interventions to improve mobility. **EB:** *Clients with severe cognitive impairments (dementia) and functional mobility problems have an increased likelihood of developing urge incontinence (Jerez-Roig et al, 2016).*
- Refer client for occupational therapy for help in obtaining assistive devices and adapting the home for optimal toilet accessibility. **EB:** *Occupational therapists are needed to assist clients with dexterity and mobility issues that may be contributing to incontinence (Spencer, McManus, & Sabourin, 2017).*
- Encourage the client to develop an action plan for self-care management of incontinence. Making an action plan facilitates behavior change.
- Document all care and advice given in a factual and comprehensive manner. **EBN:** *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (Andrews & St Aubyn, 2015).*
- Refer to Functional Urinary **Incontinence** care plan.

Risk for Urge Urinary Incontinence

Domain 3 Elimination and exchange Class 1 Urinary function

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to involuntary passage of urine occurring soon after a strong sensation or urgency to void, which may compromise health.

Risk Factors

Alcohol consumption; anxiety; caffeine consumption; carbonated beverage consumption; fecal impaction; ineffective toileting habits; involuntary sphincter relaxation; overweight; pelvic floor disorders; pelvic organ prolapse

At-Risk Population

Individuals exposed to abuse; individuals with history of urinary urgency during childhood; older adults; women; women experiencing menopause

Associated Conditions

Atrophic vaginitis; bladder outlet obstruction; depression; diabetes mellitus; nervous system diseases; nervous system trauma; overactive pelvic floor; pharmaceutical preparations; treatment regimen; urologic disease

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Urge Urinary **Incontinence**.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Disorganized Infant Behavior

Domain 9 Coping/stress tolerance Class 3 Neurobehavioral stress

Margaret Quinn, DNP, CPNP, CNE

NANDA-I

Definition

Disintegration of the physiological and neurobehavioral systems of functioning.

Defining Characteristics

Attention-Interaction System

Impaired response to sensory stimuli

Motor System

Altered primitive reflexes; exaggerated startle response; fidgeting; finger splaying; fisting; hands to face behavior; hyperextension of extremities; impaired motor tone; maintains hands to face position; tremor; twitching; uncoordinated movement

Physiological

Abnormal skin color; arrhythmia; bradycardia; inability to tolerate rate of feedings; inability to tolerate volume of feedings; oxygen desaturation; tachycardia; time-out signals

Regulatory Problems

Impaired ability to inhibit startle reflex; irritable mood

State-Organization System

Active-awake state; diffuse alpha electroencephalogram (EEG) activity with eyes closed; irritable crying; quiet-awake state; state oscillation

Related Factors

Caregiver misreading infant cues; environmental overstimulation; feeding intolerance; inadequate caregiver knowledge of behavioral cues; inadequate containment within environment; inadequate physical environment; insufficient environmental sensory stimulation; malnutrition; pain; sensory deprivation; sensory overstimulation

At-Risk Population

Infants exposed to teratogen in utero; infants with low postmenstrual age; premature infants

Associated Conditions

Congenital disorders; immature neurological functioning; impaired infant motor functioning; inborn genetic diseases; invasive procedure; oral impairment

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Child Development; Neurological Status; Newborn Adaptation; Preterm Infant Organization; Sleep; Thermoregulation: Newborn; Infant Nutritional Status

Example NOC Outcome with Indicators

Preterm Infant Organization as evidenced by the following indicators: O_2 saturation >85%/ Thermoregulation/Sleep-awake state organization/Smooth transition between states/Ability to attend to visual and auditory stimuli/Habituation. (Rate the outcome and indicators of **Preterm Infant Organization:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

● = Independent; ▲ = Collaborative; EBN = Evidence-Based Nursing; EB = Evidence-Based; ✱ = QSEN

Client Outcomes

Client Will (Specify Time Frame)

Infant/Child

- Display physiological/autonomic stability: cardiopulmonary, digestive functioning
- Display signs of organized motor system
- Display signs of organized state system: ability to achieve and maintain a state and transition smoothly between states
- Demonstrate progress toward effective self-regulation
- Demonstrate progress toward or ability to maintain calm attention
- Demonstrate progress or ability to engage in positive interactions
- Demonstrate ability to respond to sensory information (visual, auditory, tactile) in an adaptive way

Parent/Significant Other

- Recognize infant/child behaviors as a complex communication system that expresses specific needs and wants (e.g., hunger, pain, stress, desire to engage or disengage)
- Educate parents/caregivers to recognize infant's avenues of neurobehavioral communication: autonomic/physiological, motor, state, attention/interaction
- Recognize how infants respond to environmental sensory input through stress/avoidance and approach/engagement behaviors
- Recognize and support infant's self-regulatory, coping behaviors used to regain or maintain homeostasis
- Teach parents to "tune in" to their own interactive style and how that affects their infant's behavior
- Teach parents ways to adapt their interactive style in response to infant's style of communication appropriate for developmental stage and gestational age
- Identify appropriate positioning and handling techniques that will enhance normal motor development
- Promote infant/child's attention capabilities that support visual and auditory development
- Engage parents in pleasurable parent–infant interactions that encourage bonding and attachment
- Structure and modify the environment in response to infant/child's behavior and personal needs; personalize their bed space
- Identify available community resources that provide early intervention services, emotional support, community health nursing, and parenting classes
- Communicate the infant's medical, nursing, and developmental needs to the family in a culturally sensitive and appropriate way that is understandable

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Physiological and Autonomic Stability; Developmental Enhancement; Infant Care; Environmental Management; Kangaroo Care; Nonnutritive Sucking; Parent Education: Infant; Positioning and Handling; Sleep and Awake Stability; Teaching: Infant Stimulation 0-4 months; Bonding and Attachment

Example NIC Activities—Developmental Enhancement, Infant

Provide information to parent about child development and child rearing; Promote and facilitate family bonding and attachment with infant

Nursing Interventions and *Rationales*

- Sensitive nursing care must be implemented at the infant's admission to the neonatal intensive care unit (NICU), continued during the stay, and continued past discharge as the family adjusts to transitioning home and into the community. **EBN:** *"Learning the principles of neurodevelopment and understanding the meaning of preterm behavioral cues make it possible for NICU caregivers and parents to provide individualized developmentally appropriate, neuroprotective care to each infant" (Altimier & Phillips, 2016).*
- Assess the neurobehavior systems through which infants communicate organized and/or disorganized stress behaviors within the subsystems of functioning (i.e., physiological/autonomic, motor, states, attention/interactional, self-regulatory). **EBN:** *The stress responses of hospitalized preterm infants vary and are measured in all stress exposures (Nist et al, 2020).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Recognize and educate parents to recognize the behavior cues infants use to communicate stress/avoidance and approach/engagement. **EB:** *Mothers of preterm infants were as able as the mothers of full-term infants in configural processing of their own infant's face. Preterm mothers made comparable use of configural processing for the body and face of both familiar and unfamiliar infants, in keeping with the pattern of performance of the full-term mothers who had similarly low levels of maternal sensitivity (Butti et al, 2018).*
- Provide high-quality individualized developmental care for low-birth-weight preterm infants in a family-centered care environment that promotes normal neurological, physical, and emotional developmental and prevents disabilities. **EB:** *A study focused on changing NICU "to family-integrated care where parents are intimately involved in baby's care for as many hours a day" and changed the unit's name to newborn intensive parenting unit (NIPU), leading to improved outcomes for NIPU babies (Hall et al, 2017).*
- Identify and manage pain using appropriate pain management techniques during invasive procedures (e.g., tube insertion, heel sticks, intravenous lines). **EBN:** *Breastfeeding or oral sucrose and holding and swaddling reduce pain during procedures (Yilmaz & Inal, 2020).* **EB:** *The skin-to-skin method reduces procedural pain (Johnston et al, 2017).*
- Provide care that supports development state organization, such as the ability to achieve and maintain quiet sleep and awake states and transition smoothly between states. **EBN:** *Promote sleep by timing care and avoiding unnecessary procedures that disrupt sleep (Altimier & Phillips, 2016).* **EBN:** *A study found methods to reduce NICU noise are necessary and achievable (Reeves-Messner & Spilker, 2017).*
- Encourage parents to speak slowly and/or sing to their babies during visits. **EB:** *Maternal voice demonstrates increased stability in preterm infants (Filippa et al, 2017).*
- Provide infants several opportunities for nonnutritive sucking (NNS). **EB:** Infants receiving NNS during tube feedings showed reduced time transitioning to full oral feedings and decreased the length of hospital stay (*Foster, Psaila, & Patterson, 2016*).
- Provide parents opportunities to experience physical closeness through loving touch, massage, cuddling, and skin-to-skin contact (kangaroo care), which enhances parent–infant attachment. **EB:** *Premature infants receiving kangaroo mother care, compared with those who did not, have better neurodevelopmental performance between 36 and 41 weeks of postconceptual age (Gurgel de Castro Silva et al, 2016*).
- Teach parents to use calming interventions that mimic the sensory environment in the womb such as swaddling, side position, sound (white noise), swinging, and sucking (5 S's). **EBN:** *The 5 S's technique is teachable, learnable, useful, and effective in calming crying infants, and it can boost mothers' parental self-efficacy (Botha et al, 2020).*
- Encourage parental engagement and early interactions in the NICU to set the foundation for parent–infant attachment and social relationships. **EB:** *Parents' emotional closeness to NICU infants may be crucial for developing an affective parent–infant relationship (Stefana & Lavelli, 2017).*
- Support effective and pleasurable feeding practices, such as breast, bottle, or combination, as essential for healthy nutrition/calories, for mother–baby bonding and attachment, and for setting the foundation for successful feeding/eating patterns. **EBN:** *Support breastfeeding for successful oral feedings (Altimier & Phillips, 2016).* **EB:** *Full or partial breastfeeding for the first few months is protective against sudden infant death syndrome (SIDS) risk (Thompson, et al, 2017).*
- Provide infants with positive sensory experiences (e.g., visual, auditory, tactile, olfactory, vestibular, proprioceptive) to enhance development of sensory pathways and avoid overstimulation of sensory systems. **EB:** *Auditory: Music activities provide multisensory neurological stimulation (Standley & Gutierrez, 2020).* **EBN:** *Gustatory: Position infant allowing finger/fist sucking.* **EBN:** *Tactile: Skin-to-skin contact is a positive sensory experience for both mothers and babies (Baley & Committee on Fetus and Newborn, 2015).* **EB:** *Olfactory: Exposure of breast milk odor can reduce need for O_2 therapy (Karbandi et al, 2015).* **EBN:** *Visual: Provide stable lighting, shield eyes from bright lights, and monitor visual stimulation until 37 weeks' gestation (Altimier & Phillips, 2016).* **EBN:** *Vestibular: Change position every 4 hours (Altimier & Phillips, 2016). Vestibular stimulation (movement in space such as rocking, being carried while an adult is walking, being held while the infant sways) is critical for neurodevelopment (Standley & Gutierrez, 2020).*
- Incorporate parents as coparticipants of infant care by communicating daily progress of their infant's condition. **EBN:** *Parents would rather speak with a physician or nurse they are already familiar with versus outside sources for education and support* (*Wigert & Bry, 2018*).
- Provide social support to parents including all members of the family. **EB:** *Implement parent-to-parent support as an effective way for NICU parents to gain confidence, improve mental health, and prepare for discharge* (*Hall et al, 2017*).

Multicultural

- Identify cultural beliefs, norms, and values of family's perceptions of infant/child behavior. **EB:** *Additional cultural perspectives would complement research guided by attachment theory and could shed new light on this phenomenon* (*Bader & Fouts, 2019*).
- Recognize and support positive mother–infant interactive behaviors and be sensitive to cultural and ethnic backgrounds. **EB:** *In a systematic literature review, it was noted that cultural factors influence what parents expect in regard to their emotional displays and how parents will respond. Research methods suggest that perception of infant emotion is complex (Bader & Fouts, 2019).*

Client/Family Teaching and Discharge Planning

- Perform a family assessment to understand the family's specific needs and circumstances. **EB:** *A family assessment will complement the discharge readiness assessment and should be a standard part of the discharge process (Smith, 2019).*
- Assess for any sociodemographic risks within the family. **EB:** *Global maternal insensitivity was associated with higher attachment disorganization for infants of mothers with higher sociodemographic risk, but not for those of mothers with lower sociodemographic risk (Gedaly & Leeks, 2016).*
- Educate parents on safe "back-to-sleep" practice before NICU discharge. **EBN:** *Parental knowledge of safe sleep recommendations and compliance with safe sleep practices were both significantly higher after written and verbal education. The results supported previous findings that providing current written material along with modeling safe sleep practices in the hospital before discharge to home can help further reduce the incidence of SIDS (Dufer & Godfrey, 2017).*

▲ Provide information or refer to community-based follow-up programs for preterm/at-risk infants and their families. **EBN:** *Strategies may include support groups, home nurse visiting programs, psychotherapy, parent-to-parent support activities, wellness coaching, and online parent community connections (Mosher, 2017).*

▲ Refer and support transition to early intervention services on discharge. **EBN:** *Initiating NICU discharge planning earlier by a trusted health care professional may influence participation (Koldoff, 2018).*

Home Care

- Assess for domestic violence risks in the home environment. **EB:** *Infants and toddlers who witness violence in their homes or community show excessive irritability, immature behavior, sleep disturbances, emotional distress, fear of being alone, and regression in toileting and language (Hagan, Shaw, & Duncan, 2017).*
- Listening to fears, answering questions, and giving time to practice new skills before discharge may increase parents' confidence for NICU discharge. **EB:** *Some parents will have difficulty bonding with their infant, may be less responsive to infant cues, and may be less aware of their infant's development (Mosher, 2017).*
- Encourage parents to use home visitation whenever possible because it enhances neonatal progress and parental support. **EBN:** *Home visitation is effective for education and support for infants and families after NICU discharge (Parker, Warmuskerken, & Sinclair, 2015).*
- Encourage families to teach extended family and support persons to recognize and respond appropriately to the infant's behavioral cues; supportive help may be most appreciated doing physical tasks. **EB:** *Early relationship between infants and their primary caregivers is critical to future child mental health and well-being; the development of secure and organized infant attachment depends on caregiving and parenting behaviors characterized by high sensitivity, responsivity, and nurturance (Erickson, Julian, & Muzik, 2019).*
- Provide education on positioning and handling that supports optimal infant growth and development. **EB:** *Encourage the importance of tummy time when awake and supervised (Hewitt et al, 2020).*
- Suggest babywearing. Babywearing holds babies in a kangaroo position to support caregivers and promote positive health outcomes after NICU discharge. **EBN:** *The themes identified indicate that babywearing has the potential to address harms—such as stress, fear, depression, anxiety, and posttraumatic stress disorder—that may be experienced by caregivers of infants discharged from the NICU (Miller et al, 2020).*
- Encourage home visitors to recognize maternal depression resulting from the NICU or new parent experiences. **EB:** *Mothers who are at risk for depression in their infants' early lives may be hampered in their capacity to respond appropriately to their infants' mental states. Infants with mothers who have difficulty responding appropriately to their mental states, as suggested by low appropriate mind-mindedness, may feel less known and recognized by their mothers, a key theme in the origins of disorganized attachment (Bigelow et al, 2018).*
- Provide families with information about community resources, developmental follow-up services, and parent-to-parent support programs, and request primary health care providers to follow developmental

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

progress with parent-friendly developmental questionnaires. **EBN:** *The validated Premature and Young Infant Development Assessment Tool (PYIDAT) is designed for premature infants from 34 weeks' gestation to 5 months adjusted age, and is a validated tool that offers a comprehensive assessment of premature infants (DeWys et al, 2016).*

Readiness for Enhanced Organized Infant Behavior

Domain 9 Coping/stress tolerance Class 3 Neurobehavioral stress

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

An integrated pattern of modulation of the physiological and neurobehavioral systems of functioning, which can be strengthened.

Defining Characteristics

Primary caregiver expresses desire to enhance cue recognition; primary caregiver expresses desire to enhance environmental conditions; primary caregiver expresses desire to enhance recognition of infant's self-regulatory behaviors

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plans for Disorganized **Infant** Behavior and Risk for Disorganized **Infant** Behavior.

Risk for Disorganized Infant Behavior

Domain 9 Coping/stress tolerance Class 3 Neurobehavioral stress

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to disintegration in the pattern of modulation of the physiological and neurobehavioral systems of functioning, which may compromise health.

Risk Factors

Caregiver misreading infant cues; environmental overstimulation; feeding intolerance; inadequate caregiver knowledge of behavioral cues; inadequate containment within environment; inadequate physical environment; insufficient environmental sensory stimulation; malnutrition; pain; sensory deprivation; sensory overstimulation

At-Risk Population

Infants exposed to teratogen in utero; infants with low postmenstrual age; premature infants

Associated Conditions

Congenital disorders; immature neurological functioning; impaired infant motor functioning; inborn genetic diseases; invasive procedure; oral impairment

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to Disorganized **Infant** Behavior.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Risk for Infection

Domain 11 Safety/protection Class 1 Infection

Teri Hulett, RN, BSN, CIC, FAPIC

NANDA-I

Definition

Susceptible to invasion and multiplication of pathogenic organisms, which may compromise health.

Risk Factors

Difficulty managing long-term invasive devices; difficulty managing wound care; dysfunctional gastrointestinal motility; exclusive formula feeding; impaired skin integrity; inadequate access to individual protective equipment; inadequate adherence to public health recommendations; inadequate environmental hygiene; inadequate health literacy; inadequate hygiene; inadequate knowledge to avoid exposure to pathogens; inadequate oral hygiene habits; inadequate vaccination; malnutrition; mixed breastfeeding; obesity; smoking; stasis of body fluid

At-Risk Population

Economically disadvantaged individuals; individuals exposed to disease outbreak; individuals exposed to increased environmental pathogens; individuals with low level of education; infants who are not breastfed

Associated Conditions

Altered pH of secretion; anemia; chronic illness; decrease in ciliary action; immunosuppression; invasive procedure; leukopenia; premature rupture of amniotic membrane; prolonged rupture of amniotic membrane; suppressed inflammatory response

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Risk Control: Infectious Process; Immune Status

Example NOC Outcome with Indicators

Risk Control: Infectious Process: Identifies signs and symptoms of infection/Maintains a clean environment/ Practices infection control strategies: universal precautions, hand sanitization. (Rate the outcome and indicators of **Risk Control: Infectious Process:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free from symptoms of infection during contact with health care providers
- State symptoms of infection before initiating a health care–related procedure
- Demonstrate appropriate care of infection-prone sites within 48 hours of instruction
- Maintain white blood cell count and differential within normal limits within 48 hours of treatment initiation
- Demonstrate appropriate hygienic measures such as handwashing, oral care, and perineal care within 24 hours of instruction

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Immunization/Vaccination Management; Infection Control; Infection Protection

Example NIC Activities—Infection Protection and Control

Wash hands before and after each client contact; Ensure aseptic handling of all intravenous lines; Ensure appropriate wound care technique; Teach client and family members how to avoid infections

Nursing Interventions and *Rationales*

- Maintain open communication with the infection prevention (IP) department. Inquire about facility-specific targeted multidrug-resistant organism (MDRO) surveillance. Learn which MDROs are of significant importance at your facility. Acquire a basic understanding of antibiotic stewardship through collaboration with IP and pharmacy. **EB:** *Active surveillance for targeted MDROs is an integral component of infection prevention and control, allowing for early detection of colonized clients. Early detection provides the ability for early implementation of evidence-based best practices to prevent transmission in health care settings (Bastiaens et al, 2020). Antibiotic stewardship ensures that clients get the right antibiotics at the right time for the right duration. Data support that at least 1 in 3 antibiotic prescriptions, or 47 million prescriptions per year, prescribed in doctors' offices and emergency departments are unnecessary (US Task Force for Combating Antibiotic-Resistant Bacteria, 2017).*
- Obtain a travel history and history of any overnight stay in a hospital in a foreign country from clients presenting to the health care site (e.g., emergency department, clinic). **EB:** *MDROs pose a global threat. Carbapenem-resistant Enterobacteriaceae (CRE) is a worldwide urgent public health problem. Antibiotic misuse, genetic mobile elements, international travel, and ineffective infection control measures are the main predisposing factors for the emergence of resistance. Often clients are asymptomatic due to colonization versus an active infection (European Centre for Disease Prevention and Control, 2018; Alotaibi, 2019).*
- Antimicrobial resistance and health care–associated infections (HAIs) are global health problems that increase social and economic burden and are associated with higher mortality and increased hospital stays. Inappropriate antimicrobial use is estimated to be at 20% to 50% and is believed to be a key contributor to antimicrobial resistance. The Centers for Disease Control and Prevention (CDC) and the American Nurses Association (ANA) identify staff nurses as critical players in antibiotic stewardship (AS) work. Nurses play a key role in ensuring client safety and quality (Olans et al, 2017; Jeffs et al, 2018; CDC, 2019a; Monsees et al, 2020). **EB:** *Nurses are key to driving AS interventions directly at the point of care. Review microbiology laboratory culture and sensitivity reports. Actively participate in AS, including AS rounds. Facilitate discussion on antibiotic time-outs, appropriateness of switching from IV to oral antibiotic administration, and monitoring and reporting of possible antibiotic-related adverse events* (Olans et al, 2017; Jeffs et al, 2018; Monsees et al, 2020).
- Sepsis is the body's overwhelming and life-threatening response to infection that can lead to tissue damage, organ failure, and death. Sepsis and septic shock are leading causes of death worldwide. Early identification and aggressive treatment are integral to sepsis survival. Nurses play a significant role in early identification of sepsis. Monitor vital signs and mental status. **EB:** *Implement nurse-led sepsis screening interventions to improve early recognition of sepsis (Kleinpell, 2017). Monitor the client for signs and/or symptoms of sepsis (confusion or disorientation, high or low blood pressure, fever, shivering, or feeling very cold, shortness of breath, extreme pain or discomfort, clammy or sweaty skin) and notify providers immediately (CDC, 2020; Sepsis Alliance, 2020).*
- Assess temperature of neutropenic clients; report a single temperature of greater than 38°C (100.5°F). **EB:** *Fever is often the first sign of an infection (Klastersky et al, 2016).* **EB:** *Clients with depressed immune function are unable to mount the usual immune responses to the onset of infection; abnormal temperature (high or low) may be the only sign of infection. A neutropenic client with abnormal temperature (high or low) represents an absolute medical emergency. Febrile neutropenia is a medical emergency that requires urgent evaluation, the timely administration of empiric broad-spectrum antimicrobials, and careful monitoring to optimize client outcomes and mitigate the risk of complications (Braga et al, 2019).*
- Oral, rectal, tympanic, temporal artery, or axillary thermometers may be used to assess temperature in adults and infants. **EBN:** *The use of axillary in addition to oral, tympanic, and temporal artery temperature measurement is supported (Bland, Conner, & Messenger, 2020). Rectal and oral temperature measurements are more accurate than other methods of temperature measurement, such as temporal or axillary measurement (Bland, Conner, & Messenger, 2020).*

▲ Note and report laboratory values (e.g., white blood cell count and differential, serum protein, serum albumin, cultures). **EBN:** *Although the white blood cell count may be in the normal range, an increased number of immature bands may be present (Shi et al, 2015).* **EBN:** *A neutropenic client with fever represents an absolute medical emergency (Braga et al, 2019).*

- Assess skin for color, moisture, texture, and turgor (elasticity). Keep accurate, ongoing documentation of changes. **EB:** *A number of instruments have been developed to assess for risk of pressure ulcers, including the Braden, Norton, and Waterlow scales. All three scales include items related to activity mobility, nutritional status, incontinence, and cognition (Balzar & Kottner, 2015).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Carefully wash and pat dry skin, including skinfold areas. Use hydration and moisturization on all at-risk surfaces. **EBN:** *Moisturizers result in an increase of skin hydration and restoration of the skin barrier function and play a prominent role in the long-term management of atopic dermatitis (Mayo Clinic Staff, 2020a).* **EB:** *Applying moisturizer improves skin barrier repair and maintains skin's integrity and appearance by acting as humectants, emollients, and occlusives, each with its own mechanism of action and enhancing skin barrier function. Moisturizers improve skin hydration and increase stratum corneum water content (Purnamawati et al, 2017). Refer to care plan for Risk for Impaired* ***Skin*** *Integrity.*

▲ Monitor client's vitamin D level. **EB:** *Vitamin D deficiency has been correlated with increased risk and greater severity of infection, particularly of the respiratory tract. Vitamin D influences the body's immune system by influencing the production of endogenous antimicrobial peptides and regulating the inflammatory cascade (Dankers et al, 2017). Refer to care plan Readiness for Enhanced* ***Nutrition*** *for additional interventions.*

- Use strategies to prevent health care–acquired pneumonia: implement an evidence-based pneumonia prevention bundle, aggressive mobilization, assess client risk for aspiration and request swallow evaluation as necessary, position client in an upright position for all meals, and provide aggressive oral care at least twice per day (Tablan et al, 2004; Gupta et al. 2019; Naik et al, 2019). Implementation of an evidence-based ventilator-associated pneumonia (VAP) bundle should be followed. Management of ventilated clients should include avoidance of benzodiazepines to manage agitation, daily interruption of sedation (sedation vacation), daily assessment of readiness to extubate (spontaneous breathing trials), use of endotracheal (ET) tubes that accommodate subglottic suctioning, and maintaining head of bed (HOB) at 30 to 45 degrees (Tablan et al, 2004; Klompas et al, 2014). **EB:** *All-cause mortality associated with VAP has been reported to range from 20% to 50% and attributed mortality estimated to be 13%. VAP also adds an estimated cost of $40,000 to a typical hospital admission (Kalil et al, 2016).*
- Encourage fluid intake. **EB:** *Fluid intake helps thin secretions and replace fluid lost during fever (Mayo Clinic Staff, 2020b).*
- Use appropriate hand hygiene (i.e., handwashing or use of alcohol-based hand rubs). **EBN:** *Meticulous infection prevention precautions are required to prevent HAI, with particular attention to hand hygiene and standard precautions (Boyce et al, 2002).* **CEB:** *Handwashing is currently the recommended strategy for reducing transmission of Clostridioides (Clostridium) difficile. Alcohol gels do not inactivate C. difficile spores (World Health Organization [WHO], 2009).*
- When using an alcohol-based hand rub, apply an ample amount of product to the palm of one hand and rub hands together, covering all surfaces of hands and fingers, until hands are dry. Note that the volume needed to reduce the number of bacteria on hands varies by product. **EB:** *Adequate hand antisepsis reduces infection rates. The use of alcohol-based hand rubs is particularly effective; in contrast to handwashing, hand rubs kill susceptible bacteria more rapidly and to a greater extent and are less time-consuming. Also, skin health is better preserved when moisturizers are added (Boyce et al, 2002).*
- Follow standard precautions and wear gloves during any contact with blood, mucous membranes, nonintact skin, or any body substance except sweat. Use goggles and gowns when appropriate. Standard precautions apply to all clients. You must assume all clients are carrying blood-borne pathogens (Siegel et al, 2007). **EB:** *Hands of health care workers are a common cause of HAIs. Evidence supports decreased HAIs with increased handwashing frequency among hospital staff (Boyce et al, 2002).*
- Implement respiratory hygiene/cough etiquette. **CEB:** *Providing control measures (tissues and masks) and accessibility to hand hygiene materials reduces risks of transmission of respiratory illness (Siegel, 2007).*
- Follow transmission-based precautions for airborne-, droplet-, and contact-transmitted microorganisms:
  - **Airborne:** Isolate the client in a room with monitored negative air pressure, with the room door closed and the client remaining in the room. Always wear appropriate respiratory protection when you enter the room. Limit the movement and transport of the client from the room to essential purposes only. Have the client wear a surgical mask during transport.
  - **Droplet:** Keep the client in a private room, if possible. If not possible, maintain a spatial separation of 3 feet from other beds or visitors. The door may remain open. Wear a surgical mask when you must come within 3 feet of the client. Some hospitals may choose to implement a mask requirement for droplet precautions for anyone entering the room. Limit transport to essential purposes and have the client wear a mask, if possible.
  - **Contact:** Place the client in a private room, if possible, or with someone (cohorting) who has an active infection from the same microorganism. Wear clean, nonsterile gloves when entering the room. When providing care, change gloves after contact with any infective material such as wound drainage. Remove

the gloves and clean your hands before leaving the room and take care not to touch any potentially infectious items or surfaces on the way out. Wear a gown before entering the contact precaution room. Remove the gown before leaving the room. Limit transport of the client to essential purposes and take care that the client does not contact other environmental surfaces along the way. Dedicate the use of noncritical client care equipment to a single client. **CEB:** *If use of common equipment is unavoidable, adequately clean and disinfect equipment before use with other clients (Siegel et al, 2007).*

▲ Use alternatives to indwelling catheters whenever possible (external catheters, incontinence pads, and bladder control techniques). **EB:** *It is estimated that catheter-associated urinary tract infections (CAUTIs) increase length of stay by 0.5 to 1 day and increase costs between $1200 and $4700 (2009 dollars) (Brusch, 2021).*

- If a urinary catheter is necessary, follow catheter management practices. All indwelling catheters should be connected to a sterile, closed drainage system (i.e., not broken), except for good clinical reasons. Cleanse the perineum and meatus twice daily using soap and water. **EBN:** *A nurse-driven protocol CAUTI reduction process and protocol can significantly reduce catheter use and duration, as well as CAUTIs and hospital length of stay (Johnson et al, 2016).* **EB:** *Significant rates of inappropriate urinary catheter use underscore the importance of establishing guidelines and implementing policy for appropriate use of urinary catheters (Agency for Healthcare Research and Quality [AHRQ], 2015).*
- Use evidence-based practices and educate personnel in care of peripheral catheters: use aseptic technique for insertion and care, label insertion sites and all tubing with date and time of insertion, inspect every 8 hours for signs of infection, record, and report. **EB:** *Use of chlorhexidine gluconate for vascular catheter site care reduces catheter-related bloodstream infections and catheter colonization (O'Grady et al, 2011).*
- Use sterile technique wherever there is a loss of skin integrity. **EBN:** *Skin and soft tissue infections arise when skin integrity is broken by treatments associated with trauma, surgery, burns, and so forth (Stevens et al, 2014).*
- Good personal hygiene is essential for skin health but it also has an important role in maintaining self-esteem and quality of life. Supporting clients to maintain personal hygiene is a fundamental aspect of nursing care. Personal hygiene includes hair, skin, nails, mouth, perineal areas, and facial shaving (Lawton & Shepherd, 2019). Ensure the client's daily personal needs are met by either the client, family, or nurse. **EBN:** *Daily showers or baths can reduce skin pathogen bioburden. Use evidence-based bathing protocols including chlorhexidine bathing to reduce skin pathogen burden for clients with indwelling devices (Donskey & Deshpande, 2016).*
- Recommend responsible use of antibiotics; use antibiotics sparingly. **EB:** *Use and misuse of antibiotics diminishes their therapeutic benefit and facilitates the development of MDROs and* C. difficile*–associated disease and increases health care costs. Antibiotic stewardship is essential in reducing current and future resistance in bacteria (Barlam et al, 2016; CDC, 2019a).*

Pediatric

Note: Many of the preceding interventions are appropriate for the pediatric client.

- Follow meticulous hand hygiene when working with children. **EB:** *Keep nails short; prohibit false fingernails, and limit wearing jewelry because it interferes with effective hand hygiene (American Academy of Pediatrics & The American College of Obstetricians and Gynecologists, 2017).*
- Encourage early enteral feeding with human milk. *Human milk enhances immune defenses of the infant (Praveen et al, 2015).*

▲ Monitor recurrent antibiotic use in children.

- Instruct parents on appropriate indicators for medical visits and the risks associated with overuse of antibiotics. **EB:** *Guidelines addressing treatment of asthma in children state that antibiotics should not be used as part of chronic asthma therapy or for acute exacerbations, with the exception of clients with comorbid bacterial infections such as pneumonia or sinusitis (Leung et al, 2021).*

Geriatric

▲ Suspect pneumonia when the client has symptoms of disorientation, confusion, respiratory rate of 30 or higher, and fever above 37.8°C (100°F). Offer clients influenza and pneumococcal vaccinations per national guidelines (CDC, 2019b). Assess response to treatment, especially antibiotic therapy. **EB:** *Pneumonia is a leading cause of hospitalization and death among the elderly (US Department of Health and Human Services, 2021). Together, influenza and pneumonia are the eighth leading cause of mortality among*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

adults in the United States. Community-acquired pneumonia (CAP) disproportionately affects the elderly, with an annual incidence of 9.2 to 33 per 1000 person-years (Kaysin & Viera, 2016).

- Most clients develop health care–associated pneumonia (HCAP) by either aspirating contaminated substances or inhaling airborne particles. Refer to care plan for Risk for **Aspiration.**

▲ Carefully screen older women with incontinence for urinary tract infections. **CEB:** *Consider alternatives to chronic indwelling catheters, such as intermittent catheterization. CAUTI has been associated with increased morbidity, mortality, hospital cost, and length of stay (Gould et al, 2009).*

- Observe and report if the client has a low-grade fever or new onset of confusion. **EB:** *Immunosenescence is the weakening of the immune system in the elderly. Immunosenescence leaves the elderly client with a decreased ability to mount strong immune responses and therefore at increased risk of infections. Those caring for elderly clients must be alert to the potential presence of infection when even low-grade temperature elevations appear for short periods due to the client's inability to mount a strong immune response (Ventura et al, 2017).*
- Recognize that chronically ill geriatric clients have an increased susceptibility to *C. difficile* infection; practice meticulous hand hygiene and monitor antibiotic response to antibiotics. **EB:** *The incidence of* C. difficile *illness (CDI) is increasing with the greatest impact in persons older than 65 years. More than 90% of deaths from CDI have occurred in this population (CDC, 2019a).*

Home Care

- Adapt the previously mentioned interventions for home care as needed.
- Assess and treat wounds in the home. **EBN:** *Promotion of wound healing is a nursing priority. Managing wounds and promoting healing of wounds requires a set of interventions that when used together can speed healing and help to maintain overall health. Families can be taught wound care/management with nurses evaluating the client at regular intervals for management of care. Families must be educated on the triad of wound care—nutrition, technique, and infection prevention—to manage their loved ones at home (Berden, 2021).*
- Review standards for surveillance of infections in home care. **EB:** *Infection surveillance in the home care setting poses unique challenges for home care providers and clients. The lack of standard definitions and surveillance methods for home care–acquired infections hinders efforts to collect and analyze valid data on infection rates, which hampers efforts to analyze risk factors that lead to effective control efforts. Other obstacles include insufficient infrastructure to meaningfully capture numerator and denominator data (Carpenter et al, 2017).*
- Maintain infection-prevention standards of practice. **EBN:** *The increasing care complexity of clients in the home, ineffective care coordination, and communication challenges present significant safety issues, including infections (Carpenter et al, 2017).*
- Refer for nutritional evaluation; implement dietary changes to support recovery and maintain health. **EB:** *Evidence supports that individual medical nutrition therapy has strong effects on clinical outcomes, reinforcing the aim to practice "evidence-based medical nutrition" (EBMN), especially with the vulnerable malnourished population. EBMN incorporates combining clinical judgment, client preferences, and the most current scientific evidence. Such an approach may be helpful to improve clinical outcomes in the vulnerable population (Kaegi-Braun et al, 2020).*

Client/Family Teaching and Discharge Planning

- Teach the client risk factors contributing to surgical wound infection. **EB:** *The risk of infection is influenced by characteristics of the client such as age, obesity, and nutritional status (Carpenter et al, 2017).*
- Teach the client and family the importance of hand hygiene in preventing postoperative infections. **CEB:** Two-thirds of wound infections occur after discharge. Using good hand hygiene practices is effective for preventing these infections (*Siegel et al, 2007*).

▲ Encourage high-risk persons, including health care workers, to get vaccinated (CDC, 2019b; CDC, 2021).

▲ Influenza: Teach symptoms of influenza and the importance of vaccination for influenza. Provide client education using the CDC Vaccine Information Sheets (VISs). **EB:** *Influenza can be associated with serious illness, hospitalization, and death, particularly among the very young, the elderly, pregnant women, and persons of all ages with certain chronic medical conditions. Routine annual influenza vaccination is recommended for all persons age ≥6 months who do not have contraindications (Grohskopf et al, 2020).*

Risk for Surgical Site Infection

Domain 11 Safety/protection Class 1 Infection

Teri Hulett, RN, BSN, CIC, FAPIC

NANDA-I

Definition

Susceptible to invasion of pathogenic organisms at surgical site, which may compromise health.

Risk Factors

Alcoholism, obesity, smoking

At-Risk Population

Individuals exposed to excessive number of personnel during surgical procedure; individuals exposed to increased environmental pathogens; individuals with American Society of Anesthesiologists (ASA) Physical health status score ≥ 2

Associated Conditions

Diabetes mellitus; extensive surgical procedures; general anesthesia; hypertension; immunosuppression; inadequate antibiotic prophylaxis; ineffective antibiotic prophylaxis; infections at other surgical sites; invasive procedure; post-traumatic osteoarthritis; prolonged duration of surgical procedure; prothesis; rheumatoid arthritis; significant comorbidity; surgical implant; surgical wound contamination

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Risk Control: Infectious Process, Immune Status

Example NOC Outcome with Indicators

Risk Control: Infectious Process. Personal actions to understand, prevent, eliminate, or reduce the threat of acquiring an infection as evidenced by client demonstrating the following indicators: Identifies risk factors for infection/Acknowledges personal risk factors for infection/Acknowledges behaviors associated with risk for infection/Monitors personal behaviors for factors associated with infection/Maintains a clean environment/Practices hand sanitization. (Rate the outcome and indicators of **Risk Control: Infectious Process:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free from symptoms of surgical site infections (SSIs)
- Identify personal risk factors associated with increased SSI risk
- Modify personal behaviors that increase SSI risk
- Demonstrate appropriate hygienic practices to reduce infection risk such as handwashing

NIC (Nursing Interventions Classification)

Suggested NOC Outcomes

Infection Control, Infection Control: Intraoperative, Infection Protection, Teaching: Individual, Preoperative

Example NIC Activities—Risk for Surgical Site Infection

Verify that prophylactic antibiotics have been ordered and administered as appropriate; Monitor and maintain client normothermia (temperature of 35.5°C [95.9°F] or above) during the perioperative period

Nursing Interventions and *Rationales*

▲ The number of surgical procedures performed in the United States continues to rise, and surgical clients often have comorbidities that increase the complexity. It is estimated that approximately half of SSIs are deemed preventable using evidence-based strategies (World Health Organization [WHO], 2018). SSIs are a complication of surgical care and are associated with significant morbidity, mortality, and cost (Preas, O'Hara, & Thom, 2017).

▲ Optimizing the client's medical condition before surgery and eliminating or even diminishing modifiable risk factors for infection can lower the risk of SSIs (Hutzler & Williams, 2017). **EB:** *Modifiable risk factors include current or history of orthopedic infection, rheumatoid arthritis, poor oral health, urinary tract infection, obesity, methicillin-resistant* Staphylococcus aureus *(MRSA), preoperative and anticipated postoperative anemia, smoking, malnutrition, diabetes, and HIV (Hutzler & Williams, 2017). The American College of Surgeons (ACS) identifies additional modifiable risk factors as poor glycemic control and diabetic status, dyspnea, alcohol and smoking history, preoperative albumin level (<3.5 mg/dL), total bilirubin greater than 1.0 mg/dL, obesity, and immunosuppression (Ban et al, 2017).*

▲ SSI prevention, known as surgical care bundles, consists of evidence-based interventions that, when implemented together, can reduce the risk of infection. There are different surgical care bundles for specific high-risk surgical procedures, for example, colorectal surgery bundle, pediatric spinal surgery bundle, total joint arthroplasty surgery bundle, and cardiothoracic surgery bundle. **EB:** *Aspects of each*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

surgical care bundle that are universal for all surgical procedures include prehospital preoperative bathing, smoking cessation, and glucose control. Hospital-focused bundle interventions include perioperative blood glucose monitoring, surgical site hair-removal technique, surgical site skin preparation, surgical hand scrub, antibiotic prophylaxis, intraoperative normothermia, and supplemental oxygen delivery for clients undergoing general anesthesia (intubated clients) (Anderson et al, 2017; Ban et al, 2017).

▲ SSIs can occur because of either client-related (endogenous) or procedure-related (exogenous) risk factors. Risk factors are further stratified into preoperative, intraoperative, and postoperative risk.

● Review endogenous client-related risk factors. **EB:** *Review client history with client before surgical procedure to identify modifiable risk factors that can be addressed preoperatively* (*Anderson et al, 2017*; *Kahn et al, 2020*).

Compromised Host Defenses

● Age: Extremes of ages and advanced age increase client risk. **EB:** *Relationship to increased risk of SSI may be secondary to more comorbidities, impaired immune response to infectious agents, or inferior nutritional status (Triantafyllopoulos et al, 2015).*

● Wound: A wound classification scoring system is used to identify the degree of surgical site skin integrity at the time of surgery. Assess and document skin integrity during the preoperative period to identify classification of surgical site. **EB:** *The Centers for Disease Control and Prevention (CDC) recommends assessing surgical wounds and determining the probability of SSI by using a classification that consists of four types of surgical wounds: clean (sterile body site), clean-contaminated, contaminated, and dirty (heavily contaminated site) wounds (Onyekwelu et al, 2017).* **EB:** *The method of wound classification has been adopted by the ACS and has been effectively used for more than 40 years to stratify the client's risk for SSI. The traditional wound classification system of categorizing procedures into risk groups is based on the degree of microbial contamination (Allen, Apisarnthanarak, & Archer, 2017).*

● Smoking: The nicotine in tobacco products results in microvascular vasoconstriction, in addition to tissue hypoxia, which can contribute to the development of SSI. Surgical complications, such as SSI, can be decreased by 50% in clients who successfully stop smoking before surgery (Anderson et al, 2017). **EB:** *The increased risk of SSI in clients who smoke is partially related to vasoconstriction of vessels in the surgical bed, which leads to tissue hypovolemia and hypoxia. Poor tissue perfusion affects the transport of nutrients and alters the immune response, which affects healing (Ban et al, 2017). Smoking cessation before surgery is critical to optimally preparing clients for surgery. To be effective, smoking cessation needs to occur 4 to 8 weeks before surgery. Smoking cessation of less than 4 weeks does not affect risk of SSI (Anderson et al, 2017).*

▲ Assess client's smoking status and offer smoking cessation information to the receptive client. Seek nicotine patch order for client use during hospital admission.

▲ Educate the client on smoking risks using the CDC Fact Sheet on Health Effects of Cigarette Smoking (CDC, 2020).

● Nutrition status: Assess the client's nutrition status. Preoperative risk factors include albumin less than 3.5 mg/dL or total bilirubin greater than 1.0 mg/dL (Ban et al, 2017; Tsantes et al, 2020). Malnutrition leads to less competent immune response and increased risk of acquiring infections (Tsantes et al, 2020). **EBN:** *Clients who are malnourished and have low albumin levels are more likely to develop SSIs (Tsantes et al, 2020). Review preoperative laboratory tests and monitor postoperative laboratory values to assess for malnourishment. Provide nutritional consultation and support as needed. Anticipate the malnourished client to receive total parenteral nutrition (TPN) in addition to oral nutrition during the initial postoperative period. Consider the administration of oral nutritional supplements (e.g., protein shakes, high-protein snacks) as recommended by the registered dietitian after dietary consultation.*

● Immunocompromised/immunosuppression: Clients who are immunocompromised or who have immunosuppression are at increased risk of developing infection because of their weakened immune system and inability to mount a defense against pathogenic organisms. Clients who may be immunocompromised or immunosuppressed include clients receiving cancer treatment, organ transplant recipients, clients taking steroids, and clients with HIV. **EBN:** *Determine the use of chronic medications such as steroids and immunosuppressives. These medications have been shown to increase SSI rates and negatively affect wound healing. There is no recommendation to taper or discontinue systemic steroid use (when medically permissible) before elective surgery (Triantafyllapoulos et al, 2015; Berríos-Torres et al, 2017).*

● Review the client's medical history and current medications. Medications that compromise the client's immune response may increase the risk of SSI.

- Diabetes mellitus: Monitor blood glucose levels with the goal to maintain normoglycemia in the perioperative period. Educate the client of the increased risk for SSI with episodes of hyperglycemia. When available, coordinate referral to a diabetic educator as part of the discharge education. **EB:** *Due to the disruption of the vascular system in clients with diabetes, SSIs are increased. Clients with diabetes have been shown to have worse client-reported outcomes up to 2 years after spine surgery. It is recommended that hemoglobin A1C values be measured during the perioperative period. Clients with a hemoglobin A1C less than 7 had a 0% infection rate, whereas clients with hemoglobin AIC values greater than 7 had infection rates of 35.3%. Improved glycemic management can restore white blood cell function and reduce risk of infection (Anderson et al, 2017).*
- Preexisting infection: Be aware of all preoperative laboratory work, positive cultures, and actions taken to treat the infection (e.g., was the client started on oral antibiotics). **EBN:** *Remote infections should be identified and treated following evidence-based guidelines before surgical procedure (Triantafyllopoulos et al, 2015).*
- Obesity: Obesity is defined as a body mass index (BMI) greater than 30 kg/m^2. Obese clients are at significant risk for SSI, more surgical blood loss, and a longer operation time. **EB:** *Obese clients have excessive subcutaneous fat tissue, which predisposes these clients to impaired healing, low regional perfusion, and low oxygen tension at the surgical site. Longer operation times and increased blood loss greater than 1 L are significant predictors of postoperative wound infections. The obese client is also likely to have more comorbidities, such as diabetes, than nonobese clients, increasing the risk of SSI (Tjeertes et al, 2015; Anderson et al, 2017). Provide discharge teaching for signs and symptoms of poor wound healing and SSI.*

Procedure-Related Risk Factors—Exogenous

- SSI pathogenic microbes may originate from exogenous sources such as the operating room environment, members of the surgical team, and instruments and material brought within the surgical field during the procedure (Kahn et al, 2020). Observe clients identified as being at increased risk for SSI because of modifiable risk factors for signs and/or symptoms of postoperative SSI.
- Extended procedure time may increase SSI risk. **EB:** *Prolonged operations that increase the length of time that tissues are exposed increase the risk of exogenous contamination of the surgical site (Triantafyllopoulos et al, 2015; Anderson et al, 2017; Ban et al, 2017).*
- Estimated blood loss greater than 1 L requiring blood transfusion increases the risk of SSI. **EB:** *Allogeneic (donor) blood transfusion is an independent risk factor for SSI. Transfusion of allogeneic blood is considered to induce immunomodulation to the recipient, due to the presence of white blood cells (WBCs) above a critical level (Triantafyllopoulos et al, 2015). The use of allogeneic (donor) blood transfusions is associated with increased length of stay and induces immunomodulation that can lead to increased risk for infection at the surgical site (Huntzler & Williams, 2017).*
- Suboptimal timing of prophylactic antibiotic places the client at increased risk of SSI. **EB:** *Administer preoperative prophylactic antimicrobial agent(s) as prescribed (Berríos-Torres et al, 2017). Surgical antibiotic prophylaxis (SAP) should be administered within 1 hour before incision or within 2 hours for vancomycin or fluoroquinolones. This allows for maximal antibiotic concentration circulating in the blood serum and tissue at the time of surgical incision (Ban et al, 2017). Evidence shows that the administration of SAP after the incision causes a significant increase of SSI risk compared with administration of the SAP before incision (WHO, 2018).*
- Preoperative infections place the client at increased risk of SSI before elective surgery. **EB:** *Appropriately identify and treat infections (e.g., urinary tract infection) before surgical procedures. Do not routinely treat urinary tract colonization or contamination in the absence of clinical urinary tract infection symptoms (urgency, costovertebral angle pain, flank pain, pain with urination, and fever). Obtaining urine cultures when not clinically indicated, including for routine screening, promotes inappropriate antimicrobial use. Given the potential negative societal consequence of antimicrobial resistance, the Infectious Diseases Society of America (IDSA) guideline committee felt that screening for bacteriuria and treatment of asymptomatic bacteriuria (ASB) should be discouraged unless there is evidence to support a benefit of treatment for a defined population* (Nicolle et al, 2019).
- Preoperative interventions: Establish a protocol for procedure-specific preoperative testing to detect medical conditions that increase the risk of SSI. The protocol should focus on nutritional counseling, glycemic control, smoking cessation, preadmission infections, and reconciling medications with adjustments before surgery as indicated (Anderson et al, 2017; Kahn et al, 2020).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Identify high risks: diabetes, history of transplant, chemotherapy, immunosuppressed or immunocompromised, elderly, poor dentition, obese, and malnourished. Clients having a high-risk procedure with an extended surgical procedure time (e.g., cardiac surgery, joint replacement, major abdominal surgery) are at increased risk of SSI. **EB:** *Identifying high-risk clients through screening and electronic medical record alerts should be used to inform all members of the perioperative team of the client's high-risk condition(s) (Anderson et al, 2017; Kahn et al, 2020).*
- Maintain glycemic control for clients with and without diabetes. **EB:** *Elevated blood glucose levels greater than 200 mg/dL cause the release of proinflammatory cytokines that depress the immune system, increasing susceptibility to SSIs (Berríos-Torres et al, 2017). Hyperglycemia in the immediate preoperative period is associated with an increased risk of SSI (Ban et al, 2017).*
- *Staphylococcus aureus* (SA) is the most frequent pathogen causing about 50% of SSIs. MRSA accounts for up to 35% of SA infections in primary cases and up to 48% in revision surgery. Studies show that 18% to 25% of clients undergoing elective spine and orthopedic surgery are colonized with methicillin-sensitive SA (MSSA) and 3% to 5% are MRSA carriers. Carriers of MSSA are 2 to 3 times and MRSA 8 to 10 times more likely to have an SSI. Perform SA intranasal decolonization by using cotton-tipped applicators to apply a 2% mupirocin ointment in each nostril and with 2% chlorhexidine gluconate (CHG) showers for up to 5 days before surgery (Anderson et al, 2017). **EB:** *Screen for SA (MSSA and MRSA) colonization and decolonize surgical clients before high-risk procedures, including some orthopedic and cardiothoracic procedures (Anderson et al, 2017).*
- Provide education on preoperative bathing with soap (antimicrobial or nonantimicrobial) or an antiseptic agent on at least the night before and morning of the day of surgical intervention. **EB:** *It is good clinical practice for the client to bathe or shower before surgery to ensure that the skin is as clean as possible and to reduce the bacterial load, especially at the site of incision (WHO, 2018). Instruct the client to bathe, at a minimum, the night before and morning of the surgical procedure using liquid soap, clean washcloth, and clean towel each time. Instruct the client to wear freshly laundered pajamas after showering the night before the surgical procedure and freshly laundered clothes the morning of the procedure. This process of using liquid soap and clean washcloths, towels, and clothes prevents recontamination with shed epithelial cells from previously used bar soap, washcloths/towels, and clothes.*
- Address preexisting dental and nutritional status. **EB:** *Periodontal clients have higher risk of bacteremia than those with healthy periodontium (Mirzashahi et al, 2019).* **EBN:** *Preoperative dental screenings are needed to evaluate for the presence of tooth decay, inflammatory gum disease/gingivitis, periodontitis, or dental abscesses, which lead to seeding of bacteria (Mirzashahi et al, 2019). Encourage the client to seek oral and dental examinations before high-risk surgical procedures. Educate the client on the need for good oral hygiene to decrease the risk of developing SSI. Provide the client with oral hygiene products while in the hospital. Perform oral hygiene for the client if unable to perform independently.*
- Nutrition consultation as needed.
- Prepare the surgical site using an alcohol-based antiseptic agent unless contraindicated to reduce SSI risk. **EB:** *Alcohol-based antiseptic solutions for surgical site skin preparation are more effective compared with aqueous solutions in reducing SSIs (WHO, 2018; Berríos-Torres et al, 2017).* **EB:** *Overall, there is evidence that alcohol-based preparations are more effective in reducing SSIs than aqueous preparations and should be used unless contraindications exist (Ban et al, 2017).*
- Proper hair removal. **EB:** *Shaving causes microscopic cuts and abrasions, resulting in disruption of the skin's barrier defense against microorganisms. When hair removal at the operative site is necessary, removal should be done using clippers (Ban et al, 2017).* **EB:** *Do not remove hair at the operative site unless the presence of hair will interfere with the operation. Do not use razors. If hair removal is necessary, remove hair outside the operating room using clippers or a depilatory agent (Ban et al, 2017). Shaving causes microscopic cuts and abrasions, resulting in disruption of the skin's barrier defense against microorganisms (Ban et al, 2017).*

- If possible, educate the client preoperatively on the risk of shaving the surgical site, or the area near in which the surgical incision will be, because of the risk for microscopic cuts and abrasions. These cuts and abrasions increase the risk of developing an SSI. For example, for breast surgery, instruct the client not to shave underarms because the underarm is potentially in close proximity to the surgical site. Another example is instructing the client having a total knee replacement not to shave the leg involved in the surgery.
- Intraoperative interventions:

- Maintain glycemic control. **EB:** *Implement perioperative glycemic control and use blood glucose target levels less than 200 mg/dL in clients with and without diabetes clients (Berríos-Torres et al, 2017). Short-term glucose control can be more impactful in decreasing SSIs than long-term control of hemoglobin (Hgb) A1C (Ban et al, 2017).*
- Maintain normothermia (temperature of 35.5°C [95.9°F] or above) during the perioperative period in surgical clients who have an anesthesia duration of at least 60 minutes (Anderson et al, 2017). WHO defines hypothermia as a core temperature less than 36°C (WHO, 2018). **EB:** *Hypothermia can trigger subcutaneous vasoconstriction and subsequent tissue hypoxia and increase blood loss that may lead to wound hematomas or need for transfusion, both of which can increase SSI rates (Anderson et al, 2017).*
- Provide supplemental oxygenation, during surgery for intubated clients and in the immediate postoperative period for 2 to 6 hours via a nonrebreathing mask for procedures performed under general anesthesia to ensure Hgb saturation of greater than 95% is maintained. **EB:** *Studies have found that perioperative hyperoxygenation led to a 25% decrease in SSIs (WHO, 2018; Anderson et al, 2017).* **EB:** *For clients with normal pulmonary function undergoing general anesthesia with endotracheal intubation, administer increased FiO_2 intraoperatively and postextubation in the immediate postoperative period (Berríos-Torres et al, 2017). The administration of supplemental oxygen is recommended in the immediate postoperative period after surgery performed under general anesthesia (Ban et al, 2017).*

- Postoperative interventions:
  - Discharge instructions: Teach the client postoperative self-care after discharge. Provide written instructions that include information on how and when to contact the provider, date and time for the scheduled follow-up visit, and signs and symptoms of infection. **EB:** *Educational materials should be provided in multiple languages based on the population served (Anderson et al, 2017).*
  - Wound care: Wound care instructions will be based on the type of surgical wound closure. **EB:** *Protect primarily closed incisions with a sterile dressing for 24 to 48 hours postoperatively (Berríos-Torres et al, 2017). Instruct the client to keep the surgical wound clean and dry. Teach the client signs and symptoms that would indicate an SSI, such as fever, redness, drainage, swelling, pain, and foul odor at the surgical site. Stress to the client and family that any of these signs and symptoms should be promptly reported to their provider. Assess whether the client and family know how to read a thermometer and provide instructions as necessary. Provide written wound care instructions on the prevention of SSI.*
  - Nutrition follow-up: For the malnourished and obese clients, provide written dietary instructions by the registered dietitian, if appropriate. Encourage a diet that supports wound healing (high protein) and glycemic control. If appropriate, provide written information on community nutrition support group options and contact information.
  - Bathing/showering instructions: Review instructions with client and family on timing to shower and if/when the client can take a bath. Explain to the client that taking a bath is generally discouraged, at a minimum, for the first week after surgery. *Submerging a fresh surgical wound in warm bath water and allowing it to soak is not advised because this provides an environment that potentially exposes the surgical wound to pathogenic organisms, increasing the risk for surgical wound infection.*
  - Physical therapy (PT): For clients prescribed PT after discharge, review options to access services, provide contact phone numbers to call and schedule therapy, and review options for transportation to PT appointments (e.g., spouse, family, friend, senior center transport, cab, Uber, Lyft). Work with the discharge coordinator for client assistance with transport options as needed.
  - Medications: Review discharge medication prescription(s). Provide written instructions on medication(s) ordered, how often to take them, and side effects of the prescribed medication(s). Reinforce with client and family that client should not be driving if taking prescription narcotic medications. Review with client and family pain relief expectations, explaining that 100% postoperative pain relief is not realistic, but adequate pain relief should allow the client to function, to ambulate, and to perform activities of daily living (ADLs) with minimal pain.

Pediatric

- SSI prevention measures deemed effective in adults are also indicated in the pediatric surgical population (Berríos-Torres et al, 2017).

Geriatric

- The most common cause of postoperative complication in the frail elderly is delirium (Ersan & Schwer, 2021). *Delirium will affect the ability to provide postoperative education in this population.*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- For the frail, elder client who lived independently in a private home before surgical procedure, work with the discharge coordinator to assess appropriate client placement in the immediate postoperative period. Explore independent living, acute rehabilitation facility, or skilled nursing facility.
- For the cognitively impaired client being discharged back to independent living (private home or home with a family member), identify a key contact person who will participate in discharge education. Assess for any need of community services (e.g., food assistance, meal prep, transport, home health care) at time of discharge.
- Nutritional deficiencies can be common in elderly clients. Monitor laboratory tests; an albumin level less than 3.2 mg/dL and a cholesterol level of less than 160 mg/dL in the frail elderly are indicators for increased mortality. **EB:** *A BMI of less than 20 kg/m² is a marker for increased risk of wound healing. A dietary consultation should be initiated, and nutritional supplements should be provided (Ersan & Schwer, 2021).*
- As part of the discharge process, ask the client how they will be obtaining groceries: Will they be cooking? Will they need assistance with meal prep? Do they have someone (friend or family member) who can come into the home to assist with cooking? Does the client need to have a food service (i.e., Meals on Wheels) set up for the immediate postdischarge period? Refer client to community services as necessary.

Multicultural

- Consider race and ethnicity as a key factor when developing the client's plan of care. **EBN:** *Nurses should use culturally competent verbal and nonverbal communication skills to identify clients' values, beliefs, practices, perceptions, and unique health care needs. Effective cultural communication demonstrates respect, dignity, and the preservation of human rights (Douglas et al, 2014).*
- In the case of a language barrier, use a qualified interpreter rather than family members, unless as a last resort, to communicate with the non–English-speaking client. The use of family members to translate health care–specific information may risk client privacy issues and interpretation bias. Nurses must be attentive to nonverbal cues, such as effective listening, attentive body language, and use of eye contact.
- Cultural nonverbal communication may also include values of modesty, touch, silence, and provider gender (Douglas et al, 2014). Identify the need for an interpreter at time of admission and schedule an interpreter to be available, either by phone or in person, for discussions with providers and for education sessions.
- Identify and accommodate the client who prefers same-gender providers. Effective communication may be affected in the client assigned opposite-gender caregivers, which may negatively affect recovery.

Home Care

- Previously listed interventions appropriately pertain to home care.
- Coordinate with discharge planner, as necessary, for assessment of the client's home care situation that suggests potential safety and mobility concerns.
- Clients discharged back to independent living with new use of walker, crutches, wheelchair, oxygen, and so forth should have egress access evaluated, and bathing/showering options and potential need for grab bars.

I

Risk for Injury

Domain 11 Safety/protection Class 2 Physical injury

Julianne E. Doubet, BSN, RN, EMT-B

NANDA-I

Definition

Susceptible to physical damage due to environmental conditions interacting with the individual's adaptive and defensive resources, which may compromise health.

Risk Factors

Exposure to toxic chemicals; immunization level within community; inadequate knowledge of modifiable factors; malnutrition; neurobehavioral manifestations; nosocomial agent; pathogen exposure; physical barrier; tainted nutritional source; unsafe mode of transport

Associated Conditions

Altered psychomotor performance; autoimmune diseases; biochemical dysfunction; effector dysfunction; hypoxia; immune system diseases; impaired primary defense mechanisms; sensation disorders; sensory integration dysfunction

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Safety Behavior; Risk Control; Safe Home Environment; Knowledge: Fall Prevention

Example NOC Outcome with Indicators

Risk Control as evidenced by the following indicators: Monitors environmental risk factors/Develops effective risk control strategies/Follows selected risk control strategies. (Rate the outcome and indicators of **Risk Control:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of injuries
- Explain methods to prevent injuries
- Demonstrate behaviors that decrease the risk for injury

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Health Education; Environmental Management; Fall Prevention

Example NIC Activities—Health Education

Identify internal or external factors that may enhance or reduce motivation for healthy behavior; Determine current health knowledge and lifestyle behaviors of individual, family, or target group

Nursing Interventions and *Rationales*

- Prevent iatrogenic harm to the hospitalized client by following the National Patient Safety Goals.
- Accuracy of client identification:
  - Use at least two methods (e.g., client's name and medical record number or birth date) to identify the client on initial entrance to a client's room and before administering medications, blood products, treatments, or procedures.
- Effectiveness of communication among care staff:
  - Get important test results to the right staff person on time.
- Medication safety:
  - Before a procedure, label medications that are not labeled. For example, medicines in syringes, cups, and basins.
  - Take extra care with clients who take medications to thin their blood.
  - Record and pass along correct information about a client's medications. Find out what medications the client is taking. Compare those medications to new medications given to the client.
  - Give the client written information about the medicines they need to take.
  - Tell the client it is important to bring their up-to-date list of medicines every time they visit a health care provider.
- Alarm safety:
  - Make improvements to ensure that alarms on medical equipment are heard and responded to on time.
- Infection control:
  - Use the hand cleaning guidelines from the Centers for Disease Control and Prevention (2020) or the World Health Organization. Set goals for improving hand cleaning. Use the goals to improve hand cleaning.
- Identify clients with safety risks:
  - Identify which clients are at risk for suicidal behavior.
- Prevent errors in surgery:
  - Make sure that the correct surgery is done on the correct client and at the correct place on the client's body.
  - Mark the correct place on the client's body where the surgery is to be done.
  - Pause before the surgery to make sure that a mistake is not being made.

  EB: *These actions have been shown to increase client safety and are required actions for accreditation by The Joint Commission (2021).*
- See care plans for Risk for **Falls,** Risk for **Suicidal** Behavior, and Risk for **Poisoning.**
- Avoid use of physical and chemical restraints, if possible. Restraint free is now the standard of care for hospitals and long-term care facilities. Obtain a health care provider's order if restraints are necessary. **EBN:** *The use of restraints has been associated with serious client injuries and at present there is no satisfactory evidence to confirm that the use of restraints is beneficial in reducing falls and preventing injuries (Rahn et al, 2017).*
- Consider providing individualized music of the client's choice if a client is agitated. **EBN:** *In their study of the utilization of music as a complementary treatment, researchers discovered that many nurses currently employ music therapy in their client's therapy; it was found that music assists in the alleviation of anxiety, helps to stabilize vital signs, and aids in pain management (Ciğerci et al, 2019).*
- Review drug profile for potential side effects and interactions that may increase risk of injury. **EBN:** *Interventions to reduce polypharmacy are considered critical strategies to prevent disabilities in older adults (Lee et al, 2020).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

- Provide a safe environment:
  - ❍ Use one-fourth– to one-half–length side rails only and maintain bed in a low position. Ensure that wheels are locked on bed and commode. Keep dim light in room at night.
  - ❍ Remove all possible hazards in environment such as razors, medications, room clutter, wet floors, and matches.

  EBN: *The Joint Commission (2021), a national organization devoted to the health and well-being of those clients who are admitted to a hospital, directs that health care institutions must evaluate the client for fall risks using an effective and consistently dependable fall risk evaluation tool and then institute environmental interventions to establish a safe, client-centered milieu (West et al, 2018).*
- If the client has a new onset of confusion (delirium), refer to the care plan for Acute **Confusion.** If the client has chronic confusion, see the care plan for Chronic **Confusion.**

▲ Refer the client for physical therapy for strengthening as needed.

- Use nonphysical forms of behavior management for the agitated client with psychosis disorder. **EB:** *Educating staff in how to deal with a disturbed client should be a primary goal, particularly in the use of verbal communication to defuse a tense encounter (Fernández-Costa et al, 2020).*

Pediatric

- Teach parents the need for close supervision of young children playing near water. **EB:** *Most drowning victims age 6 years or less drown in swimming pools, even though adults were close by but engaged in other activities. Dynamic adult management of children near water requires "attention, proximity, and continuity" (Cohen et al, 2020).*
- Assess the client's socioeconomic status because financial hardship may correlate with increased rates of injury. **EB:** *In their review of the literature regarding children's socioeconomic status (SES) and injury, Mahboob et al (2019) found that most of the studies evaluated established an association between low SES and additional risk for injury.*
- Never leave young children unsupervised around cooking or open flames. **EB:** *Lack of adult supervision is often cited as a major factor for thermal trauma in children: the danger of burn injury is strongly associated with lack of parental awareness of risk (Juškausikienė & Raškelienė, 2018).*
- Teach parents and children the need to maintain safety for the physically active child, including wearing helmets when biking and skateboarding. **EB:** *Although this study by Axelsson & Stigson (2019) indicated that bicycle helmets successfully aided in reducing head and facial injuries, parents will want to consider additional measures to reduce other types of injuries connected to bicycle use.* **EB:** *In their analysis of skateboarding injuries seen in emergency departments over a 10-year span, Partiali et al (2020) established that there is further need for skateboarding injury prevention programs and the necessity of increasing parental awareness concerning injury protective helmet use.*
- Encourage parents to insist on safety precautions in all phases of participation in sports involving children. **EB:** *Parents and youth athletes should be aware that there are increased risks of injury caused by sports specialization and the intense volume of participation the child is subject to when involved in many sports (Post et al, 2017).*
- Provide parents of children with traumatic brain injury with written instruction and emergency phone numbers. Ensure that instructions are understood before the child is discharged from a health care setting. Instruct parents to observe for the following symptoms: nausea, mild headache, dizziness, irritability, lethargy, poor concentration, loss of appetite, and insomnia. **EBN:** *The nurse plays a pivotal part in educating the client, family, school, and perhaps coaches on the necessity of lifestyle modifications based on the client's condition (Gillooly, 2016).*
- Teach both parents and children the need for gun safety. **EBN:** *The position statement published by the American Academy of Pediatrics (2018) and endorsed by other professional organizations, including the American College of Nursing and the Emergency Nurses Association, advocate for child gun safety by educating both gun owners and children about firearm safety measures, including lock boxes, trigger locks, and high-pressure trigger mechanisms (Beal, 2019).*
- Educate parents regarding proper car safety seat use. **EBN:** *Webb (2019), in her doctoral thesis on parental knowledge of car seat safety, affirms that many children (and adolescent) deaths and injuries from motor vehicle accidents continue today due to deficiencies in the use of safety restraints; parental education on height, weight, age, and transition guidelines for car seats and booster seats remains a critical intervention.*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Geriatric

- Encourage the client to wear glasses and hearing aids and to use walking aids, including nonslip footwear when ambulating. **EBN:** *Providing community-dwelling older adults with techniques to avoid falls may allow them to live on their own longer in a secure, safe environment (Minnier et al, 2019).*
- Assess for orthostatic hypotension when getting up, and teach methods to decrease dizziness, such as rising slowly, remaining seated several minutes before standing, flexing feet upward several times while sitting, sitting down immediately if feeling dizzy, and trying to have someone present when standing. **EBN:** *In a study by Nazarko (2015), it was found that addressing physiological risk factors for falls improves functional capability, a feeling of well-being, and improvement in the quality of life.*
- Discourage driving at night. **EB:** *Elderly drivers cannot always distinguish or will not admit to a decline in their driving skills; as a result, they may well create dangerous situations for themselves and others (Albert et al, 2018).*

Multicultural

- Evaluate the influence of culture on the client's perceptions of risk for injury. **EB:** *Sael (2019), in his master's thesis concerning the increase in occupational accidents of foreign employees, found that the largest safety barrier for multicultural/multilingual workers is disparity in language and that this problem must be addressed in some way to maintain the employees' safekeeping.*
- Evaluate whether exposure to community violence is a contributor to a client's risk for injury. **EB:** *Researchers, in their study of male youth caught up in the criminal justice system, concluded that there is an association between psychological distress and gun possession, most likely triggered by previously experiencing or witnessing violence (Reid et al, 2017).*
- Use culturally relevant injury prevention programs when possible. Validate the client's feelings and concerns related to environmental risks. **EB:** *Chicago youth residing in high-crime areas explained to researchers that they have created environs of safety within dangerous neighborhoods and use certain strategies to keep themselves safe; some of these approaches may incorporate circumvention, "hypervigilance," self-protection, and emotional control (DaVieria et al, 2020).*

Home Care and Client/Family Teaching and Discharge Planning

- Previous interventions can be adapted for home care use.
- See Risk for Physical **Trauma** for Nursing Interventions and *Rationales.*

Risk for Corneal Injury

Domain 11 Safety/protection Class 2 Physical injury

Rachel Klompmaker, BScN, NP-PHC, MScN

NANDA-I

Definition

Susceptible to infection or inflammatory lesion in the corneal tissue that can affect superficial or deep layers, which may compromise health.

Risk Factors

Exposure of the eyeball; inadequate knowledge of modifiable factors

At-Risk Population

Individuals experiencing prolonged hospitalization

Associated Conditions

Artificial respiration; Blinking <5 times per minute; Glasgow Coma Scale score <6; oxygen therapy; periorbital edema; pharmaceutical preparations; tracheostomy

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes (Visual)

Sensory Function: Vision; Vision Compensation Behavior

Example NOC Outcome with Indicators

Vision Compensation Behavior as evidenced by the following indicators: Wears protective eye wear for prevention/Eye discomfort improves daily with healing. (Rate each indicator of **Vision Compensation Behavior:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate relaxed facial expressions and grimacing reduction
- Remain as independent as possible

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Remain free of physical harm resulting from vision injury risk
- Demonstrate improvement in visual acuity

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Visual Deficit; Environmental Management

Example NIC Activities—Communication Enhancement: Visual Deficit

Clearly identify yourself when you enter the client's space; Build on client's remaining vision, as appropriate

Nursing Interventions and *Rationales*

Emergency Department Visit or Primary Care Office Visit

▲ Perform a standard ophthalmic examination or examine eye with a slit lamp using fluorescein stain to optimize visualization of the abrasion injury if available.

- Attempt visual acuity measuring using the Snellen eye chart (corrected with glasses).
- Ensure immunization status is current, namely tetanus-diphtheria-pertussis status (every 10 years).
- Teach the client that foreign body corneal abrasions are one of the most common eye injuries and are at risk for complications (Zimmerman et al, 2019). **EB:** *The Cochrane systematic review of 12 randomized controlled trials (RCTs) with 1080 participants suggested that treating simple corneal abrasions with a patch may not improve healing rate or reduce pain. Application of an eye patch decreases oxygen delivery and results in higher risk of infection due to moisture. Furthermore, people receiving an eye patch may be less likely to have a healed corneal abrasion after 24 to 72 hours. Additionally, corneal abrasions in people patched probably take slightly longer to heal. Lastly, using eye patches may lead to more pain at 24 hours (Lim, Turner, & Lim, 2016; Thiel, Sarau, & Ng, 2017).*
- Topical anesthetics such as tetracaine may be used to provide pain relief for corneal abrasions (Fusco et al, 2019).

▲ Clients will require topical antibiotics to reduce the risk of infection (Thiel, Sarau, & Ng, 2017; Fusco et al, 2019). Nonsteroidal antiinflammatory drugs (NSAIDs) may be prescribed to facilitate healing and reduce pain. **EB:** *According to the Cureus systematic review of 10 RCTs, the use of topical NSAIDs decreases pain symptoms in clients with corneal abrasions and does not complicate wound healing. The use of NSAID drops also reduces the need for oral pain medication. This is important because of the absence of gastrointestinal side effects and a decreased need for narcotics (Thiel, Sarau, & Ng, 2017).*

- Injuries that penetrate the cornea are more serious. The outcome depends on the specific injury. Corneal abrasions usually heal quickly and without vision concerns. Even after the original injury is healed, however, the surface of the cornea is sometimes not as smooth as before. **EB:** *Clients who have had a corneal abrasion may notice that the eye feels irritated for a while after the abrasion heals (Cleveland Clinic, 2015).*

Hospitalization

- Traumatic corneal abrasions are common ophthalmic injuries, accounting for 8% of emergency department visits, with fingernail-induced corneal abrasions being common (Gotekar, 2017; Wakai et al, 2017).
- Perioperative corneal abrasions typically heal within 72 hours. Risk factors include advanced age, prominent eyes (proptosis, exophthalmos), ocular surface abnormalities (dry eye, recurrent erosion syndrome), surgery greater than 60 to 90 minutes, prone/lateral and Trendelenburg positions, operations on the head and neck body regions, intraoperative hypotension, and preoperative anemia. Potential sources of corneal injury in the surgical client are after induction (laryngoscope, name badge, watch band), before incision (surgical preparation, gauze/sponges/drapes), during the procedure (instruments, chemical solutions, heat sources, pressure on globe, eye shields), and awakening/recovery (oxygen face mask, fingernails) (Malafa et al, 2016; Kaye et al, 2019).

▲ All surgical clients should have eyelids secured in the closed position immediately after induction. A strip of tape is generally sufficient; however, in high-risk cases with Trendelenburg position clients may benefit from use of transparent bio-occlusive dressing, which can span the entire lid and provide strong uniform closure, minimizing tear evaporation and acting as a barrier to trauma (Malafa et al, 2016).

- Ocular lubricants support surface moisture, but studies comparing different types of lubricants fail to demonstrate differences in efficacy. However, preservative-free methylcellulose-based ointments are preferred because they are retained in the eye longer than aqueous solutions. Paraffin-based (petroleum) ointments disrupt tear film stability, carry a higher risk of eye irritation, and are flammable (Malafa et al, 2016).
- Assess for corneal abrasion and eye dryness, which are common problems in clients in the intensive care unit. Eye dryness is the main risk factor for the development of corneal abrasions. **EB:** *Sedated clients or clients in induced comas may experience ineffective eye closure, presenting higher risk for corneal injury (Kaye et al, 2019).* **EBN:** *Eye care and eye assessment should be essential parts of nursing care for clients in intensive care. To prevent corneal abrasions, use eye lubricants, which are more effective than closing eyes with adhesive tapes (Ebadi et al, 2017; French Society for Anaesthesia and Intensive Care et al, 2017).*

Client/Family Teaching and Discharge Planning

▲ First-aid principles should be reinforced in the event of an eye injury. Clients should not attempt to remove any object in the eye; reserve this for the provider. A referral to an ophthalmologist may be required (Jacobs, 2021).

- Teach clients to use caution when using household cleaners. Many household products contain strong acids, alkalis, or other chemicals. Drain and oven cleaners are particularly dangerous and can lead to blindness if not used correctly.
- If chemical exposure has occurred, flush the eye immediately with clean water for 10 minutes. Seek prompt health care attention.
- Wear safety goggles at all times when using hand or power tools or chemicals, during high-impact sports, or in other situations when eye injury is more likely.
- Most fingernail injuries to the cornea are preventable, and health teaching should be provided about the importance of supervision in children (Gotekar, 2017).
- Wear sunglasses that screen ultraviolet light when outdoors, even in winter.
- Pain is usually improved within 3 days. If pain becomes intolerable, an analgesic may be prescribed short term. Seek medical attention if pain is not resolving.
- Driving should be restricted for safety until client's visual acuity is evaluated.

Risk for Occupational Injury

Domain 11 Safety/projection Class 4 Environmental hazards

Patrick Luna, MSN, RN, CEN, NRP

NANDA-I

Definition

Susceptible to a work-related accident or illness, which may compromise health.

Risk Factors

Individual

Distraction from interpersonal relations; excessive stress; improper use of personal protective equipment; inadequate knowledge; inadequate time management skills; ineffective coping strategies; misinterpretation of information; psychological distress; unhealthy habits; unsafe work behaviors

Unmodified Environmental Factors

Environmental constraints; exposure to biological agents; exposure to chemical agents; exposure to noise; exposure to radiotherapy; exposure to teratogenic agents; exposure to vibration; inadequate access to individual protective equipment; inadequate physical environment; labor relationships; night shift work rotating to day shift work; occupational burnout; physical workload; shift work

At-Risk Population

Individuals exposed to environmental temperature extremes

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Health and Safety Behaviors; Risk Control; Adequate Training

Example NOC Outcome with Indicators

Occupational Health as evidenced by the following indicators: Knowledge and compliance with health and safety policies and procedures/Demonstration of personal health-promoting behaviors/Knowledge and self-management of a healthy lifestyle. (Rate the outcome and indicators of **Occupational Health:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Attend and participate in all required health and safety training activities
- Demonstrate safe and healthy work behaviors to reduce the risk of occupational injuries and illnesses
- Comply with the organization's health and safety policies and procedures
- Report to management any work hazards, such as facility, tools, and equipment that needs to be repaired
- Demonstrate healthy personal habits, such as healthy nutritional choices, regular exercise, smoking cessation, and effective sleep patterns

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Health Coaching; Health Education; Health Screening; Risk Identification

Example NIC Activities—Risk for Occupational Injury

Encourage early reporting of signs and symptoms related to health and safety hazard exposures

Nursing Interventions and *Rationales*

- Interventions to reduce the risks of occupational injury focus on providing resources for safe work and education to the individual to know safety rules and procedures. Occupational safety requires the individual to engage in safe acts, proper use of equipment (including personal protective equipment [PPE]), cognitive focus during work, and self-identification of stressors that may adversely affect the individual's personal safety during work.
- Encourage employee compliance with safety policies and procedures to reduce the opportunity for slips, trips, and falls; breaks in skin integrity through chemical exposure, mechanical means (trauma, friction, pressure), physical exposure (heat, cold, radiation), and exposure to biological elements (viruses, bacteria, fungi); musculoskeletal injuries; and misuse of equipment and tools. **EB:** *Workers who have a positive interpretation of their occupational safety culture are more likely to follow safety policies and avoid injury (Mazzetti et al, 2020). Initiatives to improve compliance with health and safety policies include training, posters and notices in workplaces, and use and availability of PPE (Gómez La-Rotta et al, 2020).*
- Enforce compliance with organizational and regulatory health and safety policies and procedures, demonstrating at least adequate training and the proper use of appropriate tools, equipment, and PPE to reduce risk of injury and illness and ensure that the client receives appropriate training and education on occupational tasks and equipment. **EB:** *Equipment, parts, materials, and hand tools were the major cause of injury to mechanical contractors resulting in 55% of total injuries (Shrestha et al, 2018). To increase compliance with the use of PPE, training should focus on the benefits of PPE to prevent personal injury and illness (Wright et al, 2019).*
- Assist the client in reduction of personal and work stress to increase coping skills, improve interpersonal relationships, and avoid burnout. **EBN:** *Work-related burnout is characterized by symptoms of exhaustion that are related to the client's work. Factors that decrease work-related burnout include social support, sense of community, job satisfaction, and degree of freedom at work (Ilić et al, 2017).*
- Educate clients to engage in active coping strategies to reduce work-related stress. **CEB:** *Recommendations include reducing psychological strain, work overload, and role confusion through the adoption of job redesign techniques and organizational support of counseling and stress reduction workshops (Dar et al, 2011).*
- Promote good sleep hygiene, which will result in increased alertness and decreased occupational injuries and illnesses. **EB:** *The two most common sleep disorders affecting the workplace are insomnia and obstructive sleep apnea, which can negatively affect quality of life and increase work-related injuries (Judd, 2017).*
- Educate client on the detrimental effects of shift work, atypical working time, and nonstandard work schedules. **EB:** *To prevent injuries resulting from shift work, educational strategies and safety policies aimed at developing awareness of the harmful effects of shift work are recommended (Alali et al, 2018).*
- Provide medical screening, surveillance, and postexposure testing for symptomatic employees to identify exposure and control effects that can lead to illness and injury. **CEB:** *The Occupational Safety and Health Administration (OSHA) requires that exposures to specific hazards require a medical surveillance program to identify adverse effects related to those exposures. OSHA Standards provide the opportunity to monitor exposure to health hazards from inhalation, ingestion, or skin absorption from chemical, biological agent, or radiological exposures. The fundamental purpose of screening is early diagnosis and treatment with a clinical focus, whereas surveillance is to detect and eliminate the underlying causes providing a prevention focus (US Department of Labor, OSHA, 2000).*
- Assist in the integration of personal health behaviors that promote total worker health and safety for the employee, which translates to a more productive worker generating better quality products, resulting in fewer occupational injuries and illnesses for the workers. **EB:** *Studies have shown that health education activities and materials should address prevention topics for modifiable behaviors observed to be injury risk factors, such as overuse of alcohol and drugs, stress, tobacco use, and poor sleep habits (Schuh-Renner et al, 2018).*
- Identify client risk factors that can lead to occupational injury and address them with health coaching techniques. **EBN:** *Health coaching is the use of evidence-based skillful conversation, clinical strategies, and interventions to actively and safely engage clients in health behavior change to better self-manage their health, health risks, and acute or chronic health conditions, resulting in optimal wellness, improved health outcomes, lowered health risk, and decreased health care costs (Huffman, 2016).*
- Provide resources to assist with smoking/vaping cessation. **EB:** *According to the American Lung Association (2020a), smoking is the leading cause of preventable death in the United States, causing more than 438,000 deaths per year and worsening preexisting conditions including cardiovascular disease. The process of using an e-cigarette is called "vaping" rather than smoking. The US Food and Drug Administration (FDA)*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

describes an e-cigarette as a battery-operated device that turns nicotine, formaldehyde, flavorings (diacetyl that causes popcorn lung), and other chemicals into a vapor that can be inhaled. American Lung Association (2020b) provides information about smoking and smoking cessation programs that can be helpful when counseling employees as to the adverse effects of smoking and vaping.

- Implement environmental and behavioral strategies to aid workers in maintaining a healthy weight. **EBN:** *A multicomponent approach of environmental (standing workstations, on-site walking routes, access to an onsite wellness center, access to healthy meals) and behavioral (meeting with dietitians, counseling sessions, trainer-led exercise, incentivized goal setting) strategies were successful in improving weight-related outcomes (Upadhyaya et al, 2020).*
- Promote a drug-free workplace through education, training, policy development, and evaluation. **EBN:** *A drug-free workplace program seeks to modify behaviors of employees who misuse drugs and prevents the use of illicit substances through educational programs and workplace policy (Betcher et al, 2020).*
- Identify high-risk work areas and environmental hazards by conducting periodic walkthroughs of the workplace for unsafe acts and conditions. Possible risks include excessive noise, poorly maintained equipment, lack of PPE, uneven or poorly designed workspaces, inadequate lighting, environmental toxins, and lack of safety training. **CEB:** *Identifying hazards in the work environment is the first step to maintaining a safe workplace. This information is used to establish priorities for intervention (Brnich & Mallett 2003).*
- Ensure that appropriate respiratory protection is available and used when workers can be potentially exposed to transmissible respiratory infections. **EB:** *Medical masks are recommended when in close contact with potentially infected individuals for routine interaction and care. N95 respirators are recommended for aerosol-generating medical procedures such as endotracheal intubation, extubation, noninvasive ventilation, and exposure to aerosols in an open circuit (Bartoszko et al, 2020).*
- Ensure that infection prevention and control policies and procedures are enforced. Blood-borne pathogen risks are inherent when providing nursing care in health care facilities for injured or ill employees, and appropriate measures must be taken to avoid contact with and spread of infectious organisms. **EB:** *Compliance with policies and procedures to prevent blood-borne pathogen exposure increased with continuous and regular training, posters and notices in the work area, and increased qualifications for workers (Gómez La-Rotta et al, 2020).*
- Implement measures to prevent occupational back pain, which can be prevented or limited in its severity. **EB:** *Discouraging bed rest, promoting early return to work with modified job tasks, implementing accommodations to avoid back injury risk factors, individualized interventions, and follow-up monitoring is encouraged as part of a rehabilitation program to prevent and treat occupational back pain (Al-Otaibi, 2015).*
- Ensure workers have access to and use PPE to reduce noise exposure. Engineering and administrative controls should be considered before the use of PPE. **CEB:** *A United Auto Workers/General Motors–funded study that assessed the effects of noise on blood pressure and heart rate demonstrated a significant positive relationship between acute noise exposure and both diastolic and systolic blood pressure and heart rate. In assessing the effect of chronic noise exposure, workers who used hearing protection had lower blood pressure and heart rate than workers without hearing protection (McCauley, 2012).*
- Health professionals should understand potential interruptions and cognitive distractions to adopt a task-design–oriented approach that focuses on aspects of the work environment that can be observed, measured, and controlled. **EB:** *Using signs, no-interruptions zones, personal electronics policies, and available technologies to promote attention-keeping and limit cognitive distractions can be implemented by organizations to maintain safe environments (Cohen et al, 2017).*
- Provide multiprofessional collaboration to reduce occupational risks to health and safety. **CEB:** *According to Wachs (2005), teamwork is beneficial to American business and industry because of its strength through diversity when a variety of multiprofessional health and safety professionals offer solutions to complex problems.*
- Implement an early reporting system that allows workers to safely report injuries or illness. **EB:** *OSHA requires a mechanism that identifies to whom the employees report injuries and illnesses and that they are encouraged to do so as early as possible. Educating employees on the signs and symptoms of occupational disease is critical to stop and reverse the process before disability results. Early reporting of signs and symptoms related to health hazard exposures provides for the best outcomes (US Department of Labor, OSHA, 2016).*
- Ensure appropriate medical referrals and communication with health care providers to achieve safe work environment goals and include follow-up assessment to ensure that the worker is not further injured by the accommodated work situation. **EB:** *Providing appropriate medical referrals and multiprofessional collaboration can reduce occupational risks to health and safety (US Department of Labor, OSHA, 2000).*

- Provide accurate and legal documentation for medical and exposure records with adverse health effects from health and safety exposures, maintaining confidentiality of personal medical issues. Legal requirements for documentation ensure correct communication of all aspects of the injury or illness and protects the nurse in case of litigation. **CEB:** *OSHA documentation specifics include medical, exposure, and training records that must be retained for at least 30 years. The documentation provides a history of the employee's exposure to hazards, assessment and treatment received, and any worksite hazard abatements or reduction to exposures and any outcomes of exposure and treatments (US Department of Labor, OSHA, 2020).*

Geriatric

- Consider the physiological changes in the aging population. **EB:** *The aging workforce typically has experienced changes in their physical systems that require attention to physical needs. These changes may include slower reaction times, predisposing factors to developing musculoskeletal disorders, a compromised cardiovascular system, less acute hearing and vision, and impaired cognition (Algarni et al, 2015).*
- Although older clients may experience fewer occupational injuries and illnesses, the aging workforce may take longer to heal and return to work. **EB:** *A review of current best practices by Delloiacono (2015) found that the extent of age-related physical changes in older workers is significantly influenced by chronic illnesses. However, improving lifestyles could reduce organizational costs, and reducing costs is important because although older worker statistics report lower work-related injury rates, their recovery is slower and lost work time is longer.*

Multicultural

- Address differences in cultures that affect attitudes toward health care professionals and treatment modalities. **EB:** *Understanding the written and verbal language can significantly affect the instructions and training given to workers.*
- According to the Centers for Disease Control and Prevention (CDC, 2021), young workers have high rates of job-related injury. These injuries are often the result of the many hazards present in the places they typically work, such as sharp knives and slippery floors in restaurants. Limited or no prior work experience and a lack of safety training also contribute to high injury rates. Middle and high school workers may be at increased risk for injury because they may not have the strength or cognitive ability needed to perform certain job duties. **EB:** *In 2016 there were about 19.3 million workers under the age of 24. These workers represented 13% of the total workforce, and in 2015, 403 workers under the age of 24 died from work-related injuries (CDC, 2018).*
- The US workforce is becoming more diverse (National Center for Public Policy and Higher Education, 2005). Baby boomers are remaining in the workforce past traditional retirement age because their health is better, and they need or want additional income (Bureau of Labor Statistics, 2008).
- The size of the minority workforce is growing, and more women are entering the workforce (Thompson & Wachs, 2012). There is greater diversity in the workplace, and people from different backgrounds and cultures are working alongside each other, often speaking different languages with different educational and literacy backgrounds. **CEB:** *As the minority workforce continues to grow, especially the Hispanic workforce, businesses must recognize the unique needs and contributions of this workforce in terms of language, customs, culture, and values (Thompson & Wachs, 2012). It is recommended that occupational health nurses promote health and prevent injuries among vulnerable workers at both the individual and system levels (Burgel, Nelson, & White, 2015).*
- Depending on the setting, comprehensive health care, including, for example, smoking cessation and early diagnosis and treatment of depression, could be provided to high-risk populations using culturally sensitive outreach and motivational interviewing strategies. **EB:** *Because of underreporting, active case findings for occupational injuries are needed when day laborers access any health care system. To ensure the provision of health and safety training and PPE for day laborers at the system level, occupational health nurses can advocate for comprehensive occupational health and safety legal protections for all contingent workers. Reporting health complaints and injuries, in addition to providing rest breaks, deserves further study in this population. In addition to targeted hearing conservation and respiratory protection programs for this high-risk group, the risk of falls from heights is a serious hazard facing day laborers, and this phenomenon also deserves further investigation (Burgel, Nelson, & White, 2015).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- The Americans with Disabilities Act (ADA) requires that public buildings be designed to accommodate wheelchairs and other accommodations and that jobs be modified if accommodation is reasonable so that people with disabilities can gain access to buildings and jobs (see https://www.ada.gov/ada_req_ta.htm).

Nipple-Areolar Complex Injury

Domain 11 Safety/protection Class 2 Physical injury

Nichol Chesser, RN, CNM, DNP

NANDA-I

Definition

Localized damage to nipple-areolar complex as a result of the breastfeeding process.

Defining Characteristics

Abraded skin; altered skin color; altered thickness of nipple-areolar complex; blistered skin; discolored skin patches; disrupted skin surface; ecchymosis; eroded skin; erythema; expresses pain; hematoma; macerated skin; scabbed skin; skin fissure; skin ulceration; skin vesicles; swelling; tissue exposure below the epidermis

Related Factors

Breast engorgement; hardened areola; improper use of milk pump; inadequate latching on; inappropriate maternal hand support of breast; inappropriate positioning of the infant during breastfeeding; inappropriate positioning of the mother during breastfeeding; ineffective infant sucking reflex; ineffective non-nutritive sucking; mastitis; maternal anxiety about breastfeeding; maternal impatience with the breastfeeding process; mother does not wait for the infant to spontaneously release the nipple; mother withdraws infant from breast without breaking the suction; nipple confusion due to use of artificial nipple; postprocedural pain; prolonged exposure to moisture; supplementary feeding; use of products that remove the natural protection of the nipple

At-Risk Population

Primiparous women; sole mother; women aged < 19 years; women breastfeeding for the first time; women with depigmented nipple areolar complex; women with history of inadequate nipple-areolar preparation during prenatal care; women with history of nipple trauma in breastfeeding; women with non-protruding nipples; women with pink nipple-areolar complex

Associated Conditions

Ankyloglossia; maxillofacial abnormalities

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Breastfeeding Establishment: Maternal

Example NOC Outcome with Indicators

Breastfeeding Establishment: Maternal: Suction broken before removing infant from breast. (Rate outcome and indicators of **Breastfeeding Establishment: Maternal:** 1 = not adequate, 2 = slightly adequate 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].

Client Outcomes

Client Will (Specify Time Frame)

- Avoid artificial nipple use with infant
- Use techniques to prevent nipple tenderness
- Establish a position of comfort during nursing
- Recognize infant swallowing

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Pain Management: Acute

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NIC Activities—Pain Management: Acute

Question client regarding the level of pain that allows a state of comfort and appropriate function and attempt to keep pain at or lower than identified level

Nursing Interventions and *Rationales*

- Nipple trauma and sore nipples are common complaints among breastfeeding women and are a leading cause of breastfeeding discontinuation. **EB:** *Nipple soreness usually occurs between the first 3 and 7 days after childbirth and can last for at least 6 weeks. About 90% of lactating women experience some sort of nipple soreness, with up to 26% of women experiencing painful nipple fissures (As'adi et al, 2017).*
- Identify clients at risk for nipple trauma. **EB:** *The most common causes of nipple trauma are incorrect latch and incorrect nipple suckling (Ghaheri et al, 2017; Niazi et al, 2018). Other causes of nipple trauma may include nipple infection, the infant having a short frenulum, strong or weak suckling, and washing the nipple with a harsh soap (Niazi et al, 2018). Awareness of a woman's breastfeeding technique including latch and baby positioning during breastfeeding can help prevent nipple trauma (Gianni et al, 2019).*
- Evaluate the nipple for five signs of nipple trauma in order to help reduce pain and further trauma and to promote continuation of breastfeeding. **EB:** *Erythema and swelling are the first signs of nipple trauma, followed by blistering, fissures, and scabbing (Nakamura et al, 2018). Nipple piercing seems to not interfere with lactation but may interfere with a correct latch and potentially may increase risk of infection if the piercing was obtained within the past 6 to 12 months (National Library of Medicine, 2021).*
- Use a valid and reliable tool for assessing nipple trauma associated with breastfeeding. **EB:** *Assessing pain by client self-report is the most accurate and reliable method of obtaining information on pain experienced by the client (Karcioglu, 2018). The numeric rating scale (NRS) of 0 to 10 is easily documented, easily interpreted, and meets regulatory guidelines for assessing and documenting pain (Karcioglu, 2018). The NRS can be used in conjunction with observed characteristics of nipple trauma in order to facilitate appropriate interventions.*
- Help to correct any factors that may be contributing to nipple trauma. **EB:** *Assess for correct infant mouth attachment to nipple, strong suckling of the infant and/or frequent suckling, use of the breast pump, nipple vasoconstriction, engorgement, clogged ducts, or infection (Spencer, 2021).*
- Offer options to promote healing. **EB:** *There are numerous options to promote healing, including herbal, medicinal, and nonmedicinal therapies (As'adi et al, 2017). Remedies such as lanolin, hydrogel, LED lights, and tea bag or hot water compresses are easy to use and can be initiated at home as needed (Niazi et al, 2018). Another holistic remedy includes putting breast milk on the area of trauma. This may be beneficial as topical human milk has antiinflammatory properties, which can promote healing and reduce recovery time (Amiri-Farahani et al, 2020). Aloe vera has been shown to reduce pain from cracked nipples if applied to the area 3 times per day after an episode of breastfeeding (Hekmatpou et al, 2019). LED therapy is a novel treatment for nipple trauma that can control pain and accelerate the healing process of nipple fissures/cracks (Campos et al, 2018).*
- Offer instruction on latch in order to promote effective milk transfer and decrease potential nipple trauma. **EB:** *The LATCH scoring system for infant latch during breastfeeding can help ensure adequate latch to decrease nipple trauma (Westerfield et al, 2018). The LATCH scoring system refers to latch, audible swallowing, type of nipple, comfort of the mother, help required (Westerfield, 2018).*
- Usage of a breast pump to express milk can be beneficial to promote feeding an infant breast milk when feeding at the breast is causing nipple trauma. **EB:** *Over one-quarter of women who start pumping while still in hospital postpartum cite problems with latch as the reason (Weisband et al, 2017).*
- Assist the client in alternative feeding methods if nipple trauma is severe in order to promote healing and prevent further damage. **EB:** *Breast milk is found to be the best nutrition for infants; however, not all infants are able to feed at the breast (Becker et al, 2016).*

Home Care

- Assess availability of and refer client to lactation support if nursing interventions and self-management are not alleviating the nipple trauma. **EB:** *Lactation consultations can improve nipple latch and decrease nipple pain and trauma (Patel & Patel, 2016).*
- Refer client to pediatrician to assess if the infant has an upper, anterior, or submucosal tongue and/or lip-tie. **EB:** *Infant tongue and/or lip tie can be a main cause of nipple trauma (Ghaheri et al, 2017). Frenotomy, when indicated, can improve breastfeeding success and decrease nipple trauma (Ghaheri et al, 2017).*

- Assess clients' emotional state as nipple trauma can lead to inefficient breastfeeding, which can account for unstable mood and postpartum depression. **EB:** *Studies have shown a link between health problems in the early postpartum period and depression (Cooklin et al, 2018). Breast problems, which can contribute to poor mood postpartum and an increase in physical discomfort, can be ameliorated by appropriate clinical care and support (Cooklin et al, 2018).*
- Encourage family participation and provide information to the father as appropriate in order to support the breastfeeding mother. **EB:** *Many women perceive their partner as playing a role in the breastfeeding process (Lok et al, 2017). Providing information to the partner to support the breastfeeding woman can encourage continuation of breastfeeding (Lok et al, 2017).*

Risk for Nipple-Areolar Complex Injury

Domain 11 Safety/protection Class 2 Physical injury

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to localized damage to nipple-areolar complex as a result of the breastfeeding process.

Related Factors

Breast engorgement; hardened areola; improper use of milk pump; inadequate latching on; inadequate nipple-areolar preparation during prenatal care; inappropriate maternal hand support of breast; inappropriate positioning of the infant during breastfeeding; inappropriate positioning of the mother during breastfeeding; ineffective infant sucking reflex; ineffective non-nutritive sucking; mastitis; maternal anxiety about

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

breastfeeding; maternal impatience with the breastfeeding process; mother does not wait for the infant to spontaneously release the nipple; mother withdraws infant from breast without breaking the suction; nipple confusion due to use of artificial nipple; postprocedural pain; prolonged exposure to moisture; supplementary feeding; use of products that remove the natural protection of the nipple

At-Risk Population

Primiparous women; sole mother; women aged < 19 years; women breastfeeding for the first time; women with depigmented nipple areolar complex; women with history of nipple trauma in breastfeeding; women with non-protruding nipples; women with pink nipple-areolar complex

Associated Conditions

Ankyloglossia; maxillofacial abnormalities

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* and References

Refer to care plan for Nipple-Areolar Complex **Injury**.

Risk for Urinary Tract Injury

Domain 11 Safety/protection Class 2 Physical injury

Tammy Spencer, DNP, RN, CNE, ACNS-BC, CCNS

I

NANDA-I

Definition

Susceptible to damage of the urinary tract structures from use of catheters, which may compromise health.

Risk Factors

Confusion; inadequate caregiver knowledge regarding urinary catheter care; inadequate knowledge regarding urinary catheter care; neurobehavioral manifestations; obesity

At-Risk Population

Individuals at extremes of age

Associated Conditions

Anatomical variation in the pelvic organs; condition preventing ability to secure catheter; detrusor sphincter dyssynergia; latex allergy; long-term use of urinary catheter; medullary injury; prostatic hyperplasia; repetitive catheterizations; retention balloon inflated to ≥30 mL; use of large caliber urinary catheter

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Urinary Elimination; Knowledge: Infection Management; Treatment Regimen; Treatment Procedure, Tissue Integrity: Skin and Mucous Membranes, Risk Control: Infectious Process, Risk Detection

Example NOC Outcome with Indicators

Urinary Elimination as evidenced by the following indicators: Urine clarity/Urine odor, Urine volume, fluid intake, pain with urination. (Rate the outcome and indicators of **Urinary Elimination:** 1 = severely compromised 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of urinary tract injury
- State absence of pain with catheter care and during urination
- Experience unobstructed urination after removal of catheter

- Identify signs and symptoms of urinary obstruction and urinary tract injury after removal of catheter
- Identify interventions to prevent catheter-associated urinary tract infection (CAUTI)
- Maintain adequate urine volume (0.5–1.0 mL/kg/h for adult); urine without odor; urine clear
- Maintain adequate fluid intake considering client age and comorbidities

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Urinary Elimination Management

Example NIC Activities—Urinary Elimination Management

Monitor urinary elimination, including frequency, consistency, odor, volume, and color, as appropriate; Assess client for pain and increased temperature associated with catheter

Nursing Interventions and *Rationales*

- Monitor urinary elimination, including frequency, consistency, odor, volume, and color, as appropriate.
- Teach the client and caregiver signs and symptoms of urinary tract infection and CAUTI. **EB:** *Clients may be asymptomatic or have a range of symptoms that may include a persistent and frequent urge to urinate, burning or painful sensation during urination, cloudy and/or strong-smelling urine, blood-tinged urine, fever, flank pain, suprapubic tenderness, delirium, inability to perform activities of daily living, and fatigue (Blodgett et al, 2015; Gbinigie et al, 2018).*
- Assess for appropriate use of an indwelling urinary catheter. Insert urinary catheters only when indicated and leave in only as long as clinically necessary. **EB:** *To prevent trauma to the urinary tract structure, as well as infections (e.g., CAUTI and urosepsis), use urinary catheters only as indicated (Gould et al, 2019; Kranz et al, 2020). Approximately 80% of all health care–associated urinary tract infections are caused by urinary catheterization; infection represents the most significant adverse event following urinary catheter use (Gould et al, 2019). CAUTIs are linked to increased mortality, morbidity, hospital cost, antibiotic use, and length of stay (Gould et al, 2019). Health care providers need to have written guidelines for the use, insertion, and maintenance of urinary catheters (Agency for Healthcare Research and Quality [AHRQ], 2015; Saint et al, 2016).*
- To prevent injury, educate the client and family and/or caregiver regarding the use of an indwelling urinary catheter (AHRQ, 2015; Mody et al, 2017). **EB:** *Accidental or improper removal of catheter can cause urethral injury. Urinary catheters are used in up to 16% of adult hospital inpatients (Gould et al, 2019).*
- Assess clinical indications for urinary catheter use daily. **EB:** *It is important for providers to understand the appropriate and inappropriate indications for use of urinary catheters to decrease the risk of CAUTI (Meddings et al, 2015; Gould et al, 2019). Minimize urinary catheter use in all clients, especially those at risk for CAUTIs such as women, the elderly, and immunocompromised clients (Gould et al, 2019; Kranz et al, 2020). Urinary catheter use is inappropriate in several client situations, including when used as a substitute for nursing care of the incontinent client, when obtaining a urine culture for the client who can void, and for prolonged periods after surgery without appropriate indications (AHRQ, 2015; Meddings et al, 2015). There is a 3% to 7% daily risk of bacteriuria when an indwelling urinary catheter remains in place (Gould et al, 2019). Decreasing the number of days the catheter is in place and avoiding unnecessary catheterization are the primary interventions to decrease CAUTI and unintended client harm (Meddings et al, 2015; Kranz et al, 2020).*
- To avoid catheterizations, evaluate alternative strategies for managing urine output for the client. **EB:** *Using alternative strategies decreases the risk for infection and immobility complications (AHRQ, 2015). Developing toileting schedules and scheduled nursing staff rounding can reduce urgency and incontinence episodes (Meddings et al, 2015; Saint et al, 2016). Consider using external catheters, straight catheters, bedside commode, incontinent garments, barrier creams, or intermittent catheterization in appropriate clients (AHRQ, 2015; Meddings et al, 2015). Use bladder scanner to assess for urinary retention before inserting urinary catheter (Meddings et al, 2015; Gould et al, 2019).*
- If an indwelling urinary catheter is determined to be clinically indicated in the care of a client, proper selection of the right catheter, technique during insertion, and evidence-based care management are needed to reduce infection and injury to the urinary tract structures.
  - ❍ Perform hand hygiene and use Standard Precautions before and after insertion of the urinary catheter and any time the catheter, catheter site, or collection system is accessed (AHRQ, 2015; Gould et al, 2019).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- ❍ Ensure that only properly trained personnel familiar with appropriate catheter care techniques are used for inserting and maintaining the catheter (AHRQ, 2015; Gould et al, 2019). **EB:** *Periodic in-service training helps personnel to maintain proper catheter care techniques (Gould et al, 2019; Narula et al, 2019).*

- ● Selecting the smallest catheter size (e.g., smaller than 18 French) reduces irritation and inflammation of the urethra and reduces infection risk (Gould et al, 2019).
- ● Insert the catheter using aseptic technique in the acute care setting. Wash hands and use sterile technique when opening the catheterization kit and cleansing the urethral meatus and perineal area with an antiseptic solution. Insert the catheter using a no-touch technique (AHRQ, 2015; Gould et al, 2019). **EB:** *In the nonacute care setting, nonsterile technique may be used for intermittent catheterization (Gould et al, 2019). Using a no-touch technique may reduce the risk of infection.*
- ● If a urine sample is needed from the urinary collection system sampling port, disinfect the sampling port and allow disinfectant to dry before accessing the port. **EB:** *Disinfecting the sampling port decreases the introduction of pathogens into the urinary collection system (AHRQ, 2015).*
- ● Provide routine hygiene care; once a urinary catheter is placed, optimal management includes care of the urethral meatus according to "routine hygiene" (e.g., daily cleansing of the meatal surface during bathing with soap and water and as needed, such as following a bowel movement) (AHRQ, 2015; Gould et al, 2019). **EB:** *In recent studies, no definitive method has been found for cleaning or disinfecting the external urethral orifice (Kranz et al, 2020). Do not clean the periurethral area with antiseptics while the catheter is in place (Gould et al, 2019).*
- ● Secure the catheter after placement to reduce friction and pain from movement *(Gould et al, 2019; Kranz et al, 2020).*
  - ❍ Disruptions in aseptic technique, disconnection, or leakage require the catheter and collection system to be replaced using aseptic technique and sterile equipment (AHRQ, 2015; Gould et al, 2019). **EB:** *Risk factors for CAUTI include not maintaining a closed drainage system (Gould et al, 2019).*
  - ❍ Maintain unobstructed urine flow; maintain the catheter and collecting tube below the level of the bladder and free of kinks. Do not rest the collection bag on the floor. **EB:** *Keeping the collection bag off the floor prevents contamination. Maintaining the urine collection bag below the level of the bladder and the catheter without kinks minimizes reflux into the catheter itself, preventing retrograde flow of urine and risk for infection (AHRQ, 2015; Gould et al, 2019).*
- ● Establish workflow protocols to routinely empty the drainage bag frequently and before transport to reduce urine reflux and opportunities for infection. **EB:** *Use a separate, clean collecting container for each client when emptying the collection bag; avoid splashing, and prevent contact of the drainage spout with a nonsterile container (AHRQ, 2015; Gould et al, 2019). The collection bag of a bacteriuric client is a reservoir for organisms that may be transmitted by the hands of health care personnel to other clients (AHRQ, 2015).*
- ● Change urinary catheters and drainage systems based on clinical indications such as infection, obstruction, or when the drainage system is not adequately maintained. **EB:** *Changing indwelling catheters or drainage bags at a routine time interval is not recommended because it opens a closed drainage system and predisposes the client to infection (AHRQ, 2015; Gould et al, 2019).*
- ● Monitor the client with an indwelling urinary catheter for increased temperature (>38°C; 100.4°F), suprapubic pain, frequency, urgency, and flank pain; monitor the skin around the catheter for redness, drainage, or swelling. **EB:** *The most common clinical presentation for CAUTI is fever with a positive urine culture (Lo et al, 2014).* **EB:** *Monitor the client for CAUTI symptoms caused by localized or systemic inflammatory response (Blodgett et al, 2015; Gbinigie et al, 2018).*
- ● Consider an ultrasound scanner for clients who require intermittent catheterization to assess urine volume and reduce unnecessary catheter insertion (Gould et al, 2019; Meddings et al, 2015).
- ▲ Implement systemwide quality improvement programs, including the following interventions to decrease CAUTI:
  - ❍ Establish health care provider alerts or reminders for all clients with catheters regarding the need for continued catheterization. **EB/EBN:** *Health care providers frequently forget that the catheter is in place, increasing the risk for CAUTI. Studies have shown that the rate of CAUTI was decreased with the use of daily checklists, catheter reminders, developing competencies for providers, and stop orders (Saint et al, 2016; Narula et al, 2019).*
  - ❍ Provide performance feedback and education to personnel responsible for catheter care (Gould et al, 2019; Mody et al, 2017). **EB:** *Implementing safety teams; engaging family, organizational leadership, and staff; and setting goals can decrease CAUTI (Mody et al, 2017).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

- ❍ Establish evidence-based "bladder bundles" as part of a multimodal approach to preventing CAUTI. "Bladder bundles" may include educational interventions aimed at health care providers for appropriate use of urinary catheters, use of appropriately trained personnel to insert and care for the catheter, catheter restriction and removal protocols, and the use of bladder ultrasound to assess urine volume (Saint et al, 2016; Mody et al, 2017). **EB/EBN:** *Evidence-based "bundles" of interventions, when implemented simultaneously, decrease the risk of CAUTI (AHRQ, 2015; Durant, 2017; Gould et al, 2019).*

Home Care and Client/Family Teaching and Discharge Planning

- Teach the client and family discharged with an indwelling urinary catheter or performing intermittent catheterization at home techniques for care of urinary catheter and collection bag using the interventions listed above (AHRQ, 2015).
- Ensure client has adequate supplies at home for catheter insertion and care.
- Teach the client and family to contact the health care provider regarding symptoms of CAUTI, including increased temperature (>38°C; 104°F), suprapubic pain, frequency, urgency, and flank pain; no drainage of urine in the collection bag; inability to perform activities of daily living; delirium; and foul-smelling, cloudy, or bloody urine (Blodgett et al, 2015; Gbinigie et al, 2018; Shah, 2019).
- Teach client and family to monitor for signs of obstruction such as decreased urine output after catheter is removed.

Insomnia

Domain 4 Activity/rest Class 1 Sleep/rest

Judith Ann Floyd, PhD, RN, FNAP, FAAN

NANDA-I

Definition

Inability to initiate or maintain sleep, which impairs functioning.

Defining Characteristics

Altered affect; altered attention; altered mood; early awakening; expresses dissatisfaction with quality of life; expresses dissatisfaction with sleep; expresses forgetfulness; expresses need for frequent naps during

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

the day; impaired health status; increased absenteeism; increased accidents; insufficient physical endurance; nonrestorative sleep-wake cycle

Related Factors

Anxiety; average daily physical activity is less than recommended for age and gender; caffeine consumption; caregiver role strain; consumption of sugar-sweetened beverages; depressive symptoms; discomfort; dysfunctional sleep beliefs; environmental disturbances; fear; frequent naps during the day; inadequate sleep hygiene; lifestyle incongruent with normal circadian rhythms; low psychological resilience; obesity; stressors; substance misuse; use of interactive electronic devices

At-Risk Population

Adolescents; economically disadvantaged individuals; grieving individuals; individuals undergoing changes in marital status; night shift workers; older adults; pregnant women in third trimester; rotating shift workers; women

Associated Conditions

Chronic disease; hormonal change; pharmaceutical preparations

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Comfort Level; Pain Level; Personal Well-Being; Psychosocial Adjustment: Life Change; Quality of Life; Rest; Sleep

Example NOC Outcome with Indicators

Sleep as evidenced by the following indicators: Hours of sleep/Sleep pattern/Sleep quality/Sleep efficiency/Feels rejuvenated after sleep/Sleeps consistently through the night. (Rate the outcome and indicators of **Sleep:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize plan to implement sleep-promoting routines
- Fall asleep with less difficulty a minimum of four nights out of seven
- Wake up less frequently during night a minimum of four nights out of seven
- Sleep a minimum of 6 hours most nights and more if needed to meet next stated outcome
- Awaken refreshed and not be fatigued during day most of the time

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Sleep Enhancement

Example NIC Activities—Sleep Enhancement

Monitor/record client's sleep pattern and number of sleep hours; Encourage client to establish a bedtime routine to facilitate transition from wakefulness to sleep

Nursing Interventions and *Rationales*

- Obtain a sleep history including amount of time needed to initiate sleep, duration of any awakenings after sleep onset, total nighttime sleep amounts, and dissatisfaction with daytime energy levels and alertness. **EB:** *Inability to drift off to sleep at bedtime or during the night if awakened can lead to short sleep and poor daytime functioning, as well as negatively affect physical and mental health (Khurshid, 2015).*
- From the history, assess client's current ability to initiate and maintain sleep and the short-term versus chronic nature of inability to initiate and maintain sleep. **EB:** *Adults can be considered to have insomnia*

if they report daytime tiredness or sleepiness due to shortened nighttime sleep three or more nights per week. Insomnia is considered chronic if the inability to initiate and/or maintain sleep continues beyond 3 months (Khurshid, 2015).

For Short-Term Insomnia

- For clients historically able to initiate and maintain sleep but unable to do so in the current situation: (1) minimize sleep disruptions (see Nursing Interventions and *Rationales* for Disturbed **Sleep** Pattern) and (2) promote sleep hygiene practices (see Nursing Interventions and *Rationales* for Readiness for Enhanced **Sleep**). **EB:** *Inability to initiate and maintain sleep is common in new sleep environments, especially during times of stress or worry (Honkavuo, 2018).*
- Also attend to the following factors often associated with short-term insomnia:
  - Assess pain medication use and, when feasible, advocate for pain medications that promote rather than interfere with sleep. (See Nursing Interventions and *Rationales* for Acute **Pain** and Chronic **Pain.**) **EB:** *Some pain medications also promote sleep, whereas others promote alertness and thus interfere with falling and staying asleep (Dean et al, 2017; Tan et al, 2019).*
  - Assess level of tension and encourage use of relaxation techniques as needed. **EBN:** *A review of evidence from nine intervention studies suggested that relaxation, meditation, guided imagery, or combinations of these strategies resulted in better sleep and less fatigue in heart-failure clients (Kwekkeboom & Bratzke, 2016).* **EBN:** *A clinical pilot study* (n = *12) found that client-controlled relaxation and/or imagery interventions may improve sleep for hospitalized clients (Nooner et al, 2016).*
  - Assess level of distress and use therapeutic communication to increase comfort. (See further Nursing Interventions and *Rationales* for Readiness for Enhanced **Comfort.**) **CEB:** *A qualitative study of 10 clients' experiences with sleep during hospitalization identified several themes that promote clients' comfort, increase clients' ability to initiate and maintain sleep, and support the nurse's ability to co-create a safe sleep environment with the client (Gellerstedt et al, 2014).* **EBN:** *A qualitative study of how experienced nurses promote sleep in hospitals* (n = *8) identified caring conversation as one of four sleep-promoting nursing strategies (Salzmann-Erikson et al, 2016).*

▲ Assess for signs of overactive bladder. **CEB:** *A descriptive study* (n = *24) found that subjects with overactive bladder syndrome (OAB), but no formal insomnia diagnosis, awakened during sleep as often as insomniacs; however, waking durations were shorter in OAB subjects than those with diagnosed insomnia (Preud'homme et al, 2013).* **EB:** *Among 51 subjects diagnosed with OAB, incontinence and OAB symptoms were associated with sleep disturbance and daytime fatigue (Ge et al, 2017).*

For Chronic Insomnia

▲ Rule out and/or address any disorders and syndromes associated with chronic insomnia (e.g., addiction to alcohol or other psychoactive substances, anxiety and depressive disorders, chronic pain syndrome, or other sleep disorders). **EB:** *Coexisting medical conditions, mental disorders, and sleep disorders are interactive and bidirectional (Khurshid, 2015).*

- Monitor for uncomfortable sensations in legs and involuntary leg movements during sleep. **CEB:** *In a sleep laboratory study of urban, community-based participants* (n = *592), symptoms of insomnia were significantly higher in individuals with periodic limb movements during sleep (PLMS), although African Americans were less likely to have elevated PLMS than other participants (Scofield et al, 2008).*
- Be aware that clients diagnosed with chronic insomnia may have a low pain threshold. **CEB:** *In a laboratory study* (n = *34), subjects with shortened sleep caused by chronic insomnia were twice as likely to report experiencing spontaneous pain as healthy controls with no sleep loss; they also had lower pain thresholds during applications of heat and pressure than healthy controls (Haack et al, 2012).*
- Encourage use of the following stimulus control strategies in addition to any relaxation and sleep hygiene interventions recommended for short-term insomnia that the client finds helpful; (1) if feasible, have client arise from bed to participate in calming activities whenever anxious about failure to fall asleep; (2) if not feasible for client to get out of bed when unable to sleep, encourage sitting up in bed to engage in calming activities or simply resting in bed without attempting to fall asleep; (3) avoid a focus on what time it is and subsequent worry about amount of sleep time lost to sleeplessness; and (4) distract from sleeplessness with a focus on positive aspects of life. **EB:** *A meta-analysis of 37 comparative effectiveness studies found medium to large improvements in the ability to initiate and maintain sleep when a combination of stimulus control, relaxation, and sleep hygiene strategies was used to treat insomnia in clients with comorbid medical and psychiatric conditions (Wu et al, 2015).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Consider use of warm foot baths. **EBN:** *A review of evidence from 31 papers found that passive body heating via foot baths often relaxed and improved quality of sleep in insomnia clients (Talebi et al, 2016).*
- For clients whose chronic inability to initiate and maintain sleep has led to sleep deprivation, see Nursing Interventions and *Rationales* for **Sleep** Deprivation.
- For clients with unremitting chronic insomnia, refer to a nurse practitioner trained in cognitive behavioral therapies for insomnia (CBT-I). **EB:** *A meta-analysis of 37 comparative effectiveness studies found chronic insomnia clients with comorbid medical and psychiatric conditions improved their ability to initiate and maintain sleep after completion of multicomponent CBT-I programs (Wu et al, 2015).*
- Assist clients diagnosed with chronic insomnia who have been treated with CBT-I to limit use of sleeping medications and to select intermittent nights for sleeping pill use if complete discontinuance of sleeping pills is not feasible. **EB:** *An updated review of evidence supported the ability of clients treated with CBT-I to reduce or even eliminate their dependence on sleeping pills (Winkelman, Benca, & Eichler, 2021).*
- Supplement other interventions with teaching about sleep and sleep promotion. (See further Nursing Interventions and Rationales for Readiness for Enhanced **Sleep.**)

Geriatric

- Most interventions discussed above may be used with geriatric clients. In addition, see the Geriatric section of Nursing Interventions and *Rationales* for (1) Readiness for Enhanced **Sleep** and (2) Disturbed **Sleep**, and **Sleep** Deprivation.
- Note that it is especially helpful for the elderly client with short-term or chronic insomnia to engage in routine exercise unless contraindicated by health status. **EB:** *In an evidence review of 34 research reports, exercise increased sleep efficiency and duration in healthy older adults regardless of the mode and intensity of activity, and even more so in the elderly with sleep disorders (Dolezal et al, 2017).*

Home Care

- Assessments and interventions discussed previously can all be adapted for use in home care.
- In addition, see the Home Care section of Nursing Interventions and *Rationales* for Readiness for Enhanced **Sleep.**

Client/Family Teaching

- Teach family about normal sleep and promote adoption of behaviors that enhance it. See Nursing Interventions and *Rationales* for Readiness for Enhanced **Sleep.**
- Teach family about sleep deprivation and how to avoid it. See Nursing Interventions and *Rationales* for **Sleep** Deprivation.
- Advise family of importance of not disrupting sleep of others unnecessarily. See Nursing Interventions and *Rationales* for Disturbed **Sleep** Pattern.
- Advise family about the importance of minimizing noise and light, including light from electronic devices, in the sleep environment. See Nursing Interventions and *Rationales* for Disturbed **Sleep** Pattern.
- Help family members understand the difference between the two major precursors of sleep deprivation, that is, insomnia versus externally caused sleep disruptions. **EB:** *Insomnia is defined as persistent difficulty with sleep initiation, duration, consolidation, or quality—that occurs despite adequate opportunity and circumstances for sleep—and results in daytime impairment (Tan et al, 2019).*

Deficient Knowledge

Domain 5 Perception/cognition Class 4 Cognition

Lauren McAlister, MSN, FNP-BC, DNP and Kathaleen C. Bloom, PhD, CNM

K

NANDA-I

Definition

Absence of cognitive information related to a specific topic, or its acquisition.

Defining Characteristics

Inaccurate follow-through of instruction; inaccurate performance on a test; inaccurate statements about a topic; inappropriate behavior

Related Factors

Anxiety; depressive symptoms; inadequate access to resources; inadequate awareness of resources; inadequate commitment to learning; inadequate information; inadequate interest in learning; inadequate knowledge of resources; inadequate participation in care planning; inadequate trust in health care professional; low self efficacy; misinformation; neurobehavioral manifestations

At-Risk Population

Economically disadvantaged individuals; illiterate individuals; individuals with low educational level

Associated Conditions

Depression; developmental disabilities; neurocognitive disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Knowledge: Disease Process; Energy Conservation; Health Behavior; Health Resources; Healthy Diet; Infection Management; Medication; Personal Safety; Prescribed Activity; Substance Use Control; Treatment Procedure(s); Treatment Regimen

Example NOC Outcome with Indicators

Knowledge: Health Behavior as evidenced by the following indicators: Healthy nutritional practices/Benefits of regular exercise/Safe use of prescribed and nonprescribed medication. (Rate the outcome and indicators of **Knowledge: Health Behavior:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Client Outcomes

Client Will (Specify Time Frame)

- Explain disease state, recognize need for medications, and understand treatments
- Describe the rationale for therapy/treatment options
- Incorporate knowledge of health regimen into lifestyle
- State confidence in one's ability to manage health situation and remain in control of life
- Demonstrate how to perform health-related procedure(s) satisfactorily
- Identify resources that can be used for more information or support after discharge

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Teaching: Disease Process, Individual; Learning Facilitation

Example NIC Activities—Teaching: Disease Process

Discuss therapy/treatment options; Describe rationale behind management/therapy/treatment recommendations

Nursing Interventions and Rationales

- Health care providers who are nonjudgmental and supportive can assist clients to be involved in planning individual intervention strategies that can increase compliance. **EBN:** *Health care providers need to improve their therapeutic relationships and compliance and address not only clients' assessment needs but also their health beliefs, their lifestyle and social networks, and their individualism (Chitambira, 2019).*
- Consider the health literacy and the readiness to learn for all clients and caregivers (e.g., mental acuity, ability to see or hear, existing pain, emotional readiness, motivation, previous knowledge). **EBN:** *A systematic review by McCleary-Jones (2016) discussed the importance of nursing curricula to include information on health literacy to enhance new nurses' awareness that clients' limited health literacy can have an effect on client outcomes, and therefore strategies would be used to make sure they know if their clients are understanding and if they are providing appropriate information for their clients (McCleary-Jones, 2016).* **EBN:** *A study looking at a new tool, the Newest Vital Sign (NVS), was used to measure clients' health literacy. Findings showed that this tool is efficient to administer and could help identify low health literacy clients (McCune, Lee, & Pohl, 2016).*
- Focus on the nature of spoken and written communication when teaching clients and caregivers, especially those who may have health literacy needs. **EBN:** *A recent study by Hommes et al (2018) focused on the importance of improving health care and health promotion for the deaf community by improving communication, health literacy, and client empowerment by holding health care staff and organizations accountable for ensuring adequate staffing of ASL interpreters and communication resources in order to reduce health disparities.* **EBN:** *A qualitative study explored the relationship between health literacy and effective communication. One of the overarching themes was that building trust and relationships with the older adults to achieve effective communication can then be applied to meet the individual health literacy needs of the client (Brooks et al, 2017).*
- Consider the context, timing, and order of how information is presented. **EBN:** *The ability to personalize written health information to reinforce key health messages, instructions, medication information, or discharge instructions for clients has been shown to be an effective way to improve the knowledge of the consumer (Johnson, 2016).*
- Use person-centered approaches that engage clients and caregivers as active versus passive learners. **EBN:** *In a study by Rushton et al (2017), the reduction of hospital readmission in postoperative clients with complications during a recovery period after coronary artery bypass graft can be decreased by using person-centered education with individualized education programs to meet each individual client's needs.*
- Reinforce learning through frequent repetition and follow-up sessions. **EBN:** *In a qualitative study with semistructured interviews, it was discovered that clients who were in the intensive care unit (ICU) and who attended a follow-up session were better able to process their feelings and emotions. The findings from this*

study supported the hypothesis that the follow-up session for an ICU client can aid in processing the illness after the fact (Haraldsson et al, 2015).

- Use electronic methods for delivery of information when appropriate. **EBN:** *A recent study by Wang et al (2020) concluded that the use of smart phones as a clinical platform for diabetes nurses for educational purposes can be an effective way to provide personalized coaching and care to clients remotely.*
- Help the client and caregivers locate appropriate postdischarge groups and resources. **EBN:** *A systematic review concluded that the use of postdischarge support for clients with chronic obstructive pulmonary disease (COPD) significantly reduced the readmission rates within 30 days and had an effect up to 180 days (Pedersen et al, 2017).*
- Encourage clients and caregivers to maintain and/or expand supportive social networks as self-care learning resources when appropriate. **CEB:** *In a longitudinal study of 300 clients with long-term chronic health conditions, those who had sustained or expanded community networks were more likely to sustain self-care management, maintain behavioral change and treatment regimens, and access voluntary caregiving over formal caregiving (Reeves et al, 2014).*

Pediatric

- Use family-centered approaches when teaching children and adolescents. **EBN:** *According to Manente et al (2017), when families are educated about the client and know what to expect during the transition out of the ICU, their fears and anxieties are decreased, which can promote healing for the client.*
- Guide children and adolescents to credible information about their condition. **EBN:** *A mixed methods study showed that the best way to inform adolescents about HIV and sexual/reproductive health is via radio, television, mass media, and social media (Adams et al, 2017).*

Geriatric

✱ Educate all older clients on safety issues, including fall prevention and medication management. **CEB:** *In a meta-analysis of 19 studies, clients receiving targeted fall prevention education face to face or through multimedia methods had decrease in falls from those either receiving no formal education or written education (Lee et al, 2014).*

- Use multiprofessional teams to enhance client education. **EBN:** *A qualitative study exploring medication management in people with dementia showed potential positive benefits of a community pharmacist working in a multiprofessional environment outside the pharmacy and can improve medication management (Maidment et al, 2017).*
- Consider using teaching methods and materials appropriate for older adults, especially those with cognitive challenges. **EBN:** *A study concluded that screening for cognitive impairment in the elderly population and including the family and caregivers in the discharge education has the potential to minimize the risk of readmission (Agarwal et al, 2016).*
- Assess readiness of older adults for use of technological resources. **EBN:** *In a descriptive study, the utilization of technology for the aging population solely depended on the ease of use, affordability, and convenience, and barriers included a breach in privacy or security (Depatie & Bigbee, 2015).*

Multicultural

- Use educational interventions that are culturally tailored to the health literacy needs of the client. **CEB:** *A Cochrane review of 33 randomized controlled trials focusing on diabetes type 2 found that culturally appropriate health education improved blood sugar control among participants, compared with those receiving the "usual" care, at 3, 6, 12, and 24 months after the intervention (Attridge et al, 2014).*
- Assess for cultural/ethnic self-care practices. **EB:** *The use of simulated clients can be an effective way to help foster cultural competence in nursing education. It can allow nurses to learn how to improve their knowledge, skills, and attitudes with regard to providing culturally congruent nursing care (Ozkara San, 2020).*
- Consider the potential influence of medical interpreters in information sharing and decision-making and of the possible difficulties for clients when using medical interpreters. **EBN:** *The use of medical interpreters can help bridge the culture and language gap, allowing clients to feel more comfortable expressing themselves (Rorie, 2015).*
- Consider involving bilingual members of a community who are considered outside the traditional health care system who may assist in the teaching of community health issues. **EBN:** *A cross-sectional design study examined challenges associated with migrant and English-speaking cancer clients and found that the*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

majority of participants in all migrant groups reported difficulty communicating with the health care providers and team in English (Hyatt et al, 2017).

Home Care

- All of the previously mentioned interventions are applicable to the home setting.
- Use telehealth and technology-enhanced practices as appropriate. **EBN:** *A review of 11 studies looking at the role of telehealth in diabetic foot ulcer management found that telehealth was well received by clients and providers; assessments via the telehealth modalities were congruent with face-to-face assessment (Singh et al, 2016).*

Readiness for Enhanced Knowledge

Domain 5 Perception/cognition Class 4 Cognition

Lauren McAlister, MSN, FNP-BC, DNP and Kathaleen C. Bloom, PhD, CNM

NANDA-I

Definition

A pattern of cognitive information related to a specific topic, or its acquisition, which can be strengthened.

Defining Characteristics

Expresses desire to enhance learning

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Knowledge: Health Promotion

Example NOC Outcome with Indicators

Knowledge: Health Promotion as evidenced by the following indicators: Behaviors that promote health/ Reputable health care resources. (Rate the outcome and indicators of **Knowledge: Health Promotion:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Meet personal health-related goals
- Explain how to incorporate new health regimen into lifestyle
- List sources to obtain information

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Health Education; Health System Guidance

Example NIC Activities—Health Education

Prioritize identified learner needs based on client preference, skills of nurse, resources available, and likelihood of successful goal attainment

Nursing Interventions and *Rationales*

- Assume a facilitator role versus an authority role when engaging clients seeking health-related knowledge. **EBN:** *Educators in all disciplines must practice multiprofessional education experiences in order to provide due diligence in educating both clients and the future health care workforce in order to understand expectations and role responsibilities within the profession and that of others (Furr et al, 2020).* **EBN:** *According to Stacey and Légaré (2015), by assuming a facilitator role, nurses are able to provide balanced evidence on options, understand what is most important to the client, and advocate for the client's preferences. All of this facilitates shared decision-making and enables the opportunity to determine best practice.*
- Consider "health coaching" and motivational interviewing techniques when focusing on health-related goals, priorities, and preferences. **EBN:** *A study by Chang et al (2019) found that motivational interviewing enhanced knowledge and confidence and the care of older adults.* **EBN:** *In a randomized controlled trial (RCT) by Benzo et al (2017), health coaching, using motivational interviewing, significantly improved disease-specific quality of life compared with the control group.*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Seek teachable moments for those with chronic conditions to enhance their knowledge of health promotion. **EB:** *Findings from a 2015 study indicated that using cancer diagnosis as the teachable moment for health promotion efforts should be tailored and targeted at specific comorbidities (Highland et al, 2015).*
- Refer clients to interactive and Web-based technological resources as appropriate. **EB:** *In a qualitative study by van der Gugten et al (2016), 70% of adults reported that they seek health-related information through Internet resources.*
- Refer to Deficient **Knowledge** care plan.

Pediatric

- Consider the use of mobile text messaging as a resource for delivery of health promotion information. **EB:** *A systematic review of 16 studies indicated that multimedia technologies and mobile messaging are viable adjuncts that can help engage adolescents in disease prevention and health promotion (Geckle, 2016).*
- Involve children and especially adolescents in designing health promotion programs and teaching methods. **EBN:** *In a systematic review of eight qualitative studies, when the health care professional ensures children receive education and information appropriate to their health literacy, children are apt to be more involved in their decision-making (Davies & Randall, 2015).*
- Refer to Deficient **Knowledge** care plan.

Geriatric

- Discuss healthy lifestyle changes that promote safety, health promotion, and health maintenance for older clients. **EB:** *A study by Hsu et al (2016) indicated that elderly individuals with poor health status were more apt to receive a health examination for their diseases. Early detection via health promotion and disease prevention of the potential health risks would reduce the severity of diseases in the prognosis.*
- Consider involving bilingual members of a community who are considered outside the traditional health care system who may assist in the teaching of community health issues.

Multicultural

- Refer to Geriatric interventions.
- Refer to Deficient **Knowledge** care plan.

Risk for Latex Allergy Reaction

Domain 11 Safety/protection Class 5 Defensive processes

Gail B. Ladwig, MSN, RN and Julianne E. Doubet, BSN, RN, EMT-B

NANDA-I

Definition

Susceptible to a hypersensitive reaction to natural latex rubber products or latex reactive foods, which may compromise health.

Risk Factors

Inadequate knowledge about avoidance of relevant allergens; inattentive to potential environmental latex exposure; inattentive to potential exposure to latex reactive foods

At-Risk Population

Individuals frequently exposed to latex product; individuals receiving repetitive injections from rubber topped bottles; individuals with family history of atopic dermatitis; individuals with history of latex reaction; infants undergoing numerous operations beginning soon after birth

Associated Conditions

Asthma; atopy; food allergy; hypersensitivity to natural latex rubber protein; multiple surgical procedures; poinsettia plant allergy; urinary bladder diseases

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Allergic Response: Systemic; Immune Hypersensitivity Response; Risk Control; Risk Detection; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Immune Hypersensitivity Response as evidenced by the following indicators: Respiratory, cardiac, gastrointestinal, renal, and neurological function status IER/Free of allergic reactions. (Rate the outcome and indicators of **Immune Hypersensitivity Response:** 1 = not controlled, 2 = slightly controlled, 3 = moderately controlled, 4 = well controlled, 5 = very well controlled [see Section I].)

IER, In expected range.

Client Outcomes

Client Will (Specify Time Frame)

- State risk factors for natural rubber latex (NRL) allergy
- Request latex-free environment
- Demonstrate knowledge of plan to treat NRL allergic reaction

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Allergy Management; Latex Precautions; Environmental Risk Protection

Example NIC Activities—Latex Precautions

Question client or appropriate other about history of systemic reaction to NRL (e.g., facial or scleral edema, tearing eyes, urticaria, rhinitis, and wheezing); Place an allergy band on client

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Nursing Interventions and *Rationales*

- Clients at high risk for NRL allergy need to be identified. **EB:** *Allergy to NRL remains a serious public health problem, especially in health care workers and others who are "at risk": rubber industry workers, hairdressers, and hotel/motel housekeepers (Nucera et al, 2020).*
- Clients with spina bifida are a high-risk group for NRL allergy and should remain latex free from the first day of life. **EB:** *In their research, Gold and Salsberg (2017) found that as many as 50% of those who have spina bifida may have a latex allergy probably caused by their multiple surgeries, intermittent catheterization, and condition-related susceptibility.*
- Assess for NRL allergy in clients who are exposed to "hidden" latex. **EB:** *The usual vulcanization and purification processes used in the manufacturing of latex can leave up to 2% to 3% surplus of free proteins in the finished product (Meneses et al, 2020).*
- Assess for NRL allergy in clients with a history of multiple surgeries or other latex-exposing procedures. **EB:** *According to Stinkens et al (2019), certain clients who describe a latex allergy reaction had a history of multiple surgical procedures.*
- Assess for NRL allergy in atopic individuals (persons with a tendency to have multiple allergic conditions, including allergies to certain food products). **EB:** *In his study of occupational food allergies, Fukutomi (2019) found that latex-food syndrome is relatively common among health care workers.* **EBN:** *Latex allergy related fruits and nuts include Kiwifruit, banana, chestnut, and avocado (Kajiwara et al, 2018).*
- Assess persons who have an ongoing occupational exposure to NRL. **EB:** *Latex can not only trigger occupational allergies among health care workers but could conceivably act as an allergen to produce allergic symptoms in those in the same environment (Kartel et al, 2020).*
- Assess for latex sensitization in older adults. **EB:** *The incidence of allergic disease, and anaphylaxis, in the elderly becomes more common as lifespan increases (González-de-Olano et al, 2016).*
- Obtain a thorough history of the client at risk before performing procedures that may involve latex products, such as urinary catheter insertion or venipuncture. **EBN:** *Liberatore (2019) states that one of the most important question to ask a new client is, "Are you allergic to latex?"*
- Have management protocols in place for treating anaphylaxis. **EB:** *A report from the World Allergy Organization (Kowalski et al, 2016) advised that safety measures such as continuous supervision, specific emergency equipment, and quick access to emergency services should be readily available during at-risk testing procedures.* **EB:** *As overseeing the increase in allergic clients is becoming more problematic, a systematic approach was developed by Flokstra-de Blok et al (2017) to make available for the primary care physicians a plan of action "allergy management support system" (AMAS) for diagnosis and management of allergic clients.*
- Question the client about associated symptoms of itching, swelling, and redness after contact with rubber products such as rubber gloves, balloons, and barrier contraceptives, or swelling of the tongue and lips after dental examinations. **EBN:** *The chance of hidden latex in the health care setting presents a threat to clients' safety, especially in the utilization of equipment, supplies, and procedures (Liberatore, 2019).*
- Treat all latex-sensitive clients as if they have NRL allergy. **EB:** *If it is established that a client is at risk for latex allergy, avoidance of any latex exposure is critical (Nguyen & Kohli, 2020).*
- Clients with spina bifida and others with a positive history of NRL sensitivity or NRL allergy should have all medical/surgical/dental procedures performed in a latex-controlled environment. **EBN:** *According to Méndez et al (2018), most existing surgical protocols concur that latex-sensitive clients' elective surgery should be slated as the first case of the day in an operating suite that has had no prior activity for 12 hours.*
- In select high-risk atopic individuals, a specific immunotherapy regimen should be discussed with their health care provider. **EB:** *Currently, allergen-specific immunotherapy (AIT) remains the only conclusive treatment able to mitigate the natural course of allergic disorders (Nucera et al, 2020).*
- ▲ If latex gloves are chosen for protection from blood or body fluids, a reduced-protein, powder-free glove should be selected. **EB:** *According to a study by Baid and Agarwal (2017), powdered gloves have been shown to have greater NRL proteins compared with nonpowdered gloves. These substances could cause life-threatening reactions in sensitized clients and present a risk to health care workers.*
- Ensure that the client has a medical plan if a latex response develops. **EB:** *Prompt treatment of anaphylactic symptoms decreases the probability of a life-threatening situation. Sicherer and Simons (2017) stress the importance of client, family, and community education in the recognition and immediate management of anaphylaxis.*
- Note client history and environmental assessment.

Client Family Teaching and Discharge Planning

▲ Instruct the client to inform health care professionals if he or she has an NRL allergy, particularly if the client is scheduled for surgery. **EBN:** *It is crucial that, as part of preassessment activity before surgery, clients who have elevated risk factors for latex sensitivity are detected (European Operating Room Nurses Association [EORNA], 2020).*

- Provide the client with written information about latex allergy and sensitivity. **EB:** *All latex-sensitive clients should be provided a list of substitute latex-safe products for hospital and home use, and should also include identification of cross-reacting fruits, and hidden sources of NRL (Nucera et al, 2020).*
- Teach clients that the most effective approach to preventing NRL anaphylaxis is complete latex avoidance. **EB:** *After identifying "at-risk" clients for NRL, prevention of exposure becomes critical (Nguyen & Kohli, 2020).*

▲ Teach clients that materials and items that contain NRL must be identified and latex-free alternatives must be substituted. **EB:** *The substitution of nonlatex materials and the identification of latex-derived products are valuable in the successful control of health risks linked to NRL (Quirce & Fiandor, 2016).*

- Health care workers should avoid the use of latex gloves and seek alternatives such as unpowdered gloves made from nitrile. **EB:** *According to a study by Baid and Agarwal (2017), powdered gloves have been shown to have greater NRL proteins in contrast to unpowdered gloves: these substances could cause life-threatening reactions in sensitized clients and they present a risk to health care workers.*
- Institute measures that reduce or completely avoid any latex exposure to clients. **EB:** *Any latex-sensitive individual who has experienced an allergic reaction during surgical or medical procedures should wear a Medic Alert bracelet or necklace and carry autoinjectable epinephrine and sterile nonlatex gloves if needed in an emergency. Discuss latex allergy with all health care and community providers; the concept of "latex safe" would seem a practical and complementary strategy for prevention of serious reactions in those who are latex sensitive (Nucera et al, 2020).*
- Health care institutions should develop prevention programs and establish latex-safe areas in their facilities. **EBN:** *According to Liberatore and Kelley (2018), it is essential that all health care staff maintain strict attention to the avoidance of latex products for clients with a history of latex allergy.*

L

Home Care

- Assess the home environment for presence of NRL products (e.g., balloons, condoms, gloves, and products of related allergies, such as bananas, avocados, and poinsettia plants). **EB:** *According to Wu et al (2016), latex-derived products are still in use universally and latex allergy remains a widespread health risk for many occupations and for the general populace.*
- Ensure that the client has a medical plan if a response develops. **EB:** *Prompt treatment of anaphylactic symptoms decreases the probability of a life-threatening situation. Sicherer & Simons (2017) stress the importance of client, family, and community education in the recognition and immediate management of anaphylaxis.*
- Note client history and environmental assessment.

Readiness for Enhanced Health Literacy

Domain 1 Health promotion Class 1 Health awareness

Kathaleen C. Bloom, PhD, CNM

NANDA-I

Definition

A pattern of using and developing a set of skills and competencies (literacy, knowledge, motivation, culture and language) to find, comprehend, evaluate and use health information and concepts to make daily health decisions to promote and maintain health, decrease health risks and improve overall quality of life, which can be strengthened.

Defining Characteristics

Expresses desire to enhance ability to read, write, speak and interpret numbers for everyday health needs; expresses desire to enhance awareness of civic and/or government processes that impact public health; expresses desire to enhance health communication with health care providers; expresses desire to enhance knowledge of current determinants of health on social and physical environments; expresses desire to enhance personal health care decision-making; expresses desire to enhance social support for health; expresses desire to enhance understanding of customs and beliefs to make health care decisions; expresses desire to enhance understanding of health information to make health care choices; expresses desire to obtain sufficient information to navigate the health care system

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health Beliefs: Perceived Resources; Health-Promoting Behavior; Health-Seeking Behavior

Example NOC Outcome with Indicators

Health-Seeking Behavior as evidenced by the following indicators: Completes health-related tasks/Performs self-screening/Obtains assistance from health professional/Uses reputable heath information. (Rate the outcome and indicators of **Health-Seeking Behavior:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Use reputable information sources
- Seek information from health care providers
- Communicate with health care provider about understanding of information provided

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Health Literacy Enhancement; Health Education; Health System Guidance

Example NIC Activities—Health Literacy Enhancement

Create a health care environment in which a client with impaired literacy can seek help without feeling ashamed or stigmatized; Provide understandable health information; Use strategies to enhance understanding

Nursing Interventions and *Rationales*

▲ Work collaboratively with multiprofessional groups to create and maintain health-literate health care organizations. **EB:** *A scoping review of 106 studies found that interventions focusing on support for clients, support for staff, and support for governance are all important to achieve a health-literate health care organization (Zanobini et al, 2020).*

- Use a standard tool to identify the level of health literacy. **EB:** *A variety of tools have been developed to measure individuals' health-related reading comprehension (Agency for Healthcare Research and Quality [AHRQ], 2016).*
- Identify and take into consideration factors affecting health literacy such as age, ethnicity, education, and cognitive function. **EBN:** *Improved health literacy is associated with positive outcomes, including increased health promotion (Chahardah-Cherik et al, 2018) and adherence to medical treatments (Miller, 2016).*
- Implement health literacy universal precautions: assume that all clients may have difficulty understanding health information. **EB:** *Less than 15% of adults possess the level of health literacy needed to navigate the health care system (AHRQ, 2017). All clients need health information that is accurate, accessible, and understandable (French, 2015).*
- Tailor health teaching and educational materials to accommodate the needs of those with low health literacy. **EBN:** *A systematic review and meta-analysis of diabetes self-management interventions* (n = *13 studies) found that health literacy–sensitive interventions focused on communication (both written and spoken) and empowerment in the context of language and cultural considerations were the most effective for self-care and health outcomes, including reduction of hemoglobin (Hb) A1C (Kim & Lee, 2016).*
- Modify health teaching and educational materials to client preferences. **EB:** *Individuals who have lower health literacy prefer, understand, and correctly interpret pictures and icons that are familiar, contextual, and less complex (van Beusekom et al, 2015; Arcia et al, 2016; van Beusekom et al, 2017). Individuals with low health literacy prefer to be supported with reliable, understandable information and interactions with health care providers and others experiencing similar medical issues (Visscher et al, 2020).*
- Use empowerment to enhance health literacy and improve client outcomes. **EBN:** *A study with 295 individuals with type 2 diabetes found empowerment directly leading to health literacy, which then influenced self-efficacy, self-care behaviors, and finally HbA1C levels (Lee et al, 2016).* **EB:** *A meta-analysis of 61 studies determined that health literacy was directly associated with diabetes knowledge, self-care, and glycemic control (Marciano et al, 2019).*

Geriatric

- The above interventions may be adapted for geriatric use.
- Assess health literacy as it relates to health perceptions in older adults. **EB:** *Health literacy has been found to have a substantial effect on older adults' perceptions of the importance of their overall health and, to a lesser extent, their self-awareness of health and their health locus of control (Deniz et al, 2018).*
- Use simple educational materials targeted at health-promoting behaviors. **EB:** *Older adults with good health literacy are more likely to have mammography, to exercise, and to eat nutritiously and are less likely to perform monthly breast examinations or to smoke (Fernandez et al, 2016; Geboers et al, 2016).*

Multicultural

- Take the client's culture into account when designing teaching and educational materials. **EB:** *Higher levels of health literacy challenge are associated with being from a culturally diverse background and/or not*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

speaking English (Jessup et al, 2017). **EB:** *A scoping review of 27 studies revealed three consistent barriers to health care services access: cultural differences between providers and clients, language barriers, and information barriers (Kalich et al, 2016).*

- Use educational strategies targeted at both the individual and the community. **EBN:** *Targeting both individuals and communities allows for improvement in functional health literacy as well as improvement in knowledge (Fernández-Gutiérrez et al, 2018).*

Client/Family Teaching and Discharge Planning

- Promote shared decision-making. **EB:** *Increasing health literacy has the potential to enhance clients' engagement in health care and their participation in decision-making about their care (Wigfall & Tanner, 2018).*

Risk for Impaired Liver Function

Domain 2 Nutrition Class 4 Metabolism

Janelle M. Tipton, DNP, APRN-CNS, AOCN

NANDA-I

Definition

Susceptible to a decrease in liver function, which may compromise health.

Risk Factors

Substance misuse

Associated Conditions

Human immunodeficiency virus (HIV) coinfection; pharmaceutical preparations; viral infection

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Knowledge: Health Behavior; Liver Function

Example NOC Outcome with Indicators

Knowledge: Health Behavior as evidenced by the following indicators: Safe use of prescription drugs/Adverse health effects of alcohol misuse/Adverse health effects of recreational drug use/Healthy nutritional practices/Self-screening techniques. (Rate the outcome and indicators of **Knowledge: Health Behavior:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State the upper limit of the amount of acetaminophen safely taken per day
- Verbalize understanding that over-the-counter (OTC) medications may contain acetaminophen (e.g., OTC cold medicines)
- Have normal liver enzymes, serum and urinary bilirubin levels, white blood cell count, and red blood cell count
- Be free of unexplained weight loss, jaundice, pruritus, bruising, petechiae, gastrointestinal bleeding, and hemorrhage
- Be free of abdominal tenderness/pain, increased abdominal girth, and have normal-colored stool and urine
- Be able to eat frequent small meals per day without nausea and/or vomiting
- If alcohol abuse is factor, state relationship between abuse and worsening gastrointestinal and liver disease

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Teaching: Disease Process; Substance Use Treatment

Example NIC Activities—Teaching Disease Process

Appraise the client's current level of knowledge related to specific disease process; Discuss lifestyle changes that may be required to prevent future complications and/or control the disease process

Nursing Interventions and *Rationales*

▲ Assess for signs of liver dysfunction including fatigue, nausea, jaundice of the eyes or skin, pruritus, gastrointestinal bleeding, coagulopathy, infections, increasing abdominal girth, fluid overload, shortness of

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

breath, mental status changes, light-colored stools, dark urine, and increased serum and urinary bilirubin levels. **EB:** *These are symptoms and laboratory results associated with liver disorders (Ghany et al, 2015; Lee, Divens, & Fowler, 2017).*

▲ Evaluate liver function tests. Standard liver panels include the serum enzymes aspartate transaminase (AST), alanine transaminase (ALT), alkaline phosphatase, and γ-glutamyl transferase; total, direct, and indirect serum bilirubin; and serum albumin. **EB:** *Hepatitis C is often asymptomatic early in the disease state (Kwo, Cohen, & Lim, 2017) and may be found during a routine examination when liver function test results are elevated (Kelly & Wattacheril, 2019). It is recommended that all people should be screened for hepatitis C at least once when above age 18 (Centers for Disease Control and Prevention [CDC], 2020). In immunotherapy-related hepatitis, there may be an elevation in AST and ALT without an increased bilirubin (Lleo et al, 2019).*

▲ Discuss with the client/family preparations for other diagnostic studies, such as ultrasound, computed tomography, and magnetic resonance imaging (MRI) examinations. **EB:** *Although costly, MRI has the best quantification of steatosis (Cassard, Gérard, & Perlemuter, 2017). A noninvasive tool to assess liver stiffness is through a vibration-controlled transient elastography scan. The scan detects steatosis and fibrosis, providing scored assessments (Kelly & Wattacheril, 2019).*

▲ Evaluate coagulation studies such as international normalized ratio, prothrombin time, and partial thromboplastin time, especially when there is bleeding of the mouth or gums. Prolonged prothrombin time and decreased production of clotting factors can result in bleeding.

● Monitor for signs of hemorrhage, especially in the upper gastrointestinal tract, because it is the most frequent site. **EB:** *Synthesis of coagulation factors is affected with liver impairment (McGinnis & Hays, 2018). Management may include volume replacement and pharmacologic interventions with vitamin K to promote synthesis of coagulation proteins and vasopressin analogue to reduce portal pressures and minimize bleeding.*

● Obtain a list of all medications, including OTC nonsteroidal antiinflammatory drugs, acetaminophen, herbal remedies, and dietary supplements. Review risk of drug-induced liver disease. The list includes some antibiotics, anticonvulsants, antidepressants, antiinflammatory drugs, antiplatelets, antihypertensives, calcium channel blockers, cyclosporine, lipid-lowering drugs, chemotherapy drugs, immunotherapy drugs, oral hypoglycemics, proton pump inhibitors, inhaled anesthetics, and tranquilizers, among others (Hamilton, Collins-Yoder, & Collins, 2016; Suzman et al, 2018). If client is taking either OTC medications or herbals, discuss signs and symptoms of toxic hepatitis. **EB:** *Toxic hepatitis is caused by direct toxins, drugs, herbs, and industrial chemicals. The risk of toxicity with aspirin, ibuprofen, naproxen sodium, and acetaminophen increases with frequency and in combination with use of alcohol (Hamilton, Collins-Yoder, & Collins, 2016).*

▲ For clients receiving drugs associated with liver injury, review risk factors to prevent potentially severe drug reactions. **EB:** *Drug-induced liver disease accounts for about 50% of hepatitis cases. The most common risk factors are advanced age, female gender, alcohol use with associated infection, and genetic predisposition (Hamilton, Collins-Yoder, & Collins, 2016). Cancer clients are at higher risk for developing liver dysfunction due to complex medication regimens, treatment such as radiation therapy, and disease involvement to the liver. Due to significant morbidity and mortality associated with chemotherapy drugs, drug-induced liver injury is of concern. Consultation with an oncology clinical pharmacist may be indicated (Wen et al, 2020).*

▲ Determine the total amount of acetaminophen the client is taking per day. The amount of acetaminophen ingested should not exceed 3.25 g/day, or even lower in the client with chronic alcohol intake (Hamilton, Collins-Yoder, & Collins, 2016). **EB:** *It is common for clients to take multiple pain medications, all containing acetaminophen. Acetaminophen is the most common cause of drug-induced liver injury, and approximately 46% of all people with acute liver failure in the United States have liver damage caused by acetaminophen (Ortega-Alonso et al, 2016).*

▲ Evaluation of acetaminophen-associated drug-induced liver injury is done by client history of ingestion, time, and doses of the medication per weight calculation and serum level of acetaminophen. **EB:** *One of the tools most commonly used for decision-making in the use of* N*-acetylcysteine is the Rumack-Matthew nomogram for drug overdose. Prompt intervention with* N*-acetylcysteine has reduced mortality to 0.7% for those clients who overdosed on acetaminophen (Hamilton, Collins-Yoder, & Collins, 2016).*

▲ If the client is on statin medications, ensure that liver enzyme testing is done at intervals. Liver enzymes can become elevated from taking statin medications; it is rare but possible for statins to cause actual liver damage (Hamilton, Collins-Yoder, & Collins, 2016).

▲ If the client is an alcoholic, refer to a cessation program. It is essential the client stop drinking as soon as possible to allow the liver to heal. Alcoholism is associated with malnutrition, which is harmful to the liver

(Fabrellas, 2017). Alcoholism is also associated with increased plasma endotoxins and disruption of the gut barrier, which cause inflammation and resultant damage to the liver (Cassard, Gérard, & Perlemuter, 2017). See care plans for Ineffective **Denial** and Dysfunctional **Family** Processes.

▲ Provide frequent smaller meals for easier digestion. Provide diet with optimal carbohydrates, proteins, and fats. Consult with a registered dietitian to discuss best nutritional support. **EB:** *Proteins can be increased as tolerated and serum protein, albumin levels, and bilirubin levels indicate improved liver function. The goals of nutrition therapy are to provide adequate nutrition, support growth, preserve lean body mass, and prevent micronutrient deficiencies (Leon & Lerret, 2017).*

▲ Recognize that severe malnutrition may result in acute liver failure, which is reversible with improved nutrition.

▲ Review medical history with the client, recognizing that obesity and type 2 diabetes, along with hypertriglyceridemia and polycystic ovarian syndrome, are major risk factors in the development of liver disease, specifically nonalcoholic fatty liver disease. **EB:** *For those clients showing signs of fatty liver involvement, sound nutritional support can reduce the severity and mitigate the already existing secondary malnutrition (Kelly & Wattacheril, 2019).*

● Encourage vaccinations for hepatitis A and B for all ages. **EB:** *Hepatitis A can affect anyone in the United States. Vaccination can prevent hepatitis A and B, which at times can cause liver failure (CDC, 2020).*

● Measure abdominal girth if individual presents with abdominal distention and pain. **EB:** *Increasing abdominal distention and pain are signs of impending portal hypertension with the presence of fluid shifts, resulting in ascites. Increasing leg edema may also result, causing a significant effect on quality of life in those with cirrhosis (Ghany et al, 2015; Fabrellas et al, 2020).*

● Assess for tenderness and/or pain level in the right upper quadrant. Tenderness in this area is a symptom of biliary, liver, and/or pancreatic problems. **EB:** *This pain, along with a palpable mass and weight loss, is a classic triad for malignancies (Kelly & Wattacheril, 2019).*

● Use standard precautions for handling of blood and body fluids. Review sterile techniques when giving intravenous solution and/or medications. **EB:** *This is imperative to decrease the incidence of infection with hepatitis B and hepatitis C viruses. The viruses have been spread in health care settings when injection equipment and intravenous solutions were mishandled and became contaminated (CDC, 2020).*

▲ Observe for signs and symptoms of mental status changes such as confusion from encephalopathy. **EB:** *The symptoms can fluctuate in severity within hours. Increased ammonia levels greater than 100 µg/dL have been shown to be a risk factor for developing high-grade hepatic encephalopathy. The most commonly used medical treatment is lactulose, orally or rectally, because it has a prebiotic effect, lowers the pH in the colon, and binds to ammonia, and excretion is promoted by this laxative effect (Bager, 2017; McGinnis & Hays, 2018).*

Pediatric/Parents

▲ Prescreen pregnant women for hepatitis B surface antigens. If found, recommend nursing case management during pregnancy. **EB:** *Despite advances in prevention of hepatitis B transmission, approximately half of the infections are caused by mother-to-child transmission. Efforts to prevent transmission are an essential element of perinatal maternal and infant care (Pokorska-Śpiewak et al, 2017).*

▲ Recommend implementation of postexposure prophylaxis, including the hepatitis B virus vaccine for an infant born to a hepatitis B surface antigen–positive woman (CDC, 2020).

● Encourage vaccinations for hepatitis A and B for all ages. **EB:** *Children should be vaccinated between ages 12 and 23 months for hepatitis A (CDC, 2020).*

▲ Recognize that children can develop fatty liver disease, which can result in liver failure. Most children are asymptomatic, but others complain of malaise, fatigue, or vague recurrent abdominal pain. The development of NAFLD may be affected by perinatal and in utero stressors, with increased sensitivity to environmental and genetic factors (Goldner & Lavine, 2020).

▲ During a well-baby visit, assess for signs of potential liver problems. Observe for prolonged jaundice, pale stools, and urine that is anything other than colorless. Consult with health care provider to order a split bilirubin as needed (CDC, 2020).

Home Care

● Encourage rest, optimal nutrition (high carbohydrates, sufficient protein, and essential vitamins and minerals) during initial inflammatory processes of the liver.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- The COVID-19 pandemic has increased the need for home care, telemedicine, and telephone visits for clients with chronic liver disease. Prioritization of client care is indicated, including transplantation, diagnostic evaluations, and hospitalization, with consideration for clients with NAFLD or NASH at higher risk for severity related to COVID-19 infections due to comorbidities (Boettler et al, 2020).
- Consider referral to palliative care for clients with end-stage liver disease. **EB:** *Increased symptom burden, poor quality of life, and higher health care costs emphasize the need for early integration of palliative care, including advanced care planning and discussion of goals of care (Rakoski & Volk, 2019).*

Client/Family Teaching and Discharge Planning

- Teach the client and family to examine all medications the client is taking, looking for acetaminophen as an ingredient, and reinforce the 3.25-g upper limit of intake of acetaminophen to protect liver function (Hamilton, Collins-Yoder, & Collins, 2016).
- For the caregiver or client with hepatitis A, B, or C, teach the need for careful handwashing, use of gloves, and other precautions to prevent spread of any of these diseases.
- Teach avoidance of high-risk behaviors that cause hepatitis and ways to avoid those behaviors.
- For clients with chronic liver disease, provide education and support on lifestyle changes to prevent or delay disease progression. Structured follow-up may minimize readmission to the hospital (Hjorth et al, 2018).
- Educate clients and their caregivers about treatment options and interventions for hepatitis. Recommend other informational support: risk factors, side effects of the different treatment options, and dietary advice.
- Recommend psychological support if possible during education sessions. **EBN:** *Hepatitis can result in liver inflammation and chronic liver disease and is a common reason for a liver transplant. The client may not have an understanding of liver disease or its complications, may be elderly, or may have mental health issues or additions that affect the need for nursing intervention. Developing a plan and/or services to support and to give person-centered care can provide better support to the client in dealing with liver disease (Greenslade, 2017).*
- Assess for adherence to antiviral therapies for the treatment of hepatitis and institute nursing interventions such as client education, communication, and reminder tools to assist clients in medication adherence. **EB:** *Adherence to antiviral therapies is imperative to help suppress viral load and to reduce progressive liver disease (Polis et al, 2017).*
- For those clients with mental health problems, collaborate with outreach programs to teach signs/symptoms of hepatitis, risk factors, and factors that increase transmission. **EBN:** *These clients have higher potential for substance use and injected-drug use, and increased chances of transmission because of homelessness and living conditions in night shelters. Protocols have proven to be successful in developing an effective approach to meeting the needs of clients with or at risk for infection with hepatitis A, B, and C virus and severe mental health problems. Culturally sensitive, nurse-led interventions, such as counseling and bringing vaccinations to the community through mobile services, are valuable health promotion strategies in high-risk populations (Nyamathi et al, 2015; Fabrellas, 2017).*

Risk for Loneliness

Domain 12 Comfort Class 3 Social comfort

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to experiencing discomfort associated with a desire or need for more contact with others, which may compromise health.

Risk Factors

Affectional deprivation; emotional deprivation; physical isolation; social isolation

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Loneliness Severity; Social Interaction Skills; Social Involvement; Social Support

Example NOC Outcome with Indicators

Loneliness Severity as evidenced by the following indicators: Sense of social isolation/Difficulty in establishing contact with others. (Rate the outcome and indicators of **Loneliness Severity:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain one or more meaningful relationships (growth-enhancing versus codependent or abusive in nature)
- Sustain relationships that allow self-disclosure and demonstrate a balance between emotional dependence and independence
- Participate in personally meaningful activities and interactions that are ongoing, positive, and relevant socially
- Demonstrate positive use of time alone when socialization is not possible

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Family Integrity Promotion; Socialization Enhancement; Visitation Facilitation

Example NIC Activities—Socialization Enhancement

Encourage enhanced involvement in already established relationships; Help client increase awareness of strengths and limitations in communicating with others

Nursing Interventions and *Rationales*

- Assess the client's perception of loneliness. (Is the person alone by choice, or are there other factors that contribute to the feelings of loneliness? Is the client in one of the at-risk populations for loneliness?) **EBN:** *Nyatanga (2017) stated that loneliness can be a consequence of hardship, discrimination, inequality, loss of control, decrease in independence, and lack of options.*
- Assess the client's needs through mapping to assess existing networks, current activities, and the impact on well-being. **EB:** *Mapping allows nurse and client to examine the quality of existing relationships and activities to identify where intervention is needed (Mann et al, 2017).*
- Assess the client for signs of emotional distress. **EB:** *Research found that loneliness was the strongest overall predictor of mental distress and strong social connections are needed to prevent emotional distress (McIntyre et al, 2018).*

▲ Assess the bereaved client for risk of suicide and make appropriate referrals as necessary. **EB:** *A study by Stickley and Koyanagi (2016) found that there is a connection between loneliness and suicidal ideation; therefore efforts to reduce loneliness may play a significant part in decreasing its detrimental effects on the client's health and well-being.*

- Evaluate the client's desire for social interaction. **EB:** *Nurses and other health professionals must have an awareness of the client's social disconnectedness so that they can offer assistance in making and perpetuating social connections (Dinkins, 2017).*
- Teach the client problem-focused coping strategies. **EB:** *Findings from a systematic review suggest that learning how to use problem-focused coping strategies could target loneliness (Deckx et al, 2018).*

Pediatric

- Evaluate peer relationships. **EB:** *Peer relationships have been shown to play a significant role in self-esteem development across adolescence and also to remain influential throughout adulthood (Gruenenfelder-Steiger, Harris, & Fend, 2016).*
- Encourage relationships with peers and involvement with groups and organizations. **EB:** *According to Choukas-Bradley et al (2015), researchers have reported that peer influence is not intrinsically detrimental and that attempts to fashion one's own attitude to match that of peers could be seen as a healthy, constructive growth pattern.*
- Encourage organized activity (OA) participation for adolescent clients with a diagnosis of autism spectrum disorder. **EB:** *Research indicated that OA involvement was associated with fewer depressive symptoms and less feelings of loneliness (Bohnert, Lieb, & Arola, 2019).*

▲ Refer parents of disabled or seriously ill children to support groups. **EB:** *Participation in a family-oriented support group provides community support and possible solutions to common problems in a caring and trusting environment (Mitwalli, Rabaia, & Kienzler, 2018).*

Geriatric

- Identify risk factors for loneliness in older persons. **EB:** *In their study of aging and loneliness, Brittain et al (2017) stated that recognized risks factors for loneliness include widowhood, living alone, depression, and being female.*
- Practice laughter therapy with the client through laughter exercises or other humorous activities. **EB:** *A systematic review reported significant decreases in loneliness following interventions with laughter therapy (Quan et al, 2020).*

- Consider use of technology, such as computers, video conferencing, the Internet, and apps to alleviate or reduce loneliness or social isolation among older adults. **EB:** *An integrative review found that use of these technologies reduced isolation in older adults (Gardiner, Geldenhuys, & Gott, 2018).*
- Engage the client in positive reminiscence. **EB:** *A systematic review reported significant decreases in loneliness following interventions with reminiscence therapy (Quan et al, 2020).*
- Consider telephone outreach for isolated older individuals. **EB:** *The Yale Geriatrics Student Interest Group implemented the Telephone Outreach in the COVID-19 Outbreak Program at three nursing homes with initial success. Nursing home residents report looking forward to their weekly phone calls and gratitude for social connectedness (van Dyck et al, 2020).*
- ▲ Refer client to horticulture therapy. **EB:** *A systematic review reported significant decreases in loneliness following interventions with horticulture therapy (Quan et al, 2020).*
- ▲ Refer client to pet therapy or consider pet ownership if feasible. **EB:** *An integrative review found that individual pet therapy reduced isolation in older adults (Gardiner, Geldenhuys, & Gott, 2018).*
- Encourage support for the client when the decision to stop driving must be made. **EB:** *The nurse should direct the client toward community support systems and alternate methods of transportation when it is no longer feasible for them to continue driving (Pachana, 2016).*

Multicultural

- The preceding interventions may be adapted for diverse clients. Refer to the care plan for **Social** Isolation. Use a person-centered, biopsychosocial, health-focused approach to incorporate and address social determinants of health. **EBN:** *A study found that the nurse's ability to use a person-centered approach to address social determinants of health resulted in a significant reduction of self-reported loneliness in a diverse population (Sadarangani et al, 2019).*

Home Care

- ▲ The preceding interventions may be adapted for home care use.
- ▲ Assess for depression with the lonely older client and make appropriate referrals. **EBN:** *The heightened prevalence of depressive symptoms and their relationship to the associated factors (gender, age group, schooling, marital status, and place of residence) of depression in the elderly affirm the necessity to implement means for the advancement of public policies and prioritize strategies that can best guarantee health care for the elderly population (Carréra Campos Leal et al, 2015).*
- If the client has unexplained somatic complaints, evaluate these complaints to ensure that the client's physical needs are being met and assess for a possible relationship between somatic complaints and loneliness. **EB:** *"Our bodies manifest emotions physically when we cannot effectively express them" (Spencer, 2016).* **EBN:** *In their study, Zimmerman et al (2016) confirmed that the nurse can, in collaboration with the client's physician, competently support self-management of clients with psychosomatic symptoms and their psychosocial needs.*
- Assist clients to interact with neighbors in the community when they move to supported housing. **EB:** *Those clients transferring to supported housing will be placed in an unfamiliar environment that necessitates the need to develop skills to successfully adapt to their new surroundings (Kirchen & Hersch, 2015).*
- Refer to the care plan for **Social** Isolation.

Client/Family Teaching and Discharge Planning

- Provide appropriate education for clients and their support persons about disease transmission and treatment if applicable. **EBN:** *Pandur (2015), in her study of infections in home care settings, concluded that home health clients are cared for in a totally unconstrained environment innate with infection possibilities.*
- Refer to the care plan for **Social** Isolation for additional interventions.

Ineffective Lymphedema Self-Management

Domain 4 Activity/rest Class 4
Cardiovascular/pulmonary responses

Morgan Nestingen, MSN, APRN, AGCNS-BC, OCN, ONN-CG

NANDA-I

Definition

Unsatisfactory management of symptoms, treatment regimen, physical, psychosocial, and spiritual consequences and lifestyle changes inherent in living with edema related to obstruction or disorders of lymph vessels or nodes.

Defining Characteristics

Lymphedema Signs

Fibrosis in affected limb; recurring infections; swelling in affected limb

Lymphedema Symptoms

Expresses dissatisfaction with quality of life; reports feeling of discomfort in affected limb; reports feeling of heaviness in affected limb; reports feeling of tightness in affected limb

Behaviors

Average daily physical activity is less than recommended for age and gender; inadequate manual lymph drainage; inadequate protection of affected area; inappropriate application of nighttime bandaging;

inappropriate diet; inappropriate skin care; inappropriate use of compression garments; inattentive to carrying heavy objects; inattentive to extreme temperatures; inattentive to lymphedema signs; inattentive to lymphedema symptoms; inattentive to sunlight exposure; reduced range of motion of affected limb; refuses to apply night-time bandages; refuses to use compression garments

Related Factors

Competing demands; competing lifestyle preferences; conflict between health behaviors and social norms; decreased perceived quality of life; difficulty accessing community resources; difficulty managing complex treatment regimen; difficulty navigating complex health care systems; difficulty with decision-making; inadequate commitment to a plan of action; inadequate health literacy; inadequate knowledge of treatment regimen; inadequate number of cues to action; inadequate role models; inadequate social support; limited ability to perform aspects of treatment regimen; low self efficacy; negative feelings toward treatment regimen; neurobehavioral manifestations; nonacceptance of condition; perceived barrier to treatment regimen; perceived social stigma associated with condition; unrealistic perception of seriousness of condition; unrealistic perception of susceptibility to sequelae; unrealistic perception of treatment benefit

At-Risk Population

Adolescents; children; economically disadvantaged individuals; individuals with history of ineffective health self-management; individuals with limited decision making experience; individuals with low educational level; older adults

Associated Conditions

Chemotherapy; chronic venous insufficiency; developmental disabilities; infections; invasive procedure; major surgery; neoplasms; obesity; radiotherapy; removal of lymph nodes; trauma

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcome

Lymphedema severity: Severity of adverse physical, emotional, and social responses due to lymphedema

Example NOC Outcome with Indicators

Lymphedema Severity: Identifies area of edema and impact on health as evidenced by limited physical function or mobility. (Rate outcome and indicators 1 = severe 2 = substantial 3 = moderate, 4 = mild 5 = none)

Client Outcomes

Client Will (Specify Time Frame)

- Monitor skin firmness of affected area
- Report numbness of affected area
- Report redness of affected area
- Report pain
- Report feelings of anxiety and/or depression

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Intervention

Lymphedema severity: Assist the client with understanding and minimize the side effects of radiation treatment

Example NIC Activities

Promote activities to modify the identified risk factors that may lead to lymphedema

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Nursing Interventions and *Rationales*

- Recognize individual client risk factors for development of immediate or delayed lymphedema and assess at-risk clients at each visit to promote early identification. **EB:** *Lymphedema may be primary (i.e., congenital) or secondary to illness or treatment (e.g., cancer related). Older age, obesity, inflammatory conditions, malignancy, and surgical or radiation treatment affecting the lymph node system are key risk factors for both immediate and delayed onset lymphedema. Certain specific treatments increase the risk of local lymphedema (e.g., axillary lymph node dissection and upper limb lymphedema). Early detection is key to treating and potentially reversing low-stage lymphedema; progressive stages are less amenable to treatment (National Comprehensive Cancer Network [NCCN], 2021). Isolated hand edema in breast cancer survivors may be a prognostic indicator for subsequent edema progression in the at-risk limb (Brunelle et al, 2018).*
- At each visit, ask clients if they are experiencing any early symptoms of lymphedema, including swelling or a sense of heaviness, fullness, tightness, or pain in the at-risk limb. Assess signs of lymphedema, including observation of swelling, pitting, or fibrosis. **EB:** *The NCCN recommends routine screening and assessment of lymphedema in at-risk survivors of cancer to ensure early identification and treatment (NCCN, 2021).*
- Perform detailed medication reconciliation, consider medications that may exacerbate lymphedema symptoms, and review concerning medications with client and ordering provider. **EB:** *Many commonly used medications may exacerbate or mask lymphedema symptoms, complicating early diagnosis and treatment (Tesar & Armer, 2018).*
- Assess the client's skin and understanding of skin self-care regimen. Demonstrate and instruct the client in meticulous skin care in the at-risk limb. **EB:** *A systematic review found that lymphedema self-care regimens including hygiene were associated with improved outcomes, including volume reduction and improved quality of life (Douglass et al, 2016). Assessment of the client's understanding of self-care can help to identify gaps and promote effective self-care.*
- Review the client's dietary habits and encourage a healthy diet. **EB:** *A healthy diet supports healthy weight maintenance and combats inflammatory processes to reduce the lymphedema risk and reduces fluid shifting; dietary consultation may assist in determining client's specific dietary needs (Cavezzi et al, 2019; Vafa et al, 2020).*
- If the client has experienced symptoms of lymphedema, assess the frequency, severity, and impact on activities of daily living, pain, range of motion, and strength. Inspect the at-risk limb for signs or symptoms of infection. **EB:** *Thorough assessment of related factors and limitations supports determination of lymphedema severity (NCCN, 2021).*
- Refer the client with lymphedema to a trained lymphedema specialist, if available. **EB:** *The NCCN recommends referral to a trained lymphedema specialist to ensure accuracy in volume measurements, recommendation of additional diagnostics, specialized therapeutic techniques, and expert education (NCCN, 2021).*
- When possible, assist the client in establishing baseline limb measurements for comparison with subsequent posttreatment and interval measures. Advocate for client access to a trained lymphedema specialist, if available. **EB:** *Limb measurements are an inexpensive, accessible way to evaluate lymphedema severity, particularly when measured by a trained specialist. Lymphedema specialists may perform a detailed examination of limb volume, range of motion, muscle function, circulation, sensation, hemodynamics, and mobility (NCCN, 2021).*
- Assess the client for psychosocial distress, including anxiety, depression, fear of cancer recurrence, body image disturbance, difficulty coping, financial challenges, and changes in sexuality. In cancer clients and survivors, use of a validated psychosocial screening tool may facilitate screening and assessment. **EB:** *Cancer survivors with lymphedema often face psychosocial challenges, including age-related, sexuality, body image, and relational challenges, requiring intervention (Eaton et al, 2020).*
- Connect the client with appropriate, individualized resources and referrals for any psychosocial distress identified. For example, a client struggling to cope with adherence to self-management may benefit from motivational interviewing, whereas a client suffering from lymphedema-related body image disturbance may wish to connect with a lymphedema support group. **EB:** *A recent systematic review found an association between lymphedema and lower quality of life and poor physical, psychosocial, relational, and financial functioning; lymphedema symptoms and severity were associated with a lower quality of life (Bowman et al, 2020). A phenomenological study described the supportive care needs of women with breast cancer–related lymphedema, including physical (e.g., difficulties with chores and self-care), psychosocial (e.g., uncertainty and social needs), health care systems and information (e.g., educational), and financial supportive care*

needs; these were alleviated by support from family members and health care professionals (Arikan Dönmez et al, 2021).

- Explore any client beliefs, priorities, support, and financial resources that may affect client's adherence to lymphedema self-management plan. **EB:** *Cultural beliefs may affect client's adherence to lymphedema self-management plan and should be assessed and proactively addressed to support effective self-management (Anderson & Armer, 2021).*
- Provide individualized lymphedema teaching, including basic explanation of the lymphatic system, personal risk factors, signs and symptoms of lymphedema, self-management, treatments, and potential psychosocial concerns. **EB:** *There is no clear consensus on what constitutes effective lymphedema self-management teaching; thus education varies widely and teaching may be inadequate with regard to self-care and exercise (Hurren & Yates, 2019). However, a systematic review found that self-management education was associated with improvement in lymphedema symptoms and quality of life (Howell et al, 2017).*
- Confirm fit and demonstrate donning/doffing of compression garments and devices, when applicable. Assist the client with obtaining ordered compression garments and devices and connect client with referrals and resources to address client financial responsibility. **EB:** *The Oncology Nursing Society (ONS) recommends preventive use in clients at risk for extremity, truncal, or head and neck edema, based on low-level evidence (Armer et al, 2020).*
- Demonstrate self-massage and exercises (typically a combination of resistance and strength training) to promote lymphatic drainage, as instructed by a provider or lymphedema specialist. In postoperative clients at risk for lymphedema, delay start of exercises for 7 days or until cleared by the surgeon and lymphedema specialist. **EB:** *The ONS recommends self-massage of postoperative scar tissue in clients at risk for extremity, truncal, or head and neck edema, as instructed by a surgical or lymphedema specialist and as tolerated by the client (Armer et al, 2020). Exercise is associated with decreased lymphedema symptoms in at-risk, postsurgical clients (Ali et al, 2019).*
- Provide dietary teaching. **EB:** *Dietary teaching supports maintenance of a healthy diet to reduce lymphedema risk factors (Cavezzi et al, 2019; Vafa et al, 2020).*
- Assess impact of lymphedema on client's physiological, functional, and occupational status. Consider limitations in activities of daily living and work limitations, when appropriate. **EB:** *Studies show that lymphedema can affect work through changes in physical and emotional functioning at work, work disruption for treatment, and introduction of work challenges and complicate personal factors involved in returning to work (Sun et al, 2020; Vignes et al, 2020).*
- If lymphedema symptoms worsen or fail to improve with intervention, assess client's understanding of and adherence to treatment plan. Consider approaches to improve client adherence to self-management and health-promoting behaviors (e.g., motivational interviewing). **EB:** *A recent meta-analysis found that using motivation–behavioral skills approach and teaching mindfulness skills may play in improving client adherence by supporting health-promoting behaviors (Sala et al., 2020).*
- Support client-provider interactions to identify some form of appropriate, active lymphedema treatment plan (e.g., complete decongestive therapy, resistance training, surgery) in addition to self-management if lymphedema cannot be managed by self-care alone. **EBN:** *The ONS recommends active treatment of lymphedema in addition to self-management, based on low-level evidence (Armer et al, 2020). Decongestive lymphatic therapy has been shown to significantly decrease limb volume despite previous treatment, suggesting that subsequent treatment in recurrent or refractory lymphedema may be warranted (Bozkurt et al, 2017). A recent systematic review found surgery to be associated with improved quality of life (Coriddi et al, 2020).*

Pediatrics and Adolescents

- Support caregivers of children and adolescents with lymphedema by teaching self-management techniques to both the child and caregiver, using flexible and individualized approaches, and addressing caregiver fears and anxiety over the child's health condition. **EB:** *Parents and caregivers may struggle to balance children's ability to self-manage with rigid teaching approaches provided by clinicians, while coping with fear and anxiety (Moffat et al, 2019a, 2019b).*

Multicultural

- In Latina cancer survivors, family involvement, peer-mentoring, culturally competent education, and self-care skills are important additions to the client's lymphedema self-management plan. **EB:** *A literature*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

review of factors affecting management of breast cancer–related lymphedema in Latina survivors demonstrated the importance of these additional factors (Anderson & Armer, 2021).

Client/Family Teaching and Discharge Planning

- Encourage the client to inform health care providers of any history of lymphedema, procedures that increase lymphedema risk, and contraindications against venipuncture or blood pressure in the at-risk/affected limb. **EB:** *Limited observational data suggest that air travel, venipuncture of the at-risk/affected limb, and blood pressures taken on the at-risk/affected limb are safe; however, when possible the NCCN recommends avoiding the at-risk/affected limb because this limb may be used in case of urgent medical need (NCCN, 2021).*
- Instruct the client to take medication only as ordered and review all medications with health care providers. **EB:** *Medications may exacerbate lymphedema or complicate diagnosis and should be reviewed with a provider (Tesar & Armer, 2018).*
- Teach the client to self-monitor and report early signs or symptoms of lymphedema (e.g., swelling, fullness, tightness, heaviness, or pain in the at-risk limb). **EB:** *Early-stage lymphedema is often reversible, whereas late-stage lymphedema is less responsive to treatment (NCCN, 2021). Breast cancer clients with lymphedema experience specific, timely informational needs and benefit from private education sessions provided by clinicians or social networks (Dorri et al, 2020; Arikan Dönmez et al, 2021).*
- Instruct the client to observe the at-risk limb for signs of infection, including fever, warmth, redness, or swelling, and immediately report these to a health care provider if they occur. **EB:** *Lymphedema and increased risk for lymphedema are associated with potentially serious localized infections and may require hospitalization and treatment with intravenous antibiotics (NCCN, 2021).*
- Teach meticulous skin care in the at-risk limb, including keeping skin clean and dry; applying lotion; using an electric razor versus a razor blade to shave; avoiding exposure of the limb to excessive heat, cold, or direct sunlight; and protecting skin from injury. **EB:** *A systematic review of lymphedema self-care regimens found that regimens including hygiene were commonly associated with improved outcomes, including volume reduction and improved quality of life (Douglass et al, 2016). Additionally, meticulous skin care is critical to preventing and identifying lymphedema-related infections quickly (NCCN, 2021).*
- Emphasize the importance of regular exercise in reducing lymphedema risk and severity. **EB:** *Exercise is associated with prevention, delayed onset, and decreased severity of lymphedema symptoms in at-risk clients (Ali et al, 2019).*
- Encourage the client to discuss any psychosocial concerns related to lymphedema, including anxiety, depression, body image disturbance, difficulty coping, financial challenges, and changes in sexuality. **EB:** *A recent literature review found that breast cancer survivors with lymphedema often faced age-related, sexuality, body image, and relational challenges, requiring psychosocial intervention (Eaton et al, 2020).*

Risk for Ineffective Lymphedema Self-Management

Domain 4 Activity/rest

Class 4 Cardiovascular/pulmonary responses

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

L

NANDA-I

Definition

Susceptible to unsatisfactory management of symptoms, treatment regimen, physical, psychosocial, and spiritual consequences and lifestyle changes inherent in living with edema related to obstruction or disorders of lymph vessels or nodes which may compromise health.

Related Factors

Competing demands; competing lifestyle preferences; conflict between health behaviors and social norms; decreased perceived quality of life; difficulty accessing community resources; difficulty managing complex treatment regimen; difficulty navigating complex health care systems; difficulty with decision-making; inadequate commitment to a plan of action; inadequate health literacy; inadequate knowledge of treatment regimen; inadequate number of cues to action; inadequate role models; inadequate social support; limited ability to perform aspects of treatment regimen; low self efficacy; negative feelings toward treatment regimen; neurobehavioral manifestations; nonacceptance of condition; perceived barrier to treatment regimen; perceived social stigma associated with condition; unrealistic perception of seriousness of condition; unrealistic perception of susceptibility to sequelae; unrealistic perception of treatment benefit

At-Risk Population

Adolescents; children; economically disadvantaged individuals; individuals with history of ineffective health self-management; individuals with limited decision making experience; individuals with low educational level; older adults

Associated Conditions

Chemotherapy; chronic venous insufficiency; developmental disabilities; infections; invasive procedure; major surgery; neoplasms; obesity; radiotherapy; removal of lymph nodes; trauma

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* and References

Refer to care plan for Ineffective **Lymphedema** Self-Management.

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

Risk for Disturbed Maternal–Fetal Dyad

Domain 8 Sexuality Class 3 Reproduction

Dianne F. Hayward, RN, MSN, WHNP

NANDA-I

Definition

Susceptible to a disruption of the symbiotic motherfetal relationship as a result of comorbid or pregnancy-related conditions, which may compromise health.

Risk Factors

Inadequate prenatal care; substance misuse; unaddressed abuse

Associated Conditions

Compromised fetal oxygen transport; glucose metabolism disorders; pregnancy complication; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Fetal Status: Antepartum; Maternal Status: Antepartum, Intrapartum; Depression Level; Blood Glucose Level; Family Resiliency; Knowledge: Self-Management; Nausea and Vomiting Severity; Social Support; Spiritual Support, Parent-Infant Attachment

Example NOC Outcome with Indicators

Maternal Status: Antepartum as evidenced by the following indicators: Emotional attachment to fetus/Coping with discomforts of pregnancy/Mood lability/Blood pressure/Blood glucose/Hemoglobin. (Rate the outcome and indicators of **Maternal Status: Antepartum:** 1 = Severe deviation from normal range, 2 = Substantial deviation from normal range, 3 = Moderate deviation from normal range, 4 = Mild deviation from normal range, 5 = No deviation from normal range [see Section I].)

M

Client Outcomes

Client Will (Specify Time Frame)

During Pregnancy

- Attend all scheduled prenatal visits and attend prenatal education either virtual or in person with significant other or involved family member
- Cope with fears and discomforts of high-risk pregnancy until delivery of baby
- Demonstrate emotional attachment to fetus during pregnancy
- Adhere to prescribed regimens to maintain homeostasis during pregnancy

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

High-Risk Pregnancy Care; Intrapartal Care: High-Risk Delivery

Example NIC Activities—High-Risk Pregnancy Care

Determine the presence of medical factors that are related to poor pregnancy outcome (e.g., diabetes, hypertension, lupus erythematosus, herpes, hepatitis, HIV, multiple gestation, substance abuse, epilepsy, infection); Provide educational materials that address the risk factors and usual surveillance tests and procedures.

Nursing Interventions and *Rationales*

Prenatal

- Encourage early prenatal care and regular prenatal visits. **EB:** *Prenatal care is crucial for a good pregnancy outcome for mothers and infants. Many women in the United States receive late (starting in third trimester) or no prenatal care, resulting in avoidable adverse health outcomes (Oghogho & Beck-Sagué, 2020). The World Health Organization (WHO) guidelines for prenatal care include a minimum of eight contacts to reduce perinatal mortality and improve women's experience of care, counseling about a healthy lifestyle, and keeping physically active during pregnancy (World Health Organization, 2016).*
- Determine the presence of medical factors that are related to poor pregnancy outcome (e.g., diabetes, hypertension, lupus erythematosus, herpes, hepatitis, HIV, multiple gestation, substance abuse, epilepsy, infection); provide educational materials that address the risk factors and usual surveillance tests and procedures. **EB:** *Early identification of at-risk mothers can ensure interventions either to control the risk-causing factor or delivery of timely and appropriate care as and when needed (Chaudhry et al, 2019).*
- Assess the antenatal client for fear related to high-risk pregnancy and fetal outcomes. **EBN:** *An Istanbul study found that pregnant women with a poor level of psychosocial adaptation showed more depressive symptoms (Fiskin et al, 2017).*
- Assess antepartum clients for depression using a culturally competent tool that evaluates the bio-psycho-social-spiritual dimensions. **EBN:** *Susser et al (2016) reported that nearly 20% of women in pregnancy and in the postpartum period are affected with depression. There is a high risk of morbidity and mortality when a woman is affected with perinatal depression, and this may have long-term consequences on child development.*
- Focus on the abilities of a pregnant woman with disabilities by encouraging identification of support systems, resources, and need for environmental modification. **EBN:** *In a recent study of pregnant women with disabilities, the women reported a lack of knowledge, awareness, sensitivity, and respect, as well as stereotyping, as issues that contributed to compromised perinatal care (Smeltzer et al, 2016).*
- Assess for lack of social support system, loneliness, depression, lack of confidence, maternal powerlessness, domestic violence, and socioeconomic problems. **EBN:** *Screening should include significant risk factors to detect at-risk women (Ruyak et al, 2017).*
- Identify patterns of intimate partner violence in all pregnant and postpartum women. **EBN:** *Violence during pregnancy can result in poor maternal, neonatal, and early childhood outcomes; routine screening and assessment may interrupt further abuse and promote positive outcomes (Bianchi et al, 2016).* **EBN:** *Nurses play a vital role in the identification and support of women who experience violence (Bianchi, 2016).*
- Perform accurate blood pressure readings at each client's clinic encounter. **EB:** *As hypertension is one of the most common medical disorders complicating pregnancy, good control of blood pressure during pregnancy helps prevent adverse maternal–fetal outcomes (Bello et al, 2018).*
- Provide educational materials and support for personal autonomy about genetic counseling and testing options before pregnancy with preimplantation genetic testing or during pregnancy with fetal nuchal translucency ultrasound, quadruple screen, and cystic fibrosis screening. **EBN:** *Nurses can advocate, understand the perceptions of, and assist clients in their reproductive decision-making (Shiroff & Nemeth, 2015).*
- Ensure that pregnant clients have an adequate diet and take multimicronutrient supplements containing at least 400 µg of folic acid, especially during early pregnancy. **EB:** *Nutritional information can be found at* choosemyplate.gov. *which presents healthy choices from each food group needed for a healthy pregnancy (U.S. Department of Agriculture [USDA], 2020).* **EB:** *The US Preventive Services Task Force (USPSTF) has updated its recommendation that all women who are planning or capable of pregnancy take a daily supplement containing 0.4 to 0.8 mg (400–800 µg) of folic acid to prevent neural tube defects (Bibbins-Domingo et al, 2017).*
- Provide pregnant women diagnosed with gestational diabetes with education about management and treatment. **EBN:** *Good control of blood glucose is important during delivery to reduce the risk of neonatal hypoglycemia (King, 2017).*
- Assess use of tobacco and, if positive for use, offer a tobacco cessation program and explain the health risks to the unborn fetus and mother. **EBN** *Many women who do stop smoking during their pregnancies relapse in the postpartum period. Smoking is a major cause of adverse pregnancy and birth outcomes (Fallin-Bennett et al, 2019). A free and helpful website for quitting smoking is available at https://women.smokefree.gov/tools-tips-women/text-programs/smokefreemom (U.S. Department of Health and Human Services, n.d.).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Assess for alcohol misuse and counsel women to stop drinking during pregnancy. Provide appropriate referral for treatment as needed. **EB:** *There is no safe time to drink alcohol during pregnancy, and drinking during pregnancy can result in fetal alcohol spectrum disorder (FASD). FASD is a range of physical, mental, behavioral, and/or learning disabilities with potential lifelong implications that occur after exposure to alcohol in utero (Association of Women's Health, Obstetric and Neonatal Nurses [AWHONN], 2019).*
- Screen for current illicit drug use. Emphasize the risks of drug exposure to the fetus/newborn and the potential for withdrawal. **EB:** *Pregnancy is an opportune time to identify substance misuse dependence, facilitate conversion to maintenance treatment, and coordinate comprehensive prenatal care with specialists in addiction medicine, behavioral health, and social services (Krans et al, 2015).*
- Refer clients who self-report drug misuse or have positive toxicology screens to a comprehensive treatment program designed for the pregnant woman. **EBN:** *Untreated addiction can lead to poor maternal and fetal health outcomes. Neonates born to women receiving treatment may have withdrawal symptoms and require additional treatment (Keough & Fantasia, 2017).*
- Encourage pregnant women to use digital resources, such as Text4Baby (see https://www.text4baby.org) or https://www.whattoexpect.com, to track pregnancy progress and provide education and motivation to make healthy lifestyle choices. **EBN:** *Multiple digital sources of health-related information are available, and women may need help to identify those that are most reputable and useful (Lowe & Hartley, 2018).*

Multicultural

Prenatal

- Assess the client's beliefs and concerns about pregnancy. **EB:** *Continuity of supportive care and sensitivity to the mother's cultural, religious, and individual beliefs and values reduce the risk of psychological trauma and enhance women's trust in their caregivers, their experiences of childbearing, and their willingness to accept care and to seek it in the future (LaLonde et al, 2019).*

Impaired Memory

Domain 5 Perception/cognition Class 4 Cognition

Olga F. Jarrín, PhD, RN, Nishat S. Poppy, BSN, RN, and Linda J. Hassler, DNP, RN, GCNS-BC, FGNLA

NANDA-I

Definition

Persistent inability to remember or recall bits of information or skills, while maintaining the capacity to independently perform activities of daily living.

Defining Characteristics

Consistently forgets to perform a behavior at the scheduled time; difficulty acquiring a new skill; difficulty acquiring new information; difficulty recalling events; difficulty recalling factual information; difficulty recalling familiar names; difficulty recalling familiar objects; difficulty recalling familiar words; difficulty recalling if a behavior was performed; difficulty retaining a new skill; difficulty retaining new information

Related Factors

Depressive symptoms; inadequate intellectual stimulation; inadequate motivation; inadequate social support; social isolation; water-electrolyte imbalance

At-Risk Population

Economically disadvantaged individuals; individuals aged 60 years; individuals with low educational level

Associated Conditions

Anemia; brain hypoxia; cognition disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Cognitive Orientation; Memory; Neurological Status: Consciousness

Example NOC Outcome with Indicators

Memory as evidenced by the following indicators: Recalls immediate information accurately/Recalls recent information accurately/Recalls remote information accurately. (Rate each indicator of **Memory:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate use of techniques to help with memory loss
- State he or she has improved memory for everyday concerns

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Memory Training; Dementia Management; Reality Orientation

Example NIC Activities—Memory Training

Discuss with client/family any practical memory problems experienced; Implement appropriate memory techniques, such as visual imagery, mnemonic devices, memory games, memory cues, association techniques, making lists, using computers, using name tags, or rehearsing information; Structure the teaching methods according to client's organization of information; Refer to occupational therapy, as appropriate; Monitor changes in memory with training

Nursing Interventions and *Rationales*

- Determine whether onset of memory loss is gradual or sudden; if sudden, screen for delirium using the Confusion Assessment Method (CAM) (see digital resources). **EB:** *The CAM is a standardized tool that enables non–psychiatrically trained clinicians to identify and recognize delirium quickly and accurately (Inouye, 2018).*
- Assess overall cognitive function and memory. A brief screening instrument such as the short Montreal Cognitive Assessment (s-MoCA) or Revised Metamemory in Adulthood (MIA) Questionnaire (MIA-Revised) is useful as a first level of evaluation. **EB:** *The s-MoCA is valid across neurological disorders and can be administered in approximately 5 minutes to determine whether the client has cognitive impairment and needs to be referred for further evaluation and treatment (Roalf et al, 2016, 2017).* **EBN:** *The 20-item (2-factor) version of the metamemory in adulthood questionnaire has strong internal reliability and validity for change and capacity subscales (McDonough et al, 2020).*
- Assess risk of B-vitamin deficiencies, including thiamine (vitamin B_1), associated with aging, chronic alcohol abuse, cancer, or bariatric surgery, and encourage a diet plan with adequate B vitamins. **EB:** *Low B-vitamin status is associated with cognitive dysfunction during the aging process, and supplementation with folic acid (vitamin B_9) or B-complex may improve global cognition, memory, and visuospatial skills (McGrattan et al, 2018).*
- Assess risk of vitamin D deficiency associated with history of inadequate exposure to sunlight and associated with depression and impaired cognitive function in older adults. **EBN:** *Vitamin D supplementation has a role in improving cognitive performance for those who are deficient in vitamin D (Ombech, 2020).*
- Determine the client's sleep quality and patterns; if sleep quantity and quality are insufficient and client shows symptoms of daytime sleepiness, or symptoms of sleep apnea are present, report to physician/primary care provider and refer to the care plan for Disturbed **Sleep** Pattern. **EB:** *Sleep-disordered breathing is associated with an increased risk of cognitive impairment and a small worsening of executive function (Leng et al, 2017).*
- Teach clients, including those with cognitive disorders, to use memory techniques such as concentrating and attending, repeating information, making mental associations, and placing items in strategic places so that they will not be forgotten. **EBN:** *A systemic review of memory-strategy training interventions found improvements in perceived memory ability, memory self-efficacy, strategy use, memory-related affect, psychological well-being, and quality of life (Yang et al, 2018; Hudes et al, 2019).*
- Encourage the client to incorporate daily meditation such as multimodal Kirtan Kriya or other mind-body interventions to improve memory functioning and health. **EB:** *A 12-week Kirtan Kriya meditation program (30-minute training, followed by 12-minute daily practice) resulted in significant improvement in memory, psychological well-being, mood, and sleep in community-dwelling older adults with early memory loss (Innes et al, 2016).* **EB:** *The Dejian Mind-Body Intervention (DMBI) delivered once a week for 10 weeks improved memory and subjective physical and psychological health of older adults with subjective memory complaints (Chan et al, 2017a).*

▲ Where available, refer for access to computer-based cognitive training or socially assistive robots. **EB:** *Computerized cognitive training (including commercially available Cogmed and Lumosity) and socially assistive robots are effective tools for improving cognition and memory (Alnajiar et al, 2019; Pang et al, 2021).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

M

▲ Where available and of interest to client, refer for regular yoga training and practice. **EB:** *A weekly yoga education program and self-practice improved community-dwelling older adults' scores on the Mini-Mental State Examination (MMSE) and Rivermead Behavioral Memory Test–Third Edition (RBMT-3) (Pandya, 2020).* **EBN:** *Octogenarians were able to improve their memory performance when they challenged their limits, used appropriate strategies, practiced yoga, and invested energy and time in learning novel memory techniques (McDougall et al, 2015).*

▲ Where available and of interest to client, refer for participation in calligraphy classes. **EB:** *An 8-week Chinese calligraphy writing training significantly improved working memory in clients with early mild cognitive impairment (Chan et al, 2017b).*

▲ Refer the client for participation in a multicomponent cognitive rehabilitation program that includes stress and relaxation training, physical activity, structured learning, and social interaction. **EB:** *Meditation interventions, cognitive training, cognitive rehabilitation, and exercise were the most effective interventions for adult non–central nervous system cancer clients to manage cancer-related cognitive impairment (Zeng et al, 2020).* **EBN:** *Cognitive rehabilitation in the form of memory skills training, compensatory memory strategies, and use of assistive devices may be helpful for managing the memory deficits associated with stroke or brain injury (Pamaiahgari, 2020).*

● For clients with memory impairments associated with dementia, also see care plan for Chronic **Confusion.**

Geriatric

● All interventions are appropriate for geriatric clients.

● Assess for signs and symptoms of depression using an age-appropriate screening tool such as the Geriatric Depression Scale, and notify provider of results. **EBN:** *Depression is often associated with memory loss in older adults; however, cognitive behavior therapy, competitive memory training, reminiscence group therapy, problem-adaptation therapy, and problem-solving therapy are all effective interventions to reduce depressive symptoms (Apóstolo et al, 2016).*

Multicultural

● When using cognitive assessments translated into other languages, refer to translation-specific scoring instructions and any recommended adjustment for low levels of education. **EB:** *Although cognitive assessments such as the MoCA and MMSE have been translated and validated in many languages, there is wide variation in published cutoff scores, and not correcting for educational bias may result in inappropriate referral or diagnosis (Rosli et al, 2016; Delgado, Araneda, & Behrens, 2019).*

● Visitation facilitation: stigma may result in social isolation, and older adults with memory impairment may need assistance to rebuild and strengthen their social network. **EB:** *Social network quality and emotional closeness are positively associated with cognitive functioning among older Chinese adults (Li & Dong, 2018).*

Home Care

● The previously mentioned interventions may be adapted for home care use.

● Assist clients to select and use cuing strategies or assistive technology, such as a smart watch, smart phone, pill box, calendar, alarm clock, microwave oven, whistling tea kettle, sign, or written list, to cue behaviors at designated times. **EB:** *Cues and assistive technology are positively associated with individuals' abilities to perform daily tasks regardless of age or cognitive disease (Leopold et al, 2015).*

Client Family Teaching and Discharge Planning

● Evaluate the need for skilled home health care (skilled nursing, occupational therapy).

● Discuss and assist with use of assistive technology to support client and caregiver with discharge plan: memory aids (e.g., medication reminders, pill box, timers, lists); orientation aids (e.g., electronic clocks and calendars, voice assistant, built-in "Remember This" feature); safety devices (e.g., nightlights, personal alarms); communication aids (e.g., easy-to-use landline and mobile phones, speed dialing, voice-activated dialing, or photo dialing); other devices (e.g., easy-to-use TV remote controls, microwave oven, whistling tea kettle).

● Clarify instructions for medications, treatments, and exercises in writing.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Assist with developing schedule/chart and reminder system for scheduled and as-needed medications and use of nonpharmacological strategies.

Risk for Metabolic Syndrome

Domain 2 Nutrition Class 4 Metabolism

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to developing a cluster of symptoms that increase risk of cardiovascular disease and type 2 diabetes mellitus, which may compromise health.

Risk Factors

Absence of interest in improving health behaviors; average daily physical activity is less than recommended for age and gender; body mass index above normal range for age and gender; excessive accumulation of fat for age and gender; excessive alcohol intake; excessive stress; inadequate dietary habits; inadequate knowledge of modifiable factors; inattentive to second-hand smoke; smoking

At-Risk Population

Individuals aged >30 years; individuals with family history of diabetes mellitus; individuals with family history of dyslipidemia; individuals with family history of hypertension; individuals with family history of metabolic syndrome; individuals with family history of obesity; individuals with family history of unstable blood pressure

Associated Conditions

Hyperuricemia; insulin resistance; polycystic ovary syndrome

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Weight Loss Behavior; Blood Glucose Level; Circulation Status; Exercise Participation; Hypertension Severity; Knowledge: Lipid Disorder Management; Knowledge: Hypertension Management; Knowledge: Prescribed Diet; Knowledge: Prescribed Activity; Knowledge: Weight Management; Metabolic Function; Nutritional Status: Nutrient Intake; Risk Control: Obesity; Risk Control: Lipid Disorder; Risk Control: Hypertension

Example NOC Outcome with Indicators

Risk Control: Lipid Disorder as evidenced by the following indicators: Seeks current information about lipid disorders/Identifies risk factors for lipid disorders/Modifies lifestyle to reduce risk/Develops effective risk control strategies/Maintains recommended body weight. (Rate the outcome and indicators of **Risk Control: Lipid Disorder:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain blood glucose within normal limits
- Explain actions and precautions to decrease cardiovascular risk
- Maintain waist circumference of less than 102 cm (40 inches) in men, or less than 88 cm (35 inches) in women
- Explain the risk factors associated with lipid disorders
- Maintain normal laboratory results, specifically high-sensitivity C-reactive protein, triglycerides, fasting blood glucose, and high-density lipoprotein (HDL) cholesterol
- Design lifestyle modifications to meet individual long-term goal of health, using effective risk control strategies
- Maintain weight within normal range for height and age
- Develop a system of self-management for improved dietary intake and physical activity

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Cardiac Risk Management; Exercise Promotion; Health Screening; Hyperglycemia Management; Hyperlipidemia Management; Nutritional Counseling; Teaching: Disease Process

Example NIC Activities—Cardiac Risk Management

Screen client for risk behaviors associated with adverse cardiac events; Prioritize areas for risk reduction in collaboration with client and family

Nursing Interventions and *Rationales*

- Assess for risk factors associated with metabolic syndrome. Risk factors for metabolic syndrome include central obesity, dyslipidemia, insulin resistance, and increased blood pressure. **CEB:** *Metabolic syndrome is a clustering of metabolic abnormalities associated with subsequent cardiovascular disease and mortality (Grundy et al, 2005).*
- Assess clients for elevated waist circumference measures; greater than 102 cm/40 inches or more in men, or greater than 88 cm/35 inches or more in women. **EB:** *An elevated waist circumference reflects central obesity, and metabolic syndrome screening is recommended in the effort to combat cardiovascular disease and type 2 diabetes mellitus (Cheong et al, 2015).*
- Assess clients for problematic eating behaviors and relationship with food. **EB:** *Logistic regression found that endorsement of problematic eating behaviors at an average age of 35 years was associated with metabolic syndrome and diabetes (Yoon et al, 2019).*
- Assess for metabolic syndrome in adults with intellectual disabilities. **EB:** *Individuals with intellectual disability and behavior problems showed a 46% prevalence of metabolic syndrome (Room, Timmermans, & Roodbol, 2016).*
- Examine the client's skin for acanthosis nigricans, acrochordons, keratosis pilaris, hyperandrogenism, and hirsutism, which are skin diseases associated with insulin resistance and obesity. **EB:** *Early recognition of insulin resistance and obesity-associated skin diseases may facilitate an earlier metabolic syndrome diagnosis and therapy initiation (Uzuncakmak et al, 2018).*
- Assess and report abnormal laboratory results, specifically high-sensitivity C-reactive protein, triglycerides, fasting blood glucose, and HDL cholesterol. **EB:** *A recent study found that high-sensitivity C-reactive protein, triglycerides, fasting blood glucose, and HDL cholesterol were factors associated with metabolic syndrome (Tayefi et al, 2018).*
- Screen clients who are prescribed antipsychotic medications for metabolic syndrome during routine health treatment. **EBN:** *A recent study found that despite an increased awareness of comorbid physical health issues among mental health consumers, guidelines and policy directives to clinical practice to address this disparity remain low (Ward et al, 2018).*
- Screen clients with a family history of polycystic ovary syndrome for metabolic syndrome. **EB:** *A recent meta-analysis suggests that mothers, fathers, sisters, and brothers of women with polycystic ovary syndrome have an increased risk of metabolic syndrome, hypertension, and dyslipidemia when compared with parents and siblings of women without polycystic ovary syndrome (Yilmaz et al, 2018).*
- Assist obese clients to develop a system of self-management, which may include self-monitoring of weight, body mass index (BMI), realistic goal setting, planning, and action planning for improved dietary intake and physical activity; problem-solving; and tracking dietary intake and exercise. **EB:** *A key component of successful weight loss and maintenance is regular self-monitoring (Thomason et al, 2016).*
- Encourage strength training for the client to address modifiable risk factors of metabolic syndrome. **EBN:** *A 2017 study of a 12-week strength training protocol demonstrated a significant reduction in C-reactive protein level, a positive trend in other biomarkers, and increased functional outcomes of premenopausal women with moderate cardiovascular risk (Flandez et al, 2017).*
- Provide nutritional teaching targeted at reducing daily energy, fat intakes, and sugar intakes, and increasing the frequency of eating two portions of vegetables during each meal. **EB:** *A randomized controlled trial demonstrated a reduction in metabolic syndrome risk factors after the implementation of lifestyle modifications focused on dietary intake and physical activity (Watanabe et al, 2017). A study of clients with metabolic*

syndrome showed that consumption of added sugar decreased after 1 year with American Heart Association dietary counseling (Zhang et al, 2018).

- Encourage the client to engage in vigorous-intensity physical activity for at least 150 minutes weekly or moderate-intensity physical activity for at least 300 minutes weekly to improve cardiorespiratory fitness and influence body shape and weight. **EB:** *A recent study indicated that being highly fit increased the likelihood of lower metabolic risk approximately 2 and 2.5 times independently of central adiposity compared with average and low fitness, respectively (Lätt et al, 2018).*
- Counsel clients to slow the pace of their eating during meals. **EB:** *A Japanese study found that a fast eating speed was associated with obesity and future prevalence of metabolic syndrome (Yamaji et al, 2018).*
- Provide teaching about reducing intake of ultra-processed foods and increasing intake of minimally processed foods. **EB:** *A study divided foods into ultra-processed, processed, and minimally processed. Ultra-processed foods consisted mainly of fast foods, snacks, sausage, nuts, sweets, and liquor, whereas minimally processed foods consisted mostly of fruits, vegetables, legumes, breads, cheeses, and eggs. Participants in the highest quartile of the "minimally processed/processed" pattern had significantly lower odds for metabolic syndrome (Nasreddine et al, 2018).*
- Encourage once or more weekly consumption of lean fish. **EB:** *A Norwegian study found that lean fish consumption once a week or more was significantly associated with decreased future metabolic score, decreased triglycerides, and increased HDL cholesterol in both men and women. In addition, men also showed decreased waist circumference and decreased blood pressure (Tørris et al, 2017).*
- Use social media for communication with clients to implement social support and share information about lifestyle modifications. **EB:** *A study using social media to augment the delivery of, and provide support for, a weight management program delivered to overweight and obese individuals during a 24-week intervention found that the Facebook group reported a 4.8% reduction in initial weight and numerically greater improvements in BMI, waist circumference, fat mass, lean mass, and energy intake (Monica et al, 2017).*
- Refer clients with Class II and III obesity and diabetes for bariatric surgery consideration. **EB:** *A recent review found that metabolic surgery is highly effective in obtaining significant and durable weight loss, enhancing glycemic control, and achieving diabetes remission (Pareek et al, 2018).*

Pediatric

- Assess adolescent clients for vitamin D deficiency with additional screening for prediabetes if deficiencies are found. **EBN:** *A recent study found an association of vitamin D deficiency with an increased risk of elevated fasting blood glucose levels (Kim et al, 2018).*
- Assess and report uric acid levels in at-risk children. **EB**: *A systematic review and meta-analysis found a significant association between serum uric acid levels and metabolic syndrome components in at-risk children (Goli et al, 2020).*
- Provide preventive interventions for obesity during early childhood. **EBN:** *A meta-analysis found that overweight or obesity in early childhood was associated with a higher risk of adult metabolic syndrome compared with the controls (Kim et al, 2017).*

Geriatric

Note: Many of the preceding interventions also apply.

- Encourage strength training for older women. **EB:** *A recent study found that women who participated in a 12-week resistance training program showed decreased C-reactive protein concentrations, reduced blood glucose levels, decreased waist circumference, and lowered systolic blood pressure regardless of diet (Tomeleri et al, 2018).*
- Encourage Tai chi training for older adults. **EB:** *Recent research found that the practice of Tai chi exercise was associated with a statistically significant decrease in hemoglobin (Hb) A1C concentration and oxidative stress score in a group of older adults (Mendoza-Núñez et al, 2018).*

Multicultural

- Use criteria in addition to overweight and obesity when screening for cardiometabolic abnormalities in racial/ethnic minority populations. **EB:** *A cross-sectional study with participants from several U.S. racial/ethnic groups found that nearly a third of the participants with normal weight had cardiometabolic abnormalities (Gujral et al, 2017).*
- Provide African American women with community-based prevention education targeted toward improving knowledge, reducing clinical risk profiles, adoption of heart-healthy lifestyles, reducing inflammatory

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

burden, and decreasing cardiometabolic risk. **EB:** *A 4-month precardiovascular/postcardiovascular disease preventive educational intervention found that compared with baseline, there was a 60% reduction ($p < 0.05$) in the number of participants who met diagnostic criteria for metabolic syndrome (Villablanca et al, 2016).*

- Provide Hispanic clients at risk of metabolic syndrome with cultural and language appropriate teaching and cooking demonstrations. **EB:** *A cultural- and language-appropriate intervention included a Spanish-language lecture on metabolic syndrome and healthy nutrition and an interactive cooking demonstration for the participants and their significant others. Participants showed reductions in BMI, blood pressure, lipid levels, and HbA1C, and increased nutrition knowledge (Marks, 2016).*

Home Care

- Previously discussed interventions may be adapted for home care use.
- Screen clients who are cancer caregivers for signs and symptoms of metabolic syndrome. **EB:** *A prospective study of advanced cancer caregivers had higher rates of metabolic syndrome than had the general population (Steel et al, 2019).*

Client/Family Teaching and Discharge Planning

- Many of the preceding interventions involve teaching.
- Work with the family members regarding information on how to identify and reduce risk factors related to metabolic syndrome.

Impaired Bed Mobility

Domain 4 Activity/rest Class 2 Activity/exercise

Wendie A. Howland, MN, RN-BC, CRRN, CCM, CNLCP, LNCC

M

NANDA-I

Definition

Limitation in independent movement from one bed position to another.

Defining Characteristics

Difficulty moving between long sitting and supine positions; difficulty moving between prone and supine positions; difficulty moving between sitting and supine positions; difficulty reaching objects on the bed; difficulty repositing self in bed; difficulty returning to the bed; difficulty rolling on the bed; difficulty sitting on edge of bed; difficulty turning from side to side

Related Factors

Decreased flexibility; environmental constraints; impaired postural balance; inadequate angle of headboard; inadequate knowledge of mobility strategies; insufficient muscle strength; obesity; pain; physical deconditioning

At-Risk Population

Children; individuals experiencing prolonged bed rest; individuals in the early postoperative period; older adults

Associated Conditions

Artificial respiration; critical illness; dementia; drain tubes; musculoskeletal impairment; neurodegenerative disorders; neuromuscular diseases; Parkinson's disease; pharmaceutical preparations; sedation

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Immobility Consequences: Physiological; Mobility; Self-Care: Activities of Daily Living (ADLs)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NOC Outcome with Indicators

Immobility Consequences: Physiological as evidenced by the following indicators: Pressure sores/Constipation/Hypoactive bowel/Paralytic ileus/Urinary calculi/Contracted joints/Venous thrombosis/Pneumonia. (Rate the outcome and indicators of **Immobility Consequences: Physiological:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate optimal independence in positioning, exercising, and performing functional activities in bed
- Demonstrate ability to direct others on how to do bed positioning, exercising, and functional activities

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Bed Rest Care

Example NIC Activities—Best Rest Care

Position in proper body alignment; Teach bed exercises, as appropriate

Nursing Interventions and *Rationales*

▲ Normal bed mobility includes rolling, bridging, scooting, long sitting, and sitting upright. Begin with the client supine, flat in bed. Promote normal movements that are bilateral, segmental, and well-timed, with set positions using weight-bearing and trunk centering. Consult a physical therapist (PT) for individualized instructions and mobility strategies.

- Choose therapeutic beds and positions based on client's history and risk profile.
  - ❍ Advocate for specialty beds for bedbound clients incorporating low-air-loss pressure relief, shear reduction with position changes, turn assist, and moisture management.
  - ❍ Use devices such as trapeze, friction-reducing slide sheets, mechanical lateral transfer aids, or ceiling-mounted or floor lifts to move (rather than drag) clients in bed to prevent injury to caregivers.
  - ❍ Use a special bed and equipment, such as mattress overlay, sliding/roller board, trapeze, and stirrup with pulley attached to overhead traction system (holds one leg up during peri care).
- Place clients in free-standing or ceiling-mounted lifts with padded slings while changing bed linen. **EB:** *Turn-assist features in beds greatly decreased spine loading and pull forces for nurses turning and lateral repositioning in clients of both normal and obese weight, thus decreasing injury potential to staff (Wiggerman, 2016). Staff should use lifting/transfer equipment and devices, ergonomic assessments, no-lift policies, and education to decrease risk of injury (Choi & Brings, 2016; Olinsky & Norton, 2017). Only about one-third of nurses with available lifting equipment use it (Lee & Lee, 2017). A sliding sheet is preferable over a regular cotton sheet to decrease musculoskeletal load for caregivers (Weiner et al, 2017).*
- Many clients can benefit from a high sitting position to potentially minimize orthostatic intolerance (*Khan et al., 2002*).
- Assess to determine whether positioning for one condition may negatively affect another; use critical thinking skills for risk–benefit analysis. Use critical thinking to determine when specialty bed surfaces will help protect clients from tissue injury if frequent turning is contraindicated by client instability.
- Elevate head of bed (HOB) to 30 to 45 degrees unless contraindicated, and elevate HOB to 90 degrees during oral intake of fluids, solids, and oral medications. **EB:** *Elevation of HOB to at least 30 degrees is an effective, low-cost, and low-risk intervention associated with a decreased incidence of aspiration and ventilator-associated pneumonia (Agency for Healthcare Research and Quality [AHRQ], 2017).*

- Raise HOB to 30 degrees for clients with acute increased intracranial pressure and brain injury. Refer to care plan for Decreased **Intracranial** Adaptive Capacity.
- ▲ Consult health care provider for HOB elevation for acute stroke and monitor response. Refer to care plan for Decreased **Intracranial** Adaptive Capacity.
- Raise HOB as close to 45 degrees as possible for critically ill ventilated clients to prevent pneumonia (this height may place clients at higher risk for pressure ulcers). **EB:** *Elevating the HOB decreases regurgitation and risk for aspiration of gastric contents (Green et al, 2016).*
- Assist client with dysphagia to sit as upright as possible for oral intake, including solids, fluids, and oral medications. Refer to care plan for Impaired **Swallowing.**
- Periodically sit client upright as tolerated in bed; dangle client, if vital signs and oxygen saturation levels remain stable. **EB:** *Placing a client who is generally immobilized in an upright position is beneficial, using adaptive equipment if necessary (Green et al, 2016). Being vertical has many physiological and psychological benefits (Green et al, 2016).*
- To decrease risk of pressure injury, maintain HOB at lowest elevation that is medically possible and raise the foot of the bed to prevent shear-related injury. Assess the client's sacrum, ischial tuberosities, and heels at least every 2 hours. **EB:** *Shear results when external friction stretches the top layers of the skin as it slides against underlying layers and as internal tissues slide over deeper muscle and bone. These forces increase over the ischial tuberosities and sacrum when the backrest of the bed is elevated and result in tissue damage. Raising the foot of the bed in proportion to the HOB to distribute weight brings the body into maximum contact with the supporting surface, helping to eliminate shear. Placing a client who is generally immobilized in a recliner is a good alternative to the bed only if shear- and pressure-reducing bed surfaces cannot be obtained (Martin et al, 2017). Use critical thinking and consult with a nurse specialist in pressure injury harm reduction to determine when advocating for specialty bed surfaces will help protect clients from tissue injury.*
- Try periods of prone positioning for clients and monitor their tolerance/response. **EB:** *Prone positioning after both above the knee and below the knee amputations promotes extension, preventing flexor contractions (Monaro, West, & Gullick, 2017). Prone positioning improves oxygenation in respiratory failure (Lucchini et al, 2020).*
- Assess client's risk for falls using a valid fall risk assessment tool, such as the Morse Fall Scale (Morse, Tylko, & Dixon, 1987; Dykes, 2020) and implement specific measures to mitigate identified risk factors. **EB:** *Establish individualized fall prevention strategies and perform postfall assessment to further refine fall prevention interventions. Self-reported fear of falling has been shown to be a significantly more sensitive predictor for fall risk than the STRATIFY fall risk assessment tool (Strupeit, Buss, & Wolf-Ostermann, 2016).*
- Beds should be kept locked and in the lowest position when occupied.
- ▲ Although placing all four bed rails up is considered a form of restraint and requires a provider's prescription, two and even three rails up can be a support for bed mobility (Zhao et al, 2019).
- Place frequently used items within client's reach; demonstrate use of call bell (Zhao et al, 2019).
- Use a formalized screening tool to identify clients who are at high risk for deep venous thrombosis (e.g., obesity, cancer diagnosis, pelvic surgery, immobility, prior history of deep vein thrombosis). **EB:** *Best clinical practice encourages adherence to a clinical decision tool for deep venous thrombosis risk and prescribed therapy (Elder et al, 2016).*
- ▲ Assess for injury associated with thromboembolism prophylaxis and other prescribed treatment (e.g., anticoagulants, compression stockings, elastic leg wraps, sequential compression devices, feet/ankle exercises, and hydration). Refer to care plan for Ineffective Peripheral **Tissue Perfusion.**
- Use a valid and reliable tool to assess a client's risk for pressure injury. **EB:** *Routine assessment of risk factors is crucial in planning individualized interventions to diminish the risk of hospital-acquired pressure injury occurrences (Moyse et al, 2017).*
- Implement interventions to prevent pressure ulcers and complications of immobility. **EB:** *Delay in using an upgraded support surface for clients has been associated with greater numbers of pressure injuries in the critically ill (Bly et al, 2016).*
- Refer to care plan for Risk for Impaired **Skin** Integrity.
- Explain importance of avoiding breath-holding (Valsalva maneuver) and straining during bed mobility.
- Reassess pain level, especially before movement and/or exercising, and accept clients' pain ratings and levels they think are appropriate for comfort. Administer analgesics based on clients' pain rating. Refer to Acute **Pain** or Chronic **Pain.**

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Exercise

- Test strength in bilateral grips, arms at elbow flexion and extension, bilateral arm abduction and adduction, bilateral leg or thigh raise (one at a time in bed or chair), and quadriceps and hamstring strength to extend and flex at knee to assess baseline and interval strength gains.
- Perform passive range of motion (ROM) of three repetitions, at least twice a day, to immobile joints. Perform ROM slowly and rhythmically. Do not range beyond point of pain. Range only to point of resistance in those with loss of sensation and mentation. Fast, jerky ROM increases pain and tone. Slow, rhythmical movements relax/lengthen spastic muscles so they can be ranged further. For clients with neuromuscular conditions, consult with physical therapy for ROM exercises.
- Range or move a hemiplegic arm with the shoulder slightly externally rotated (hand up).

▲ Encourage client's practice of exercises taught by therapists (muscle setting, strengthening, contraction against resistance, and weight lifting). *Exercises and weight lifting help maintain muscle tone, strength, and lengthening.*

Bed Positioning

- Incorporate the following measures to promote normal tone and prevent complications in clients with neurological impairment:
  - ❍ Use a flat head pillow when clients are supine. Use a small pillow behind the head and/or between shoulder blades if neck extension occurs to prevent contractures of the cervical spine and abnormal tone of the neck.
  - ❍ Abduct the shoulders of clients with high paraplegia or quadriplegia horizontally to 90 degrees briefly two to three times a day while client is supine.
  - ❍ Position a hemiplegic shoulder fairly close to the client's body.
- Tilt hemiplegics onto both unaffected and affected sides with the affected shoulder slightly forward (e.g., move/lift the affected shoulder, not the forearm/hand).

▲ Elevate a client's paralyzed forearms on a pillow when client is supine. Elevate edematous legs on a pillow supporting the knees to prevent hyperextension. Apply resting wrist, hand, and foot/ankle splints and pressure garments or other devices as prescribed. Range joints before applying splints. Adhere to on/off schedule as prescribed by the PT. Remove splints and compression garments or devices to check underlying tissues for signs of pressure/poor circulation every 2 hours or more often if client resists or manipulates them.

Geriatric

- Assess caregiver's strength, health history, and cognitive status to predict ability/risk for assisting bedbound clients at home. Explore alternatives if risk is too high. Caregivers are often frail older adults with chronic health problems who cannot physically help loved ones. Refer to care plan for **Caregiver** Role Strain.
- Assess the client's stamina and energy level during bed activities/exercises; if limited, spread out activities and allow rest breaks.

Home Care

▲ Collaborate with nurse case managers, care coordinators, social workers, visiting nurses, and physical/occupational therapists to assess home support systems and needs and to provide for home safety and access modifications, durable medical equipment as needed for condition (e.g., bariatric), handling equipment (e.g., friction pads, slide boards, lifts) needed for safe bed mobility, exercise, toileting, and bathing, ramps, rails, assistive technology, and home health follow-up.

- Encourage use of the client's own bed unless contraindicated. Raise HOB with commercial blocks or grooved-out pieces of wood under legs; set bed against walls in a corner. Emotionally, clients may benefit from sleeping in their own beds with familiar partners.
- Stress psychological/physical benefits of clients being as self-sufficient as possible with bed mobility/care even though it may be time-consuming. Allowing independence and autonomy may help prevent disuse syndromes and feelings of helplessness and low self-esteem.
- Offer emotional support and help client identify usual coping responses to help with adjustment and loss issues. The home environment may trigger the reality of lost function and disability.
- Discuss support systems available for caregivers to help them cope. Refer to care plan for **Caregiver** Role Strain.

▲ Institute case management for frail older adults to support continued independent living as much as possible or as desired by the client.

● Refer to the home care interventions in the care plan for Impaired Physical **Mobility.**

Client/Family Teaching and Discharge Planning

● Teach client/caregivers correct ROM, exercises, positioning, self-care activities, and use of devices. Assess readiness and learning styles, which vary but may be enhanced with visual/auditory/tactile/cognitive stimuli such as the following:
  ❍ Demonstrations, sketches, online resources (e.g., YouTube), written directions/schedules, notes
  ❍ Verbal instructions, recorded audiotapes, timers, reading written directions aloud, and self-talk during activities
  ❍ Motor task practice/repetition, return demonstrations, note taking, manual guidance, or staff's-hand-on-client's-hand technique
  ❍ Referral to community group activities, support groups, parish nursing, adaptive recreation, or other out-of-the-home resources

▲ Schedule time with family/caregivers for education and practice for nursing, physical therapy, and occupational therapy. Suggest family come prepared with questions and wear comfortable, safe clothing/shoes. Practice provides opportunity for learning; repetition helps memory retention.

▲ Teach safe approaches for caregivers/home care staff and reinforce an adequate number of people to decrease risk of injury *(Olinsky & Norton, 2017)*.

Impaired Physical Mobility

Domain 4 Activity/rest Class 2 Activity/exercise

Wendie A. Howland, MN, RN-BC, CRRN, CCM, CNLCP, LNCC

NANDA-I

Definition

Limitation in independent, purposeful movement of the body or of one or more extremities.

Defining Characteristics

Altered gait; decreased fine motor skills; decreased gross motor skills; decreased range of motion; difficulty turning; engages in substitutions for movement; expresses discomfort; movement-induced tremor; postural instability; prolonged reaction time; slowed movement; spastic movement; uncoordinated movement

Related Factors

Anxiety; body mass index >75th percentile appropriate for age and gender; cultural belief regarding acceptable activity; decreased activity tolerance; decreased muscle control; decreased muscle strength; disuse; inadequate environmental support; inadequate knowledge of value of physical activity; insufficient muscle mass; insufficient physical endurance; joint stiffness; malnutrition; neurobehavioral manifestations; pain; physical deconditioning; reluctance to initiate movement; sedentary lifestyle

Associated Conditions

Altered bone structure integrity; contractures; depression; developmental disabilities; impaired metabolism; musculoskeletal impairment; neuromuscular diseases; pharmaceutical preparations; prescribed movement restrictions; sensory-perceptual impairment

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Ambulation; Ambulation: Wheelchair; Mobility; Self-Care: Activities of Daily Living (ADLs); Instrumental Activities of Daily Living (IADLs); Transfer Performance

Example NOC Outcome with Indicators

Ambulation as evidenced by the following indicators: Walks with effective gait/Walks at moderate pace/Walks up and down steps/Walks moderate distance. (Rate the outcome and indicators of **Ambulation:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Meet mutually defined goals of increased ambulation and exercise that include individual choice, preference, and enjoyment in the exercise prescription
- Describe feeling stronger and more mobile
- Describe less fear of falling and pain with physical activity
- Demonstrate use of adaptive equipment (e.g., wheelchairs, walkers, gait belts, weighted walking vests) to increase mobility
- Increase exercise to 20 minutes/day for those who were previously sedentary (less than 150 minutes/week). Note: Light to moderate intensity exercise may be beneficial in deconditioned persons. In very deconditioned individuals exercise bouts of less than 10 minutes are beneficial
- Increase pedometer step counts with a daily goal for most healthy adults of at least 4400 steps per day (Harvard Women's Health Watch, 2019)
- Perform resistance exercises that involve all major muscle groups (legs, hips, back, chest, abdomen, shoulders, and arms) performed 2 or 3 days/week

- Perform flexibility exercise (stretching) for each of the major muscle-tendon groups 2 days/week for 10 to 60 seconds to improve joint range of motion (ROM); greatest gains occur with daily exercise
- Engage in neuromotor exercise 20 to 30 minutes/day including motor skills (e.g., balance, agility, coordination, gait), proprioceptive exercise training, and multifaceted activities (e.g., Tai chi, yoga) to improve and maintain physical function and reduce falls in those at risk for falling (older persons)
- Engage in purposeful moderate-intensity cardiorespiratory (aerobic) exercise for 30 to 60 minutes/day at least 5 days/week for a total of 2 hours and 30 minutes (150 minutes) per week

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Exercise Therapy: Ambulation; Joint Mobility; Positioning

Example NIC Activities—Exercise Therapy

Assist the client to use footwear that facilitates walking and prevents injury; Instruct in use of assistive devices, if appropriate

Nursing Interventions and *Rationales*

- Adults should be as physically active as their abilities allow and avoid inactivity. Use "start low and go slow" approach for intensity and duration of physical activity if client is deconditioned, functionally limited, or has chronic conditions affecting performance of physical tasks. When progressing client's activities, use an individualized and tailored approach based on client's tolerance and preferences (US Department of Health and Human Services, 2018).
- Screen for mobility skills in the following order: (1) bed mobility; (2) dangling and supported and unsupported sitting; (3) weight-bearing for sit to stand, transfer to chair; (4) standing and walking with assistance; and (5) walking independently. **EBN:** *Use a structured tool to assess and determine the client's highest activity level and guide planning exercise progression toward independence (Jackman et al, 2016).*
- Assess muscle strength and other factors affecting balance, mobility, and endurance. Immobility can affect tissue perfusion and increase risk of postural hypotension; shortness of breath decreases endurance and increases fear; bowel or bladder incontinence can decrease motivation to be mobile; cognitive and neuromuscular deficits, including side effects of medications that affect balance, coordination, and movement; and pain, fear, or sick role because expectations can decrease willingness to be mobile. **EBN:** *Assess for mobility impairment and hazards of limited mobility, and plan care to mitigate complications (Crawford & Harris, 2016).*
- Assess for fear of falling. **EBN:** *Self-reported fear of falling has been shown to be a significantly more sensitive predictor for fall risk than the STRATIFY fall risk assessment tool (Strupeit, Buss, & Wolf-Ostermann, 2016).*

▲ Consult physical therapist (PT) for recommendations for assistive devices, such as gait belt, weighted vest, walker, cane, crutches, wheelchair, shower chairs; lifts; lateral transfer devices.

- Refer to care plans for Risk for **Falls,** Acute **Pain,** Chronic **Pain,** Ineffective **Coping,** or **Hopelessness.**
- Increase activity tolerance with graded increases in self-care (function-focused care [FFC]), such as bathing, walking to the bathroom instead of using a bedpan/urinal, and ROM. **EBN:** *A study of FFC in older adults hospitalized after trauma found greater improvement in function, less fear of falling, and better physical resilience than controls at discharge and 30 days after (Resnick et al, 2016b).*

▲ Before activity, observe for and, if possible, treat pain with massage, heat pack to affected area, or medication. **EB:** *Pain limits mobility and if exacerbated by specific movements should be temporarily avoided (American College of Sports Medicine [ACSM], 2018).*

- Monitor and record the client's response to activity, such as pulse rate, blood pressure, dyspnea, skin color, subjective report. Refer to the care plan for Decreased **Activity** Tolerance. Intolerance. **EB:** *Use valid and reliable screening procedures and tools to assess the client's preparticipation in exercise health screening and risk stratification for exercise testing (low, moderate, or high risk) (ACSM, 2018).*

Special Considerations: Immobility

- Refer to the care plan for Impaired Bed **Mobility.**
- Help the client achieve mobility and start walking as soon as possible if not contraindicated. **EB:** *Older clients who are hospitalized for medical illness often leave the hospital with increased disability in*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

activities of daily living, even when the condition that led to admission is successfully treated (Covinsky, 2017). **EB:** *Early mobilization after hip replacement surgery resulted in decreased time until readiness for discharge (Okamoto et al, 2016).*

- Initiate a "no lift" policy where appropriate assistive devices are used for manual lifting. Refer to the care plan for Impaired Bed **Mobility**.

Other Clinical Conditions

▲ Osteoarthritis or rheumatoid arthritis: Consult with a physical therapist on ways to integrate aerobic exercise, resistance exercise, and flexibility exercise (stretching) into care.

▲ Cerebrovascular accident (CVA) with hemiparesis: Consult with physical therapist on constraint-induced movement therapy, in which the functional extremity is purposely constrained and the client is forced to use the involved extremity (Wattchow, McDonnell, & Hillier, 2018) or graded motor mirror therapy (Mekonen, 2019). **EB:** *These noninvasive therapeutic approaches produced significant positive effects in improving arm function after stroke.*

- If the client does not feed or groom self, sit side by side with the client, put your hand over the client's hand, support the client's elbow with your other hand, and help the client complete these simple movements.

Geriatric

- Assess ability to move using valid and reliable criterion-referenced standards for fitness testing that can predict the level of capacity associated with maintaining physical independence into later years of life (e.g., Get Up and Go test).
- Help the mostly immobile client achieve mobility as soon as possible, depending on physical condition. **EB:** *A meta-analysis found exercise beneficial in increasing gait speed and improving balance and ADL performance (Lipardo et al, 2017). Mobilization should occur at least three times daily, mobilization should be progressive and scaled, and assessment should take place within 24 hours of admission (Liu et al, 2017).*
- Use the FFC rehabilitative philosophy of care in older adults to prevent avoidable functional decline. **EBN:** *Mood, satisfaction with staff and activities, and social support for exercise were directly associated with time spent in physical activity (Holmes, Galik, & Resnick, 2017).*
- If the client will have elective surgery that will result in immobility, initiate a rehabilitation program with warm-up, aerobic activity, strength, flexibility, neuromotor, and functional task work. **EBN:** *The risk of declines in functional status when older adults are hospitalized requires using evidence-based strategies to reduce the incidence and effect of decreased mobility, pressure ulcers, pain, dehydration, malnutrition, and sequelae of invasive treatments (Resnick et al, 2016a).*
- Use gestures and nonverbal cues when helping clients move if they are anxious or have difficulty understanding and following verbal instructions. Nonverbal gestures are part of a universal language that can be understood when the client is having difficulty with communication.
- Recognize that wheelchairs are not a good mobility device and often serve as a mobility restraint.
- Ensure that chairs fit clients. Chair seat should be 3 inches above the height of the knee. Provide a raised toilet seat if needed. Raising the height of a chair can dramatically improve the ability of many older clients to stand up. Low, deep, soft seats with armrests that are far apart reduce a person's ability to get up and down without help.
- If the client is mainly immobile, provide opportunities for socialization and sensory stimulation. Refer to the care plan for Deficient **Diversional** Activity.
- Recognize that immobility and a lack of social support and sensory input may result in confusion or depression in older adults. Refer to nursing interventions for Acute **Confusion** or **Hopelessness** as appropriate.

Home Care

- All preceding interventions should be applied and used for home care.

▲ Begin discharge planning as soon as possible with a personal health navigator (e.g., nurse care coordinator or case manager) to assess need for and arrange home support systems, assistive devices, community or home health services, and provider follow-up. **EB:** *Nurses are often the first health care providers to assess the client on admission; this creates the opportunity for early discharge planning (McNeil, 2016).*

▲ Assess home environment for factors that create barriers to physical mobility. Refer to occupational therapy for home safety evaluation and adaptive technology. **EB:** *Use the Home Safety Self-Assessment Tool to identify fall risk, prevent falls, and improve mobility and function (Horowitz, Almonte, & Vasil, 2016).*

- ▲ Refer to home health services to support the client and family through changing levels of mobility. Reinforce need to promote independence in mobility as tolerated. **EB:** *Providing unnecessary assistance with transfers, bathing, and dressing activities may promote dependence and a loss of mobility rather than optimizing a person's underlying physical capability. Such attentive care may actually prevent older adults from using their remaining abilities (Resnick et al, 2016b).*
- ▲ Refer to home physical therapy for evaluation, gait training, strengthening, and balance training. **EB:** *Physical therapists can provide direct interventions and assess need for assistive devices (e.g., cane, walker) (Miller, Sabol, & Pastva, 2017).*
- Assess skin condition at every visit. Establish a skin care program that enhances circulation and maximizes position changes. Impaired mobility decreases circulation to dependent areas. Decreased circulation and shearing place the client at risk for skin breakdown.
- Once the client is able to walk independently, suggest that the client enter an exercise program or walk with a friend. **EB:** *Nurse practitioners providing primary care should prescribe regular physical activity to minimize progressive impaired mobility (Miller, Sabol, & Pastva, 2017).*
- Provide support to the client and family/caregivers during long-term impaired mobility. Long-term impaired mobility may necessitate role changes within the family and precipitate caregiver stress. Refer to the care plan for **Caregiver** Role Strain.

Client/Family Teaching and Discharge Planning

- Consider using motivational interviewing techniques to increase a client's activity. Refer to the care plan for **Sedentary** Lifestyle or Motivational Interviewing.
- Teach the client and caregivers processes and tools used during care to use at home to assess fall risk and promote progressive mobility. Involve them in planning for these activities at home. **EBN:** *Few studies have investigated the point of view of older clients on prevention of this decline. This study shows that participants are sensitive to the risk of functional decline but have internal and external barriers to implementing preventive strategies to maintain physical abilities and good spirits, keep a clear mind, and foster nutrition and sleep. Older hospitalized clients would benefit from more helpful nursing strategies (Lafrenière et al, 2017).*

Impaired Wheelchair Mobility

Domain 4 Activity/rest Class 2 Activity/exercise

Wendie A. Howland, MN, RN-BC, CRRN, CCM, CNLCP, LNCC

NANDA-I

Definition

Limitation of independent operation of wheelchair within environment.

Defining Characteristics

Difficulty bending forward to pick up object from the floor; difficulty folding or unfolding wheelchair; difficulty leaning forward to reach for something above head; difficulty locking brakes on manual wheelchair; difficulty maneuvering wheelchair sideways; difficulty moving wheelchair out of an elevator; difficulty navigating through hinged door; difficulty operating battery charger of power wheelchair; difficulty operating power wheelchair on a decline; difficulty operating power wheelchair on an incline; difficulty operating power wheelchair on curbs; difficulty operating power wheelchair on even surface; difficulty operating power wheelchair on uneven surface; difficulty operating wheelchair backwards; difficulty operating wheelchair forward; difficulty operating wheelchair in corners; difficulty operating wheelchair motors; difficulty operating wheelchair on a decline; difficulty operating wheelchair on an incline; difficulty operating wheelchair on curbs; difficulty operating wheelchair on even surface; difficulty operating wheelchair on stairs; difficulty operating wheelchair on uneven surface; difficulty operating wheelchair while carrying an object; difficulty performing pressure relief; difficulty performing stationary wheelie position; difficulty putting feet on the footplates of the wheelchair; difficulty rolling across side-slope while in wheelchair; difficulty selecting drive mode on power wheelchair; difficulty selecting speed on power wheelchair; difficulty shifting weight; difficulty sitting on wheelchair without losing balance; difficulty stopping wheelchair before bumping something; difficulty transferring from wheelchair; difficulty transferring to wheelchair; difficulty turning in place while on wheelie position

Related Factors

Altered mood; environmental constraints; inadequate adjustment to wheelchair size; inadequate knowledge of wheelchair use; insufficient muscle strength; insufficient physical endurance; neurobehavioral manifestations; obesity; pain; physical deconditioning; substance misuse; unaddressed inadequate vision

At-Risk Population

Individuals using wheelchair for short time; individuals with history of fall from wheelchair; older adults

Associated Conditions

Musculoskeletal impairment; neuromuscular diseases; vision disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Ambulation: Wheelchair

Example NOC Outcome with Indicators

Ambulation: Wheelchair as evidenced by the following indicators: Propels wheelchair safely/Transfers to and from wheelchair/Maneuvers curbs, doorways, ramps. (Rate the outcome and indicators of **Ambulation: Wheelchair:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate independence in operating and moving a wheelchair or other wheeled device
- Demonstrate ability to direct others in operating and moving a wheelchair or other device

- Demonstrate therapeutic positioning, pressure relief, and safety principles while operating and moving a wheelchair or other wheeled device

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Exercise Therapy: Muscle Control; Positioning: Wheelchair

Example NIC Activities—Positioning

Wheelchair
Collaborate with occupational therapist [OT]/physical therapist [PT] to select the appropriate wheelchair for the client: standard adult, semi-reclining/fully reclining/tilt-in-space, amputees; Monitor client's ability to maintain correct positioning in wheelchair

Nursing Interventions and *Rationales*

- Assess the client's coccyx and encourage frequent repositioning. **EB:** *Deep tissue pressure injury (DTPI) begins in muscles closest to bone and may not be visible early on. They are most common over coccyx, sacrum, buttocks, and heels (Preston et al, 2017).*
- ▲ Refer to physical and occupational therapy or wheelchair seating clinic. **EB:** *Seating for wheelchair-dependent clients should be assessed by health care specialists, not vendors, in conjunction with client/caregiver education on weight-shift maneuvers (Howland & McMahon, 2015). There are many pressure-relieving cushions. Several commonly used are the ROHO cushion, Varilite Evolution, and Invacare Matrix cushions.* Refer to care plan for Risk for Adult **Pressure Injury**; Risk for Child **Pressure Injury.**
- ▲ Support surfaces on chairs and beds should redistribute pressure and be used for at-risk clients as an adjunct to reduce risk of pressure injury. **EB:** *Current clinical practices for pressure injury prevention include the use of pressure distribution systems; frequent monitoring of skin integrity, moisture, and temperature; use of low-friction textiles and dressings; and continuous repositioning of clients (Kottner et al, 2019).*
- Tilt-in-space chairs are effective at off-loading pressure areas. **EB:** *Cell deformation from shear is more important that tissue ischemia in the development of tissue necrosis and pressure injury. Frequent small adjustments in tilt-in-space and recline angle might be important for preventing cell deformation and any associated cell necrosis. Larger angles of tilt-in-space and recline seem to support blood flow returning to the tissues, which is likely to play a positive role in healing damaged tissue (Zemp et al, 2019).*
- Intervene to maintain continence or use air-permeable absorbent underpads or diapers to help prevent skin breakdown caused by excessive moisture and macerated skin. Some wheelchair cushions have moisture-wicking characteristics.
- Assess client's sitting posture frequently and reposition for alignment. Document specific measures to allow for reproducibility. **EB:** *Pressure mapping alone insufficiently describes tissue health (National Pressure Ulcer Advisory Panel, 2016; Slayton et al, 2017).*
- Implement use of friction-coated projection hand rims and leather gloves for clients to propel manual wheelchairs. Friction-coated projection rims are less invasive and slippery than aluminum rims; gloves absorb forces of propulsion and help prevent nerve damage/carpal tunnel injury.
- Manually guide or explain to the client to push forward on both wheel rims to move ahead, push the right rim to turn left and vice versa, and pull backward on both wheel rims to back up.
- Recommend that clients back wheelchair into an elevator. If entering face first, instruct them to turn chairs around to face the elevator doors and controls.
- ▲ In conjunction with physical therapy for teaching and assessment, reinforce principle of descending a curb backward ("popping a wheelie") if balance, trunk control, strength, and timing are adequate. Backward descent carries less risk of clients losing control and falling forward out of the wheelchair.
- Ascend curbs in a forward position by popping a wheelie or having someone aid in tilting the chair back, place front wheels over curb, and roll chair up. If surface is muddy or sandy, ascend backward. Front casters will not roll on soft surfaces; a backward approach requires less energy and prevents getting stuck or falling forward.
- During assisted wheelies, helper must hold wheelchair until all four wheels are back on the ground and client has control of wheelchair. Releasing one's grip too soon may alter client's balance and cause injury.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ Follow therapist's recommendations for how clients should propel manual wheelchairs to prevent upper extremity pain and joint degeneration.

- Recognize that ultra-lightweight, push rim–activated, power-assisted, or powered wheelchairs may be indicated. Striking the balance between optimum independence and preventing injury (e.g., rotator cuff injury from years of manual propulsion) is a consideration. Consider push rim–activated power-assisted wheelchairs (manual wheelchairs with a motor linked to the push rim in each rear hub) because they reduce energy needed for propulsion and reserve energy for uneven terrain or obstacle negotiation. Recommend antirollback devices for inclined planes to decrease stress on shoulders. **EB:** *Manual wheelchair users rely on their upper limbs to provide independent mobility, which leads to high muscular demand on their upper extremities and often results in shoulder pain and injury (Walford et al, 2019). If the client does not have sufficient strength or motor control of the extremities to propel a standard wheelchair, the client should be evaluated for a power chair.*

▲ Reduce floor clutter and establish safety rules for drivers of electric/power mobility devices; make referrals to physical or occupational therapy for driver reevaluations if accidents occur or client's health deteriorates.

- Request and receive client's permission before moving an unoccupied wheelchair. Wheelchair-dependent clients may view the chair as part of their identity and independence.
- Reinforce compensatory strategies for unilateral neglect and agnosia (e.g., visual scanning, self-talk, self-questioning as to what could be wrong) as clients propel wheelchair through doorways and around obstacles. Too often nurses physically move the wheelchair or obstacle instead of cueing the client to detect and solve problems. Refer to care plan for **Unilateral Neglect.**
- Offer support to help clients cope with issues related to physical disability. Depression and anxiety may occur with physical loss. Refer to care plan for Ineffective **Role** Performance.
- Provide information on support group and reliable Internet resource options.
- Provide information about advocacy, accessibility, assistive technology, and issues under the Americans with Disabilities Act as Amended (2008) (U.S. Department of Justice, Civil Rights Division, 2020).

▲ Make social service or wheelchair clinic referral to educate clients on financial coverage/regulations of third-party payers and Health Care Financing Association for wheelchairs. It is wise to recognize cost, advantages, and durability of different wheelchair models before purchasing one.

- Recommend that clients test-drive wheelchairs and try out cushions/postural supports with the advice of a qualified seating professional, not a vendor, before purchasing. If a specialty chair is indicated, for example, for sports or outdoor use, having clients test-drive the wheelchair is especially important. Equipment is expensive, and different models have different advantages and disadvantages.
- Optimize nutrition and hydration for skin and tissue health.

Pediatric

- Consult physical or occupational therapist for special considerations for wheelchair fitting and positioning for pediatric client **EB:** *In children with cerebral palsy, poor trunk control can lead to spinal deformity and pulmonary compromise. Evidence links posture and pulmonary function; special techniques for measuring these may be necessary (Barks & Shaw, 2011).*
- Help client/family transition from a manual to a powered wheelchair/scooter if disability is severe. **EB:** *Wheelchairs are essential for maximizing mobility and function. Power wheelchairs can enhance independence for children who are able to use them with hand, head, or mouth mechanisms but may prompt grief in parents when introduced (Paguinto et al, 2020).*

Geriatric

- Avoid using restraints on fidgeting clients who slide down in a wheelchair. Instead, assess for deformities; spinal curvatures; abnormal tone; limited joint range; discomfort from clothing, pressure, or constriction areas; social isolation; and toileting needs.
- Ensure proper seat depth/leg positioning and use custom footrests (not elevated leg rests) to prevent older adults from sliding down in wheelchairs.

▲ Assess for side effects of medications and potential need for dosage readjustments to increase wheelchair tolerance. Give prescribed hydration and medications to treat orthostatic hypotension. Consider leg wraps. Assist client to perform warm-up bed exercises if possible. Cerebral hypoperfusion and prolonged bed rest are common causes of orthostatic intolerance and hypotension. Refer to the care plan for Impaired Bed **Mobility**.

- Allow client to control speed to propel wheelchair independently if possible. Older adults may move slowly because of diminished range of motion/strength, stiff/sore joints, and cardiopulmonary compromise. Observe carefully for fatigue, shoulder pain, or other signs of activity intolerance.
- Assess the client's ability to safely maneuver independently using a wheelchair. **EB:** *Use an evidence-based tool to assess the client's skill and physical ability to safely use a wheelchair (AHRQ, 2017).*

Home Care

▲ Establish a support system for emergency and contingency care (e.g., remote monitoring, emergency call system, alert local emergency medical system, smart speaker). Wheelchair dependence may be life-threatening during a crisis (e.g., fall, fire, or other environmental emergency).

- Recommend the following changes to the home to accommodate the use of a wheelchair: *Refer to the Easter Seals Summary on Home Accessibility* (see http://www.easterseals.com/shared-components/document-library/easy_access_housing.pdf).
  - ❍ Arrange traffic patterns so they are wide enough to maneuver a wheelchair.
  - ❍ Recognize that a 5-foot turning space is necessary to maneuver wheelchairs, doorways need to have 32 to 36 inches clear width, and entrance ramps/path slope should be assessed before permanent ramps are installed because standardized slopes may not be appropriate. Temporary ramps are cost-effective and easier to adjust.
  - ❍ Replace door hardware with fold-back hinges, remove doorway encasements (if too narrow), remove/replace thresholds (if too high), hang wall-mounted sinks/handrails, grade floors in showers for roll-in chairs, and use nonskid/nonslip floor coverings (e.g., nonwaxed wood, linoleum, or Berber carpet).
  - ❍ Rearrange room functions, furniture, and storage so that toileting, sleeping, bathing, and preparing/eating meals can safely take place on one level of the home.

▲ Request physical and occupational therapy referrals to evaluate wheelchair fitting, skills, safety, and maintenance. Suggest community resources for servicing and tuning up wheelchairs and/or locating parts so clients can service their own chairs; an annual tune-up is recommended.

Client/Family Teaching and Discharge Planning

▲ Assess pain levels of long-term wheelchair users and make referrals to therapists or wheelchair clinics for modifications as needed. Have client check warranty information for servicing options.

- Instruct and have client return demonstrate reinflation of pneumatic tires; encourage client to monitor tire pressure every 2 to 3 weeks.
- Instruct family/clients to remove large wheelchair parts (leg rests, armrests) when lifting wheelchair into car for transport; when reassembling, check that all parts are fastened securely and temperature is tepid. This reduces weight that needs to be lifted; locked parts and a safe temperature prevent injury/thermal injury.
- Teach the critical importance of using seatbelts and secure chair tie-downs when riding in motor vehicles in a wheelchair. Never transport a client in an unsecured wheelchair in any kind of vehicle or allow this to occur with any method of transport. Teach users and family to check safe tie-downs in any transport vehicle.
- For further information, refer to care plan for Impaired **Transfer** Ability.

Impaired Mood Regulation

Domain 9 Coping/stress tolerance Class 2 Coping response

Friso Raemaekers, B Health, RN, CEN and Helen I. de Graaf-Waar, MSc, RN

NANDA-I

Definition

A mental state characterized by shifts in mood or affect and which is comprised of a constellation of affective, cognitive, somatic, and/or physiologic manifestations varying from mild to severe.

Defining Characteristics

Altered verbal behavior; appetite change; disinhibition; dysphoria; excessive guilt; excessive self-awareness; flight of thoughts; hopelessness; impaired attention; irritable mood; psychomotor agitation; psychomotor retardation; sad affect; self-blame; social alienation

Related Factors

Altered sleep-wake cycle; anxiety; difficulty functioning socially; external factors influencing self-concept; hypervigilance; loneliness; pain; recurrent thoughts of death; recurrent thoughts of suicide; social isolation; substance misuse; weight change

Associated Conditions

Chronic disease; functional impairment; psychosis

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Agitation Level; Hope; Symptom Control; Mood Equilibrium; Comfort Status: Psychospiritual; Concentration; Symptom Severity; Self-Esteem

Example NOC Outcome with Indicators

Mood Equilibrium as evidenced by the following indicators: Exhibits affect that fits situation/Exhibits impulse control/Shows interest in surroundings. (Rate the outcome and indicators of **Mood Equilibrium:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State feelings related to changes in mood
- Follow exercise plan
- Have no attempts at self-harm
- Attention during activities
- Have a regular sleep-wake cycle
- Have sense of self-efficacy
- Achieve a mindfulness-based awareness

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Activity Therapy; Aromatherapy; Art Therapy; Cognitive Restructuring; Emotional Support; Environmental Management; Forgiveness Facilitation; Hope Inspiration; Milieu Therapy; Presence; Mood Management; Suicide Prevention; Exercise Promotion; Health Education

Nursing Interventions and *Rationales*

- Monitor the client's mood with a rating scale. **EB:** *Daily recording of mood symptoms such as through a mood diary or a self-rating scale can help identify early warning signs of relapse, as well as outline relationships between mood and treatment or lifestyle factors such as diet, exercise, or stress (Yatham et al, 2018).*
- Enable the client to express his or her feelings and try to support the client emotionally if necessary. **EBN:** *A nurse-led psychological intervention program designed to provide emotional support found significantly lower mood disturbance, anxiety, and depression in the intervention group (Kim et al, 2018).*
- Promote the self-efficacy of the client. **EB:** *A study of clients discharged from cardiac rehabilitation found self-efficacy was negatively correlated with anxiety (r = −0.4009) and depression (Madueño Caro et al, 2017).*
- Instill hopefulness in client about regaining his or her health. **EBN:** *A qualitative study of clients waiting for day surgery found that regardless of mood, feeling hope about regaining health may help clients to balance their mood (Svensson, Nilsson, & Svantesson, 2016).*
- Encourage physical activities. **EBN:** *Findings from the meta-analysis suggest that physical activity interventions can improve adolescents' mental health, but additional studies are needed to confirm the effects of physical activity on children's mental health. Findings from observational studies suggest that promoting physical activity and decreasing sedentary behavior might protect mental health in children and adolescents (Rodriguez-Ayllon et al, 2019).*
- Encourage regular physical exercise to increase physical mobility and independence in daily activities. **EB:** *Kobylańska et al (2018) found that improvement in mobility and independence in daily activities positively correlated with mood improvement in the rehabilitation process after stroke.*
- Inform clients about the negative effects associated with excessive mobile phone and social media use. **EB:** *A large-scale cross-sectional study of Korean adolescents found that smartphone usage time was positively associated with depressive symptoms, suicidal thoughts, and suicide attempts (Kim et al, 2020).* **EB:** *A review of observational studies about the links between mobile phone use and mental health found associations between depressive symptoms and sleep problems (Thomée, 2018).*
- Avoid circadian rhythm disturbances. **EB:** *Molecular mechanisms linking the circadian clock with neurological functions have been uncovered, suggesting that disruption of the clock may be critically involved in the development of mood disorders (Albrecht, 2017).*
- Encourage the client to practice dance therapy. **EBN:** *Dance therapy is beneficial in improving executive function, including mood, for adults with Parkinson's disease (Zhang et al, 2019).*
- Encourage the client to listen to music when in a negative mood. **EB:** *Findings of a meta-analysis indicate that music therapy provides short-term beneficial effects for people with depression (Aalbers et al, 2017).*
- ▲ Refer to aromatherapy massage. **EBN:** *Participants in an aromatherapy massage intervention reported multiple positive effects including improvement of mood (Ho et al, 2017).*
- ▲ Refer to cognitive behavior therapy. **EBN:** *A nurse-delivered, cognitive behavioral therapy intervention for adherence and depression among antiretroviral therapy users with depression in South Africa found improvements in mood and adherence (Andersen et al, 2018).*

Moral Distress

Domain 10 Life principles Class 3 Value/belief/action congruence

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CNEcl, CHSE, ANEF, FAAN

NANDA-I

Definition

Response to the inability to carry out one's chosen ethical or moral decision and/or action.

Defining Characteristics

Reports anguish about acting on one's moral choice

Related Factors

Conflict among decision-makers; difficulty making end-of-life decisions; difficulty making treatment decision; information available for decision making conflicts; time constraint for decision-making; values incongruent with cultural norms

At-Risk Population

Individuals experiencing loss of personal autonomy; individuals physically distant of decision-maker

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Autonomy; Client Satisfaction; Protection of Rights

Example NOC Outcomes with Indicators

Client Satisfaction: Protection of Rights as evidenced by the following indicators: Requests respected/Included in decisions about care/Care consistent with religious and spiritual needs. (Rate the outcome and indicators of **Client Satisfaction: Protection of Rights:** 1 = not at all satisfied, 2 = somewhat satisfied, 3 = moderately satisfied, 4 = very satisfied, 5 = completely satisfied [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Be able to act in accordance with values, goals, and beliefs
- Regain confidence in the ability to make decisions and/or act in accord with values, goals, and beliefs
- Express satisfaction with the ability to make decisions consistent with values, goals, and beliefs
- Have choices respected

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Patient Rights Protection; Emotional Support

Example NIC Activities—Patient Rights Protection

Provide environment conducive for private conversations between client, family, and health care professionals

Nursing Interventions and *Rationales*

- Assess if moral distress is present and its relationship to intrinsic or extrinsic factors. **EBN:** *Meghani and Lalani (2020) completed a literature review about front-line nurses working during the COVID-19 pandemic and found that they experienced fear, anxiety, depression, posttraumatic symptoms, spiritual distress, and moral distress related to extrinsic factors such as lack of staff, lack of personal protective equipment, limited knowledge regarding standard infection control practices, isolation protocols, lack of administrative support, transportation, accommodation, and child care facility.*
- Affirm the distress, commitment "to take care of yourself," and your obligations. Validate feelings and perceptions with others. **EB:** *Hjelle et al (2017) qualitatively studied reablement (a home-based, intensive, goal-oriented rehabilitation intervention for older adults) using semistructured interviews with eight clients, and four main themes emerged: "My willpower is needed," "Being with my stuff and my people," "The home-trainers are essential," and "Training is physical exercises, not everyday activities." **EBN:** McAdam and Erikson (2020) found that critical care nurses who provide end-of-life care are at high risk for frequent moral distress, compassion fatigue, and burnout. Using a case study approach, the researchers incorporated self-care into what critical care nurses normally do on the job to assist in maintaining health and well-being.*
- Implement strategies to change situations causing moral distress. **EBN:** *Karagozoglu et al (2017) studied the use of a moral distress tool in another country to evaluate the moral distress of nurses (n = 200) in an intensive care unit (ICU) by descriptive and cross-sectional design. The results concluded that the tool was reliable and valid, and the study identified communication as key to decreasing moral distress. **EB:** Halper et al (2020) surveyed pediatric medical residents who were experiencing moral distress during half-day pediatric intensive care (PICU) rotations. Handing off PICU client care was producing moral distress, which was alleviated by keeping the same provider on the PICU for a full day.*
- Assess sources and severity of distress. **EBN:** *Young, Froggatt, and Brearley (2017) studied moral distress in nursing home clinicians (n = 16) with clients who are near the end of life using an interpretive descriptive design and found participants described holding "good dying" values that influenced their practice, including advocating, caring, communicating, and relating with residents, and were found to influence interactions with residents, relatives, general practitioners, and colleagues. Moral distress was described when the right thing could not be done and a "bad death" incurred because of a feeling of powerlessness. **EB:** Ross and Clayton (2019) and the research team on the BabySeq genetic identification project experienced moral distress when an adult-onset condition was identified. The team changed the study protocol due to knowing information that was not requested, but important enough that they felt obligated to disclose.*
- Give voice/recognition to moral distress and express concerns about constraints to supportive individuals. **EBN:** *Researchers explored moral distress in Chief Nursing Officers (CNOs) (n = 20) using interviews and found six themes: lacking psychological safety, feeling a sense of powerlessness, seeking to maintain moral compass, drawing strength from networking, moral residue, and living with the consequences. This research demonstrated that CNOs experience moral distress but are pressed to show moral courage (Prestia, Sherman, & Demezier, 2017). **EB:** Griffin et al (2020) completed an exploratory study about the experience of moral distress among veteran students (n = 498) and the associated psychological, social, and religious or spiritual consequences. Themes identified by the participants (1) troubled by what they witnessed, (2) troubled by what they did, (3) troubled by what they failed to do, (4) betrayed by military leaders, or (5) betrayed by fellow service members. The study suggests that understanding the events that led up to moral distress can help health care providers and educators develop individual plans of study and appropriate referrals.*
- Engage in healthy problem-solving. **EBN:** *Authors studied strategies to decrease nurses' moral distress and provide better client care and strategies including legitimizing the experience, mentoring and empowering one*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

another, allocating a safe haven, and improving the ethical climate of organizations (Forozeiya et al, 2017). **EBN:** *Lachance (2017) completed a review of moral courage and how it emerges to offset moral distress and found that it encompasses building safe, collaborative client- and family-centered teams.*

- Engage in multiprofessional problem-solving forums, including family meeting and/or multiprofessional rounds. **EB:** Helmers et al (2020) *explored the experience of health care providers in a PICU related to moral distress to identify attributes of moral resilience. Participants relayed that moral resilience can be assisted by strategies for positive adaptation including active, reflective, and structured supports.*
- Identify/use a support system. **EBN:** *Ramdinmawii (2017) completed a descriptive study to understand the level of stress, social support, and life satisfaction among parents* (n = *60) who have a child with autism spectrum disorder (ASD). Results showed that parents have moderate stress, moderate social support, and a neutral life satisfaction, and social support is correlated inversely to stress and positively with life satisfaction.* **EB:** *Barimani et al (2017) qualitatively studied the transition to parenthood. The elements that helped the transition to parenthood included perceiving parenthood as normal, enjoying the child's growth, being prepared, having knowledge, and having social support.*
- Initiate an ethics consultation or ethics committee review. **EBN:** *Ohnishi et al (2020) studied nurses' moral distress in Japan and provided an online mental health consultant. Nurses who used the mental health consultant online provided the researchers with positive feedback and assisted in improving client care, managing nurses' moral distress, and building ethics into decision-making.*

Pediatric

- Consider the developmental age of children when evaluating decisions and conflict. **EB:** *Malas et al (2017) studied somatic symptom disorder (SSD) in children who present disproportionate or inconsistent physical manifestations with history, physical examination, laboratory, and other assessment findings and made recommendations on how to evaluate and assist parents and children who exhibit manifestations and their underlying cause.* **EBN:** *Mooney-Doyle and Ulrich (2020) completed a dimensional analysis to describe family moral distress in serious pediatric conditions. Three themes emerged from the literature surrounding parent moral distress: an intrapersonal dimension, an interpersonal dimension, and a spiritual/existential dimension. Therefore moral distress is present for families facing severe pediatric illnesses and needs to be assessed and addressed by nurses.*

Multicultural

- Acknowledge and understand cultural differences that may influence a client's moral choices. **EBN:** *Bressler, Hanna, and Smith (2017) qualitatively studied moral distress in a nursing care unit with elderly Orthodox Jewish clients at the end of life to better understand the cultural complexity and differences in expectations for client care between nurses and families. Interviews revealed the incongruence of perspectives indicating there is needed educational strategies, clinical interventions, and research to address moral distress and cultural complexity.* **EB:** *Welles and Cervantes* (2019) *studied care providers of undocumented immigrants who have end-stage renal disease and receive emergency-only hemodialysis. The treatment is not optimal and therefore produces moral distress and negatively affects the clients' quality of life.*

Geriatric and Home Care

- Previous interventions may be adapted for geriatric or home care use.
- Assess for the effect of functional independence. **EB:** *Harigane et al (2017) explored the relationship between psychological distress and degree of functional independence among elderly adults* (n = *20,282) and found that psychological distress was significantly associated with decreased independence in all activities of daily living.*
- Refer to a palliative care team as needed. **EBN:** *Koch and Grier (2020) used a case study method to identify moral distress in a situation of community palliative care involving a pregnant mother who was carrying a fetus with a life-threatening genetic disease. The palliative care team used five assumptions to decrease moral distress: (1) identification of biases, (2) utilization of a culturally safe approach, (3) effective communication, (4) assessment and support, and (5) knowledge of community resources.*

Risk for Dry Mouth

Domain 11 Safety/protection Class 2 Physical injury

Katherine Foss, MSN, RN

NANDA-I

Definition

Susceptible to discomfort or damage to the oral mucosa due to reduced quantity or quality of saliva to moisten the mucosa, which may compromise health.

Risk Factors

Dehydration; depressive symptoms; excessive stress; excitement; smoking

At-Risk Population

Pregnant women

Associated Conditions

Chemotherapy; depression; fluid restriction; inability to feed orally; oxygen therapy; pharmaceutical preparations; radiotherapy to the head and neck; systemic diseases

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Oral Health; Self-Care: Oral Hygiene; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Oral Health as evidenced by the following indicators: Cleanliness of mouth and teeth/Moisture of oral mucosa and tongue/Color of mucous membranes/Oral mucosa/Tongue/Gum integrity. (Rate the outcome and indicators of **Oral Health:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain intact, moist oral mucous membranes that are free of ulceration, inflammation, infection, and debris
- Demonstrate measures to maintain or regain oral health
- Demonstrate oral hygiene knowledge and skills to maintain moisture within the mouth
- Be free of halitosis and oral discomfort
- State tolerable to no changes in taste sensation (dysgeusia)

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Oral Health Restoration

Example NIC Activities—Oral Health Restoration

Monitor condition of client's mouth including character of abnormalities; Instruct client to perform regular oral hygiene measures

M

Nursing Interventions and *Rationales*

- Perform a comprehensive extraoral and intraoral examination for associated conditions and risk factors that reduce quantity or quality of saliva and client complaints of oral dryness and difficulty speaking, eating, or swallowing. **EB:** *Inspection is a critical assessment and diagnostic tool that can lead to identification of current oral health and impending problems (van der Waal, 2015).*
- Assess for symptoms of dry mouth. **EB:** *Observe for atrophic and erythematous oral mucosa, loss of papillae on the tongue, and lips that peel and crack. Traumatic lesions may be visible on the buccal mucosa and the lateral borders of the tongue (Plemons, Al-Hashimi, & Marek, 2014).*
- Inspecting and palpating major salivary glands and lymph nodes for masses, enlargement, tenderness, purulent discharge, or absence of salivary pooling/secretions are components of a comprehensive head and neck examination to differentiate between salivary and nonsalivary causes of dry mouth (Plemons, Al-Hashimi, & Marek, 2014).
- Inspect nasal turbinates for enlargement, swelling, polyps, and nasal flow because nasal blockages increase mouth breathing, which may exacerbate oral dryness symptoms.
- Assess client for oral candidiasis, dental caries, and gingival recession (Plemons, Al-Hashimi, & Marek, 2014). Oral candidiasis may suggest the client is immunocompromised or on a treatment that increases the risk of fungal infection, which can lead to additional health care concerns.
- Assess client for dental caries and gingival recession **EB:** *Clinical signs of hyposalivation also include increased incidence of tooth decay at the gingival margin and nonspecific gingival inflammation (Plemons, Al-Hashimi, & Marek, 2014).*
- Assess client for difficulty chewing, swallowing (dysphagia), or speaking. **EB:** *Dry mouth may cause difficulties with chewing and swallowing, which may place the client at risk of choking and/or malnutrition (Plemons, Al-Hashimi, & Marek, 2014; American Academy of Oral Medicine [AAOM], 2016).*

- Assess client for mouth breathing caused by functional impairment of the upper airway and/or presence of nasal, endotracheal, or orogastric tubes that may prevent mouth closure or irritate oral mucosa, which may contribute to an increase in dry mouth symptoms experienced by clients.
- Assess client hydration status. A dry tongue and mucous membranes are symptoms of decreased hydration status. Decreased hydration status can worsen symptoms of dry mouth.
- Assess fluid status because dehydration will also affect salivary flow *(Plemons, Al-Hashimi, & Marek, 2014)*. Consider fluid loss associated with fever, cachexia, vomiting, or diarrhea. Recognize that dehydration is prevalent in older adults and may affect salivary flow (Plemons, Al-Hashimi, & Marek, 2014).

▲ Dry mouth, mouth dryness, or oral dryness (xerostomia) is a dryness of the oral cavity resulting from insufficient or complete lack of saliva secretion. Although dry mouth is a common symptom of salivary gland hyposecretion, there is a distinction between dryness caused by malfunction of the salivary glands and the client's subjective report of oral dryness despite normal salivary gland function (Tanasiewicz, Hildebrandt, & Obersztyn, 2016). **EB:** *In a review summary of 90 articles, clinical application to the etiology, diagnosis, and treatment of dry mouth requires an interdisciplinary approach to symptom assessment, clinical examination, functional and cognitive assessment, and identifying goals of care. The management of dry mouth begins with a thorough history of symptoms; review of medical, dental, and medication use history; clinical examination; salivary flow rate measurements; salivary imaging studies; and biopsies and laboratory analysis (Han, Suarez-Durall, & Mulligan, 2015).*

▲ The client may require a dental referral to evaluate salivary flow rate as a tool to monitor dry mouth symptoms (Plemons, Al-Hashimi, & Marek, 2014).

▲ Consider use of oral screening, client self-report tool, and/or subjective questioning regarding dry mouth symptoms to assess client oral health and to predict need for dental intervention and degree of salivary hypofunction. **CEB:** *One validated screening tool, for use by nondental professionals, to assess client oral health and identification of need for a dental examination is the Oral Health Assessment Tool (OHAT) and can be used to monitor client progress during an oral hygiene plan of care (State of Victoria, Health and Human Services, 2018).* **EB:** *A study comparing oral health assessments by nurses with oral health interventionists found that with proper training nurses using the OHAT implemented interventions that improved oral care of hospitalized older adults* ($p < 0.001$) *(Gibney et al, 2019).*

▲ Use client self-report to measure symptoms of dry mouth. **EB:** *The Xerostomia Inventory (XI) questionnaire, developed in Australia during the 1990s and validated in international studies, provided a summative rating of client's xerostomia symptoms (Thomson, 2015).* **EB:** *A Cochrane review found that a change in XI score of 6 or more points is likely to be meaningful, and the tools measure the severity of dry mouth and act as a responsive measure to interventions for dry mouth (Furness et al, 2013).*

- Ask the client about symptoms of hyposalivation. **CEB/EB:** *A study of subjective oral dryness compared with salivary flow reports that certain complaints were highly predictive of impaired salivary flow. Positive responses to any of the following complaints are associated with significant hyposalivation: oral dryness when eating, need to sip fluids to swallow dry foods, difficulty swallowing, and the perception of too little saliva (Fox, Busch, & Baum, 1987).* **EB:** *Ask the client to describe symptoms, triggers, and treatments that exacerbate or help oral discomfort associated with hyposalivation (Epstein & Beier Jensen, 2015).*

▲ Review client medication usage for dry mouth as a side effect of medication. If symptoms are present consult with provider, or refer client to see a dentist or specialist. **EB:** *Assess the client's use of xerostomic medications or medications that are known to directly inhibit saliva flow (Plemons, Al-Hashimi, & Marek, 2014). Anticholinergic and antihypertensive drugs (angiotensin-converting enzyme inhibitors, angiotensin receptor blockers, α- and β-adrenergic blockers, and diuretics), antihistamines, opioids, antidepressants, immunostimulants, and antipsychotic and skeletal muscle relaxant drugs are identified as common causes of dry mouth.* **EBN:** *Consult with a pharmacist regarding timing of medications and possible drug substitutions. Most medications do not cause damage to salivary glands but can reduce salivary flow (Plemons, Al-Hashimi, & Marek, 2014; Tanasiewicz, Hildebrandt, & Obersztyn, 2016).*

▲ Administer pilocarpine and cevimeline as prescribed because these medications are considered first-line therapy in Sjögren's syndrome and head and neck cancer clients with radiotherapy-induced dry mouth and hyposalivation. **EB:** *A systematic review and meta-analysis of 1732 clients in 20 studies indicated that both cevimeline and pilocarpine can reduce dry mouth symptoms and increase salivary flow compared with placebo (Mercadante et al, 2017).*

▲ The American Dental Association (ADA) Council on Scientific Affairs report identifies that pilocarpine and cevimeline have US Food and Drug Administration approval for treating dry mouth caused by Sjögren's syndrome or radiation therapy (Plemons, Al-Hashimi, & Marek, 2014).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Teach clients about conditions that can exacerbate dry mouth symptoms:
  - Avoidance of low-humidity environments
  - Avoidance of oral irritants: acidic fluids such as carbonated beverages and juices, caffeine, alcohol, tobacco
  - Avoidance of salty, spicy, acidic, or high-sucrose content foods
  - Avoidance of dry, hard, and sticky foods
  - Referral of client to smoking and/or alcohol cessation program

  EB: *Avoiding conditions that can worsen dry mouth can facilitate client self-management of the symptom severity (Plemons, Al-Hashimi, & Marek, 2014; Cohen et al, 2016).*
- Teach the client good oral hygiene:
  - Twice daily toothbrushing with regular topical fluoride toothpaste.
  - Use of soft bristle toothbrush. **EB:** *Twice daily use of a soft bristle toothbrush is an accepted standard of care by the ADA to maintain and promote oral health and dentition (ADA, 2020).*
  - Daily use of dental floss or another interdental cleaner. **EB:** *Daily use of dental floss or interdental cleaner is an accepted standard of care to maintain and promote oral health and dentition (ADA, 2020).*
  - Daily use of alcohol-free mouth rinse. **EB:** *Systematic review by an expert panel recommends regular use of fluoride toothpastes or mouth rinses as highly effective in preventing caries in dry mouth (Zero et al, 2016).*
  - Recommend use of prescription-strength fluoride toothpastes for severe salivary hypofunction. **EB:** *Use 1.1% neutral sodium fluoride, or fluoride gel in custom-fit oral tray, or 0.09% fluoride mouth rinse daily (Plemons, Al-Hashimi, & Marek, 2014; ADA, 2021).*
- Provide instruction regarding cleaning, and assist with care of dental prosthesis as needed. Daily cleansing of a dental prosthetic is an accepted standard of care to maintain and promote oral health and dentition (ADA, 2020).

▲ Provide instruction on candidiasis prevention and control. Administer antifungal topical treatments as prescribed using available suspensions, pastilles, and lozenges for uncomplicated oral candidiasis. Systemic antifungal agents may be prescribed for complicated candidiasis mucosal infection (*Baer & Sankar, 2020*).

▲ Soak partial or complete dental prosthesis overnight in 0.2% chlorhexidine HCl. **EB:** *A literature review of treatment of dry mouth and other nonocular sicca symptoms in Sjögren's syndrome identified that oral candidiasis mucosal infection is common in clients with salivary gland hypofunction. Administer prescribed antifungal rinses, ointments, or lozenges. Include daily partial or complete denture antifungal treatment; soak dentures overnight in 0.2% chlorhexidine HCl (Baer & Sankar, 2020).*

▲ Recommend professional dental oral examination every 3 to 6 months. Recommend professional teeth cleaning at least every 6 months. **EB:** *ADA Council of Scientific Affairs identifies preventive oral health care for clients with hyposalivation as essential. This includes more frequent dental visits and associated management of secondary infections (Plemons, Al-Hashimi, & Marek, 2014).*

- Discuss selection and use of salivary substitutes with client and health care provider to assist in maintaining mouth moisture. **EB:** *A Cochrane review of nonpharmacological topical treatments for dry mouth that included salivary substitutes of sugar-free gums, mints, lozenges, sprays, gels, oils, and toothpastes indicated lack of strong evidence that topical therapies are effective in improving salivary flow. Many saliva substitutes are available without prescription and contain a mix of components such as carboxymethylcellulose, polyethylene glycol, sorbitol, and electrolytes. These products typically provide more viscosity and lubrication than water. A saliva spray that contains oxygenated glycerol trimester (OGT) is more effective than a water-based electrolyte spray (McMillan et al, 2016).* **EB:** *A review of the primary aspects of saliva preparations, including biological properties and antimicrobial effect, identified that saliva substitutes reduce symptoms of dry mouth albeit temporarily. The data on saliva substitutes that try to mimic human saliva with antimicrobial substances and remineralization properties are "ambiguous." For oral lubrication, mucin-based preparations are better than those with carboxymethylcellulose (Łysik et al, 2019).*
- Teach the client that any topical product that is acidic or contains sugar, or noted as sugarless with high fructose, should be avoided. **EB:** *Citrus-flavored sugar-free tablets or oral drops with malic acid may stimulate salivary flow. Additional nonpharmacological management of dry mouth using gel-releasing devices worn in the mouth requires more research. Client preference also appears to have a significant effect in the acceptance and attribution of topical agent efficacy (Furness et al, 2013; Treister, Villa, & Thompson, 2020).* **EB:** *A predesign and postdesign study of 118 elderly clients using an edible oral moisturizing jelly (OMJ) examined the efficacy of OMJ with results of reduced symptoms of dry mouth and prevention of decline of*

saliva pH, but further study is needed with a larger population and randomized-controlled study design (Dalodom et al, 2016).

- Encourage the client to try several products, based on client preference, to find a suitable saliva substitute. Clients reported that use of saliva substitutes may be more helpful before sleep because of diurnal variation on reduction in salivary flow at night. It is also suggested that clients mix and match salivary agents based on their daily schedules or activities such as eating or public speaking (Baer & Sankar, 2020). **CEB/EB:** *A literature review through September 2017 of treatment of dry mouth and other nonocular sicca symptoms in Sjögren's syndrome that use saliva substitutes is supported by several randomized trials and studies that show benefit when compared with placebo in relieving symptoms of dry mouth, burning tongue, and difficulties with chewing and swallowing (Wu, 2008; National Institute of Dental and Craniofacial Research, 2018).* **EB:** *A systematic review of the effects of acupuncture on dry mouth and hyposalivation concluded absence of significant effect on saliva production or dry mouth symptoms in Sjögren's syndrome (Assy & Brand, 2018) with the recommendation that additional, well-designed studies are needed to determine the benefit of acupuncture, and current cost of acupuncture does not justify use outside of clinical trials.*
- Lubricate lips every 2 hours, while awake, and as needed. Apply moisturizer (e.g., lanolin) to dry lips every 2 hours, as needed to assist with dryness.
- Teach clients preventive measures to reduce oral dryness:
  - Maintain adequate oral hydration by sipping water regularly and/or sucking on ice chips (AAOM, 2016).
  - While eating, drink fluids carefully.
  - Maintain an oral intake log.
  - Rinse with normal saline or clean water as a part of daily oral care to prevent dry mouth, or sodium bicarbonate solution (1 teaspoon salt and 1 teaspoon baking soda to 1 L of water).
    EB: *Oral rinses with clean water or normal saline every 2 hours while awake promote a moist oral mucosa, neutralize oral pH, and are readily available with minimal side effects and are inexpensive (AAOM, 2016; ADA, 2020).*
- Encourage the client to use sugar-free gum or sugar-free candy to promote salivary flow. **EB:** *A Cochrane review of nonpharmacological topical treatments for dry mouth included salivary substitutes of sugar-free gum and candy. Although mastication increases saliva production, the evidence is not conclusive that sugar-free chewing gum is better or worse than other saliva substitutes for symptom management of dry mouth, but the use of these interventions also was supported by extensive clinical experience (Furness et al, 2013).* **EB:** *A randomized phase III trial using customized sugar-free gum to alleviate radiation-induced xerostomia confirmed an immediate stimulating effect of salivary flow and viscosity after 5 minutes of chewing. However, changes in flow and viscosity between the intervention group (chewing gum) and standard care (control) was not significant over time. The subjective feeling of xerostomia was reduced in the intervention group in spite of objective assessment of hyposalivation. "This finding emphasizes the importance of talking with clients about symptom burdens, as subjective and objective assessment do not always correlate" (Kaae et al, 2020).*
- Encourage the client to use saline nasal sprays to maintain open nasal passages. **EB:** *Maintenance of open nasal passage to avoid mouth breathing includes saline nasal sprays or gentle nasal lavage to remove dried secretions (AAOM, 2016; Baer & Sankar, 2020).*
- The client may find the use of a humidifier during sleep at night helpful in reducing symptoms.

▲ Discuss with the client the use of acupuncture, electrical nerve stimulation, and powered versus manual toothbrushes to assist in maintaining mouth moisture. **CEB:** *In a systematic review, nonpharmacological therapies using acupuncture, transcutaneous electrical nerve stimulation, and powered versus manual toothbrushing were reported as insufficient or low-quality evidence to determine effects of these interventions on dry mouth or saliva production but continued to be studied as alternatives for symptom relief (Furness et al, 2013; Simcock et al, 2013).*

▲ Encourage the client to discuss the use of emerging preventive treatments with the health care provider such as gene therapy, tissue engineering, stem cell therapy, and growth factors for etiologies associated with dry mouth. **EB:** *Current research of Sjögren's syndrome and head and neck radiation etiologies associated with salivary hypofunction reported that future approaches to treatment and/or prevention of the feeling of dry mouth include gene therapy, stem cell therapy, and tissue engineering (Quock, 2016).* **EB:** *In a review of 90 articles with clinical application, there are emerging therapies for radiation-induced salivary hypofunction, but the most efficacious with cost-effectiveness are not identified (Han, Suarez-Durall, & Mulligan, 2015). Emerging therapies also include use of hyperbaric oxygen after head and neck radiation (Millsop et al, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ Discuss use of bethanechol HCl saliva stimulant in head and neck cancer clients with radiotherapy-induced dry mouth and hyposalivation with the client and health care provider. **EB:** *Clinical application of bethanechol HCl to treat dry mouth in clients with radiotherapy-induced dry mouth and salivation is not supported because further research is needed to determine optimal dosing, frequency of use, long-term efficacy, and safety (Han, Suarez-Durall, & Mulligan, 2015; McMillan et al, 2016).*

Geriatric

- Recognize that symptoms of dry mouth are more common in menopausal women and geriatric clients. **CEB/EB:** *Symptoms of dry mouth are more common in menopausal women and almost 50% of the elderly population because of an age-related increase of systemic disease occurrence and disease treatment, including medications (Turner & Ship, 2007; Thomson, 2015; Dalodom et al, 2016).* **EB:** *Composition of saliva changes with age, including decreased sodium and potassium ions, IgA, lactoferrin and lysozyme, and proline-rich proteins, including reduced antimicrobial factors in the saliva. Xerostomia in the elderly can be severe with the addition of missing teeth and use of dentures (Łysik et al, 2019).*
- Age-associated increase of systemic disease and subsequent disease treatment are the primary causes of dry mouth. **EB:** *Older adults experience increased incidence of xerostomia, hyposalivation, and oral health disorders because of the high prevalence of polypharmacy. Daily oral assessment and interventions to reduce severity of oral dryness are needed to improve oral health, address nutritional concerns, and prevent cavities. The most commonly prescribed pharmaceutical treatment options are pilocarpine (a parasympathomimetic agent with potent muscarinic, cholinergic, salivation-stimulating properties) and cevimeline (a quinuclidine analog with therapeutic and side effects similar to those of pilocarpine) (Barbe, 2018).*
- Older adults are at risk of xerostomia from a variety of etiologies. **EB:** *In a narrative review of systemic disease in older adults and review of the literature of xerostomia caused by various etiologies, it is recommended to assess the client for dehydration, nutritional alteration manifested by weight loss, decreased appetite, increased thirst, and any changes in food or beverage preferences. Oral symptoms of malnutrition, such as sore tongue, burning mouth, and gingivitis, may be caused by iron, vitamin B_1, B_2, B_6, and B_{12} or vitamin C deficiencies (Tanasiewicz, Hildebrandt, & Obersztyn, 2016; Critchlow, 2017).*
- Review client medication list routinely. **EB:** *In a cross-sectional study to examine the relationship between nutrition, oral health, and drug use among adults age 75 and older, it was found that excessive polypharmacy, the use of particular drug groups, and depressive symptoms were associated with xerostomia, supporting the need for a multiprofessional approach to care (Thomson, 2015; Viljakainen et al, 2016).*

Multicultural and Home Care Considerations

- The previously mentioned nursing interventions and client teaching may be adapted for multicultural and home care considerations. See care plan on Impaired **Oral Mucous Membrane** Integrity.

Nausea Domain 12 Comfort Class 1 Physical comfort

Janelle M. Tipton, DNP, APRN-CNS, AOCN

NANDA-I

Definition

A subjective phenomenon of an unpleasant feeling in the back of the throat and stomach, which may or may not result in vomiting.

Defining Characteristics

Food aversion; gagging sensation; increased salivation; increased swallowing; sour taste

Related Factors

Anxiety; exposure to toxin; fear; noxious taste; unpleasant sensory stimuli

At-Risk Population

Pregnant women

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Associated Conditions

Abdominal neoplasms; altered biochemical phenomenon; esophageal disease; gastric distention; gastrointestinal irritation; intracranial hypertension; labyrinthitis; liver capsule stretch; localized tumor; Ménière's disease; meningitis; motion sickness; pancreatic diseases; pharmaceutical preparations; psychological disorder; splenetic capsule stretch; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Comfort Level; Hydration; Nausea and Vomiting Severity; Nutritional Status: Food and Fluid Intake; Nutrient Intake

Example NOC Outcome with Indicators

Nausea and Vomiting Severity as evidenced by the following indicators: Frequency of nausea/Intensity of nausea/Distress of nausea. (Rate the outcome and indicators of **Nausea and Vomiting Severity:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State relief of nausea
- Explain methods clients can use to decrease nausea and vomiting (N&V)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Distraction; Medication Administration; Progressive Muscle Relaxation; Simple Guided Imagery; Therapeutic Touch

Example NIC Activities—Distraction

Encourage the individual to choose the distraction techniques desired, such as music, engaging in conversation or telling a detailed account of event or story, guided imagery, or humor; Advise client to practice the distraction technique before the time needed, if possible

Nursing Interventions and *Rationales*

▲ Determine cause or risk for N&V (e.g., medication effects, infectious causes [viral and bacterial gastroenteritis], disorders of the gut and peritoneum [mechanical obstruction, motility disorders, or other intraabdominal causes], central nervous system causes [including anxiety], endocrine and metabolic causes [including pregnancy], postoperative-related status). **EB:** *Because N&V are clinically identifiable symptoms, it is important for the cause to be determined and appropriate plan and interventions to be developed. Review the client's medication record, alcohol history, and electrolytes as appropriate for early identification of cause of nausea (Koth & Kolesar, 2017).* **EB:** *Prophylactic interventions given before chemotherapy have proven to be most successful in preventing N&V. Client expectancy of nausea after chemotherapy is predictive of that treatment-related side effect (Oncology Nursing Society, 2019; Patel et al, 2017).*

▲ Evaluate and document the client's history of N&V, with attention to onset, duration, timing, volume of emesis, frequency of pattern, setting, associated factors, aggravating factors, and medical and social histories. **EB:** *The onset and duration of N&V may be distinctly associated with specific events and may be treated differently (Dranitsaris et al, 2017).*

● Document each episode of nausea and/or vomiting separately and the effectiveness of interventions. Consider an assessment tool for consistency of evaluation. **EB:** *A systematic approach can provide consistency, accuracy, and measurement needed to direct care. It is important to recognize that nausea is a subjective experience (Dranitsaris et al, 2017).*

- Identify and eliminate contributing causative factors. This may include eliminating unpleasant odors or medications that may be contributing to nausea. These interventions are theory based; however, there is no research evidence to support these interventions outside of expert opinion.

▲ Implement appropriate dietary measures such as nothing by mouth (NPO) status as appropriate; small, frequent meals; and low-fat, high-protein meals. It may be helpful to avoid foods that are spicy, fatty, or highly salty. Reverting to previous practices when ill in the past and consuming "comfort foods" may also be helpful at this time. **EB:** *Expert opinion consensus recommends these interventions, with no research data available (Marx et al, 2016).*

▲ Recognize and implement interventions and monitor complications associated with N&V. This may include administration of intravenous fluids and electrolytes. **EB:** *Recognition of complications of N&V is critical to prevent and manage complications of dehydration, electrolyte imbalance, and malnourishment. Adequate hydration corrects imbalances and reduces further emesis (Tilleman et al, 2018).*

▲ Administer appropriate antiemetics, according to guidelines, with consideration to emetic cause, most effective route, and side effects of the medication, and with attention to and coverage for the time frames in which the nausea is anticipated. **EB:** *Antiemetic medications are effective at different receptor sites and treat different causes of N&V. A combination of agents may be more effective than a single agent (Koth & Kolesar, 2017; Razvi et al, 2019).*

- Consider nonpharmacological interventions such as acupressure, acupuncture, music therapy, distraction, and slow, deliberate movements. **EB:** *Nonpharmacological interventions can augment pharmacological interventions because they predominantly affect the higher cortical centers that trigger N&V. Nonpharmacological interventions are often low cost, relatively easy to use, and have few adverse events. The nonpharmacological interventions most likely to be effective include progressive muscle relaxation, hypnosis for anticipatory chemotherapy-induced N&V (CINV), and managing client expectations. Effectiveness has not been established for several other nonpharmacological interventions, primarily because of study limitations, lack of effect in small studies, and inconsistent results (Oncology Nursing Society, 2019; Patel et al, 2017).*
- Provide oral care after the client vomits. Oral care helps remove the taste and smell of vomitus, reducing the stimulus for further vomiting.

Nausea in Pregnancy

- Early recognition and conservative measures are recommended to successfully manage nausea in pregnancy and to prevent progression to hyperemesis gravidarum. Dietary and lifestyle modifications should be implemented before pharmacological interventions. Avoidance of any aversive odors or foods is recommended. Eating multiple small meals per day is also recommended to have some food in the stomach at all times, avoiding hypoglycemia and gastric overdistention. Foods with higher protein (before bedtime) and carbohydrate and lower fat content are helpful (between meals and before getting out of bed early in the morning). Drinking smaller volumes of liquids at multiple times throughout the day is recommended. **EB:** *These are traditional strategies for alleviating nausea during pregnancy, and there is limited evidence supporting the effectiveness of dietary changes in minimizing N&V with pregnancy symptoms (Campbell et al, 2016; Argenbright, 2017).*
- Recognize that certain maternal characteristics may be at higher risk for nausea and vomiting in pregnancy and hyperemesis gravidarum. **EB:** *Young mothers, women of black and Asian ethnic origin, those from lower socioeconomic status, and women with multiple pregnancies are more likely to be affected (Fiaschi et al, 2019).*

▲ It is well established that *Helicobacter pylori* infection is associated with hyperemesis gravidarum. **EB:** *It may also be recommended to test for* H. pylori *if there are persistent symptoms of nausea with pregnancy, prolonged symptoms of gastroesophageal reflux disease (GERD), or a previous history of* H. pylori *infection.* H. pylori *is an independent risk factor for vomiting in pregnancy, and in women with daily vomiting there is an association of adverse birth outcomes such as reduced birth weight (Grooten et al, 2017).*

▲ Coexisting psychosocial factors may also influence the severity of N&V with pregnancy. Symptoms of anxiety and depression can occur in early pregnancy, especially when N&V is severe and can make the treatment of the N&V more challenging and even ineffective. **EB:** *Timely diagnosis and treatment is recommended (Argenbright, 2017).*

▲ The American College of Obstetricians and Gynecologists (ACOG) currently recommends converting the prenatal vitamin to folic acid only if nausea persists. Pharmacological options include a combination

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

of oral pyridoxine hydrochloride (vitamin B_6, 10–25 mg) and doxylamine succinate (antihistamine 12.5 mg) to be used three to four times a day as first-line treatment for N&V of pregnancy after failure of pyridoxine alone. This combination agent of pyridoxine and doxylamine (Diclegis) is the only US Food and Drug Administration pregnancy Category A approved therapy for N&V of pregnancy. There are, however, several pharmacological treatments outlined by the ACOG. **EB:** *A stepwise, cost-effective strategy may be helpful in approaching N&V. Considerable N&V with associated dehydration may require intravenous antiemetics, hydration, and/or parenteral nutrition (Campbell et al, 2016; ACOG, 2018).*

▲ Nonpharmacological interventions that are recommended include P6 acupressure with wrist bands and ginger capsules, 250 mg four times a day. **EB:** *These interventions have been shown to be safe and beneficial for the treatment of N&V with pregnancy (Campbell et al, 2016; ACOG, 2018). Mindfulness-based cognitive therapy may also be a helpful adjunct to pyridoxine therapy (Campbell et al, 2016).*

Nausea After Surgery

▲ Evaluate for risk factors for postoperative N&V (PONV). **EB:** *Strong evidence suggests that client-related risk factors such as female gender, age group (<50 years), history of PONV, history of motion sickness, nonsmoking behavior, and environmental risk factors such as postoperative opioid use, emetogenic surgery (type and duration), and volatile anesthetics may increase the risk for PONV. It is important to determine this risk in the preoperative period to better plan strategies to reduce baseline risk (Smith & Ruth-Sahd, 2016). Childhood risk factors include surgery duration of more than 30 minutes, age older than 3 years, strabismus surgery, and a history of postoperative vomiting or a relative with PONV (Simon, 2020). PONV in children is twice as common as it is in adults, with the occurrence of 13% to 42% in all pediatric cases (Matthews, 2017).*

▲ Reduction of risk factors associated with PONV is beneficial for both adults and children. **EB:** *Avoidance of the use of general anesthesia by the use of regional anesthesia has been associated with a decreased incidence of PONV. The avoidance of both nitrous oxide and volatile anesthetics has also minimized PONV. Decreased and minimal use of intraoperative and postoperative opioids has demonstrated reduction in PONV. Adequate hydration is also an intervention to decrease the risk of PONV (Matthews, 2017; Simon, 2020).*

▲ Medicate the client prophylactically for nausea as ordered, throughout the period of risk. **EB:** *Antiemetic medications can reduce the incidence of PONV and use of combination treatment such as 5-HT3 antagonist plus dexamethasone is more effective than monotherapy. This recommendation is for clients at moderate or high risk for PONV. Other antiemetics, such as the neurokinin (NK-1) receptor antagonists, may have a role, particularly in preventing vomiting and severity 24 to 48 hours after surgery. Antihistamines may be helpful in those with previous motion sickness or after ear surgery (Matthews, 2017).*

▲ Alleviate postoperative pain using ordered analgesic agents (refer to the care plan for Acute **Pain**). Pain is known to be a factor in the development of PONV (Bruderer et al, 2017).

● Consider the use of nonpharmacological techniques, such as P6 acupoint stimulation, as an adjunct for controlling PONV, which has been shown to be effective in reducing PONV by 30%. Acupoint pressure is noninvasive, is inexpensive, and has no side effects; thus it is part of a combined approach with antiemetic medication. **EB:** *Acupuncture and acustimulation have been studied with the most consistent results, similarly effective across methods of stimulation (acupuncture or acupressure or wristlike electrical stimulation) (Matthews, 2017). Aromatherapy may be a modality that can be considered as treatment for adult PONV. Additional research should be conducted for support (Asay et al, 2019).*

● Include client education on the management of PONV for all outpatients and discuss key assessment criteria.

Nausea After Chemotherapy

● Perform risk assessment before chemotherapy administration. Risk factors include female gender, younger age, history of low alcohol consumption, history of morning sickness during pregnancy, anxiety, previous history of chemotherapy, client expectancy of nausea, and emetic potential of the regimen. **EB:** *It is important to recognize the many risk factors individual clients may have and tailor the antiemetic strategy accordingly. N&V continues to be among the most feared side effects of cancer treatment and can significantly affect quality of life and other complications. Poor control of N&V also has an economic impact, with increased costs related to increased emergency department visits, hospitalizations, and outpatient visits (Koth & Kolesar, 2017).*

▲ Initiate antiemetic strategy prophylactically or when N&V occurs in accordance with evidence-based guidelines. **EB:** *Preventing N&V is important; one failure in antiemetic therapy can result in anticipatory*

nausea for the remainder of the client's treatments, and interventions are less likely to be effective (Tageja & Groninger, 2016).

▲ Drug classes that are recommended for practice include serotonin receptor antagonists, NK-1 receptor antagonists, and cannabinoids. **EB:** *Triple-drug regimens including serotonin receptor antagonists, NK-1 receptor antagonists, and dexamethasone are recommended for adults receiving highly emetogenic chemotherapy. Recently, olanzapine has been used for highly emetogenic chemotherapy (Razvi et al, 2019).*

▲ Consider the use of the following integrative therapies that are likely to be effective in reducing N&V: hypnosis with anticipatory N&V, and progressive muscle relaxation and guided imagery with antiemetics. Ginger may be effective for acute N&V and showed significant efficacy in a recent meta-analysis. **EB:** *There has been benefit associated with these interventions; however, further data are warranted (Chang & Peng, 2019; Oncology Nursing Society, 2019).*

● Consider managing client expectations about CINV. **EBN:** *Education and discussion are interventions that may minimize negative expectations. This intervention is based on the idea that if a client expects to experience a problem, he or she is more likely to do so. If a client believes that an intervention will be effective for symptoms, it is more likely to be effective (Oncology Nursing Society, 2019).*

Geriatric

● There are no specific guidelines that address the prophylaxis of CINV in older adults. Risk still needs to be assessed, although many older clients are often treated with less emetic chemotherapy. Chemotherapy, however, can cause increased toxicity caused by age-related decreases in organ function, comorbidities, and drug–drug interactions secondary to polypharmacy. Additionally, adherence may be an issue because of cognitive decline, impaired senses, and economic issues. **EB:** *Increased caution is warranted in this population because of increased safety concerns. Some drugs, such as olanzapine, are recommended to be given at lower doses in the elderly due to increased sedation (Clemons, 2018; Razvi et al, 2019).*

Pediatric

● Interventions for CINV should be implemented before and after chemotherapy. **EB:** *Despite the extensive use of antiemetics, it is estimated that nausea occurs in 40% to 70% of children treated for cancer (Hockenberry & Rodgers, 2015).*

● Use of a validated nausea tool in pediatrics for estimating incidence and severity of CINV is useful in clinical trials and standard practice. Examples include the PeNAT and pictorial scales (Sherani, Boston, & Mba, 2019).

● Relatively few systematic reviews exist examining the antiemetic medications used for CINV in children. It appears that a triple-drug regimen, including 5-HT3 antagonists, combined with dexamethasone and aprepitant, is recommended in children receiving highly emetogenic chemotherapy (Sherani, Boston, & Mba, 2019).

● Integrative therapies for control of nausea in children with cancer have not yet been studied as adequately as they have with adults. Some integrative therapies with potential include cognitive distraction, hypnosis, and acupressure (Momani & Berry, 2017).

Home Care

● Previously mentioned interventions may be adapted for home care use.

▲ In palliative care and hospice care clients, N&V is common and can considerably affect quality of life. Assessment is relevant in the management of N&V and should include history, physical examination, and evaluation of reversible causes. **EB:** *There can be multiple causes of nausea in clients with advanced cancer, and the causes may be treatment related or nontreatment related. The causes may be obstructive; examples include increased intracranial pressure and bowel obstruction. Metabolic causes may be related to hypercalcemia, hyponatremia, or opioids (Walsh et al, 2017).* **EBN:** *Nausea can effectively be controlled if a cause can be identified. An N&V protocol (e.g., Horvitz Center for Palliative Medicine N&V Protocol) can be used to identify and resolve any reversible causes of nausea, such as metabolic abnormalities or medications (Gupta et al, 2013). If none are found and symptoms persist, a flat-plate radiograph of the abdomen is done to evaluate for obstruction or constipation. Appropriate medications can then be used to treat central nervous system causes and obstructive or nonobstructive causes (Moorthy & Letizia, 2018).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Assist the client and family with identifying and avoiding irritants in the home that exacerbate nausea (e.g., strong odors from food, plants, perfume, and room deodorizers). All medications except antiemetics should be given after meals to minimize the risk of nausea. **EB:** *Nausea triggered by odors is related to altered chemoreceptors and pathology (Moorthy & Letizia, 2018).*

Client/Family Teaching and Discharge Planning

- Teach the client techniques to use before and after chemotherapy, including antiemetics/medication management schedules and dietary approaches, such as eating smaller meals, avoiding spicy and fatty foods, and avoiding an empty stomach before chemotherapy (Marx et al, 2016).

Neonatal Abstinence Syndrome

Domain 9 Coping/stress tolerance Class 3 Neurobehavioral stress

Patricia Hindin, PhD, CNM and Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

A constellation of withdrawal symptoms observed in newborns as a result of in-utero exposure to addicting substances, or as a consequence of postnatal pharmacological pain management.

Defining Characteristics

Diarrhea (00013); disorganized infant behavior (00116); disturbed sleep pattern (00198); impaired comfort (00214); ineffective feeding pattern (00107); neurobehavioral stress; risk for aspiration (00039); risk for impaired attachment (00058); risk for impaired skin integrity (00047); risk for ineffective thermoregulation (00274); risk for injury (00035)

Related Factors

To be developed

At-Risk Population

Neonates exposed to maternal substance misuse in utero; neonates iatrogenically exposed to substance for pain control; premature neonates

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Comfort Status: Physical; Breastfeeding Establishment: Infant; Bottle Feeding Establishment: Infant; Parent-Infant Attachment; Stress Level; Sleep; Thermoregulation: Newborn; Tissue Integrity: Skin and Mucous Membranes; Newborn Adaptation; Risk Control; Bowel Elimination; Risk Control: Aspiration

Example NOC Outcome with Indicators

Parent-Infant Attachment as evidenced by the following indicators: Holds infant close/Uses eye contact/Infant looks at parent/Consoles infant/Responds to infant cues. (Rate the outcome and indicators of **Parent-Infant Attachment:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Tolerate small frequent formula feedings or frequent breastfeedings
- Maintain weight and readjust feedings frequency as necessary for appropriate growth
- Provide calorie-dense formula, which is appropriate for weight gain
- Maintain proper hydration with elastic skin turgor and moist mucous membranes
- Maintain adequate nutrition, which will promote adequate growth
- Preserve skin integrity in perianal area

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Diarrhea Management; Bottle Feeding; Infant Care: Newborn; Developmental Enhancement: Infant; Feeding

Example NIC Activities—Diarrhea Management

Monitor for signs and symptoms of diarrhea; Observe skin turgor regularly; Monitor skin in perianal area for irritation and ulceration; Weigh client regularly

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Nursing Interventions and *Rationales*

- Provide supportive nonpharmacological care with formula feeding as prescribed. **EBN:** *A randomized controlled trial (N = 49) assessed the early initiation of feeding infants with a high-calorie formula compared with feeding with standard-calorie formula. The authors concluded that high-calorie feeding might be advantageous for weight gain (Bogen et al, 2018).*
- Encourage breastfeeding for nutrition and nonpharmacological supportive care. **EB:** *A retrospective cohort study of neonatal abstinence syndrome (NAS) neonates (N = 3725) indicated that there is an association between breastfeeding and a 9.4% decrease in length of stay when compared with nonbreastfed neonates (Short, Gannon, & Abatemarco, 2016).*
- Use nursing skills to provide supportive nonpharmacological care. **EBN:** *An ethnographic study described the culture of care provided by 12 full-time registered nurses to infants with NAS in an intensive care unit (ICU). The six themes point to the direction for the culture of care practice: learn the baby, team relationships, role satisfaction, grief, making a difference, and educate and care for the mother (Nelson, 2016).*
- Use vibrotactile stimulation (VS) as a nonpharmacological supportive care option. **EB:** *A prospective study was conducted on 26 opioid-exposed newborns to determine whether exposure to a specially constructed mattress that delivered a dose of stochastic (randomly determined) VS would affect symptoms. The results indicated a 35% reduction in movement with a significant increase in normal breathing and heart rate (Zuzarte et al, 2017).*
- Practice supportive nursing interventions with an understanding of the levels of evidence. **EB:** *Ryan et al (2019) reviewed research papers on NAS from the years 2000 and 2017. The author's goal was to substantiate the efficacy of supportive interventions for the treatment of NAS. The authors determined that level I to III evidence (experimental studies) exists for breastfeeding, swaddling, rooming-in, skin to skin, and environmental control for NAS infants.* **EBN:** *A systematic review performed by MacMullen, Dulski, and Blobaum (2014) evaluated supportive nursing care with NAS infants. The authors found level IV evidence (expert opinion, case reports, and descriptive studies) for interventions such as swaddling, gentle awaking, quiet environment, and nonnutritive sucking.*
- Provide pharmacological treatment as indicated for symptoms. **EB:** *A double-blind, randomized control trial assigned term infants who had been exposed to opioids in utero to either a sublingual buprenorphine treatment group or an oral morphine treatment group. The authors noted that the infants treated with sublingual buprenorphine experienced a shorter duration of treatment (15 days versus 28 days) and a shorter length of hospital stay (21 days versus 33 days) (Kraft et al, 2017).* **EB:** *Streetz, Gildon, and Thompson (2016) engaged in a systematic review of clonidine as treatment for NAS. There is limited evidence that clonidine as a single therapy or in combination with other therapies can be effective with limited adverse reactions and a shorter treatment time.*
- Use of nonpharmacological and complementary therapy to comfort infants and provide relief of symptoms. **EB:** *A prospective, cohort, pilot study was conducted with a sample of infants who were given a one-dose, 30-minute Reiki massage session. The authors found the treatment to be safe for the infants and acceptable to the mothers (Radziewicz et al, 2018).*
- Use of rooming-in and promotion of maternal–infant bonding for mother–infant dyad. **EB:** *A systematic review and meta-analysis were conducted on 549 infants with NAS. MacMillan et al (2018) concluded that rooming-in was associated with a reduction in pharmacological treatment and earlier discharge when compared with infants treated in the ICU.* **EB:** *Howard et al (2017) performed a retrospective, single cohort study with 86 mother–infant dyads. Infants with NAS were treated with pharmacological modalities and the rooming-in model of care. The presence of the parents was associated with decreased NAS scores and reduction in opioid treatment days.* **EB:** *Boucher (2017) reviewed eight studies on the rooming-in model of care and the use of acupuncture for NAS infants. The author established that the rooming-in model might decrease use of opioids and length of stay and that acupuncture is safe for infants.*
- Provide compassionate care, free of judgment, to substance-abusing mothers. **EBN:** *A qualitative study was conducted with 15 mothers with substance abuse disorders. The judgmental attitudes and behaviors of health care professionals served to retraumatize them during their hospitalization. The importance of nursing care with the empathic approach is essential in the care of these women (Cleveland, Bonugli, & McGlothen, 2016).* **EBN:** *The use of a structured communication tool based on the organization of the concepts of knowledge creates circumstances for reflection, teaching, and support (ACTS). The ACTS was an implementation to assist neonatal ICU (NICU) nurses in developing positive strategies to change negative attitudes among their peers toward substance-abusing mothers (Marcellus & Poag, 2016).*

Pediatric

- When available, consider professional, supportive programs for infants with a history of NAS. **EB:** *Beckwith and Burke (2015) followed the development of 28 infants exposed to prenatal drugs over a 3-year period and determined that the exposed infants have a limitation in language and cognition.*
- Refer children and adolescents with a diagnostic history of NAS to educational supports and resources. **EB:** *A diagnostic code of NAS is strongly associated with poor school performance. Children and adolescents with a history of NAS must be identified early and provided with support to minimize the consequences of poor educational outcomes (Oei et al, 2017).*

Multicultural

- Identify specific rural areas that are high risk for NAS. **EB:** *Brown, Goodin, and Talbert (2018) reviewed data in Kentucky and determined that rural Appalachian counties in Kentucky experienced NAS rate per 1000 births that are 2 to 2.5 times greater than urban and non-Appalachian counties in the state.* **EB:** *The authors evaluated NAS admissions from the Uniform Billing data from the West Virginia Health Care Authority. They found that the NAS rate in rural West Virginia increased from 7.74 to 31.5 per live births per year, indicating an increased need for services for this growing health problem (Stabler et al, 2017).*

Client/Family Teaching and Discharge Planning

- Develop plans of safe care for opioid-exposed mother–infant dyads before discharge. **EB:** *Safe discharge planning will include home visiting programs, maternal opioid use disorder treatment, parenting education, support for breastfeeding, and postdischarge follow-up with the baby's provider (Whalen, Holmes, & Blythe, 2019).*
- Provide parenting education before discharge that includes infant signs of hunger, infant feeding, ways to calm a fussy baby, the importance of never shaking a baby, safe sleep practices (including safe swaddling), and the importance of not co-sleeping. **EB**: *Safe discharge planning includes parental education that enhances the safe transition from hospital to the home setting (Whalen, Holmes, & Blythe, 2019).*

Home Care

- Consider alternative models of care for treatment for infants with NAS. **EB:** *A review article by Whalen, Holmes, and, Blythe concluded that models of care for NAS that are baby-centered and function-based, provide nonpharmacological care, and have the mother as the primary means of treatment may be more effective in reducing length of treatment and length of stay than models focused on specific medications, protocol standardization, or home-based pharmacotherapy (Whalen, Holmes, & Blythe, 2019).* **CEB:** *Belcher et al (2005) reported on three community programs implemented in Baltimore to provide services to substance-abusing mothers and their infants. The Early Transition Center provided 24-hour on-call services for newly discharged mother and infant dyads. The Home-U-Go-Safely program used community nurses to provide supportive care, health monitoring of the infant, and education to mothers.*

Readiness for Enhanced Nutrition

Domain 2 Nutrition Class 1 Ingestion

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

A pattern of nutrient intake, which can be strengthened.

Defining Characteristics

Expresses desire to enhance nutrition

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Nutritional Status; Nutritional Status: Food and Fluid Intake; Nutrient Intake; Weight Control

Example NOC Outcome with Indicators

Nutritional Status as evidenced by the following indicators: Food and fluid intake/Hydration/Body mass index/Weight-height ratio/Hematocrit. (Rate the outcome and indicators of **Nutritional Status:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Explain how to eat according to the US Dietary Guidelines
- Design dietary modifications to meet individual long-term goal of health, using principles of variety, balance, and moderation
- Maintain weight within normal range for height and age

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Nutrition Management; Nutritional Counseling; Weight Reduction Assistance

Example NIC Activities—Nutrition Management

Determine the client's motivation for changing eating habits; Develop with the client a method to keep a daily record of intake

Nursing Interventions and *Rationales*

- Assess the meaning and importance of food in the client's life. **EB:** *Recent research found strong associations between the different domains of food meanings and behavioral outcomes (Arbit et al, 2017).*
- Assess client readiness to determine whether he or she is ready to discuss enhanced nutrition and/or would like nutrition information. **EB:** *Client motivation is a key component of success in a weight loss program and a prerequisite for weight loss therapy (*Raynor & Champagne, 2016).
- Use a motivational interviewing technique when working with clients to promote healthy eating and improved nutrition. **EB:** *Research shows significant weight loss for clients when motivational interviewing techniques were used (Barnes et al, 2018).*
- Counsel the client to measure regularly consumed foods periodically. Help the client learn usual portion sizes. Measuring food alerts the client to normal portion sizes. Estimating amounts can be extremely inaccurate. **EB:** *A randomized controlled trial of 278 overweight and obese participants was conducted to increase portion size awareness with results that demonstrated that the intervention improved portion control behavior and in turn influenced body mass index (BMI) (Poelman et al, 2015).*
- Assist the client to develop a system of self-management, which may include self-monitoring of weight and BMI; realistic goal setting, planning, and action planning for improved dietary intake and physical activity; problem-solving; and tracking dietary intake and exercise. **EB:** *A key component of successful weight loss and maintenance is regular self-monitoring (Thomason et al, 2016).*
- Document the client's height and weight and teach the significance of his or her BMI in relation to current nutritional health. Use a chart or a website such as http://www.cdc.gov/healthyweight/assessing/bmi/index.html (Centers for Disease Control and Prevention [CDC], 2020a). **EB:** *Successful enhancement of nutrition in adults requires adoption and maintenance of effective self-monitoring (Raynor & Champagne, 2016).*
- Recommend that the client avoid eating in fast-food restaurants. **EB:** *A study found that fast-food consumption was the most frequent risk factor for adiposity found in 61.67% of study participants (Popa et al, 2020).*
- Assist the client to reframe slips in nutrition or physical activity behavior as lapses that are a single event and not a full return to previous unhealthy behaviors. Relapse prevention strategies include managing lapses in healthy behavior, identifying high-risk situations for relapses, self-monitoring, providing social support, enhancing skills for coping, and increasing self-efficacy for avoiding relapse. **EB:** *A study of a weight maintenance intervention, delivered primarily by telephone, modestly slowed the rate of weight regain (Voils et al, 2017).*
- Assist clients to engage their social support systems either digitally or face to face in ways that facilitate healthy eating and physical activity behavior change. **EB:** *Significant others, family, friends, and coworkers can facilitate or hinder weight loss success (Romo, 2018).*
- Assist the client to implement informal and formal mindfulness-based interventions (MBIs). Informal MBIs include mindful eating, increasing awareness of hunger and satiety cues, taste satisfaction, and decreasing impulsive tendencies to overeat when experiencing negative emotions. Meditation practice is a formal MBI. **EB:** *Results of a research review suggest that a combination of formal and informal MBIs are effective in reducing weight and improving obesity-related eating behaviors among individuals with overweight and obesity (Carrière et al, 2018).*
- Assist the client to develop stimulus control techniques designed to reduce environmental cues associated with eating behaviors. Specifically, clients should be taught to limit the presence of high-calorie/high-fat foods in the home; to reduce the visibility of unhealthy food choices in the home; to limit where and when they eat; to avoid distractions like reading, using the computer, or watching television when eating; and to eat more slowly. **EB:** *Stimulus control strategies are the keys to healthy eating (Butryn et al, 2017).*
- Encourage 7.5 to 8.5 hours of sleep nightly. **EB:** *Evidence suggests that weight management is hindered when attempted in the context of sleep restriction because there is an upregulation of reward, pleasure, and salience networks in response to food stimuli (St-Onge, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Recommend the CDC behavior modification approach "reflect, replace, and reinforce" to improve eating habits. **EB:** *Reflect, replace, and reinforce consists of the following: (1) Reflect about intake through food journals, listing food habits, and identification of eating cues. (2) Replace habits identified during reflection with new and healthier behaviors, such as eating more slowly or planning meals ahead of time. (3) Reinforce changes made and having patience with the process (CDC, 2020b).*

Pediatric

- Offer obese or overweight adolescents healthy methods for weight loss. **EB:** *A study showed statistically significant health behavior improvements after implementing a developmentally informed intervention to increase positive health diet and exercise behaviors (Issner et al, 2017).*
- Offer families of obese or overweight children prejudice-free, individually accepting, and supportive interventions to address weight loss. **EB:** *A review summarized recent evidence on weight stigma and found that it is highly prevalent among youth with high body weight, who are targets of weight-based victimization from peers, parents, and teachers (Puhl & Lessard, 2020).*
- Recommend that families eat together for at least one meal per day. **EB:** *A large Korean study found that the frequency of family meals was strongly an inverse association with childhood overweight or obesity (Lee, Lee, & Park, 2016).*
- Recommend involving the family in planning meals and food preparation. Children can learn about nutrition as they help plan and make meals. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed increased cooking skills among the children participating (Fulkerson et al, 2018).*
- Assist parents at being good role models of healthy eating. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed significantly improved parental self-efficacy for identifying appropriate portion sizes (Fulkerson et al, 2018).*
- Recommend that the family try new foods, either a new food or recipe every week. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed decreasing child neophobia scores over time that were developmentally appropriate (Fulkerson et al, 2018).*

Geriatric

- Observe for social, psychological, and economic factors that influence diet quality. **EB:** *An exploratory study of diet quality influences in community-dwelling older individuals revealed the following influences: food experiences, retirement, bereavement, medical conditions, food environment, food-related habits, social engagement, personal/psychological factors, and transportation (Bloom et al, 2017).*

Multicultural

- Tailor nutritional interventions to be consistent with cultural beliefs, norms, and values. **EB:** *A systemic review of culturally tailored interventions for Hispanic women included literacy modification, Hispanic foods/recipes, cultural diabetes beliefs, family/friend participation, structured community input, and innovative experiential learning (McCurley et al, 2016).*
- Offer tailored lifestyle counseling via the telephone. **EBN:** *Investigators have included biweekly and/or monthly health coach calls for African American participants with significant weight gain prevention (Goode et al, 2017).*
- Integrate weight loss and weight maintenance interventions with church faith-based supports for cultural congruence with African American clients. **EB:** *Recent research found that a church-based weight loss intervention using automated text messages was well-received by African American participants and resulted in significant weight loss (Newton et al, 2018).*

Client/Family Teaching and Discharge Planning

- The majority of the preceding interventions involve teaching.
- Work with the family members regarding information on how to support and promote enhanced nutritional choices and healthy intakes.

Imbalanced Nutrition: Less Than Body Requirements

Domain 2 Nutrition Class 1

Ingestion

Jody L. Vogelzang, PhD, RDN, CHES, FAND

NANDA-I

Definition

Intake of nutrients insufficient to meet metabolic needs.

Defining Characteristics

Abdominal cramping, abdominal pain; body weight below ideal weight range for age and gender; capillary fragility; constipation; delayed wound healing; diarrhea; excessive hair loss; food intake less than recommended daily allowance (RDA); hyperactive bowel sounds; hypoglycemia; inadequate head circumference growth for age and gender; inadequate height increase for age and gender; lethargy; muscle hypotonia; neonatal weight gain < 30 g per day; pale mucous membranes; weight loss with adequate food intake

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Related Factors

Altered taste perception; depressive symptoms; difficulty swallowing; food aversion; inaccurate information; inadequate food supply; inadequate interest in food; inadequate knowledge of nutrient requirements; injured buccal cavity; insufficient breast milk production; interrupted breastfeeding; misperception about ability to ingest food; satiety immediately upon ingesting food; sore buccal cavity; weakened muscles required for swallowing; weakened of muscles required for mastication

At-Risk Population

Competitive athletes; displaced individuals; economically disadvantaged individuals; individuals with low educational level; premature infants

Associated Conditions

Body dysmorphic disorders; digestive system diseases; immunosuppression; kwashiorkor; malabsorption syndromes; mental disorders; neoplasms; neurocognitive disorders; parasitic disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Nutritional Status; Food and Fluid Intake; Nutrient Intake; Weight Control

Example NOC Outcome with Indicators

Nutritional Status as evidenced by the following indicators: Food and fluid intake/Body mass index/Weight-height ratio/Hematocrit. (Rate the outcome and indicators of **Nutritional Status:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Promote weight gain of 5% to 10% of body weight
- Receive feeding assistance and texture modification as needed
- Identify factors contributing to being underweight
- Identify nutritional requirements based on specific client needs
- Increase overall intake
- Minimize further decline of weight status
- Be free of signs and symptoms of malnutrition

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Feeding; Nutrition Management; Nutrition Therapy; Weight Gain Assistance

Example NIC Activities—Nutrition Management

Ascertain the client's food preferences; Provide the client with high-protein, high-calorie, nutritious finger foods and drinks that can be readily consumed, as appropriate

Nursing Interventions and *Rationales*

- Conduct a nutrition screen on all clients within 24 hours of admission and refer to a dietitian as deemed necessary. **EB:** *Clients who received malnutrition screening and subsequent nutritional therapy is a prerequisite to beginning an evidence-based nutritional therapy (Eglseer et al, 2017). A study showed that malnutrition at admission and poor food intake early during hospitalization were associated with prolonged length of stay, suggesting that prompt nutrition intervention and monitoring should be performed when clients are admitted to the hospital (Allard et al, 2016).*

- The screening tool should be based on the unique characteristics of the client population and the validity and reliability of the screening tool. **EB:** *Screening is the starting point of high-quality nutritional care, which needs to be completed using a valid screening tool that fits the population (Eglseer et al, 2017).*
- Recognize the importance of rescreening and monitoring oral intake in hospitalized individuals to help facilitate the early identification and prevention of nutritional decline. **EB:** *Poor food intake during hospitalization is common and can lead to or perpetuate malnutrition; insufficient (i.e., ≤50%) food intake, regardless of nutritional state, is an independent predictor of length of stay (McCullough et al, 2017).*
- Recognize the characteristics that classify individuals as malnourished and refer to a dietitian for a complex nutritional assessment and intervention. **CEB:** *According to the Academy of Nutrition and Dietetics and the American Society of Parenteral and Enteral Nutrition, two or more of the following characteristics are recommended to support the diagnosis of malnutrition: insufficient energy intake, weight loss, loss of muscle mass, loss of subcutaneous fat, localized or generalized fluid accumulation, and/or decreased functional status (White, Guenter, & Jensen, 2012).* **EB:** *Dietetic consultations for adults in primary care settings appear to be effective for improvement in diet quality, diabetes outcomes (including blood glucose and glycated hemoglobin values), and weight loss outcomes (e.g., changes in weight and waist circumference) and to limit gestational weight gain (Mitchell et al, 2017).*
- Recognize clients who are likely to experience malnutrition in the context of social or environmental circumstances, characterized by cachexia without the presence of an inflammatory process (chronic disease-related malnutrition: those with organ failure, pancreatic cancer, rheumatoid arthritis, sarcopenic obesity, acute disease, or injury-related malnutrition; those with major infection, burns, trauma, or closed-head injuries accompanied by a marked inflammatory response). **EB:** *Mortality during admission was increased 10-fold in malnourished complex clients with chronic needs, and a clear influence of malnutrition on mortality at 5 months was observed (Burgos et al, 2020).* **EB:** *Clients who were identified with preexisting malnutrition had more days of ventilator support and a longer hospital stay than those who were not preburn malnutrition (Rosenfeld et al, 2019).*

▲ Note laboratory values cautiously; decrease in albumin and prealbumin may be indicators of the inflammatory response that often accompanies acute malnutrition, but it should not be used to diagnose malnutrition. Other potential indicators of inflammatory response include C-reactive protein, white blood cell count, and blood glucose values.

- Weigh the client daily in acute care and weekly to monthly in extended care at the same time (usually before breakfast) with same amount of clothing.
- Observe for potential barriers to eating such as willingness, ability, and appetite. **EB:** *Research findings provide evidence to support the positive impact of using visual assistance and full physical assistance to improve residents' pace of food intake and thus potentially improve the amount of food and fluid consumption (Liu et al, 2019).*
- If the client is unable to feed self, refer to Feeding **Self-Care** Deficit. If the client has difficulty swallowing, refer to Nursing Interventions for Impaired **Swallowing.** If the client is receiving tube feedings, refer to the Nursing Interventions for Risk for **Aspiration.**
- Advocate for the implementation of a feeding protocol, if not already in place, to avoid unnecessary and/or prolonged nothing by mouth/clear liquid diet (NPO/CLD) status in hospitalized clients. **EB:** *A study found that, on average, clients with unjustified NPO or CLD orders spent 3 days on an NPO or CLD diet, which corresponded to a mean of 10 missed meals (Gallinger et al, 2017).*
- For the client with anorexia nervosa, consider offering high-calorie foods and snacks often. **EB:** *Evidence supports a switch in current care practices for refeeding from a conservative approach to higher calorie refeeding, although this should only occur in a hospital setting (Bargiacchi et al, 2019).*
- For the client who is able to eat but has a decreased appetite, try the following activities:
  - Offer oral nutritional supplements (ONSs) based on client preference and indication of need. **EB:** *The use of high-protein ONSs (>20% energy from protein) reduces complications and readmissions with no impact on normal food intake (Loman et al, 2019).*
  - Avoid interruptions during mealtimes and offer companionship; meals should be eaten in a calm and peaceful environment. **EB:** *The average number and length of interruptions decreased and the average length of mealtime assistance provided to clients increased when the protected mealtime policy was implemented, resulting in a slight increase in energy and protein consumption (Goarley et al, 2020).*
  - Allow for access to meals or snacks during "off times" if the client is not available at time of meal delivery, monitor food and ONS intake, and communicate with dietitian/health provider. **EB:** *According to*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

a study conducted in an adult setting, interruption of mealtimes and not receiving food when a meal was missed were obstacles to poor food intake in clients (Keller et al, 2015).

- ❍ If the client lacks endurance, schedule rest periods before meals, and open packages and cut up food for the client. **EB:** *Residents who receive physical help more often during mealtimes have more calories and protein intake, whereas those who receive physical help intermittently have less intake (Keller et al, 2017).*

- ● For the client who has had a stroke, repeat nutritional screenings weekly and provide timely interventions for those at risk or who may already be malnourished. **EB:** *A systematic review revealed that malnutrition was present in up to 49% of clients after stroke and the incidence increased during rehabilitation (Sakai et al, 2019).*
- ● Monitor state of oral cavity (gums, tongue, mucosa, and teeth). Provide good oral hygiene before each meal. **EB:** *Xerostomia showed an association with incident malnutrition in edentulous people; hyposalivation can reduce the retention of the dentures as well as the comfort of wearing dentures, which may explain the interaction between xerostomia and dental status with regard to malnutrition (Kiesswetter et al, 2019).*
- ▲ Administer antiemetics and pain medications as ordered and needed before meals. *The presence of nausea or pain decreases the appetite.*
- ● If client is nauseated, remove cover of food tray before bringing it into the client's room. *The sudden, concentrated food odors that come when the cover is removed in front of the client can trigger nausea.*
- ● Work with the client to develop a plan for increased activity. *Immobility leads to negative nitrogen balance, which fosters anorexia.*

Critical Care

- ● Recognize the need to begin enteral feeding within 24 to 48 hours of admission to the critical care environment, once the client is free of hemodynamic compromise, if the client is unable to eat. **EB:** *Provision of early enteral nutrition was associated with a significant reduction in mortality and infectious morbidity, compared with withholding early enteral nutrition (delayed enteral nutrition or standard therapy) (McClave et al, 2016).*
- ● Recognize that it is important to administer feedings to the client and that frequently checking for gastric residual and fasting clients for procedures can be a limiting factor to adequate nutrition in the tube-fed client. **EB:** *Several studies have challenged the usefulness of residual gastric volume monitoring by gastric suction, showing that it led to reduced caloric intake without any benefits in terms of reducing the occurrence of vomiting or incidence of ventilator-associated pneumonia (Bouvet et al, 2020).*
- ● Refer to care plan for Risk for **Aspiration.**

Pediatric

- ▲ Use a nutritional screening tool designed for nurses such as the Subjective Global Nutrition Assessment (SGNA), and if the child's malnutrition is identified as moderate or severe, refer to a dietitian.
- ● Watch for symptoms of malnutrition in the child, including short stature; thin arms and legs; poor condition of skin and hair; visible vertebrae and rib cage; wasted buttocks; wasted facial appearance; lethargy; and, in extreme cases, edema.
- ● Weigh and measure the length (height) of the child and use a growth chart to help determine growth pattern, which reflects nutrition. Age-related growth charts are available from https://www.cdc.gov/growthcharts/.
- ▲ Refer to a health provider and a dietitian a child who is underweight for any reason. **EB:** *Good nutrition is extremely important for children to ensure sufficient growth and development of all body system (Pearson et al, 2018).*
- ● Work with the child and parent to develop an appropriate weight gain plan. *The goal for a child is sometimes to maintain existing weight as the body grows taller.*
- ● Recognize that a large percentage of girls and teenagers are dieting, which can result in nutritional problems.

Geriatric

- ● Screen for malnutrition in older clients. **EB:** *To find out which clients need a dietitian and further nutritional interventions, the nutritional status of each client must be routinely screened when they are admitted to the hospital and each week if they stay in hospital for a longer time period (Eglseer, 2017).*
- ● Screen for dysphagia in all older clients. **EB:** *Clients with impaired nutritional status (risk of malnutrition, malnutrition, and sarcopenia) is very high among clients with oropharyngeal dysphagia associated with*

either chronic diseases or aging and those with community-acquired pneumonia (Carrión et al, 2017). See the care plan for Impaired ***Swallowing.***

- Recognize that geriatric clients with moderate or severe cognition impairment have a significant risk for developing malnutrition. **EBN:** *Dementia is one of the factors most consistently associated with poor nutrition (Liu et al, 2019).*

▲ Interpret laboratory findings cautiously. Watch the color of urine for an indication of fluid balance; darker urine demonstrates dehydration. Low axillary moisture could indicate mild to moderate dehydration. **EB:** *Because urine color is correlated with urine specific gravity and urine osmolality, observing urine color is a low-cost method of monitoring dehydration (Kostelnik et al, 2021).*

- Consider using dining assistants and trained nonnursing staff, to provide feeding assistance care in extended care facilities to ensure adequate time for feeding clients as needed. **EB:** *A study found that when trained volunteers were able to deliver mealtime assistance on a large scale, nursing staff could complete clinical tasks (Roberts et al, 2017).*
- Encourage high-protein foods for the older client unless medically contraindicated by organ failure. **EB:** *Higher dietary protein intake was associated with a lower risk of becoming dependent in functional tasks requiring strength and endurance (Mustafa et al, 2018).*
- Recognize the implications of malnutrition on client strength and mobility. **EB:** *Dietary protein and/or amino acid intake combined with resistance exercise can stimulate muscle protein synthesis and slow breakdown (resulting in positive net protein balance) despite advancing age (Mustafa et al, 2018).*
- Monitor for onset of depression. **EB:** *Depression and eating styles contributed independently to poorer diet quality and higher intake of sweets and snacks/fast foods (Paans et al, 2019).*
- If the client is unable to feed self, refer to Nursing Interventions and *Rationales* for Feeding **Self-Care** Deficit. If client has impaired physical function, malnutrition, depression, or cognitive impairment, refer to care plan for **Frail Elderly** Syndrome.
- Emphasize the importance of good oral care in the older client.
- Initiate multiprofessional approach if the client is at high risk for pressure ulcers or has a pressure ulcer. **EB:** *This study suggests that it might be cost effective to provide basic preventive pressure injury care to all hospitalized clients; however, hospitals still need to invest in treatment technologies and skilled practitioners that enhance these preventive efforts (Padula et al, 2019).*

Home Care

- The preceding interventions may be adapted for home care use.
- Monitor food intake. Instruct the client in the intake of small frequent meals of foods with increased calories and protein.
- Assess the client's willingness and ability to eat. **EB:** *Poor intake among older adults has been found to be associated with lack of self-feeding ability, poor dining environment, inadequate time to eat, poor sensory properties of the food, and lack of choice and variety of the food (Keller et al, 2015).*
- Consider social factors that may interfere with nutrition (e.g., lack of transportation, inadequate income, lack of social support).
- Continue to encourage intake of oral nutritional support to help optimize oral intake. **EB:** *Consumption of oral nutrition supplements in hospitalized older adults in postdischarge settings improves overall nutrient intake (Loman et al, 2019).*

▲ Recognize that the client on home parenteral nutrition requires regularly scheduled laboratory work for electrolyte monitoring, increased risk of catheter-related complication, parenteral nutrition–associated liver disease (PNALD), and metabolic bone disease.

Client Family Teaching and Discharge Planning

- Develop a client-centered nutrition plan with measurable goals.
- Amplify the identified strengths in the client/family's food habits. Select appropriate teaching aids for the client/family's background and educational level.
- Review food safety guidelines and hand hygiene when working with food.
- Implement instructional follow-up to answer the client/family's questions.
- Recommend that clients discuss with their primary health provider before taking any supplements such as vitamins, minerals, and botanicals.
- Suggest community resources for home-delivered or congregate meals.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Encourage socialization at meal time.
- Teach the client and family how to manage tube feedings or parenteral therapy at home as needed.

Impaired Oral Mucous Membrane Integrity

Domain 11 Safety/protection Class 2 Physical injury

Morgan Nestingen, MSN, APRN, AGCNS-BC, OCN, ONN-CG

NANDA-I

Definition

Injury to the lips, soft tissue, buccal cavity, and/or oropharynx.

Defining Characteristics

Bad taste in mouth; bleeding; cheilitis; coated tongue; decreased taste perception; desquamation; difficulty eating; difficulty swallowing; dysphonia; enlarged tonsils; geographic tongue; gingival hyperplasia; gingival pallor; gingival pocketing deeper than 4 mm; gingival recession; halitosis; hyperemia; macroplasia; mucosal denudation; oral discomfort; oral edema; oral fissure; oral lesion; oral mucosal pallor; oral nodule; oral pain; oral papule; oral ulcer; oral vesicles; pathogen exposure; presence of mass; purulent oral-nasal drainage; purulent oral-nasal exudates; smooth atrophic tongue; spongy patches in mouth; stomatitis; white patches in mouth; white plaque in mouth; white, curd-like oral exudate; xerostomia

Related Factors

Alcohol consumption; decreased salivation; dehydration; depressive symptoms; difficulty performing oral self-care; inadequate access to dental care; inadequate knowledge of oral hygiene; inadequate oral hygiene habits; inappropriate use of chemical agent; malnutrition; mouth breathing; smoking; stressors

At-Risk Population

Economically disadvantaged individuals

Associated Conditions

Allergies; autosomal disorder; behavioral disorder; chemotherapy; decreased female hormone levels; decreased platelets; depression; immune system diseases; immunosuppression; infections; loss of oral support structure; mechanical factor; nil per os (NPO) >24 hours; oral trauma; radiotherapy; Sjögren's syndrome; surgical procedures; trauma; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Oral Health; Oral Hygiene; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Oral Health as evidenced by the following indicators: Cleanliness of mouth and teeth/Moisture of oral mucosa and tongue/Color of mucous membranes/Oral mucosa/tongue/gum integrity. (Rate the outcome and indicators of **Oral Health:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain intact, moist oral mucous membranes that are free of ulceration, inflammation, infection, and debris
- Demonstrate measures to maintain or regain intact oral mucous membranes
- Demonstrate oral hygiene knowledge and skills

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Oral Health Restoration

Example NIC Activities—Oral Health Restoration

Monitor condition of client's mouth including character of abnormalities; Instruct client to avoid commercial mouthwashes

Nursing Interventions and *Rationales*

▲ Inspect the oral cavity/teeth/gingiva at least once daily and note any discoloration; presence of debris; amount of plaque buildup; presence of lesions such as white lesions or patches, edema, or bleeding; and intactness of teeth. Refer to a dentist or periodontist as appropriate. **EB:** *Inspection is a critical diagnostic tool; observations can identify impending problems. Leukoplakia is the presence of uncharacterized white lesions, which can be a precursor to squamous cell carcinoma. If leukoplakia is observed, prompt referral for diagnosis and potential biopsy is indicated (Lingen et al, 2017; Abadeh et al, 2019).*

- If the client is free of bleeding disorders and able to swallow, encourage toothbrushing with a soft toothbrush using fluoride-containing toothpaste at least two times per day. **EB:** *The toothbrush is the most effective method for reducing plaque and controlling periodontal disease (Brignardello-Petersen, 2019).*
- Recommend the use of a power, rotation-oscillation toothbrush for removal of dental plaque and prevention of gingivitis. **EB:** *Two systematic reviews found the powered/oscillating toothbrush to be safe for use on both hard and soft dental tissues and more effective in cleaning teeth (Adam, Erb, & Grender, 2020; Elkerbout et al, 2020).*
- Use foam sticks to moisten the oral mucous membranes, clean out debris, and swab out the mouth of the edentulous client. Do not use foam sticks to clean the teeth unless the platelet count is very low and the client is prone to bleeding gums. **EB:** *Use of swabs is not an adequate substitute for toothbrushing but may be used to improve oral cleanliness and appearance (Onubogu et al, 2019). Adequate cleaning with toothbrush and fluoride toothpaste helps to reduce biofilm and prevent secondary infection of mucosal ulcers; if thrombocytopenia is severe, swabs with saline may reduce mucosal trauma to damaged tissues (Madeswaran et al, 2019).*
- Avoid lemon-glycerin swabs for oral care. **EB:** *Lemon-glycerin swabs are no longer recommended for use in tooth cleaning, prevention of ventilator-associated pneumonia, or treating xerostomia because they may cause disturbances in the pH and microbial balance within the oral cavity, decalcification, and worsening of xerostomia (Lavigne & Lavigne, 2019).*
- If the client does not have a bleeding disorder, encourage the client to perform interdental hygiene by flossing or cleaning between teeth with interdental brushes, woodsticks, or oral irrigation. If the client is unable to floss, assist with flossing or encourage the use of an oral irrigator (i.e., "water flossing"). **EB:** *A Cochrane review determined that all forms of interdental cleaning performed in addition to toothbrushing are associated with decreased gingivitis; no specific method of interdental cleaning was found to be superior (Worthington et al, 2019). Some interdental cleaning techniques may also assist with interdental plaque removal, but current findings are inconsistent (Ng & Lim, 2019; Slot, Valkenburg, & Van der Weijden, 2020).*
- Over-the-counter mouthwashes containing mint or essential oils may be used in combination with toothbrushing and interdental cleaning to maintain oral health. Avoid routine use of hydrogen peroxide, chlorhexidine, or alcohol-based mouthwashes. **EB:** *Mint and essential oil mouthwashes have been shown to exert an antimicrobial effect on biofilm, reduce loss of mineralization, and improve halitosis when used with toothbrushing and interdental cleaning with minimal discomfort and other adverse effects (Alaee et al, 2017; Albuquerque et al, 2018; Kulaksiz et al, 2018).*
- Provide oral hygiene if the client is unable to care for himself or herself. The nursing diagnosis Bathing **Self-Care** Deficit is then applicable.
- If the client is unable to brush own teeth, follow this procedure:
  - ❍ Position the client sitting upright or on side.
  - ❍ Use a soft bristle toothbrush.
  - ❍ Use fluoride toothpaste and tap water or saline as a solution.
  - ❍ Brush teeth in an up-and-down manner.
  - ❍ Suction as needed.

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

O

EB: *Each client must receive oral care including toothbrushing two times every day to maintain healthy teeth and mouth and to prevent complications associated with periodontitis (the advanced form of gum disease that can cause tooth loss), which is associated with health problems, such as cardiovascular disease, stroke, and bacterial pneumonia (American Dental Association [ADA], 2020).*

- Monitor the client's nutritional and fluid status to determine whether it is adequate. Dehydration and malnutrition predispose clients to impaired oral mucous membranes. Refer to the care plan for Deficient **Fluid** Volume or Imbalanced **Nutrition:** Less Than Body Requirements if applicable.
- Encourage fluid intake of up to 3000 mL/day if not contraindicated by the client's medical condition. Fluids help increase moisture in the mouth, which protects the mucous membranes from damage.

▲ Determine the client's usual method of oral care and address any concerns regarding oral hygiene. If the client has a dry mouth (xerostomia):

- ❍ Recognize that more than 50 classes of medications may cause xerostomia, which is often exacerbated by polypharmacy. When feasible, medications can be discontinued or replaced to increase the client's comfort (Marcott et al, 2020).
- ❍ Provide saliva substitutes as ordered. **EB:** *Saliva substitutes are helpful to decrease the discomfort of dry mouth and may help prevent stomatitis (Vinke et al, 2020).*
- ❍ Suggest the client chew sugarless gum or sugarless sour candy to promote salivary flow. **EB:** *Both sugarless gum and candy stimulate the formation of saliva (Hemalatha et al, 2019).*
- ❍ Examine the oral cavity for signs of caries, dental plaque, infection, mucositis ulceration, and oral candidiasis. **EB:** *Untreated xerostomia may result in these conditions (Hemalatha et al, 2019; Kurapati et al, 2020).*

- Recommend that the client decrease or preferably stop intake of soft drinks. Sugar-containing soft drinks can cause cavities, and the low pH of the drink can cause erosion in teeth. **EB:** *Diets high in sugar are strongly associated with formation of caries in adults and children (Laniado et al, 2020).*
- If client has halitosis, review good oral care with the client including brushing teeth, using floss, and brushing the tongue. **EB:** *Halitosis can be a beginning sign of gingivitis and can be eradicated by a good program of dental hygiene (Raghu Ram, 2019).*
- Instruct the client with halitosis to clean the tongue when performing oral hygiene; brush tongue with tongue scraper or toothbrush and follow with a mouth rinse. **EB:** *A Cochrane review found limited evidence that tongue cleaning, chewing gum, systemic deodorizing agents, topical agents, and specialized toothpastes/mouth rinses were effective in controlling halitosis; toothbrushing combined with tongue cleaning and mouthwash has been identified as the most effective method of control (Van der Sluijs et al, 2018; Nagraj et al, 2019).*

▲ Assess the client for underlying medical conditions that may be causing halitosis. Causes of halitosis can be subdivided into three categories: oral origin, in which good mouth care can help prevent halitosis; halitosis from the upper respiratory tract, including the sinuses and nose; and halitosis from systemic diseases that are blood-borne, volatilized in the lungs, and expelled from the lower respiratory tract. Potential sources of blood-borne halitosis are some systemic diseases, metabolic disorders, medication, and certain foods such as onions and garlic (*Raghu Ram, 2019*).

- Keep the lips well lubricated using a water-based or aloe-based lip balm. **EB:** *This is a comfort measure (Kurapati et al, 2020).*

Client Receiving Chemotherapy and/or Radiation

- Ensure that the client receives a comprehensive oral examination before initiation of chemotherapy or radiation, with aggressive preventive dental care given as needed. **EB:** *Baseline assessment is necessary to identify posttreatment changes to oral health (Hong et al, 2019; Quinn et al, 2020b).*
- Provide both verbal and written instruction about the need for and method of providing frequent oral care to the client before radiation therapy or chemotherapy. Assess the condition of the oral cavity daily in the client receiving radiation or chemotherapy. **EB:** *Ongoing reassessment supports early identification and management of treatment-related changes to oral health (Hong et al, 2019; Quinn et al, 2020b).*
- For measurement of presence or severity of mucositis, use the Oral Mucositis Assessment Scale (OMAS). **EBN:** *This is an instrument that has two components: clinician's assessment of presence and severity of mucositis and client report about pain, difficulty swallowing, and ability to eat. Scores indicating the presence of a more severe oral mucositis are associated with decreased quality of life (Franco et al, 2017; Minhas et al, 2021).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Use a protocol to prevent/treat mucositis that includes the following:
  - ❍ Use a soft toothbrush that is replaced on a regular basis; brush teeth at least two times a day and for at least 90 seconds. Continue to floss teeth daily.
  - ❍ Use a bland, alcohol-free rinse to remove debris and moisten the oral cavity. Rinse the mouth often (every 2 hours while awake) if the client has mouth sores.
  - ❍ Avoid tobacco, alcohol, and irritating foods (hot, rough, acidic, or spicy).
  - ❍ Use a valid and reliable pain assessment tool and treatment of pain as needed.

  EB: *Use of an oral care protocol helps to decrease oral mucositis in clients receiving treatment for cancer (Hong et al, 2019; Naibaho et al, 2020).*
- Help the client use a mouth rinse of normal saline or salt and soda every 1 to 2 hours for prevention and treatment of stomatitis. A typical mixture is 1 teaspoon of salt or sodium bicarbonate per pint of water. Clients are directed to take a tablespoon of the rinse and swish it in the mouth for 30 seconds, then expectorate. **EB:** *Rinses are helpful to remove debris and hydrate the oral mucous membranes; sodium bicarbonate can discourage yeast colonization (Hong et al, 2019; Naibaho et al, 2020).*

▲ If the mouth is severely inflamed and it is painful to swallow, contact the health care provider for a topical anesthetic or analgesic order. Modification of oral intake (e.g., soft or liquid diet) may also be necessary to prevent friction trauma. *The nursing diagnosis Imbalanced* ***Nutrition:*** *Less Than Body Requirements may apply.*

- If the client's platelet count is lower than 50,000/mm^3 or the client has a bleeding disorder, use a soft toothbrush or a toothette that is not soaked in glycerin or flavorings; if the client cannot tolerate a toothbrush or a toothette, a piece of gauze wrapped around a finger can be used to remove plaque and debris. **EB:** *Use of toothettes is not an adequate substitute for toothbrushing but may be used to improve oral cleanliness and appearance (Onubogu et al, 2019). Adequate cleaning with toothbrush and fluoride toothpaste helps to reduce biofilm and prevent secondary infection of mucosal ulcers; if thrombocytopenia is severe, toothettes with saline may reduce mucosal trauma to damaged tissues (Madeswaran et al, 2019).*

Critical Care—Client on a Ventilator

- Use a soft toothbrush to brush teeth to clean the client's teeth at least every 12 hours; use suction to remove secretions. Provide oral moisturizer to oral mucosa and lips every 4 hours. Recognize that good oral care is paramount in the prevention of ventilator-associated events (VAEs) and ventilator-associated pneumonia (VAP). **EBN:** *Increased plaque on the teeth is associated with increased contamination of the mouth and incidence of VAP (Takahama et al, 2021). An integrative review of the literature found that consistently performing frequent oral care along with other interventions (e.g., head of bed >30 degrees, adequate endotracheal tube cuff pressure to reduce aspiration, daily evaluation of client's readiness for extubation) and oral moisturizing reduced VAP and decreased overall health care expenses (Quinn et al, 2020a).*

▲ Apply chlorhexidine gluconate mouthwash or gel in the oral cavity after performing tooth brushing, which may reduce the risk of the client developing VAEs and VAP. **EB:** *Routine oral care with chlorhexidine gluconate in the care of ventilated clients is associated with reduced risk of VAEs and VAP (Quinn et al, 2020a).*

Geriatric

- Determine the functional ability of the client to provide his or her own oral care. Interventions must be directed toward both treatment of the functional loss and care of oral health.
- Provide appropriate oral care to older adults with a self-care deficit, brushing the teeth after breakfast and in the evening. **EB:** *The ADA recommends toothbrushing twice daily in addition to interdental cleaning (ADA, 2021). Numerous references have found oral care effective in preventing new-onset pneumonia, although heterogeneity in interventions weakens the level and consistency of evidence* (Mitchell et al, 2019; Quinn et al, 2020a; Satheeshkumar, Papatheodorou, & Sonis, 2020).
- If the client has dementia or delirium and exhibits care-resistant behavior, such as fighting, biting, or refusing care, use the following method:
  - ❍ Ensure client is in a quiet environment such as own bathroom, sitting or standing at the sink to prime memory for appropriate actions.
  - ❍ Approach the client at eye level within his or her range of vision.
  - ❍ Approach with a smile and begin conversation with a touch of the hand and gradually move up.
  - ❍ Use mirror–mirror technique, standing behind the client, and brush and floss teeth.

- ❍ Use respectful adult speech. Avoid "elderspeak," a style of speech characterized by short phrases and questions uttered in a sing-song voice and use of collective pronouns and intimate terms (e.g., first name, nicknames, "deary" or "honey"). **EB:** *Elderspeak is perceived as demeaning and is a documented trigger for care-resistant behavior (Schnabel et al, 2020; Zhang, Zhao, & Meng, 2020).*
- ❍ Promote self-care in which client brushes own teeth if possible.
- ❍ Use distractors when needed: talking, reminiscing, singing. **EBN:** *Use of specific techniques can decrease resistance to nursing care and increase the effectiveness of nurses providing oral care to older clients (National Institute for Health and Care Excellence [NICE], 2016).*

- ● Carefully observe the oral cavity and lips for abnormal lesions such as white or red patches, masses, ulcerations with an indurated margin, or a raised granular lesion. **EB:** *Malignant lesions are more common in older adults than in younger persons, especially if there is a history of smoking or alcohol use. Suspicious lesions identified on inspections should be referred for potential biopsy and diagnosis (Lingen et al, 2017; Abadeh et al, 2019).*
- ● Ensure that dentures are removed and cleaned regularly, preferably after every meal and before bedtime. Dentures left in the mouth at night may impede circulation to the palate and predispose the client to oral lesions.

Home Care

- ● The interventions described previously may be adapted for home care use.
- ● Instruct the client in ways to soothe the oral cavity (e.g., cool beverages, popsicles, viscous lidocaine).
- ▲ If necessary, refer for home health aide services to support the family in oral care and observation of the oral cavity.

Client/Family Teaching and Discharge Planning

- ● Teach the client how to inspect the oral cavity and monitor for signs and symptoms of infection or complications and when to call the health care provider. **EB:** *Education is key to supporting clients' understanding of their oral health and thus their self-care behaviors (Albano et al, 2019).*
- ● Recommend the client not smoke, use chewing tobacco, or drink excessive amounts of alcohol. **EB:** *Tobacco use, alcohol consumption, human papillomavirus, and poor oral hygiene are all independently associated with the development of squamous cell carcinomas of the head, neck, and oral cavity (Ganly et al, 2019); use of alcohol and tobacco may synergistically increase overall risk (Mello et al, 2019).*
- ● Teach the client and family, if necessary, how to perform appropriate mouth care. Use the motivational interviewing technique. **EB:** *Recent systematic reviews have demonstrated an association between motivational interviewing with improved adherence to oral hygiene self-care and may decrease gingival bleeding times and plaque scores; results are more significant among high-risk groups (Carra et al, 2020; Carrinconde Colvara et al, 2021). See Appendix C on Evolve for motivational interviewing.*

Risk for Impaired Oral Mucous Membrane Integrity

Domain 11 Safety/protection
Class 2 Physical injury

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to injury to the lips, soft tissues, buccal cavity, and/or oropharynx, which may compromise health.

Risk Factors

Alcohol consumption; decreased salivation; dehydration; depressive symptoms; difficulty performing oral self-care; inadequate access to dental care; inadequate knowledge of oral hygiene; inadequate oral hygiene habits; inappropriate use of chemical agent; malnutrition; mouth breathing; smoking; stressors

At-Risk Population

Economically disadvantaged individuals

Associated Conditions

Allergies; autosomal disorder; behavioral disorder; chemotherapy; decreased female hormone levels; decreased platelets; depression; immune system diseases; immunosuppression; infections; loss of oral support structure; mechanical factor; nil per os (NPO) >24 hours; oral trauma; radiotherapy; Sjögren's syndrome; surgical procedures; trauma; treatment regimen

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching, and References

Refer to care plan for Impaired **Oral Mucous Membrane** Integrity.

O

Obesity

Domain 2 Nutrition Class 1 Ingestion

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

A condition in which an individual accumulates excessive fat for age and gender that exceeds overweight.

Defining Characteristics

Adult: Body mass index >30 kg/m^2; Child 2 to 18 years: body mass index >30 kg/m^2 or >95th percentile or 30 kg/m^2 for age and gender; Child <2 years: term not used with children at this age

Related Factors

Abnormal eating behavior patterns; abnormal eating perception patterns; average daily physical activity is less than recommended for age and gender; consumption of sugar-sweetened beverages; dyssomnias; energy expenditure below energy intake based on standard assessment; excessive alcohol consumption; fear regarding lack of food supply; frequent snacking; high frequency of restaurant or fried food; insufficient dietary calcium intake by children; portion sizes larger than recommended; sedentary behavior occurring for ≥2 hours/day; shortened sleep time; solid foods as major food source at <5 months of age

At-Risk Population

Economically disadvantaged individuals; individuals who experienced premature pubarche; individuals who experienced rapid weight gain during childhood; individuals who experienced rapid weight gain

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

during infancy; individuals who inherit interrelated factors; individuals who were not exclusively breastfed; individuals who were overweight during infancy; individuals whose mothers had gestational diabetes; individuals whose mothers have diabetes; individuals whose mothers smoke during childhood; individuals whose mothers smoke during pregnancy; individuals with high disinhibition and restraint eating behavior score; individuals with parents who are obese neonates whose mothers had gestational diabetes

Associated Conditions

Inborn genetic diseases

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Nutritional Status; Nutritional Status: Food and Fluid Intake; Nutrient Intake; Weight Control

Example NOC Outcome with Indicators

Nutritional Status as evidenced by the following indicators: Food and fluid intake/Hydration/Body mass index/Weight-height ratio/Hematocrit. (Rate the outcome and indicators of **Nutritional Status:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Explain how to eat according to the US Dietary Guidelines
- Design dietary modifications to meet individual long-term goal of health, using principles of variety, balance, and moderation
- Maintain weight within normal range for height and age

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Nutrition Management; Nutritional Counseling; Weight Reduction Assistance

Example NIC Activities—Nutrition Management

Determine the client's motivation for changing eating habits; Develop with the client a method to keep a daily record of intake

Nursing Interventions and *Rationales*

- Assess the meaning and importance of food in the client's life. **EB:** *Research found strong associations between the different domains of food meanings and behavioral outcomes (Arbit et al, 2017).*
- Assess client readiness to determine whether the client is ready to discuss weight loss and/or would like weight loss information. **EB:** *Client motivation is a key component of success in a weight loss program and a prerequisite for weight loss therapy (Raynor & Champagne, 2016).*
- Use a motivational interviewing technique when working with clients to promote healthy eating and weight loss. **EB:** *Research shows significant weight loss for clients when motivational interviewing techniques were used (Barnes et al, 2018).*
- Counsel the client to measure regularly consumed foods periodically. Help the client learn usual portion sizes. Measuring food alerts the client to normal portion sizes. Estimating amounts can be extremely inaccurate. **EB:** *A randomized controlled trial of 278 overweight and obese participants was conducted to increase portion size awareness with results that demonstrated the intervention improved portion control behavior and in turn influenced body mass index (BMI) (Poelman et al, 2015).*
- Assist the client to develop a system of self-management, which may include self-monitoring of weight and BMI; realistic goal setting, planning, and action planning for improved dietary intake and physical

activity; problem-solving; and tracking dietary intake and exercise. **EB:** *A key component of successful weight loss and maintenance is regular self-monitoring (Thomason et al, 2016).*

- Encourage the client to adopt dietary as well as physical activity changes. **EB:** *A research review found that aerobic exercise without additional dietary changes achieves only a 3% to 5% weight loss in clients with obesity (McCafferty, Hill, & Gunn, 2020).*
- Document the client's height and weight and teach the significance of his or her BMI in relationship to current health. Use a chart or a website such as http://www.cdc.gov/healthyweight/assessing/bmi/index.html (Centers for Disease Control and Prevention [CDC], 2020a). **EB:** *Successful treatment of overweight and obesity in adults requires adoption and maintenance of effective self-monitoring (Raynor & Champagne, 2016).*
- Encourage the client to engage in moderate- to vigorous-intensity physical activity for at least 200 to 300 minutes weekly for weight loss. **EB:** *There is strong evidence to demonstrate that clients who engage in moderate- to vigorous-intensity physical activity for greater amounts of time decrease weight gain (Jakicic et al, 2019).*
- Recommend that the client limit fast food and take-out meals. **EB:** *A study found that fast-food consumption was the most frequent risk factor for adiposity found in 61.67% of study participants (Popa et al, 2020).*
- Assist the client to reframe slips in weight loss or physical activity behavior as lapses that are a single event and not a full return to previous unhealthy behaviors. Relapse prevention strategies (Centers for Disease Control and Prevention, 2020a) include managing lapses in healthy behavior, identifying high-risk situations for relapses, self-monitoring, providing social support, enhancing skills for coping, and increasing self-efficacy for avoiding relapse. **EB:** *A study of a weight maintenance intervention, delivered primarily by telephone, modestly slowed the rate of weight regain (Voils et al, 2017).*
- Assist clients to engage their social support systems either digitally or face to face in ways that facilitate weight loss, healthy eating, and physical activity behavior change. **EB:** *Significant others, family, friends, and coworkers can facilitate or hinder weight loss success (Romo, 2018).*
- Assist the client to reframe the goal from a focus on outcome (weight loss) to a focus on process (weight-loss behaviors) for weight loss. **EB:** *A study found that the self-monitoring behaviors of self-weigh-in, daily steps, high-intensity activity, and persistent food logging were significant predictors of weight loss during a 6-month intervention (Painter et al, 2017).*
- Assist the client to implement informal and formal mindfulness-based interventions (MBIs). Informal MBIs include mindful eating, increasing awareness of hunger and satiety cues, taste satisfaction, and decreasing impulsive tendencies to overeat when experiencing negative emotions. Meditation practice is a formal MBI. **EB:** *Results of a research review suggested that a combination of formal and informal MBIs are effective in reducing weight and improving obesity-related eating behaviors among individuals with overweight and obesity (Carrière et al, 2018).*
- Assist the client to develop stimulus control techniques designed to reduce environmental cues associated with eating behaviors. Specifically, clients should be taught to limit the presence of high-calorie/high-fat foods in the home; to reduce the visibility of unhealthy food choices in the home; to limit where and when they eat; to avoid distractions (Newton et al, 2018) such as reading, using the computer, or watching television when eating; and to eat more slowly. **EB:** *Stimulus control strategies are a key to successful weight loss and weight maintenance in conjunction with other weight-loss strategies (Butryn et al, 2017).*
- Encourage 7.5 to 8.5 hours of sleep nightly. **EB:** *Evidence suggests that weight management is hindered when attempted in the context of sleep restriction because there is an upregulation of reward, pleasure, and salience networks in response to food stimuli (St-Onge, 2017).*
- Refer the client to a weight loss–related therapy group. **EBN:** *A study found significant changes in BMI, waist circumference, body fat percentage, and strength of the lower limbs for weight-loss group therapy participants (Ferrari et al, 2017).*
- Recommend that clients use dietary supplements such as vitamins and minerals after consulting with their primary health care provider. **EB:** *Research shows that micronutrient deficits are prevalent in weight-loss plans, especially vitamin B_{12}, calcium, and vitamin D (Engel et al, 2018).*
- Recommend the CDC behavior modification approach "reflect, replace, and reinforce" to improve eating habits. **EB:** *Reflect, replace, and reinforce consists of the following: (1) Reflect about intake through food journals, listing food habits, and identification of eating cues. (2) Replace habits identified during reflection with new and healthier behaviors, such as eating more slowly or planning meals ahead of time. (3) Reinforce changes made and having patience with the process (CDC, 2020b).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Incorporate the following recommendations from the Academy of Nutrition and Dietetics "Interventions for the Treatment of Overweight and Obesity in Adults" (Raynor & Champagne, 2016):
  - Assess food- and nutrition-related history; anthropometric measures; biochemical data, medical tests, and procedures; nutrition-focused physical findings; and client history.
  - Assess the energy intake and nutrient content of the diet.
  - Use height and weight to calculate BMI; use waist circumference to determine risk of cardiovascular disease, type 2 diabetes, and all-cause mortality.
  - Use a measured resting metabolic rate to determine energy needs.
  - Set a realistic weight-loss goal such as one of the following: up to 2 pounds/week, up to 10% of baseline body weight, or a total of 3% to 5% of baseline weight if cardiovascular risk factors (hypertension, hyperlipidemia, and hyperglycemia) are present.
  - To achieve weight loss, use an individualized diet, including client preferences and health status, to achieve and maintain nutrient adequacy and reduce caloric intake, based on one of the following caloric reduction strategies: 1200 to 1500 kcal/day for women and 1500 to 1800 kcal/day for men, with an energy deficit of approximately 500 or 750 kcal/day.

▲ Refer for medical management of obesity. **EB:** *Pharmacological intervention for clients with obesity is indicated for individuals with a BMI of >30 kg/m², or ≥27 kg/m² with obesity-related comorbidities (McCafferty, Hill, & Gunn, 2020).*

Pediatric

- Offer obese or overweight adolescents healthy methods for weight loss. **EB:** *A recent study showed statistically significant health behavior improvements after implementing a developmentally informed intervention to increase positive health diet and exercise behaviors (Issner et al, 2017).*
- Offer families of obese or overweight children prejudice-free, individually accepting, and supportive interventions to address weight loss. **EB:** *A review summarized recent evidence on weight stigma and found that it is highly prevalent among youth with high body weight, who are targets of weight-based victimization from peers, parents, and teachers (Puhl & Lessard, 2020).*
- Recommend that families eat together for at least one meal per day. **EB:** *A large Korean study found that the frequency of family meals was inversely associated with childhood overweight or obesity (Lee, Lee, & Park, 2016).*
- Recommend involving the family in planning meals and food preparation. Children can learn about nutrition as they help plan and make meals. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed increased cooking skills among the children participating (Fulkerson et al, 2018).*
- Assist parents at being good role models of healthy eating. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed significantly improved parental self-efficacy for identifying appropriate portion sizes (Fulkerson et al, 2018).*
- Recommend that the family try new foods, either a new food or recipe every week. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed decreasing child neophobia scores over time that were developmentally appropriate (Fulkerson et al, 2018).*

Geriatric

- Determine the risks and benefits of weight loss in the older client. A BMI greater than 30 in the older client suggests a moderate weight-loss approach. **EB:** *Recommendations for treating obesity in the elderly include ensuring a balanced and appropriately distributed intake of high-quality nutrients, particularly of high-quality protein (i.e., 1.2 to 1.5 g/kg of body weight), limiting the intake of simple carbohydrates and saturated fats, and providing sufficient intake of calcium and vitamin D_3 (Blaž, 2016).*
- Observe for social, psychological, and economic factors that influence diet quality. **EB:** *An exploratory study of diet quality influences in community-dwelling older individuals revealed the following influences: food experiences, retirement, bereavement, medical conditions, food environment, food-related habits, social engagement, personal/psychological factors, and transportation (Bloom et al, 2017).*

Multicultural

- Tailor nutritional interventions to be consistent with cultural beliefs, norms, and values. **EB:** *A systemic review of culturally tailored interventions for Hispanic women included literacy modification, Hispanic foods/recipes, cultural diabetes beliefs, family/friend participation, structured community input, and innovative experiential learning (McCurley et al, 2017).*

- Offer tailored lifestyle counseling via the telephone. **EBN:** *Investigators have included biweekly and/or monthly health coach calls for African American participants with significant weight gain prevention (Goode et al, 2017).*
- Integrate weight loss and weight maintenance interventions with church faith–based supports for African American clients. **EB:** *Recent research found a church-based weight loss intervention using automated text messages was well-received by African American participants and resulted in significant weight loss (Newton, 2018).*

Client/Family Teaching and Discharge Planning

- The majority of the preceding interventions involve teaching.
- Work with the family members regarding information on how to support and promote weight loss and healthy intakes.

Overweight Domain 2 Nutrition Class 1 Ingestion

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

A condition in which an individual accumulates abnormal or excessive fat for age and gender.

Defining Characteristics

Adult: Body mass index >25 kg/m^2; Child 2 to 18 years: Body mass index >85th percentile or 25 kg/m^2 but <95th percentile or 30 kg/m^2 for age and gender; Child <2 years: Weight-for-length >95th percentile

Related Factors

Abnormal eating behavior patterns; abnormal eating perception patterns; average daily physical activity is less than recommended for age and gender; consumption of sugar-sweetened beverages; dyssomnias; energy expenditure below energy intake based on standard assessment; excessive alcohol consumption; fear regarding lack of food supply; frequent snacking; high frequency of restaurant or fried food; inadequate knowledge of modifiable factors; insufficient dietary calcium intake by children; portion sizes larger than recommended; sedentary behavior occurring for ≥ 2 hours/day; shortened sleep time; solid foods as major food source at < 5 months of age

At-Risk Population

ADULT: Body mass index approaching 25 kg/m^2; CHILD 2 to 18 years: Body mass index approaching 85th percentile or 25 kg/m^2; CHILD < 2 years: Weight-for-length approaching 95th percentile; children with body mass index crossing percentiles upward; children with high body mass index percentiles for age and gender; economically disadvantaged individuals; individuals who experienced premature pubarche; individuals who experienced rapid weight gain during childhood; individuals who experienced rapid weight gain during infancy; individuals who inherit interrelated factors; individuals who were not exclusively breastfed; individuals who were obese during childhood; individuals whose mothers have diabetes; individuals whose mothers smoke during childhood; individuals whose mothers smoke during pregnancy; individuals with high disinhibition and restraint eating behavior score; individuals with parents who are obese

Associated Conditions

Inborn genetic disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Nutritional Status; Nutritional Status: Food and Fluid Intake; Nutrient Intake; Weight Control

Example NOC Outcome with Indicators

Nutritional Status as evidenced by the following indicators: Food and fluid intake/Hydration/Body mass index/Weight-height ratio/Hematocrit. (Rate the outcome and indicators of **Nutritional Status:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Explain how to eat according to the US Dietary Guidelines
- Design dietary modifications to meet individual long-term goal of health, using principles of variety, balance, and moderation
- Maintain weight within normal range for height and age

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Nutrition Management; Nutritional Counseling; Weight Reduction Assistance

Example NIC Activities—Nutrition Management

Determine the client's motivation for changing eating habits; Develop with the client a method to keep a daily record of intake

Nursing Interventions and *Rationales*

- Assess the meaning and importance of food in the client's life. **EB:** *Research found strong associations between the different domains of food meanings and behavioral outcomes (Arbit et al, 2017).*
- Assess client readiness to determine whether the client is ready to discuss weight loss and/or would like weight-loss information. **EB:** *Client motivation is a key component of success in a weight-loss program and a prerequisite for weight-loss therapy (Raynor & Champagne, 2016).*
- Use a motivational interviewing technique when working with clients to promote healthy eating and weight loss. **EB:** *Research shows significant weight loss for clients when motivational interviewing techniques were used (Barnes et al, 2018).*
- Counsel the client to measure regularly consumed foods periodically. Help the client learn usual portion sizes. Measuring food alerts the client to normal portion sizes. Estimating amounts can be extremely inaccurate. **EB:** *A randomized controlled trial of 278 overweight and obese participants was conducted to increase portion size awareness with results that demonstrated the intervention improved portion control behavior and in turn influenced body mass index (BMI) (Poelman et al, 2015).*
- Assist the client to develop a system of self-management, which may include self-monitoring of weight and BMI; realistic goal setting, planning, and action planning for improved dietary intake and physical activity; problem-solving; and tracking dietary intake and exercise. **EB:** *A key component of successful weight loss and maintenance is regular self-monitoring (Thomason et al, 2016).*
- Document the client's height and weight and teach the significance of his or her BMI in relationship to current health. Use a chart or a website such as http://www.cdc.gov/healthyweight/assessing/bmi/index.html (Centers for Disease Control and Prevention [CDC], 2020a). **EB:** *Successful treatment of overweight and obesity in adults requires the adoption and maintenance of effective self-monitoring (Raynor & Champagne, 2016).*
- Encourage the client to engage in vigorous-intensity physical activity for at least 150 minutes weekly or moderate-intensity physical activity for at least 300 minutes weekly. **EB:** *Research evidence suggests that regular physical activity is critical for weight loss and weight-loss maintenance (Ostendorf et al, 2018).*
- Recommend the client avoid eating in fast-food restaurants. **EB:** *A study found that fast-food consumption was the most frequent risk factor for adiposity found in 61.67% of study participants (Popa et al, 2020).*
- Assist the client to reframe slips in weight loss or physical activity behavior as lapses that are a single event and not a full return to previous unhealthy behaviors. Relapse prevention strategies include managing lapses in healthy behavior, identifying high-risk situations for relapses, self-monitoring, providing social

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

support, enhancing skills for coping, and increasing self-efficacy for avoiding relapse. **EB:** *A study of a weight maintenance intervention, delivered primarily by telephone, modestly slowed the rate of weight regain (Voils et al, 2017).*

- Assist clients to engage their social support systems either digitally or face to face in ways that facilitate weight loss, healthy eating, and physical activity behavior change. **EB:** *Significant others, family, friends, and coworkers can facilitate or hinder weight-loss success (Romo, 2018).*
- Assist the client to reframe the goal from a focus on outcome (weight loss) to a focus on process (eating behaviors) for weight loss. **EB:** *A study found that the self-monitoring behaviors of self-weigh-in, daily steps, high-intensity activity, and persistent food logging were significant predictors of weight loss during a 6-month intervention (Painter et al, 2017).*
- Assist the client to implement informal and formal mindfulness-based interventions (MBIs). Informal MBIs include mindful eating, increasing awareness of hunger and satiety cues, taste satisfaction, and decreasing impulsive tendencies to overeat when experiencing negative emotions. Meditation practice is a formal MBI. **EB:** *Results of a research review suggest that a combination of formal and informal MBIs are effective in reducing weight and improving obesity-related eating behaviors among individuals with overweight and obesity (Carrière et al, 2018).*
- Assist the client to develop stimulus control techniques designed to reduce environmental cues associated with eating behaviors. Specifically, clients should be taught to limit the presence of high-calorie/high-fat foods in the home; to reduce the visibility of unhealthy food choices in the home; to limit where and when they eat; to avoid distractions such as reading, using the computer, or watching television when eating; and to eat more slowly. **EB:** *Stimulus control strategies are the key to successful weight loss and weight maintenance in conjunction with other weight-loss strategies (Butryn et al, 2017).*
- Encourage 7.5 to 8.5 hours of sleep nightly. **EB:** *Evidence suggests that weight management is hindered when attempted in the context of sleep restriction because there is an upregulation of reward, pleasure, and salience networks in response to food stimuli (St-Onge, 2017).*
- Refer the client to a weight loss–related therapy group. **EBN:** *A study found significant changes in BMI, waist circumference, body fat percentage, and strength of the lower limbs for weight-loss group therapy participants (Ferrari et al, 2017).*
- Recommend that clients use dietary supplements such as vitamins and minerals after consulting with their primary health care provider. **EB:** *Research shows that micronutrient deficits are prevalent in weight-loss plans, especially vitamin B_{12}, calcium, and vitamin D (Engel et al, 2018).*
- Recommend the CDC behavior modification approach "reflect, replace, and reinforce" to improve eating habits. **EB:** *Reflect, replace, and reinforce consists of the following: (1) Reflect about intake through food journals, listing food habits, and identification of eating cues. (2) Replace habits identified during reflection with new and healthier behaviors, such as eating more slowly or planning meals ahead of time. (3) Reinforce changes made and having patience with the process (CDC, 2020b).*
- Incorporate the following recommendations from the Academy of Nutrition and Dietetics "Interventions for the Treatment of Overweight and Obesity in Adults" (Raynor & Champagne, 2016):
  - Assess food- and nutrition-related history; anthropometric measures; biochemical data, medical tests, and procedures; nutrition-focused physical findings; and client history.
  - Assess the energy intake and nutrient content of the diet.
  - Use height and weight to calculate BMI and waist circumference to determine risk of cardiovascular disease, type 2 diabetes, and all-cause mortality.
  - Use a measured resting metabolic rate to determine energy needs.
  - Set a realistic weight-loss goal such as one of the following: up to 2 pounds/week, up to 10% of baseline body weight, or a total of 3% to 5% of baseline weight if cardiovascular risk factors (hypertension, hyperlipidemia, and hyperglycemia) are present.
  - To achieve weight loss, use an individualized diet, including client preferences and health status, to achieve and maintain nutrient adequacy and reduce caloric intake, based on one of the following caloric reduction strategies: 1200 to 1500 kcal/day for women and 1500 to 1800 kcal/day for men, and energy deficit of approximately 500 or 750 kcal/day.

Pediatric

- Offer obese or overweight adolescents healthy methods for weight loss. **EB:** *A study showed statistically significant health behavior improvements after implementing a developmentally informed intervention to increase positive health diet and exercise behaviors (Issner et al, 2017).*

- Offer families of obese or overweight children prejudice-free, individually accepting, and supportive interventions to address weight loss. **EB:** *A review summarized recent evidence on weight stigma and found that it is highly prevalent among youth with high body weight, who are targets of weight-based victimization from peers, parents, and teachers (Puhl & Lessard, 2020).*
- Recommend that families eat together for at least one meal per day. **EB:** *A large Korean study found that the frequency of family meals was inversely associated with childhood overweight or obesity (Lee, Lee, & Park, 2016).*
- Recommend involving the family in planning meals and food preparation. Children can learn about nutrition as they help plan and make meals. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed increased cooking skills among the children participating (Fulkerson et al, 2018).*
- Assist parents at being good role models of healthy eating. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed significantly improved parental self-efficacy for identifying appropriate portion sizes (Fulkerson et al, 2018).*
- Recommend that the family try new foods, either a new food or recipe every week. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed decreasing child neophobia scores over time that were developmentally appropriate (Fulkerson et al, 2018).*

Geriatric

- Determine the risks and benefits of weight loss in the older client. A BMI greater than 30 in the older client suggests a moderate weight-loss approach. **EB:** *Recommendations for treating obesity in the elderly include ensuring a balanced and appropriately distributed intake of high-quality nutrients, particularly of high-quality protein (i.e., 1.2 to 1.5 g/kg of body weight), limiting the intake of simple carbohydrates and saturated fats, and providing sufficient intake of calcium and vitamin D_3 (Blaž, 2016).*
- Observe for social, psychological, and economic factors that influence diet quality. **EB:** *An exploratory study of diet quality influences in community-dwelling older individuals revealed the following influences: food experiences, retirement, bereavement, medical conditions, food environment, food-related habits, social engagement, personal/psychological factors, and transportation (Bloom et al, 2017).*

Multicultural

- Tailor nutritional interventions to be consistent with cultural beliefs, norms, and values. **EB:** *A systemic review of culturally tailored interventions for Hispanic women included literacy modification, Hispanic foods/recipes, cultural diabetes beliefs, family/friend participation, structured community input, and innovative experiential learning (McCurley et al, 2017).*
- Offer tailored lifestyle counseling via the telephone. **EBN:** *Investigators have included biweekly and/or monthly health coach calls for African American participants with significant weight gain prevention (Goode et al, 2017).*
- Integrate weight loss and weight maintenance interventions with church faith-based supports for African American clients. **EB:** *Recent research found that a church-based weight loss intervention using automated text messages was well-received by African American participants and resulted in significant weight loss (Newton, 2018).*

Client/Family Teaching and Discharge Planning

- The majority of the preceding interventions involve teaching.
- Work with the family members regarding information on how to support and promote weight loss and healthy intakes.

O

Risk for Overweight

Domain 2 Nutrition Class 1 Ingestion

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to excessive fat accumulation for age and gender, which may compromise health.

Risk Factors

Abnormal eating behavior patterns; abnormal eating perception patterns; average daily physical activity is less than recommended for age and gender; consumption of sugar-sweetened beverages; dyssomnias;

energy expenditure below energy intake based on standard assessment; excessive alcohol consumption; fear regarding lack of food supply; frequent snacking; high frequency of restaurant or fried food; inadequate knowledge of modifiable factors; insufficient dietary calcium intake by children; portion sizes larger than recommended; sedentary behavior occurring for ≥ 2 hours/day; shortened sleep time; solid foods as major food source at < 5 months of age

At-Risk Population

ADULT: Body mass index approaching 25 kg/m^2; CHILD 2-18 years: Body mass index approaching 85th percentile or 25 kg/m^2; CHILD < 2 years: Weight-for-length approaching 95th percentile; children with body mass index crossing percentiles upward; children with high body mass index percentiles for age and gender; economically disadvantaged individuals; individuals who experienced premature pubarche; individuals who experienced rapid weight gain during childhood; individuals who experienced rapid weight gain during infancy; individuals who inherit interrelated factors; individuals who were not exclusively breastfed; individuals who were obese during childhood; individuals whose mothers have diabetes; individuals whose mothers smoke during childhood; individuals whose mothers smoke during pregnancy; individuals with high disinhibition and restraint eating behavior score; individuals with parents who are obese

Associated Conditions

Inborn genetic diseases

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Nutritional Status; Nutritional Status: Food and Fluid Intake; Nutrient Intake; Weight Control

Example NOC Outcome With Indicators

Nutritional Status as evidenced by the following indicators: Food and fluid intake/Hydration/Body mass index/Weight-height ratio/Hematocrit. (Rate the outcome and indicators of **Nutritional Status:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

O

Client Outcomes

Client Will (Specify Time Frame)

- Explain how to eat according to the US Dietary Guidelines
- Design dietary modifications to meet individual long-term goal of health, using principles of variety, balance, and moderation
- Maintain weight within normal range for height and age

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Nutrition Management; Nutritional Counseling; Weight Reduction Assistance

Example NIC Activities—Nutrition Management

Determine the client's motivation for changing eating habits; Develop with the client a method to keep a daily record of intake

Nursing Interventions and *Rationales*

- Assess the meaning and importance of food in the client's life. **EB:** *Recent research found strong associations between the different domains of food meanings and behavioral outcomes (Arbit et al, 2017).*
- Assess client readiness to determine whether the client is ready to discuss weight loss and/or would like weight-loss information. **EB:** *Client motivation is a key component of success in a weight-loss program and a prerequisite for weight-loss therapy (Raynor & Champagne, 2016).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Use a motivational interviewing technique when working with clients to promote healthy eating and weight loss. **EB:** *Research shows significant weight loss for clients when motivational interviewing techniques were used (Barnes et al, 2018).*
- Counsel the client to measure regularly consumed foods periodically. Help the client learn usual portion sizes. Measuring food alerts the client to normal portion sizes. Estimating amounts can be extremely inaccurate. **EB:** *A randomized controlled trial of 278 overweight and obese participants was conducted to increase portion size awareness with results that demonstrated the intervention improved portion control behavior and in turn influenced body mass index (BMI) (Poelman et al, 2015).*
- Assist the client to develop a system of self-management, which may include self-monitoring of weight and BMI; realistic goal setting, planning, and action planning for improved dietary intake and physical activity; problem-solving; and tracking dietary intake and exercise. **EB:** *A key component of successful weight loss and maintenance is regular self-monitoring (Thomason et al, 2016).*
- Document the client's height and weight and teach significance of his or her BMI in relationship to current health. Use a chart or a website such as http://www.cdc.gov/healthyweight/assessing/bmi/index.html (Centers for Disease Control and Prevention [CDC], 2020a). **EB:** *Successful treatment of overweight and obesity in adults requires adoption and maintenance of effective self-monitoring (Raynor & Champagne, 2016).*
- Encourage the client to engage in moderate-intensity physical activity (at least 150 minutes/week of moderate physical activity) to prevent weight gain. **EB:** *Research evidence suggests that regular physical activity is critical for weight loss and weight-loss maintenance (McCafferty, Hill, & Gunn, 2020).*
- Recommend that the client avoid eating in fast-food restaurants. **EB:** *A study found that fast-food consumption was the most frequent risk factor for adiposity found in 61.67% of study participants (Popa et al, 2020).*
- Assist the client to reframe slips in weight loss or physical activity behavior as lapses that are a single event and not a full return to previous unhealthy behaviors. Relapse prevention strategies include managing lapses in healthy behavior, identifying high-risk situations for relapses, self-monitoring, providing social support, enhancing skills for coping, and increasing self-efficacy for avoiding relapse. **EB:** *A study of a weight maintenance intervention, delivered primarily by telephone, modestly slowed the rate of weight regain (Voils et al, 2017).*
- Assist clients to engage their social support systems either digitally or face to face in ways that facilitate weight loss, healthy eating, and physical activity behavior change. **EB:** *Significant others, family, friends, and coworkers can facilitate or hinder weight-loss success (Romo, 2018).*
- Assist the client to reframe the goal from a focus on outcome (weight loss) to a focus on process (eating behaviors) for weight loss. **EB:** *A study found the self-monitoring behaviors of self-weigh-in, daily steps, high-intensity activity, and persistent food logging were significant predictors of weight loss during a 6-month intervention (Painter et al, 2017).*
- Assist the client to implement informal and formal mindfulness-based interventions (MBIs). Informal MBIs include mindful eating, increasing awareness of hunger and satiety cues, taste satisfaction, and decreasing impulsive tendencies to overeat when experiencing negative emotions. Meditation practice is a formal MBI. **EB:** *Results of a research review suggested that a combination of formal and informal MBIs are effective in reducing weight and improving obesity-related eating behaviors among individuals with overweight and obesity (Carrière et al, 2018).*
- Assist the client to develop stimulus control techniques designed to reduce environmental cues associated with eating behaviors. Specifically, clients should be taught to limit the presence of high-calorie/high-fat foods in the home; to reduce the visibility of unhealthy food choices in the home; to limit where and when they eat; to avoid distractions such as reading, using the computer, or watching television when eating; and to eat more slowly. **EB:** *Stimulus control strategies are a key to successful weight loss and weight maintenance in conjunction with other weight-loss strategies (Butryn et al, 2017).*
- Encourage 7.5 to 8.5 hours of sleep nightly. **EB:** *Evidence suggests that weight management is hindered when attempted in the context of sleep restriction because there is an upregulation of reward, pleasure, and salience networks in response to food stimuli (St-Onge, 2017).*
- Refer the client to a weight loss–related therapy group. **EBN:** *A study found significant changes in BMI, waist circumference, body fat percentage, and strength of the lower limbs for weight-loss group therapy participants (Ferrari et al, 2017).*
- Recommend that clients use dietary supplements such as vitamins and minerals after consulting with their primary health care provider. **EB:** *Research shows that micronutrient deficits are prevalent in weight-loss plans, especially vitamin B_{12}, calcium, and vitamin D (Engel et al, 2018).*

- Recommend the CDC behavior modification approach "reflect, replace, and reinforce" to improve eating habits. **EB:** *Reflect, replace, and reinforce consists of the following: (1) Reflect about intake through food journals, listing food habits, and identification of eating cues. (2) Replace habits identified during reflection with new and healthier behaviors, such as eating more slowly or planning meals ahead of time. (3) Reinforce changes made and having patience with the process (CDC, 2020b).*
- Incorporate the following recommendations from the Academy of Nutrition and Dietetics "Interventions for the Treatment of Overweight and Obesity in Adults" (Raynor & Champagne, 2016):
  - Assess food- and nutrition-related history; anthropometric measures; biochemical data, medical tests, and procedures; nutrition-focused physical findings; and client history.
  - Assess the energy intake and nutrient content of the diet.
  - Use height and weight to calculate BMI and waist circumference to determine risk of cardiovascular disease, type 2 diabetes, and all-cause mortality.
  - Use a measured resting metabolic rate to determine energy needs.
  - Set a realistic weight-loss goal such as one of the following: up to 2 pounds/week, up to 10% of baseline body weight, or a total of 3% to 5% of baseline weight if cardiovascular risk factors (hypertension, hyperlipidemia, and hyperglycemia) are present.
  - To achieve weight loss, use an individualized diet, including client preferences and health status, to achieve and maintain nutrient adequacy and reduce caloric intake, based on one of the following caloric reduction strategies: 1200 to 1500 kcal/day for women and 1500 to 1800 kcal/day for men and energy deficit of approximately 500 or 750 kcal/day.

Pediatric

- Offer obese or overweight adolescents healthy methods for weight loss. **EB:** *A study showed statistically significant health behavior improvements after implementing a developmentally informed intervention to increase positive health diet and exercise behaviors (Issner et al, 2017).*
- Offer families of obese or overweight children prejudice-free, individually accepting, and supportive interventions to address weight loss. **EB:** *A review summarized recent evidence on weight stigma and found that it is highly prevalent among youth with high body weight, who are targets of weight-based victimization from peers, parents, and teachers (Puhl & Lessard, 2020).*
- Recommend that families eat together for at least one meal per day. **EB:** *A large Korean study found that the frequency of family meals was inversely associated with childhood overweight or obesity (Lee, Lee, & Park, 2016).*
- Recommend involving the family in planning meals and food preparation. Children can learn about nutrition as they help plan and make meals. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed increased cooking skills among the children participating (Fulkerson et al, 2018).*
- Assist parents at being good role models of healthy eating. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed significantly improved parental self-efficacy for identifying appropriate portion sizes (Fulkerson et al, 2018).*
- Recommend that the family try new foods, either a new food or recipe every week. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed decreasing child neophobia scores over time that were developmentally appropriate (Fulkerson et al, 2018).*

Geriatric

- Determine the risks and benefits of weight loss in the older client. A BMI greater than 30 in the older client suggests a moderate weight-loss approach. **EB:** *Recommendations for treating obesity in the elderly include ensuring a balanced and appropriately distributed intake of high-quality nutrients, particularly of high-quality protein (i.e., 1.2 to 1.5 g/kg of body weight), limiting the intake of simple carbohydrates and saturated fats, and providing sufficient intake of calcium and vitamin D_3 (Blaž, 2016).*
- Observe for social, psychological, and economic factors that influence diet quality. **EB:** *An exploratory study of diet quality influences in community-dwelling older individuals revealed the following influences: food experiences, retirement, bereavement, medical conditions, food environment, food-related habits, social engagement, personal/psychological factors, and transportation (Bloom et al, 2017).*

Multicultural

- Tailor nutritional interventions to be consistent with cultural beliefs, norms, and values. **EB:** *A systemic review of culturally tailored interventions for Hispanic women included literacy modification, Hispanic*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

foods/recipes, cultural diabetes beliefs, family/friend participation, structured community input, and innovative experiential learning (McCurley et al, 2017).

- Offer tailored lifestyle counseling via the telephone. **EBN:** *Investigators have included biweekly and/or monthly health coach calls for African American participants with significant weight gain prevention (Goode et al, 2017).*
- Integrate weight loss and weight maintenance interventions with church faith–based supports for African American clients. **EB:** *Recent research found a church-based weight loss intervention using automated SMS text messages was well-received by African American participants and resulted in significant weight loss (Newton et al, 2018).*

Client/Family Teaching and Discharge Planning

- The majority of the preceding interventions involve teaching.
- Work with the family members regarding information on how to support and promote weight loss and healthy intakes.

Acute Pain Domain 12 Comfort Class 1 Physical comfort

Denise Sullivan, MSN, ANP-BC, ACHPN, AP-PMN and Maureen F. Cooney, DNP, FNP-BC, ACHPN, AP-PMN

NANDA-I

Definition

Unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage (International Association for the Study of Pain); sudden or slow onset of any intensity from mild to severe with an anticipated or predictable end, and with a duration of less than 3 months.

Defining Characteristics

Altered physiological parameter; appetite change; diaphoresis; distraction behavior; evidence of pain using standardized pain behavior checklist for those unable to communicate verbally; expressive behavior; facial expression of pain; guarding behavior; hopelessness; narrow focus; positioning to ease pain; protective behavior; proxy report of activity changes; proxy report of pain behavior; pupil dilation; reports intensity using standardized pain scale; reports pain characteristics using standardized pain instrument; self-focused

O

Related Factors

Biological injury agent; inappropriate use of chemical agent; physical injury agent

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Pain Control; Pain Level; Pain: Adverse Psychological Response

Example NOC Outcome

Pain Level as evidenced by severity of observed or reported pain
Note: **Pain Level** is the NOC Outcome label; this text recommends use of the self-report numerical pain rating scale in place of the NOC indicator scales because of the amount of research supporting its use.

Client Outcomes

Client Will (Specify Time Frame)

For the Client Who Is Able to Provide a Self-Report

- Use a self-report pain tool to identify current pain intensity level and establish a comfort-function goal
- Report that the pain management regimen achieves comfort-function goal without side effects
- Notify member of the health care team promptly for pain intensity level that is consistently greater than the comfort-function goal, or occurrence of side effects
- Describe nonpharmacological methods that can be used to help achieve comfort-function goal
- Perform activities of recovery or activities of daily living (ADLs) easily
- Describe how unrelieved pain will be managed
- State ability to obtain sufficient amounts of rest and sleep

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

For the Client Who Is Unable to Provide a Self-Report

- Decrease in pain-related behaviors
- Perform activities of recovery or ADLs easily as determined by client condition
- Demonstrate the absence of side effects of analgesics
- No pain-related behaviors will be evident in the client who is completely unresponsive; demonstrate a reasonable absence of side effects related to the prescribed pain treatment plan

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Analgesic Administration; Pain Management; Client-Controlled Analgesia (PCA) Assistance

Example NIC Activities—Pain Management

Ensure client-attentive analgesic care; Perform a comprehensive assessment of pain to include location, characteristics, onset/duration, frequency, quality, intensity or severity of pain, and precipitating factors

Nursing Interventions and *Rationales*

- During the initial assessment and interview, if the client is experiencing pain, or when pain first occurs, conduct and document a comprehensive pain assessment, using appropriate pain assessment tools. **CEB/EBN:** *Determining location, quality, onset/duration, temporal aspects, pain intensity, characteristics, and the effect of pain on function and quality of life are critical to determine the underlying cause of pain and effectiveness of treatment (McCaffery, 1968; Drew & Peltier, 2018). The initial assessment includes all pain information that the client can provide for the development of the individualized pain management plan (Drew & Peltier, 2018; Raja et al, 2020).*
- Assess if the client is able to provide a self-report of pain intensity, and if so, assess pain intensity level using a valid and reliable self-report pain tool. **EB:** *Acute pain should be regularly and routinely assessed both at rest (important for comfort) and during movement (important for function and decreased client risk for cardiopulmonary and thromboembolic events) and with interventions or procedures likely to cause pain (Chou et al, 2016; Drew & Peltier, 2018; Raja et al, 2020).*
- Ask the client to describe prior experiences with pain, effectiveness of pain management interventions, responses to analgesic medications (including occurrence of side effects), and concerns about pain and its treatment (e.g., fear about addiction, worries, anxiety). **EBN:** *Obtaining an individualized pain history helps identify potential factors that may influence the client's willingness to report pain, as well as factors that may influence pain intensity, the client's response to pain, anxiety, and response to analgesic interventions (Drew & Peltier, 2018).* **EB:** *Anxiety and fear may intensify pain, and pain may trigger emotional responses such as fear and anxiety (Zhuo, 2016).*
- Using a self-report pain tool, ask the client to identify a comfort-function goal that will allow the client to perform necessary or desired activities easily. **EBN:** *The comfort-function goal provides the basis for individualized pain management plans and assists in determining effectiveness of pain management interventions (Arnstein et al, 2019).*
- Use the Hierarchy of Pain Measures as a framework for pain assessment: (1) consider the client's condition and search for possible causes of pain (e.g., presence of tissue injury, pathological conditions, exposure to procedures/interventions that are thought to result in pain); (2) attempt to obtain the client's self-report of pain; (3) observe for behaviors that may indicate pain presence (e.g., facial expressions, crying, restlessness, changes in activity); (4) speak with the client's significant others (i.e., parent, spouse, health care provider) about the client's customary behavioral responses to pain; and (5) conduct an analgesic trial. **EBN:** *When a client is unable to use a self-report tool (e.g., developmental age, intellectual disability, advanced dementia, critical illness/unconscious, anesthetized or sedated), the presence of pain may be assessed by observing specific client behaviors using a valid and reliable behavioral tool (e.g., Critical Care Observation Tool in the critically ill or Checklist of Nonverbal Pain Indicators in cognitively impaired older adults) (Herr et al, 2019).*
- Vital signs should not be used to determine or validate the presence or absence of pain. **EBN:** *Vital signs do not provide strong evidence for the presence of pain, particularly in the neurosurgical intensive care unit client, but may be used as cues for the presence of pain when behavioral indicators are not validated in*

unconscious clients (Erden et al, 2018). **EB:** *Vital signs do not reflect or substantiate self-reported acute pain in clients in the emergency department (Daoust et al, 2016).*

- ● Assume that pain is present if the client is unable to provide a self-report and has tissue injury, has a pathological condition, or has undergone a procedure that is thought to produce pain, and conduct an analgesic trial. **EBN:** *Pain is associated with actual or potential tissue damage such as pathological conditions (e.g., cancer) and procedures (e.g., surgery or trauma, fractures). In the absence of self-report (e.g., anesthetized, critically ill, or cognitively impaired client), the health care provider should use clinical judgment and assume pain is present, and then implement pain management interventions accordingly (Herr et al, 2019).*
- ✱ Obtain and review an accurate and complete list of medications the client is taking or has taken. **EB:** *Accurate medication reconciliation can guide analgesic plan development and prevent errors associated with incorrect medications, dosages, omission of components of the home medication regimen, drug–drug interactions, and toxicity that can occur when incompatible drugs are combined or when allergies are present (Rungvivatjarus et al, 2020).*
- ▲ Recognize the adverse effects of unrelieved pain. **EB:** *Unrelieved acute pain can have harmful effects that facilitate negative client outcomes such as increased morbidity, decreased quality of life, functional impairment, and prolonged recovery time and duration of opioid use and may lead to the development of chronic pain (Gan, 2017).*
- ▲ Explain to the client the pain management approach, including pharmacological and nonpharmacological interventions, the assessment and reassessment process, potential side effects, and the importance of prompt reporting of unrelieved pain. **EBN:** *Clients who receive education interventions preoperatively have been shown to readily report medication side effects and use more nonpharmacological methods for pain control compared to those who do not receive preoperative educational interventions (O'Donnell, 2018).*
- ▲ Reassure the client that pain will be regularly assessed and treated and that they will be observed for medication side effects and signs of opioid use disorder (OUD). **CEB:** *Cogan et al (2014) reported that among 379 clients scheduled for cardiac surgery, 31% stated that it is easy to become addicted to pain medication, 20% report that "good clients" do not talk about their pain, and 35% believe that pain medication should be "saved in case the pain worsens."*
- ● Teach the client about pain and pharmacological and nonpharmacological interventions when pain is relatively well controlled. **EB:** *Pain causes cognitive impairment (Baker et al, 2017).*
- ▲ Regularly reassess the client for the presence of pain and response to pain management interventions, including effectiveness and the presence of adverse effects related to pain management interventions. Review the client's pain flow sheet and medication administration record to evaluate effectiveness of pain relief, previous 24-hour opioid requirements, and occurrence of side effects. **EBN:** *Systematic tracking of pain is an important factor in improving pain management and making adjustments to the pain management regimen (Eksterowicz & DiMaggio, 2018).*
- ▲ Advocate for and manage acute pain using a multimodal, opioid-sparing approach. **EB:** *A multimodal approach (combining two or more drugs that act by different mechanisms for providing analgesia) enhances pain relief and allows the lowest effective dose of each drug to be administered, resulting in fewer or less severe side effects, such as nausea, sedation, and respiratory depression (Sullivan et al, 2016; Polomano et al, 2017).*
- ▲ Select the route for administration of analgesics based on client condition and pain characteristics. **EB:** *Routes have different rates of onset and duration. The oral route is preferred because of its convenience and the resulting relatively steady blood levels; the rectal route may be used when the oral route is not feasible; the intravenous (IV) route is preferred for rapid control of severe pain and would therefore not generally be used for chronic pain; and intramuscular (IM) injections are avoided because of variable absorption and the potential for nerve injury and tissue damage (Chou et al, 2016).*
- ▲ Support the use of perineural infusions and intraspinal analgesia when appropriate and available. **EB:** *Regional analgesia techniques offer the advantages of reduced opioid use, improved satisfaction, early mobility, and prevention of chronic postoperative surgical pain (Hassell & Stimpson, 2019).*
- ▲ Use diverse analgesic delivery methods such as PCA to improve postoperative pain control and increase clients' satisfaction with pain management. **EB:** *In a systematic review of the use of PCA for postoperative pain, moderate- to low-quality evidence was found that PCA provided better pain control and increased client satisfaction compared with non–client-controlled approaches (McNicol et al, 2015).*
- ▲ Administer a nonopioid analgesic for mild to moderate pain and add an opioid analgesic if indicated for moderate to severe acute pain. **EB:** *Nonopioids, such as acetaminophen and nonsteroidal antiinflammatory*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

drugs, are first-line analgesics for the treatment of mild and some moderate acute pain, whereas opioids are included for the treatment of moderate to severe acute pain (Chou et al, 2016).

- Avoid administering analgesics based solely on a client's pain intensity rating. **EB:** *Administering opioid doses based solely on pain intensity disregards the other essential elements of the pain assessment and may contribute to adverse client outcomes such as excessive sedation and respiratory depression as a result of overmedication or result in poorly controlled pain from undermedication (Pasero et al, 2016).*
- Administer nonopioid analgesics around the clock for acute postoperative pain and if necessary opioid analgesics for intermittent or breakthrough pain. **EB:** *Postoperative pain is often constant during the first 24 hours after surgery, therefore necessitating the use of around-the-clock analgesics (Chou et al, 2016).*
- Prevent pain by administering analgesia before painful procedures whenever possible (e.g., endotracheal suctioning, wound care, heel puncture, venipunctures, and peripherally inserted IV catheters). **CEB:** *Adult clients in the intensive care setting experience numerous sources of procedural pain, and chest tube removal, wound drain removal, and arterial line insertion are identified as the most painful procedures (Puntillo et al, 2014).*
- Perform nursing care during the peak effect of analgesics to optimize client comfort and participation in care. **EB:** *Providing care such as mobilization and bathing should be performed when analgesics have reached peak effect: oral medications peak in 60 minutes, subcutaneous opioids in 30 minutes, and IV analgesics in 15 to 30 minutes (Eksterowicz & DiMaggio, 2018).*
- Advocate for the use of "as needed" opioid range orders to provide effective and appropriate pain relief. **EB:** *Correctly prescribed range orders for the delivery of IV opioids give nurses the flexibility needed to treat clients' pain in a timely manner while allowing for differences in client response to pain and to analgesia (Drew et al, 2018).*
- Choose analgesic and dose based on orders that reflect the client's report of pain severity and response to the previous dose in terms of pain relief, occurrence of side effects, and ability to perform the activities of recovery or ADLs. **EB:** *Safe and effective pain management requires opioid dose adjustment based on individualized adequate pain and sedation assessment, opioid administration, and evaluation of the response to treatment (Drew et al, 2018).*

▲ When converting opioids from parenteral doses to oral doses (the preferred route when the client can tolerate and absorb oral medications), use equianalgesic dosing charts and carefully monitor the client's response to the new medication route and dose. **EB:** *Equianalgesic dosing calculations should be used cautiously to guide dose conversion of an opioid from one route to another to avoid the toxicity associated with overdosing and the inadequate pain control caused by underdosing (Fudin et al, 2017).*

▲ Although all clients who are receiving opioids for acute pain are at risk for serious opioid-related adverse effects such as advancing sedation and respiratory depression, some are at even higher risk. Clients should have frequent respiratory assessment (rate, rhythm, noisiness, and depth) and systematic assessment of sedation level using a sedation scale. **EB:** *Opioid-induced respiratory depression occurs with the greatest frequency in postoperative clients during the first 24 hours after surgery, and factors contributing to postoperative respiratory depression include opioid dosage, administrative route, client-specific factors, concurrent administration of other sedating medications, and inadequate nursing assessments of sedation and respiratory status (Gupta et al, 2018; Jungquist et al, 2020).*

▲ When opioids are included in the multimodal analgesic plan, clients need regular assessment for common side effects such as constipation, nausea, pruritus, lack of appetite, and changes in rest and sleep, and preventive measures are implemented when possible.

- Monitor frequency of bowel movements and alert the opioid prescriber when frequency is reduced. **EB:** *Opioid-induced constipation significantly affects quality of life. There is controversy as to the most effective prevention and treatment. Opioid reduction strategies and use of nonopioid analgesics are recommended to reduce risk (Müller-Lissner et al, 2017).*

▲ Support the client's use of nonpharmacological methods to supplement pharmacological analgesic approaches to help control pain, such as distraction, imagery, music therapy, simple massage, relaxation, and application of heat and cold. **EBN:** *Although more evidence is needed to conclude effectiveness, nonpharmacological methods (which are low cost and low risk) can be used to complement pharmacological treatment of pain (dos Santos Felix et al, 2019).* **EBN:** *Evidence suggests efficacy and satisfaction when complementary therapies are integrated into pain treatment plans of older adults (Bruckenthal et al, 2016).*

▲ Assist client to identify resources for coping with psychological impact of pain. **EB:** *Cognitive behavioral (mind–body) strategies can restore the client's sense of self-control, personal efficacy, and active participation in his or her own care.* **EB:** *Nurses should advocate for cognitive behavioral therapy as first-line therapy and*

especially when medications are contraindicated, not well tolerated, or refused and when clients are exhibiting ineffective coping skills (O'Connor-Von & Heck, 2018).

Pediatric

- Assess for the presence of pain using a valid and reliable pain scale based on age, cognitive development, and the child's ability to provide a self-report. Pain intensity scales should be used in conjunction with valid and reliable tools that assess the impact of pain on the child's quality of life (Manworren & Stinson, 2016). **EB:** *The Face, Legs, Activity, Cry, Consolability (FLACC) Scale demonstrated strong reliability in clients ages 6 months to 5 years in the pediatric emergency department (Kochman et al, 2017).* **EB:** *Whenever possible, a child's report of pain should be obtained. In a study of children ages 3 to 7.5 years with acute pain in the emergency department, there was no agreement between child's self-report and caregiver report of pain (Lawson et al, 2019).*

▲ Administer prescribed analgesics using a multimodal approach to treat pain in children, infants, and neonates. **EB:** *Multimodal analgesia improves pain and reduces opioid requirements in postoperative pediatric clients (Manworren et al, 2016).* **EB:** *Multimodal analgesia, including nonpharmacological and pharmacological approaches, reduces procedural pain and anxiety in pediatric acute care (Olsen & Weinberg, 2017).*

- Prevent procedural pain in neonates, infants, and children by using analgesics and sedatives as indicated. **EB:** *The use of intranasal fentanyl and midazolam when administered alone or in combination can provide effective pain and anxiety relief for pediatric clients undergoing minor procedures in the pediatric urgent care setting (Williams et al, 2020; Young, 2017).*
- Use a topical local anesthetic treatment or other nonpharmacological treatment before performing venipuncture in neonates, infants, and children. **EBN:** *Nonpharmacological methods can be used to reduce pain and fear in children during painful procedures. Mechanical vibration with use of the Buzzy System has been shown to be more effective than the ShotBlocker or bubble blowing in children undergoing IM injections in the emergency department (Yilmaz & Alemdar, 2019).*
- For the neonate, use oral sucrose and nonnutritional sucking (NNS) or human milk for pain of short duration such as heel stick or venipuncture. Neonates, especially preterm neonates, are more sensitive to pain than older children. **CEB:** *In an integrated literature review, Naughton (2013) found that the combination of oral sucrose and NNS is a safe and effective method of relieving pain in neonates and increases the calming effect in infants undergoing painful procedures.* **EBN:** *In a randomized control trial involving newborns undergoing heel stick, the use of either breastfeeding, oral sucrose, NNS, or skin-to-skin contact decreased pain when compared with the control group (Chang et al, 2020).*
- As with adults, use nonpharmacological analgesic interventions to supplement, not replace, pharmacological interventions in pediatric clients. **EB:** *Infants who underwent upper limb massage before venipuncture had significantly less pain with venipuncture than when massage was not used (Chik et al, 2017). Pain and distress in children receiving immunizations were significantly reduced when live music therapy was used during the immunization procedure (Sundar et al, 2016).*

Geriatric

- Refer to the Nursing Interventions and *Rationales* in the care plan for Chronic **Pain.**

Multicultural

- Refer to the Nursing Interventions and *Rationales* in the care plan for Chronic **Pain.**

Home Care

▲ Develop the treatment plan with the client and caregivers. **EB:** *Client education and motivation play important roles in self-management of clients with pain. Self-management is influenced by client–provider communication (Drake & Williams, 2017; Haverfield et al, 2018).*

✱ Assess the client's full medication profile, including medications prescribed by all health care providers and all over-the-counter (OTC) medications for drug interactions, and educate the client about the need to discuss use of all medications, including OTC medications, with the health care provider. **EB:** *A medication safety improvement project using an evidence-based medication management software system was used to address the need for accurate identification of medications taken by clients, early identification of medication-related problems, identification of drug duplication, and identification of problems with medication self-management, with the goal of improving medication safety in home health care (LeBlanc & Choi, 2015).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ Assess the client/family's knowledge of side effects and safety precautions associated with pain medications. **EB:** *Educational activities related to pain medications are necessary to ensure that clients are knowledgeable about opioid side effects and safety. McCarthy et al (2015) found that clients who read a one-page information sheet they were given about hydrocodone-acetaminophen safety had better knowledge of precautions related to acetaminophen dosing, and they were less likely to drive a car within 6 hours of taking the medication than those who did not receive this educational intervention.*

- If medication is administered using highly technological methods, assess the home for the necessary resources (e.g., electricity) and ensure that there will be responsible caregivers available to assist the client with administration. **EB:** *The use of advanced medical technologies is part of the technical nursing process, and nurses have a key role supporting clients and family care providers in their safe use (Ten Haker et al, 2018).*
- Assess the knowledge base of the client and family regarding highly technological medication administration and provide necessary education, including the procedure to follow if analgesia is unsatisfactory. **EB:** *With appropriate education and training, the use of PCA in home care has been shown to be a safe and effective analgesic modality for children and young adults with cancer (Anghelescu et al, 2015).*

Client/Family Teaching and Discharge Planning

Note: To avoid the negative connotations associated with the words "drugs" and "narcotics," use the term "pain medicine" when teaching clients.

- Discuss the various discomforts encompassed by the word "pain" and ask the client to give examples of previously experienced pain. Explain the pain assessment process and the purpose of the pain rating scale. **EB:** *It is often difficult for clients to understand the concept of pain and describe their pain experience. Using alternative words and providing a complete description of the assessment process, including the use of scales, ensures that an accurate treatment plan is developed (Drew & Peltier, 2018).*
- Teach the client to use the self-report pain tool to rate the intensity of past or current pain. Ask the client to set a comfort-function goal by selecting a pain level on the self-report tool that will allow performance of desired or necessary activities of recovery with relative ease (e.g., turn, cough, deep breathe, ambulate, participate in physical therapy). If the pain level is consistently above the comfort-function goal, the client should take action that decreases pain or notify a member of the health care team so that effective pain management interventions may be implemented promptly. **EB:** *The use of comfort-function goals provides the basis for the direction and modification of the treatment plan (Eksterowicz & DiMaggio, 2018).*
- Provide written educational materials on various aspects of pain control to improve client understanding of pain and pain-related interventions. **EB:** *Written materials and other educational tools assist in improving clients' knowledge related to pain management. In knee replacement clients, the use of a simple educational pain management card was associated with reduced opioid use without compromising pain satisfaction in pain relief or participation in rehabilitation therapy. The education card listed scheduled and as-needed (PRN) analgesic medications, the indication and frequency of availability, and a pain rating scale (Yajnik et al, 2019).*
- Discuss and evaluate the client's understanding of the total plan for pharmacological and nonpharmacological treatment, including the medications prescribed and their indication, proper dosing schedule, and adverse events and what to do should they occur. **EB:** *Appropriate instruction increases the accuracy and safety of medication administration (Drew & Peltier, 2018).*
- Teach basic principles of pain management using a variety of educational strategies, and evaluate learning. **EB:** *Client educational strategies that have been shown to increase knowledge, decrease anxiety, and increase satisfaction include the use of computer technology, audiotapes and videotapes, written materials, and demonstrations, or combinations of these strategies (Curtiss & Wrona, 2018).*

▲ Reinforce the importance of taking pain medications to maintain the comfort-function goal. **EB:** *Teaching clients to stay on top of their pain and prevent it from getting out of control will improve the ability to accomplish the goals of recovery (Eksterowicz & DiMaggio, 2018).*

▲ Reinforce that short-term use of opioids for acute pain relief is an appropriate part of their multimodal pain treatment plan. **EB:** *Taking opioids only as directed, avoiding alcohol, and talking with the health care provider when pain is poorly controlled are strategies that will lessen the risks for OUD or major opioid-related adverse effects such as respiratory depression and arrest (Costello, 2015).*

▲ Reinforce the importance of safe storage of opioid medications out of the reach of others, and teach clients how to responsibly dispose of any unused opioids. **EBN:** *Perianesthesia nurses have a responsibility to educate their clients on discharge from ambulatory surgery about safe opioid use, storage, and disposal (Odom-Forren et al, 2019).*

- ✱ Client education by nurses in the emergency department setting related to the use, storage, and disposal of pain medications may increase client knowledge and promote safety (Waszak et al, 2018).
- ▲ Demonstrate the use of appropriate nonpharmacological approaches in addition to pharmacological approaches to help control pain, such as application of heat and/or cold, distraction techniques, relaxation breathing, visualization, rocking, stroking, listening to music, and watching television. **EB:** *Nonpharmacological interventions are used to complement, not replace, pharmacological interventions (Bruckenthal et al, 2016).*

Chronic Pain

Domain 12 Comfort Class 1 Physical comfort

Maureen F. Cooney, DNP, FNP-BC, ACHPN, AP-PMN and Denise Sullivan, MSN, ANP-BC, ACHPN, AP-PMN

NANDA-I

Definition

Unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage (International Association for the Study of Pain); sudden or slow onset of any intensity from mild to severe, constant or recurring without an anticipated or predictable end, and a duration of greater than 3 months.

Defining Characteristics

Altered ability to continue activities; anorexia; evidence of pain using standardized pain behavior checklist for those unable to communicate verbally; expresses fatigue; facial expression of pain; proxy report of activity changes; proxy report of pain behavior; reports altered sleep-wake cycle; reports intensity using standardized pain scale; reports pain characteristics using standardized pain instrument; self-focused

Related Factors

Body mass index above normal range for age and gender; fatigue; ineffective sexuality pattern; injury agent; malnutrition; prolonged computer use; psychological distress; repeated handling of heavy loads; social isolation; whole-body vibration

At-Risk Population

Individuals aged >50 years; individuals with history of being abused; individuals with a history of genital mutilation; individuals with history of over indebtedness; individuals with history of static work postures; individuals with history of substance misuse; individuals with history of vigorous exercise; women

Associated Conditions

Bone fractures; central nervous system sensitization; chronic musculoskeletal diseases; contusion; crush syndrome; imbalance of neurotransmitters, neuromodulators, and receptors; immune system diseases; impaired metabolism; inborn genetic diseases; ischemia; neoplasms; nerve compression syndromes; nervous system diseases; post-trauma related condition; prolonged increase in cortisol level; soft tissue injuries; spinal cord injuries

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Comfort Level; Pain Control; Pain: Disruptive Effects; Pain Level

Example NOC Outcome with Indicators

Pain Level as evidenced by use of a numerical pain rating scale (NRS), asking the client to rate the level of pain from 0 to 10. Self-report is considered the single most reliable indicator of pain presence and intensity (American Pain Society [APS], 2016)

Note: **Pain Level** is the NOC Outcome label; this text recommends use of the self-report NRS in place of the NOC indicator scales because of the amount of research supporting its use.

Client Outcomes

Client Will (Specify Time Frame)

For the Client Who Is Able to Provide a Self-Report

- Provide a description of the pain experience including physical, social, emotional, and spiritual aspects
- Use a self-report pain tool to identify current pain level and establish a comfort-function goal
- Report that the pain management regimen achieves comfort-function goal without the occurrence of side effects
- Describe nonpharmacological methods that can be used to supplement, or enhance, pharmacological interventions and help achieve the comfort-function goal
- Perform necessary or desired activities at a pain level less than or equal to the comfort-function goal
- Demonstrate the ability to pace activity, taking rest breaks before they are needed
- Describe how unrelieved pain will be managed
- State the ability to obtain sufficient amounts of rest and sleep
- Notify a member of the health care team for pain level consistently greater than the comfort-function goal or occurrence of side effect

For the Client Who Is Unable to Provide a Self-Report

- Demonstrate decrease or resolved pain-related behaviors
- Perform desired activities as determined by client condition
- Demonstrate the absence of side effects
- No pain-related behaviors will be evident in the client who is completely unresponsive; a reasonable outcome is to demonstrate the absence of side effects related to the prescribed pain treatment plan

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Analgesic Administration; Pain Management

Example NIC Activities—Pain Management

Ensure that the client receives attentive analgesic care; Perform comprehensive assessment of pain, including location, characteristics, onset and duration, frequency, quality, intensity or severity, and precipitating factors

Nursing Interventions and *Rationales*

- ▲ During the initial assessment and interview, if the client is experiencing pain, conduct and document a comprehensive pain assessment, using appropriate pain assessment tools. **CEB/EBN:** *Determining location, temporal aspects, pain intensity, characteristics, and the effect of pain on function and quality of life is critical to determine the underlying cause of pain and effectiveness of treatment (McCaffery, 1968; Turk et al, 2016).* **EB:** *The initial assessment includes all pain information that the client can provide for the development of the individualized pain management plan (Stanos et al, 2016).*
- ▲ Determine the quality of the pain and whether the pain has persisted beyond the usual duration for tissue healing. **EB:** *Chronic pain is persistent, lasting beyond the expected time or usual time of tissue healing (usually 3 months). Descriptors such as "sharp," "shooting," or "burning" assist in discriminating neuropathic pain from nociceptive pain (Treede et al, 2019).* Refer to the care plan for Acute **Pain** and discussion of the Hierarchy of Pain Measures for assessment approach in clients who are unable to provide self-report of pain.
- ▲ Perform a pain assessment using a reliable self-report pain tool. **EB:** *Tools such as the 0 to 10 Numerical Rating Scale (NRS) or Faces Pain Scale (FPS) and the Wong-Baker FACES Pain Rating Scale assess pain intensity. Multidimensional tools such as the Brief Pain Inventory (BPI), the McGill Pain Questionnaire (MPQ), the Pain Relief Scale (PRS), or the Chronic Pain Grade Scale (CPGS) provide a comprehensive evaluation of the client with persistent pain assessing the characteristics and quality of pain; satisfaction with pain control; and how pain affects mood, activity, sleep, and diet (Fillingim et al, 2016).* **EBN:** *Assessment of function, using a functional pain assessment tool, allows clients to describe how pain affects their daily behaviors, including physical and cognitive abilities (Halm et al, 2019).*
- ▲ Ask the client to describe prior experiences with pain, effectiveness of pain management interventions, responses to analgesic medications (including occurrence of side effects), and concerns about pain and its treatment (e.g., fear about addiction, worries, anxiety) and informational needs. **EBN:** *Obtaining an individualized pain history helps identify potential factors that may influence the client's willingness to report pain, as well as factors that may influence pain intensity, the client's response to pain, anxiety, and pharmacokinetics of analgesics (Drew & Peltier, 2018; Raja et al, 2020).*
- ● Using a self-report tool, ask the client to identify a comfort-function goal that will allow the client to perform necessary or desired activities easily. **EBN:** *The comfort-function goal provides the basis for individualized pain management plans and assists in determining effectiveness of pain management interventions (Boswell & Hall, 2017).*
- ▲ Assess chronic pain regularly, including the impact of chronic pain on activity; sleep; eating habits; and social conditions, including relationships, finances, and employment. **EB:** *Regular assessment of clients with chronic pain is critical because changes in the underlying pain condition, presence of comorbidities, and changes in psychosocial circumstances can affect pain intensity and characteristics and require revision of the pain management plan (Turk et al, 2016).* **EB:** *Sleep disturbance and decreased physical activity are adverse effects of people with chronic pain. In a study of clients with chronic pain, those who participated in a 4-week multiprofessional program that included psychoeducation and training related to pain, sleep, exercise, and activity training had improvement in sleep quality and pain intensity (de la Vega et al, 2019).*
- ▲ Assess the client for the presence of psychiatric conditions, including anxiety and depression. **EB:** *Among clients with chronic pain, there is an increased incidence of mental health disorders, including major depression and personality disorders, which increase the risks for suicidality (Pergolizzi et al, 2018). Among clients who receive specialized care for chronic pain, the prevalence of depression is as high as 68% (Works & Culmer, 2020).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

P

▲ If opioid therapy is considered, assist the provider with aspects of an opioid risk assessment, which includes a comprehensive client interview and examination with a pain focus, mental health screening, use of an opioid risk assessment tool, examination of prescription drug monitoring program results, and urine drug screening. **EB:** *Although prevalence rates vary, there is evidence of opioid misuse and opioid use disorder (OUD) among those who are prescribed opioids for chronic pain; thus to reduce risk and optimize safe opioid use, risk assessment and stratification are recommended (Cheatle et al, 2019).*

▲ For the client who is receiving outpatient opioid therapy, at each visit, assess effect of opioids on pain status, function, goal achievement, and presence of side effects, including sleep disturbance and sexual dysfunction; assessment for signs of misuse and OUD should be included, which may involve the use of random urine drug toxicology screening, pill counts, and review of prescription monitoring database. **EB:** *Opioid therapy is associated with risk for misuse and OUD and overdose, whereas the evidence for the long-term use of opioid therapy in chronic pain is inconclusive. To minimize risk, a number of risk mitigation practices, including careful assessment of the client response to opioid therapy, are recommended (Dowell et al, 2016).*

● Ask the client to maintain a diary (if able) of pain ratings, timing, precipitating events, medications, and effectiveness of pain management interventions. **EB:** *Systematic tracking of pain has been demonstrated to be an important factor in improving pain management (Fillingim et al, 2016). In a study of a smartphone-based pain app with two-way messaging option for clients with cancer and noncancer chronic pain, clients and providers found the app to be easy to use, and with two-way messaging, there was an increase in the frequency of daily pain assessments and client perception of beneficial connection to the health care providers (Jamison et al, 2017).*

▲ Obtain and review an accurate and complete list of medications the client is taking or has taken. **EBN:** *In a study using the "Brown Bag Medication Tool" developed by the Agency for Healthcare Research and Quality, clients cared for at a low-income clinic were asked to bring their medications, including empty bottles and discontinued bottles, in a brown bag to their clinic appointment, and health providers compared the bottles of medications and amount of remaining medication with their medical record to assess compliance with medication prescriptions, identify barriers to adherence, errors, safety concerns, and opportunities for improved adherence (Murtha et al, 2020).*

✱ Medication review has been found to improve the quality of medication interventions, including client adherence, and outcomes (Rose et al, 2015).

▲ Explain to the client the pain management approach that has been ordered or revised, including therapies, medication administration, side effects, and complications. **EB:** *One of the most important steps toward improved control of pain is a better client understanding of the nature of pain, its treatment, pain management goals, and the role the client needs to play in pain control (Curtiss & Wrona, 2018).*

● Discuss the client's fears of undertreated pain, side effects, OUD, and overdose and reassure the client that there will be regular assessment and treatment of pain and assessment for side effects and signs of OUD. **EBN:** *St. Marie (2016), in a qualitative study of clients with chronic pain who receive opioid therapy, reported that clients fear OUD or relapse, loss of access to opioids, and undertreated pain.*

▲ Manage chronic pain using an individualized, multimodal nonopioid or opioid-sparing approach. **EB:** *A multimodal approach (combining two or more drugs that act by different mechanisms for providing analgesia) such as acetaminophen, an anticonvulsant, an antidepressant, and an opioid in chronic pain enhances pain relief and allows the lowest effective dose of each drug to be administered, resulting in fewer or less severe side effects such as nausea, sedation, and respiratory depression. Nonopioid therapy is the treatment of choice in chronic noncancer pain. Opioids may be considered when all other reasonable attempts at analgesia have failed; however, evidence for long-term effectiveness is not clear (Dowell et al, 2016; Jungquist et al, 2016).*

▲ When chronic pain has a neuropathic component, treat with adjuvant analgesics, such as anticonvulsants, antidepressants, and topical local anesthetics. **EB:** *First-line analgesics for neuropathic pain belong to the adjuvant analgesic group and include anticonvulsants, antidepressants, and some topical local anesthetics. Analgesic efficacy with opioids in chronic neuropathic pain is inconclusive (Dowell et al, 2016; Fornasari, 2017).*

▲ Administer a nonopioid analgesic for mild to moderate chronic pain and as a component of the treatment for all levels of pain for clients with cancer pain. **CEB:** *Nonopioids, such as acetaminophen and nonsteroidal antiinflammatory drugs (NSAIDs), are first-line analgesics for the treatment of mild and moderate pain conditions (e.g., osteoarthritis pain) (Dowell et al, 2016). Consider adding nonopioid analgesics such as acetaminophen and NSAIDs for cancer pain, provided comorbidities and other risks do not prevent the use of these analgesics; NSAIDs are used cautiously, especially when used chronically, because many cancer*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

clients may be at high risk for renal, gastrointestinal (GI), or cardiac toxicities; thrombocytopenia; or bleeding problems (National Comprehensive Cancer Network [NCCN], 2017).

- ▲ Recognize that opioid therapy may be indicated for some clients experiencing chronic pain. **EB:** *Opioids are often used in the management of moderate to severe chronic cancer pain. Opioid initiation for chronic, noncancer pain is controversial because of the limited data on long-term efficacy and safety. Opioid therapy may be considered with careful client selection when the benefits for pain control and function outweigh client risk (Dowell et al, 2016; Busse et al, 2018).*
- ▲ Administer analgesics around the clock for continuous pain and as needed (PRN) for intermittent or breakthrough pain as may be experienced by clients with cancer pain. **EB:** *The use of immediate-release opioids for clients with advanced cancer who have adequately controlled background pain are necessary to provide adequate relief for breakthrough pain episodes (Vellucci et al, 2017; Azhar et al, 2019).*
- ▲ Long-acting or extended-release opioids may be indicated for clients with cancer pain if clients require the regular use of short-acting opioids and receive adequate relief with them. **EB:** *Controlled-release preparations are helpful because the long duration lessens the severity of end-of-dose pain and decreases analgesic gaps (Swarm et al, 2019).*
- ▲ At regular intervals, assess inpatient clients with chronic pain for opioid-related adverse events and include frequent assessment of pain level, assessment of respiratory status (including rate, rhythm, noisiness, and depth), and systematic assessment of sedation level using a sedation scale. **EB:** *Tolerance to opioid-induced respiratory depression usually develops within a week of regular daily opioid dosing, making this side effect less likely to occur in those who are opioid tolerant than those who are not tolerant; however, opioid-tolerant clients are at similar risk for respiratory depression when they misuse opioids, are admitted to the hospital for surgery, or receive more than their usual opioid dose to treat an acute condition, or receive concomitant sedating medications (Jungquist et al, 2016).*
- ▲ During outpatient follow-up, assess clients receiving opioids for risk factors that may increase opioid-related harm. **EB:** *Clients who are receiving higher opioid doses, prescribed concurrent benzodiazepines, have cognitive impairment that could lead to accidental ingestion of excess opioids, mental health disorders that place a client at greater risk for suicide, or a history of OUDare at greater risk for opioid overdose. Take-home naloxone for the treatment of opioid-induced respiratory depression is recommended by numerous federal, state, and professional organizations (Coe & Walsh, 2015).*
- ▲ Provide the client with a bowel regimen, including adequate hydration, fiber, and laxatives to prevent/treat opioid-related constipation. Ask about other opioid-related side effects including nausea, pruritus, lack of appetite, and changes in rest and sleep. **EB:** *Although clients may develop tolerance to nausea, pruritus, and other opioid side effects, they do not develop tolerance to opioid-induced constipation (Nelson & Camilleri, 2016).*
- ▲ In addition to administering analgesics, support the client's use of nonpharmacological methods to help control pain, such as distraction, imagery, relaxation, and application of heat and cold. **EBN:** *Evidence suggested efficacy and satisfaction when complementary therapies are integrated into pain treatment plans of older adults (Bruckenthal et al, 2016).*
- ▲ Cognitive behavioral techniques have been shown to be useful in the management of chronic pain. **EBN:** *In a review of 35 studies involving the use of cognitive behavioral therapy (CBT) in the management of chronic pain, CBT was found to reduce pain intensity in 43% of the trials (Knoerl et al, 2016).* **EB:** *Motivational interviewing, a counseling method that aims to resolve a client's ambivalence about behavior change, may improve chronic pain treatment adherence, but more study is needed to determine whether it will improve pain intensity and function (Alperstein & Sharpe, 2016).* **EB:** *Multiprofessional outpatient rehabilitation using physical therapy, occupational therapy, and CBT can significantly improve function in people with chronic pain (Kurklinsky et al, 2016).*
- ▲ Encourage the client to plan activities around periods of greatest comfort whenever possible. **EB:** *Some literature supported the use of pacing (a CBT strategy), which is an active self-management strategy in which individuals learn to balance activity and rest for the purpose of increasing function (Racine et al, 2018).*
- ▲ Explore appropriate resources for long-term management of chronic pain (e.g., hospice, pain care center). **EB:** *Outpatient pain management resources must be identified to ensure appropriate chronic pain management. In a study involving a multisite telehealth group model for chronic pain management in rural/remote settings, when compared with face-to-face programs, clients experienced similar improvements in pain acceptance and pain interference, as well as improvements in overall function, mood, and physical activity (Scriven et al, 2019).*

▲ If the client has progressive cancer pain, assist the client and family with handling issues related to death and dying and provide access to palliative care programs and hospice services. **CEB:** *In a study by Temel et al (2010), clients with non–small cell lung cancer who received early palliative care intervention had significant improvements in quality of life and mood, less aggressive care at the end of life, and longer survival.*

Pediatric

- Assess for the presence of pain using a valid and reliable pain scale based on age, cognitive development, and the child's ability to provide a self-report. **EB:** *Pain intensity scales should be used in conjunction with other valid and reliable tools that assess the impact of pain on the child's quality of life (Manworren & Stinson, 2016).* **CEB:** *Behavioral tools such as the Face, Legs, Activity, Cry, Consolability (FLACC) Scale may be used to assess pain in infants and children who cannot provide a self-report (Crellin et al, 2015).*

▲ Manage chronic pain children, infants, and neonates with an interdisciplinary and multimodal approach. **EB:** *There is a lack of randomized controlled trials among pediatric clients to identify the best approach to the treatment of pain in this age group. Expert consensus recommends treatment using a multiprofessional approach, including physical therapies and CBT, and when pharmacological approaches are needed, a multimodal pharmacological approach, using medications from a variety of classes, is recommended (Mathew et al, 2016; Bruce et al, 2017).*

- Use a variety of nonpharmacological analgesic interventions to address chronic pain in pediatric clients. **EBN:** *Complementary therapies such as cognitive behavioral strategies, mindfulness-based approaches, and other nonpharmacological approaches may play an important role in chronic pain management in children and adolescents (Bruce et al, 2017).* **EB:** *In a study of children ages 9 to 14 years with functional abdominal pain, the use of tailored CBT compared with standard medical treatment showed greater improvements in pain-related disability but not pain levels, and greater improvements in anxiety symptoms compared with usual medical treatment (Cunningham et al, 2021).*

Geriatric

▲ An older client's report of pain should be taken seriously and assessed and treated. **EB:** *Chronic pain in the elderly is associated with an increase in physical, social, and psychological frailty (Coelho et al, 2017).* **EBN:** *Among the elderly, the presence of severe daily pain is positively correlated with the presence of depression and the frequency of falls and fatigue (Crowe et al, 2017).*

- When assessing pain, speak clearly, slowly, and loudly enough for the client to hear; ensure hearing aids and glasses are in place as appropriate; enlarge pain scales and written materials; and repeat information as needed. **EB:** *Older clients often have multiple sensory deficits, including vision and hearing difficulties, which can affect cognition, lead to loneliness and isolation, and contribute to declines in social interactions and relationships (Humes & Young, 2016; Stephan et al, 2017).*
- Handle the client's body gently and allow the client to move at his or her own speed. **EB:** *Older adults are particularly susceptible to injury during care activities. Age-related skeletal muscle changes result in weakness and muscle loss, placing clients at risk for injuries. Slow walking and turns may preserve muscle mass and strength in the trunk and limbs, which may enable continued independence (Araki et al, 2017).*

▲ Use nonpharmacological approaches including physical therapy, exercise, or other movement-based programs as the core components to persistent pain management in the older adult. **EB:** *In a randomized controlled trial of older adults with chronic pain, when compared with a control group, those who participated in an 8-week physical activity and education program had lower pain intensity and frailty and improved physical performance after participation and at 3 months after the program (Otones et al, 2020).*

▲ When pharmacological measures are needed to address chronic pain in the elderly, use a multimodal approach, including nonopioid analgesics for mild to moderate pain. **CEB:** *Acetaminophen (maximum dosage 3000 mg/day) is preferred and recommended, unless contraindicated, as first-line therapy for older persons with persistent pain; NSAIDs (preferably in topical form because there is less system absorption than in the oral form) should be used short term and with extreme caution because of the higher GI, cardiovascular, and renal adverse effects; if a systemic NSAID is needed, naproxen has the safest cardiac profile (Mehta et al, 2019).*

▲ Use opioids cautiously in the older client with chronic pain. **EB:** *In a systematic review consisting of seven studies of the use of opioids for the treatment of chronic noncancer pain in community-dwelling older adults, the majority of people experienced continued pain despite the use of opioids, and the results in terms of social engagement and participation in activities daily living were mixed; There was limited evidence to support the long-term use of opioids in this client population (O'Brien & Wand, 2020).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ Monitor for signs of depression in older clients and refer to specialists with relevant expertise. **EB:** *Both depression and pain are common in older clients and have a bidirectional relationship. Pharmacological treatment of each condition may provide better outcomes than the treatment of one of these conditions. There is increasing evidence to support the role of neuroinflammation in the development of depression and pain (Zis et al, 2017).*

Multicultural

▲ Assess for and identify the presence of pain disparities among clients and work to develop opportunities for equal care. **EB:** *Ethnicity, culture, race, gender, and socioeconomic status are among factors that place clients at greater risk for disparities in pain treatment, and nurses have an obligation to raise attention to these disparities and take action to eliminate them (Vallerand, 2018).*

▲ Assess for the influence of cultural beliefs, norms, and values on the client's perception and experience of pain. **EB:** *The large variations in chronic back pain prevalence and prognosis across different countries may be influenced by culturally determined health beliefs (Henschke et al, 2016).*

▲ Social support should be facilitated as it has a positive impact on the client's ability to cope with chronic pain. **EB:** *In a study of the effect of social support on the attendance and participation in treatment sessions of clients with chronic back pain, social support provided a significant positive impact on treatment adherence and disability (Oraison & Kennedy, 2021).*

▲ Use culturally relevant pain scales to assess pain in the client. **CEB:** *Clients from minority cultures may express pain differently than clients from the majority culture. The FPS-Revised was shown to be preferred over other self-report pain rating tools in older minority adults (Ware et al, 2006) and in Chinese adults (Li et al, 2009). A later study demonstrated that the Iowa Pain Thermometer was the preferred tool in older Chinese adults (Li et al, 2009).*

Home Care

● The interventions previously described may be adapted for home care use. Refer to the Nursing Interventions and *Rationales* in the care plan for Acute **Pain.**

Client Family Teaching and Discharge Planning

Note: To avoid the negative connotations associated with the words "drugs" and "narcotics," use the term "pain medicine" when teaching clients.

● Discuss the various discomforts encompassed by the word "pain" and ask the client to give examples of previously experienced pain. Explain the pain assessment process and the purpose of the pain rating scale. **EB:** *It is often difficult for clients to understand the concept of pain and describe their pain experience. Using alternative words and providing a complete description of the assessment process, including the use of scales, ensures that an accurate treatment plan is developed (Drew & Peltier, 2018; Raja et al, 2020).*

● Teach the client that if the pain level is consistently above the comfort-function goal, the client should take action that decreases pain or should notify a member of the health care team so that effective pain management interventions may be implemented promptly. (See information on teaching clients to use the pain rating scale.) **EB:** *The use of comfort-function goals provides direction for the treatment plan. Changes are made according to the client's response and achievement of the goals of recovery or rehabilitation (Boswell & Hall, 2017).*

● Provide educational materials on various aspects of pain control to improve client understanding of pain and pain-related interventions. **EBN:** *In a pilot study of the use of a guided Internet-based program for clients with chronic pain, Internet delivery of client education and evidence-based therapies, along with content in audio, video, and text formats, increased client access to these therapies; the pilot study identified benefits of this approach and informed the need for further intervention refinement, content development, and research (Perry et al, 2017).*

● Discuss and evaluate the client's understanding of the total plan for pharmacological and nonpharmacological treatment, including the medication plan, the maintenance of a pain diary, and the use of supplies and equipment. **EBN:** *In a study of 279 clients with chronic pain, those who received comprehensive nurse-led intervention on healthy lifestyle, self-esteem, pain awareness, communication, and relaxation techniques noted improvement in quality of life, pain intensity, and mental health compared with those who received usual care (Morales-Fernández et al, 2021).*

▲ Reinforce that opioids, when prescribed for chronic pain, may be an appropriate component of multimodal pain treatment plan, but clients require knowledge of safe opioid use and potential adverse effects.

EB: *Taking opioids only as directed, avoiding alcohol, and talking with the health care provider when pain is poorly controlled are strategies that will lessen the risks for OUD or major opioid-related adverse effects such as respiratory depression and arrest (Denenberg & Curtiss, 2016).*

▲ Reinforce the importance of safe storage of opioid medications out of the reach of others and to responsibly dispose of any unused opioids. **EB:** *Community medication "take back" days and drop boxes are becoming increasingly popular. Encourage clients/families to check community resources (Hawk et al, 2015).*

● Demonstrate the use of appropriate nonpharmacological approaches in addition to pharmacological approaches for helping control pain, such as application of heat and/or cold, distraction techniques, relaxation breathing, visualization, rocking, stroking, listening to music, and watching television. Teach these methods when pain is relatively well controlled, because pain interferes with cognition. **EBN:** *In an integrative review, evidence suggests that when nurses educate clients on nonpharmacological modalities for the management of chronic noncancer pain, they may be more motivated to try these modalities, which may lead to improved outcomes (Andrews-Cooper & Kozachik, 2020).*

▲ Emphasize to the client the importance of participating in a structured, individualized pacing activity and taking rest breaks before they are needed to reduce fatigue, reduce joint stiffness, and maintain physical activity. **EB:** *In a systematic review that included seven studies involving the use of pacing as a strategy to assist with chronic pain management, a learned pacing intervention reduced fatigue interference, joint stiffness, and variability in physical activity but did not reduce pain severity (Guy et al, 2019).*

● Teach nonpharmacological methods when pain is relatively well controlled. **EB:** *Pain interferes with cognition (Baker et al, 2017).*

Chronic Pain Syndrome

Domain 12 Comfort Class 1 Physical comfort

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Recurrent or persistent pain that has lasted at least 3 months and that significantly affects daily functioning or well-being.

Defining Characteristics

Anxiety (00146); constipation (00011); disturbed sleep pattern (00198); fatigue (00093); fear (00148); impaired mood regulation (00241); impaired physical mobility (00085); insomnia (00095); social isolation (00053); stress overload (00177)

Related Factors

Body mass index above normal range for age and gender; fear of pain; fear-avoidance beliefs; inadequate knowledge of pain management behaviors; negative affect; sleep disturbances

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Acute **Pain** and Chronic **Pain.**

Labor Pain

Domain 12 Comfort Class 1 Physical comfort

Nichol Chesser, RN, CNM, DNP

NANDA-I

Definition

Sensory and emotional experience that varies from pleasant to unpleasant, associated with labor and childbirth.

Defining Characteristics

Altered blood pressure; altered heart rate; altered muscle tension; altered neuroendocrine functioning; altered respiratory rate; altered urinary functioning; anxiety; appetite change; diaphoresis; distraction behavior; expressive behavior; facial expression of pain; narrow focus; nausea; perineal pressure; positioning to ease pain; protective behavior; pupil dilation; reports altered sleep-wake cycle; self-focused; uterine contraction; vomiting

Related Factors

Behavioral Factors

Insufficient fluid intake; supine position

Cognitive Factors

Fear of childbirth; inadequate knowledge about childbirth; inadequate preparation to deal with labor pain; low self efficacy; perception of labor pain as nonproductive; perception of labor pain as negative; perception of labor pain as threatening; perception of labor pain as unnatural; perception of pain as meaningful

Social Factors

Interference in decision-making; unsupportive companionship

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Unmodified Environmental Factors

Noisy delivery room; overcrowded delivery room; turbulent environment

At-Risk Population

Women experiencing emergency situation during labor; women from cultures with negative perspective of labor pain; women giving birth in a disease based health care system; women whose mothers have a high level of education; women with history of pre-pregnancy dysmenorrhea; women with history of sexual abuse during childhood; women without supportive companion

Associated Conditions

Cervical dilation; depression; fetal expulsion; high maternal trait anxiety; prescribed mobility restriction; prolonged duration of labor

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Client Satisfaction: Pain Management, Comfort Status; Knowledge: Pain Management, Pain Control, Pain Level

Example NOC Outcomes with Indicators

Labor Pain management as evidenced by the following indicators: Recognizes pain onset/Discusses pain treatment options with health care professional/Monitors therapeutic effects of analgesic/Uses effective coping strategies/Reports changes in pain symptoms to health care provider. (Rate the outcome and indicators of **Labor Pain:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Recognize pharmacological and nonpharmacological interventions to address labor pain
- Demonstrate coping strategies to address labor pain
- Verbalize pain relief effectiveness throughout the labor process

NIC (Nursing Intervention Classification)

Suggested NIC Interventions

Acute, Analgesic Administration: Intraspinal, Analgesic Administration, Aromatherapy, Dance Therapy, Distraction, Environmental Management: Comfort, Guided Imagery, Massage, Medication Administration: Intraspinal, Meditation Facilitation, Relaxation Therapy, Transcutaneous Electrical Nerve Stimulation

Example NIC Activity—Acute Pain Management

Explore the client's knowledge and beliefs about labor pain including cultural influences; Monitor pain using a valid and reliable rating tool

Nursing Intervention and *Rationales*

- Initial assessment and interview, if the client is experiencing pain, conduct and document a comprehensive pain assessment, using appropriate pain assessment tools. **EB:** *A pain assessment tool consists of obtaining all the information that a client can provide to help individualize a pain management plan of care. This includes presence of pain and pain treatment (Karcioglu et al, 2018). Information includes location, intensity, characteristics, quality, ability to cope, and desire for pharmacological or nonpharmacological interventions. Pain level, as evidenced by client self-report of coping or not coping with pain from labor contractions, is considered the best indicator of pain presence and intensity. The pain level a client experiences can be seen by behavioral indices such as facial expressions, verbal expressions, tone of voice, body movement, ability to relax, and breathing rate (Asl et al, 2018). Use an evidence-based coping algorithm to help the client*

find the best means available to cope well with labor pain (Fairchild et al, 2017). The Coping with Labor Algorithm (CWLA) is especially useful for nurses as it allows them to look for specific cues from the client to determine how well they are coping with pain (Fairchild et al, 2017).

- Observe for nonverbal pain assessment such as grimacing, lackluster eyes, and fixed or scattered movements.
- Assess pain on pain level tool such as the 0 to 10 numerical pain rating scale (NRS) if appropriate or the CWLA (Fairchild et al, 2017). Discuss with client the desire for pain management for this labor, past experiences with labor and effectiveness of pain management techniques employed at that time, concerns about pain and its treatment, and information needs (e.g., pain coping techniques that are both analgesic and nonpharmaceutical). **EBN:** *Obtaining individualized history and goals for coping with pain during labor and birth helps identify how to better guide a client through childbirth and increase client satisfaction with the process. Women's satisfaction with the childbirth process is not directly correlated with pharmacological pain relief, but it is greatly enhanced by continuity of care and care provider presence (Van der Gucht & Lewis, 2015).*
- Goal is for the client to manage labor pain from admission until delivery of infant with either natural childbirth and associated pain management techniques or pharmaceutical measures to reduce pain experience. **EB:** *For the client who is able to self-report, when using a self-report pain tool, caution must be used because a high or low score is not always associated with lack of coping or suffering when used for labor pain (Caughey & Tilden, 2021).*
- Based on the client's ability to cope with labor pain, discuss with client pain management options, including pharmacological and nonpharmacological interventions. Coping strategies women may implement include being still or rocking, focusing on breathing, relaxing muscles, changing position, listening to soothing music, making noises, and being in water (ACNM, 2020). **EB:** *Implement strategies or request orders to help client cope with labor pain. This may include massage, movement (such as rocking or swaying, sitting on birthing ball, and position changes), rhythmic breathing, relaxation techniques, aromatherapy, intradermal water blocks, intravenous (IV) narcotics, transcutaneous electrical nerve stimulation (TENS), nitrous oxide, hydrotherapy, and neuraxial anesthesia (Gilbert, 2020).* **EBN:** *Self-identified nonpharmacological coping strategies, such as relaxation techniques, movement, distraction, imagery, breathing techniques, and making noises, can assist with labor pain (ACNM, 2020).*
- Based on the client's ability to cope and their perception of labor pain, assess the physiological-natural process of labor, physical environment, and emotional/psychosocial dynamics and behaviors (Asl et al, 2018). **CEB:** *Labor pain is a combination of physiological and psychosocial process (Koyyalamudi et al, 2016). The best way to help a laboring woman cope includes continuous support, creating a safe environment, and helping to relieve feelings of fear and vulnerability (Van der Gucht & Lewis, 2015). Being present with a laboring woman and observing indicators of pain can also help a laboring woman cope (Van der Gucht & Lewis, 2015; Asl et al, 2018).*
- Based on the client's ability to cope, offer intervention (either nonpharmacological or pharmacological). **EBN:** *Nonpharmacological pain interventions are low cost and low risk. They are also directed at increasing comfort during labor, preventing suffering, and allowing women to cope with labor pain (Caughey & Tilden, 2021). Nonpharmacological pain measures can be used by themselves or in combination with pharmacological intervention during labor. If the client is unable to cope with labor by using nonpharmacological pain relief measures, offering pharmacological pain relief measures is appropriate. A client may be able to proceed through labor and delivery without pain medication but should never be denied medication if she requests it (Caughey & Tilden, 2021).*
- Nonpharmacological pain relief measures are low-risk and low-resource interventions (Caughey & Tilden, 2021). These approaches can encompass the physical sensation of pain and the psychoemotional and spiritual components of care. By addressing all aspects of client needs (physical, emotional, and spiritual), suffering can be reduced during labor (Caughey & Tilden, 2021).
  - Ambulation/rocking/swaying is a safe and effective coping measure for labor pain. This is usually a client-initiated response to labor pain; however, caregivers can encourage women to ambulate or change position to ease pain or allow clients to cope better with labor pain.
  - Hydrotherapy either as immersion in water or bathing can be used to promote relaxation, decrease acute anxiety, help cope with pain, promote greater maternal movement, reduce the need for pharmacological pain relief measures, and promote normal physiological labor (Shaw-Battista, 2017; Sidebottom et al, 2020). **EBN:** *Water labor may be indicated for women to help with relaxation during labor.*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

This may enable the client to proceed through labor without pharmacological intervention because it may reduce anxiety around labor and contraction pain (Shaw-Battista, 2017).

- ❍ TENS is a small, handheld device that transmits low-voltage electrical impulses to the skin (Caughey & Tilden, 2021). The device suppresses the conduction of pain through pain fibers by using small electrical impulses (Shahoei et al, 2017). **EBN:** *The use of this device is controlled by the client herself and can vary the pattern and intensity of the cutaneous electrical impulse depending on the contraction pattern and pain (Caughey & Tilden, 2021). The use of TENS has no adverse side effects and can improve overall satisfaction with the labor and birth experience when used correctly (Shahoei et al, 2017).*

- Pharmacological measures for pain relief are high resource and high risk; they require professional training for administration, incur cost, and have a greater risk to mother and baby (Caughey & Tilden, 2021).
- Nitrous oxide is a blend of 50% nitrous oxide with 50% oxygen. The use of nitrous oxide may not alleviate pain, but it may help with satisfaction of the birth experience (Richardson et al, 2019). **EBN:** *Nitrous should be avoided in clients with vitamin B_{12} deficiency or MHFR mutation/deficiency (Hays, 2020). Most common side effects of nitrous oxide are nausea and dizziness (Richardson et al, 2019). Correct usage of nitrous is needed for optimum efficacy; it must be initiated before contraction pain because the peak onset is 50 seconds from initial inhalation (Collins et al, 2018).*
- IV medications for pain management are an alternative for some women who do not desire an epidural; IV medications are generally opioids. **EBN:** *These are advantageous because they are easy to administer, are widely available, and are less invasive than neuraxial techniques of pain relief (i.e., an epidural). Side effects are common and include nausea, vomiting, and drowsiness (Collins et al, 2018).*
- Epidural, combined spinal-epidural (CSE), and dural puncture epidural (DPE) are appropriate for laboring women when requested by the client (unless there is a contraindication). **EB:** *Contraindications to neuraxial anesthesia may include cardiac disease, hematologic disorders, spinal muscular or neurologic disease, and/or hepatic or renal disease (American College of Obstetricians and Gynecologists' Committee on Practice Bulletins—Obstetrics, 2016).* **EBN:** *During placement of neuraxial anesthesia maternal oxygen saturation and heart rate should be measured continuously. Blood pressure should be measured every 5 minutes, and fetal heart rate should be monitored at least before and after administration according to institution guidelines. Continue to monitor maternal blood pressure, pain control, motor function, and sensory levels at regular intervals to make sure the anesthesia is working properly. Also, continue to document client's vital signs and pain assessment (Collins et al, 2018).*
- Account for clients' abilities to cope with labor pain regarding their psychosocial, cultural, and spiritual backgrounds. A woman's positive perceptions of how she will be able to cope with labor are associated with reduced anxiety, pain, and intervention during labor (Van der Gucht & Lewis, 2015; Caughey & Tilden, 2021). **EB:** *Coping has many facets, including cognitive, behavioral, and emotional aspects (Van der Gucht & Lewis, 2015). How a woman copes with pain during labor includes factors such as personality traits, type of stress, religious thoughts and beliefs, confidence in ability to cope, support available, and attitude toward pain; coping methods encompass physiological, psychological, cognitive, and spiritual methods (Van der Gucht & Lewis, 2015). Each method of coping is an individual decision and greatly influenced by personality traits. Culturally learned values and attitudes as well as personality traits and emotional behavior may greatly influence how women cope with acute labor pain (Segerstrom & Smith, 2019).*
- Document pain assessment through direct observation. Also document interventions to facilitate labor pain management through the continuum of the women's labor experience (Van der Gucht & Lewis, 2015).

Impaired Parenting

Domain 7 Role relationship Class 1 Caregiving roles

Marina Martinez Kratz, MS, RN, CNE

NANDA-I

Definition

Limitation of primary caregiver to nurture, protect, and promote optimal growth and development of the child, through a consistent, empathic exercise of authority and appropriate behavior in response to the child's needs.

Defining Characteristics

Parental Externalizing Symptoms

Hostile parenting behaviors; impulsive behaviors; intrusive behaviors; negative communication

Parental Internalizing Symptoms

Decreased engagement in parent-child relations; decreased positive temperament; decreased subjective attention quality; extreme mood swings; failure to provide safe home environment; inadequate response to infant behavioral cues; inappropriate child-care arrangements; rejects child; social alienation

Infant or Child

Anxiety; conduct problems; delayed cognitive development; depressive symptoms; difficulty establishing healthy intimate interpersonal relations; difficulty functioning socially; difficulty regulating emotion; extreme mood alterations; low academic performance; obesity; role reversal; somatic complaints; substance misuse

Related Factors

Altered parental role; decreased emotion recognition abilities; depressive symptoms; difficulty managing complex treatment regimen; dysfunctional family processes; emotional vacillation; high use of internet-connected devices; inadequate knowledge about child development; inadequate knowledge about child health maintenance; inadequate parental role model; inadequate problem-solving skills; inadequate social support; inadequate transportation; inattentive to child's needs; increased anxiety symptoms; low self efficacy; marital conflict; nonrestorative sleep-wake cycle; perceived economic strain; social isolation; substance misuse; unaddressed intimate partner violence

At-Risk Population

Parent

Adolescents; economically disadvantaged individuals; homeless individuals; individuals experiencing family substance misuse; individuals experiencing situational crisis; individuals with family history of

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

post-traumatic shock; individuals with history of being abused; individuals with history of being abusive; individuals with history of being neglected; individuals with history of exposure to violence; individuals with history of inadequate prenatal care; individuals with history of prenatal stress; individuals with low educational level; sole parents

Infant or Child

Children experiencing prolonged separation from parent; children with difficult temperament; children with gender other than that desired by parent; children with history of hospitalization in neonatal intensive care; premature infants

Associated Conditions

Parent

Depression; mental disorders

Infant or Child

Behavioral disorder; complex treatment regimen; emotional disorder; neurodevelopmental disabilities

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Cessation; Abuse Protection; Abuse Recovery: Abusive Behavior Self-Restraint; Child Development (all); Coping; Family Functioning; Family Social Climate; Knowledge: Child Physical Safety; Neglect Recovery; Parent-Infant Attachment; Parenting Performance; Psychosocial Safety; Role Performance; Social Support

Example NOC Outcome with Indicators

Parenting Performance: Psychosocial Safety as evidenced by the following indicators: Fosters open communication/Recognizes risks for abuse/Uses strategies to eliminate risks for abuse/Selects appropriate supplemental caregivers/Uses strategies to prevent high-risk social behaviors/Provides required level of supervision/Sets clear rules for behavior/Maintains structure and daily routine in child's life. (Rate the outcome and indicators of **Parenting Performance: Psychosocial Safety:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

P

Client Outcomes

Client Will (Specify Time Frame)

- Initiate appropriate measures to develop a safe, nurturing environment
- Acquire and display attentive, supportive parenting behaviors and child supervision
- Identify appropriate strategies to manage a child's inappropriate behaviors
- Identify strategies to protect child from harm and/or neglect and initiate action when indicated

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Abuse Protection Support: Child; Attachment Promotion; Caregiver Support; Developmental Enhancement: Adolescent, Child; Environmental Management: Family Integrity Promotion; Impulse Control Training; Infant Care; Parent Education: Adolescent, Childrearing Family, Infant; Parenting Promotion; Role Enhancement; Substance Use Prevention, Treatment; Teaching: Infant Stimulation; Toddler Nutrition; Toddler Safety

Example NIC Activities—Family Integrity Promotion

Identify typical family coping mechanisms; Determine typical family relationships for each family; Counsel family members on additional effective coping skills for their own use; Assist family with conflict resolution; Monitor current family relationships; Facilitate a tone of togetherness within and among the family; Encourage family to maintain positive relationships; Refer for family therapy, as indicated

Nursing Interventions and *Rationales*

- Use the Parenting Sense of Competence (PSOC) scale to measure parental self-efficacy. **EB:** *The PSOC contains three useful factors that reflect satisfaction with the parental role, parenting efficacy, and interest in parenting. Mothers and fathers will differ in parenting of their children and their sense of competence* (*Karp et al, 2015*).
- Determine parent/family sources of stress, using the Parental Stress Scale. **CEB:** *The Parental Stress Scale is a valid and reliable self-report scale that contains 18 items representing pleasure or positive themes of parenthood* (*Berry & Jones, 1995*).
- Use family-centered care and role modeling for holistic care of families. **EBN:** *Incorporating family-centered care helps enhance the parents' role in caring for their child (Cady et al, 2015).*
- Assess for the following signs of parental burnout: exhaustion in one's parental role, contrast with previous parental self, feelings of being fed up with one's parental role, and emotional distancing from one's children. **EB:** *A study to measure parental burnout identified the four dimensions of parental burnout syndrome as exhaustion in one's parental role, contrast with previous parental self, feelings of being fed up with one's parental role, and emotional distancing from one's children (Roskam, Brianda, & Mikoljczak, 2018).*

▲ Institute abuse/neglect protection measures if evidence exists of an inability to cope with family stressors or crises, signs of parental substance abuse are observed, or a significant level of social isolation is apparent. **EBN:** *Encouraging parents to be involved with social networking can help reduce stressors and assist with coping in a crisis (Bennett et al, 2017).*

- Evaluate the family's perceived strength of its social support system. Encourage the family to use social support. **EB:** *A study of African American mothers found that social support moderated the relationship between parental stress and child behavior* (*Royal et al, 2017*).
- Support parents' competence in appraising their infant's behavior and responses and aim supportive interventions to minimize parents' experiences of strain or stress. **EBN:** *Encourage and support the presence of the parents with the care of the infant (Ottosson & Lantz, 2017).*

▲ Refer to parenting training programs. **EB:** *For parents of young children with neurodevelopmental disabilities, a systematic review found that parental participation in parent training programs significantly increased parental self-efficacy levels (Hohlfeld et al, 2018).*

- Refer to Readiness for Enhanced **Parenting** for additional interventions.

Multicultural

- Acknowledge racial/ethnic differences at the onset of care. **EBN:** *Providing culturally competent care is important to health care equality and is important for nurses to understand the importance of identifying the cultural differences that their clients will require* (*Dzubaty, 2016*).
- Assess for the influence of stigma related to parent help-seeking behaviors. **EB:** *A study found that self-stigma was the strongest predictor of help-seeking among African American parents (Dempster et al, 2015).*
- Assess for the influence of cultural beliefs, norms, and values on the client's perceptions of the parental role. **EBN:** *Understanding the cultures and beliefs of parents can enhance the interactions between nurse and family and assist the nurse to better care for the child and the family* (*Xiong et al, 2016*).
- Acknowledge that value conflicts arising from acculturation stresses may contribute to increased anxiety and significant conflict with the parental role. **EB:** *Study results suggest that lower acculturation conflict is associated with higher perceptions of general parenting competence for both Asian and Latin American parents (Kiang, Glatz, & Buchanan, 2017).*
- Refer parents of young children in specific cultural communities to support programs. **EBN:** *Parents and children benefit when a support group is incorporated into the care (Thomson-Salo et al, 2017).*

Home Care

- The interventions previously described may be adapted for home care use.

Client/Family Teaching and Discharge Planning

- Encourage children and parent involvement in bereavement support groups, as an adjunct to grief therapy. **EB:** *A systematic review found that online support groups may be a useful adjunct to, but not an alternative to, grief therapy or counseling* (*Robinson & Pond, 2019*).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- ▲ Refer to a parenting program to facilitate learning of parenting skills. **EBN:** *A study of foster parents showed that participation in parenting programs increased levels of skills and knowledge following training than did those in the control group (Solomon, Niec, & Schoonover, 2017).*
- Teach the client about available community resources (e.g., therapists, ministers, counselors, self-help groups). **EBN:** *Community-based resources can support caregivers and ensure that they can identify needed services (Tallon et al, 2017).*
- Teach parents the importance of involvement with and monitoring of child/adolescent technology usage, social media presence, and online activities for digital safety. **EB:** *A study found that parents' parental involvement was associated with a change in adolescent online risk-taking behavior through co-viewing, discussion of content viewed, and joint decision making regarding online activities (Wang & Xing, 2018).*
- Promotion of better-quality relationships between parents and children is an effective strategy that can lead to enhanced learning. Good-quality parenting leads to improved cognitive and social skills for children. **EBN:** *Parents have a positive effect on their children, which can lead to improved self-confidence and a stronger parent–child relationship (Kim et al, 2015).*

Readiness for Enhanced Parenting

Domain 7 Role relationship Class 1 Caregiving roles

Marina Martinez Kratz, MS, RN, CNE

NANDA-I

Definition

A pattern of primary caregiver to nurture, protect, and promote optimal growth and development of the child, through a consistent, empathic exercise of authority and appropriate behavior in response to the child's needs, which can be strengthened.

Defining Characteristics

Expresses desire to enhance acceptance of child; expresses desire to enhance attention quality; expresses desire to enhance child health maintenance; expresses desire to enhance childcare arrangements; expresses desire to enhance engagement with child; expresses desire to enhance home environmental safety; expresses desire to enhance mood stability; expresses desire to enhance parent-child relations; expresses desire to enhance patience; expresses desire to enhance positive communication; expresses desire to enhance positive parenting behaviors; expresses desire to enhance positive temperament; expresses desire to enhance response to infant behavioral cues

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Child Development; Knowledge: Child Physical Safety; Parenting Performance; Parenting: Psychosocial Safety

Example NOC Outcome with Indicators

Parenting Performance as evidenced by the following indicators: Provides preventive and episodic health care/Stimulates cognitive and social development/Stimulates emotional and spiritual growth/Empathizes with child/Expresses satisfaction with parental role/Expresses positive self-esteem. (Rate the outcome and indicators of **Parenting Performance:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

P

Client Outcomes

Client/Family Will (Specify Time Frame)

- Affirm desire to improve parenting skills to further support growth and development of children
- Demonstrate loving relationship with children
- Provide a safe, nurturing environment
- Assess risks in home/environment and take steps to prevent possibility of harm to children
- Meet physical, psychosocial, and spiritual needs or seek appropriate assistance

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Anticipatory Guidance; Attachment Promotion; Developmental Enhancement: Adolescent; Child; Family Integrity Promotion: Childbearing Family; Infant Care; Newborn Care; Parent Education: Adolescent, Childrearing Family, Infant; Parenting Promotion; Teaching: Infant Stimulation

Example NIC Activities—Parenting Promotion

Assist parents to have realistic expectations appropriate to developmental and ability level of child; Assist parents with role transition and expectations of parenthood

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Nursing Interventions and *Rationales*

- Use family-centered care and role modeling for holistic care of families. **EBN:** *Incorporating family-centered care helps enhance the parents' role in caring for their child (Cady et al, 2015).*
- Use cell phone technology to enhance parenting interventions. **EB:** *A study found that a cellular phone–supported version of a parent–child interactions intervention promoted intervention retention and improved children's behavior* (*Lefever et al, 2017*).
- Promote low-technology interventions, such as massage and multisensory interventions (maternal voice, eye-to-eye contact, and rocking) and music, to reduce maternal and infant stress and improve mother–infant relationship. **EB:** *When mothers sing to their infants it can calm the infants and make them feel safe (de l'Etoile et al, 2017).*
- Promote mindful parenting techniques such as being fully present during interactions, maintaining freedom from distractions or judgment, and responding with an open mind. **EB:** *A study of parent–adolescent recurrent conflict found that higher levels of mindful parenting were significantly related to lower levels of recurrent conflict 2 to 3 months later and lower levels of recurrent conflict were significantly related to lower levels of externalizing problems and internalizing problems 1 year later (Park et al, 2020).*
- Support skin-to-skin care for infants at risk at birth; maintain infants in an upright position during skin-to-skin contact. **EB:** *Skin-to-skin care helps the mother and infant bond and assists in the infant's growth and development (Gavhane, Eklare, & Mohammad, 2016).*
- Encourage family meals and rituals. **EB:** *Study findings suggest that dinnertime rituals can potentially moderate the effects of parenting stress on child outcomes (Yoon et al, 2015).*
  - ❍ Refer to parenting training programs. **EB:** *For parents of young children with neurodevelopmental disabilities, a systematic review found that parental participation in parent training programs significantly increased parental self-efficacy levels* (*Hohlfeld et al, 2018*).
  - ❍ Refer to the care plan for Impaired **Parenting** for additional interventions.

Multicultural

- Understand and incorporate cultural differences into interventions to enhance the impact of interventions. **EB:** *Tailoring interventions to the customs, beliefs, preferences, and strengths of specific groups may increase effectiveness (McCalman et al, 2017).*
- Support programs for parents of young children in specific cultural communities. **EBN:** *Parents and children benefit when a support group is incorporated into the care (Thomson-Salo et al, 2017).*
- Acknowledge and praise parenting strengths noted. **EBN:** *Parents see what they are doing right and are encouraged to continue the behavior (Ludmer et al, 2017).*

Home Care

- The nursing interventions previously described should be used in the home environment with adaptations as necessary. **EB:** *Clinicians should help educate parents on the care the child will need at home and modify to meet the family's needs (Thrasher et al, 2018).*

▲ Refer to a parenting program to facilitate learning of parenting skills. **EBN:** *A study of foster parents showed that participation in parenting programs increased levels of skills and knowledge following training more than did those in the control group (Solomon, Niec, & Schoonover, 2017).*

Client/Family Teaching and Discharge Planning

- Refer to Client/Family Teaching and Discharge Planning for Impaired **Parenting** for suggestions that may be used with minor adaptations.
- Teach parents home safety: reduction of hot water temperature, proper poison storage, use of smoke alarms, and installation of safety gates for stairs. **EB:** *Participation in a parent training program that emphasized home safety found significant reductions in home hazards after program participation (Rostad et al, 2017).*
- Provide parent teaching about supportive emotion communication practices such as listening and connection, labeling feelings, and providing emotional support. **EB:** *The Let's Connect program is an emotion-focused parenting intervention that showed significant increases in supportive emotion communication practices as well as significant reductions in unsupportive emotion communication in a pilot study (Shaffer et al, 2019).*

- ▲ Refer mothers of children with type 1 diabetes for community support in babysitting, child care, or respite. **EB:** *Families raising children with diabetes need to have support and interventions to assist with the care of the child to help reduce the burden of care on the parents (Kobos & Imiela, 2015).*
- ▲ Refer parents of sexual minority adolescents to supportive parenting resources and programs. **EB:** *The Parent Resource for Increasing Sexual Minority Support (PRISMS) is an interactive online intervention designed to promote parental self-efficacy and behavioral intentions for supporting a sexual minority child. Participation in PRISMS appears to be effective for parents who were highly distressed about their child's sexual orientation* (*Goodman & Israel, 2020*).
- ● Teach parents the importance of involvement with and monitoring of child/adolescent technology usage, social media presence, and online activities for digital safety. **EB:** *A study found that parental involvement was associated with a change in adolescent online risk-taking behavior through co-viewing, discussion of content viewed, and joint decision-making regarding online activities (Wang & Xing, 2018).*
- ● Promotion of better-quality relationships between parents and children is an effective strategy that can lead to enhanced learning. Good-quality parenting leads to improved cognitive and social skills for children. **EBN:** *Parents have a positive effect on their children, which can lead to improved self-confidence and a stronger parent–child relationship (Kim et al, 2015).*

Risk for Impaired Parenting

Domain 7 Role relationship Class 1 Caregiving roles

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Primary caregiver susceptible to a limitation to nurture, protect, and promote optimal growth and development of the child, through a consistent, empathic exercise of authority and appropriate behavior in response to the child's needs.

Risk Factors

Altered parental role; decreased emotion recognition abilities; depressive symptoms; difficulty managing complex treatment regimen; dysfunctional family processes; emotional vacillation; high use of Internet-connected devices; inadequate knowledge about child development; inadequate knowledge about child health maintenance; inadequate parental role model; inadequate problem-solving skills; inadequate social support; inadequate transportation; inattentive to child's needs; increased anxiety symptoms; low self efficacy; marital conflict; nonrestorative sleep-wake cycle; perceived economic strain; social isolation; substance misuse; unaddressed intimate partner violence

At-Risk Population

Parent

Adolescents; economically disadvantaged individuals; homeless individuals; individuals experiencing family substance misuse; individuals experiencing situational crisis; individuals with family history of post-traumatic shock; individuals with history of being abused; individuals with history of being abusive; individuals with history of being neglected; individuals with history of exposure to violence; individuals with history of inadequate prenatal care; individuals with history of prenatal stress; individuals with low educational level; sole parents

Infant or Child

Children experiencing prolonged separation from parent; children with difficult temperament; children with gender other than that desired by parent; children with history of hospitalization in neonatal intensive care; premature infants

Associated Conditions

Parent

Depression; mental disorders

Infant or Child

Behavioral disorder; complex treatment regimen; emotional disorder; neurodevelopmental disabilities

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plans for Readiness for Enhanced **Parenting** and Impaired **Parenting**.

Risk for Perioperative Positioning Injury

Domain 11 Safety/protection Class 2 Physical injury

Kristen A. Oster, DNP, APRN, ACNS-BC, CNOR, CNS-CP

NANDA-I

Definition

Susceptible to inadvertent anatomical and physical changes as a result of posture or positioning equipment used during an invasive/surgical procedure, which may compromise health.

Risk Factors

Decreased muscle strength; dehydration; factors identified by standardized, validated screening tool; inadequate access to appropriate equipment; inadequate access to appropriate support surfaces; inadequate availability of equipment for individuals with obesity; malnutrition; obesity; prolonged non-anatomic positioning of limbs; rigid support surface

At-Risk Population

Individuals at extremes of age; individuals in lateral position; individuals in lithotomy position; individuals in prone position; individuals in Trendelenburg position; individuals undergoing surgical procedure >1 hour

Associated Conditions

Diabetes mellitus; edema; emaciation; general anesthesia; immobilization; neuropathy; sensoriperceptual disturbance from anesthesia; vascular diseases

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Circulation Status; Immobility Consequences: Physiological; Joint Movement; Neurological Status; Respiratory Status; Risk Control; Sensory Function; Skeletal Function; Tissue Integrity: Skin and Mucous Membranes; Tissue Perfusion: Peripheral

Example NOC Outcome with Indicators

Tissue Perfusion: Peripheral as evidenced by the following indicators: Peripheral edema/Localized extremity pain/Skin breakdown/Muscle cramps/Peripheral pulses/Numbness/Tingling/Necrosis. (Rate the outcome and indicators of **Tissue Perfusion: Peripheral:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate unchanged skin condition, with exception of the incision, throughout the perioperative experience
- Demonstrate resolution of redness of the skin at points of pressure within 30 minutes after pressure is eliminated
- Remain injury-free related to surgical positioning, including intact skin and absence of pain and/or numbness associated with surgical positioning
- Demonstrate unchanged or improved physical mobility from preoperative status
- Demonstrate unchanged or improved peripheral sensory integrity from preoperative status

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Circulatory Precautions; Fall Prevention; Neurological Monitoring; Peripheral Sensation Management; Positioning: Intraoperative; Pressure Ulcer Prevention; Risk Identification; Skin Surveillance; Surgical Precautions

Example NIC Activities—Positioning: Intraoperative

Use an adequate number of personnel to transfer client; Maintain client's proper body alignment

Nursing Interventions and *Rationales*

General Interventions for Any Surgical Client

▲ Positioning of the client during a surgical procedure is the responsibility of all members of the perioperative team, including registered nurse, surgical technologist, surgeon, and anesthesia professional (Spruce, 2018).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Assess the client's skin integrity throughout the perioperative process to avoid skin breakdown during surgical/invasive procedures. Continuous evaluation of clinical changes in the client is necessary to assess outcomes and effects of nursing interventions for surgical positioning (Bjorkland-Lima et al, 2019). **EB:** *Developing skin breakdown manifested as a skin tear, pressure ulcer, deep tissue injury, or burn is a significant client complication affected by the duration of surgery and client positioning (National Pressure Injury Advisory Panel [NPIAP] & European Pressure Ulcer Advisory Panel [EPUAP], 2019; Van Wicklin, 2019).*
- Recognize that surgery increases a client's risk for skin injury because of the time the client is immobile for the procedure (Park, Park, & Hwang, 2019).
- An operating room–related pressure injury is any pressure injury that develops within 48 to 72 hours intraoperatively, interoperatively, or postoperatively of a surgical procedure (Khong et al, 2020).

Prevention of Pressure Injuries

- Complete a preoperative assessment to identify client factors that will increase a client's risk for pressure injuries. This includes physical alterations that may require additional precautions for procedure-specific positioning and to identify specific procedural positioning needs, type of anesthesia, and so on. **EBN:** *Factors to consider when assessing the surgical client to plan for proper positioning are preexisting conditions such as vascular disease or diabetes, range of motion, presence of prostheses and/or fractures, skin condition, advanced age, nutritional status, weight, American Society of Anesthesiologists (ASA) physical status classification, and the presence of moisture (Spruce, 2017; Van Wicklin, 2019).*
- Identify procedure risk factors such as length and type of surgery, potential for intraoperative hypotensive episodes, low core temperatures, and decreased mobility on postoperative day 1. **EB:** *Assess the client for additional risk factors, including the duration of immobilization before and during the surgical procedure, client severity of illness, preoperative nutritional status, position for the procedure, and type of anesthesia (NPIAP & EPUAP, 2019; Van Wicklin, 2019). Increased length of surgery has been identified as an intraoperative-specific risk factor to pressure injury development (Miller et al, 2020). Surgeries lasting more than 3 hours provide a significant risk for pressure ulcer development, with continued risk for development increasing every hour (Riemenschneider, 2018).* **EB:** *Recent studies have identified the use of vasopressor as a significant risk for pressure ulcer development (NPIAP & EPUAP, 2019). Additional review showed the number of surgeries a client has during his or her hospital inpatient stay and the length of surgery (over 1 hour), body mass index, Braden score, mortality risk, and history of diabetes are also risk factors for pressure ulcer development (Tschannen & Anderson, 2020).*
- Recognize that all surgical clients should be considered at high risk for pressure ulcer development, because pressure ulcers can develop in as little as 20 minutes in the operating room. **EBN:** *Operating room mattresses, the client support surface, should be chosen for their pressure redistribution (Spruce, 2017). Support surfaces that redistribute pressure are recommended. Alternating pressure overlays may improve outcomes in regard to pressure injuries, including clients deemed at high risk for pressure injury development during surgery (Joseph et al, 2019).*
- Remove all client jewelry and accessories. **EBN:** *Jewelry and accessories, such as body piercings and hair devices, can get caught and torn out, causing skin injury; the client can lie on them and develop a pressure injury; or the client can experience a burn from cautery equipment (Van Wicklin, 2019).*
- Protect the heels during surgery by elevating the heels completely. **EB:** *Ensure that the heels are free of the surface of the operating table (NPIAP & EPUAP, 2019). Heel pressure ulcers are one of the most common sites for pressure injury during surgery. Traditional devices such as egg crates, booties, and heel pads do not decrease the pressure. It is recommended that a device be used to elevate the heels and distribute the weight of the client's leg along the calf (Van Wicklin, 2019).*
- Use pressure-reducing devices and pressure-relieving mattresses as necessary to prevent pressure injury. **EB:** *Use a high-specification reactive or alternating pressure support surface on the operating table for all individuals identified as being at risk for pressure ulcer development (NPIAP & EPUAP, 2019). Additional support surfaces may be indicated to offload pressure points on the face and body when the client is placed in a prone position (NPIAP & EPUAP, 2019; Van Wicklin, 2019). Support surfaces may be made of foam, gel, air, fluid, or a combination of these surfaces. The goal is to have pressure distributed over the largest area possible. This is accomplished by having the surface envelop the client (Van Wicklin, 2019). Assess for shearing forces that may cause tissue injury when placing the client in the Trendelenburg position for selected robotic surgical procedures (Das et al, 2019).*
- Avoid using rolled sheets and towels as positioning devices because they tend to produce high and inconsistent pressures. Special positioning devices are available that redistribute pressure. **EBN:** *Towels and*

rolled sheets contribute to friction injuries and increase pressure on the client. Pillows are an acceptable alternative when other positioning devices are unavailable (Van Wicklin, 2019).

- Avoid covering positioning devices or placing extra blankets on top of a pressure-reducing surface. **EB:** *Adding material to a pressure-reduction surface actually increases the pressure, producing a negative result (Van Wicklin, 2019). Use of rolled sheets and towels beneath overlays decreases the overlays' effectiveness and causes pressure (Van Wicklin, 2019).*
- The nurse should demonstrate knowledge not only of the equipment but also of anatomy and the application of physiological principles to properly position the client. **EBN:** *Preplanning ensures that the correct positioning devices are available and in good working condition, and that appropriate numbers of personnel are available to position the client safely and appropriately. High-specification reactive foam mattresses should be used for clients at high risk for pressure injury (Van Wicklin, 2019).*
- Monitor client position and pressure being applied to the client intraoperatively by staff, equipment, and/or instruments. *Clients may move slightly or shift during surgery, especially during long procedures or when new equipment is introduced, requiring that the client be repositioned to avoid pressure or nerve injury (Van Wicklin, 2019).*
- Use additional pressure-redistributing padding on all bony prominences. **EB:** *Additional padding increases client comfort, helps redistribute pressure, and decreases the chance for development of pressure or nerve injuries (Van Wicklin, 2019). Some positioning devices are solid and can increase pressure over bony prominences (Bjøro et al, 2020).*
- Recognize that reddened areas or areas injured by pressure should not be massaged. **EB:** *Rubbing causes friction that can lead to damage to skin/tissue (NPIAP & EPUAP, 2019; Van Wicklin, 2019).*
- Implement measures to prevent inadvertent hypothermia. *Anesthesia can compromise perfusion by causing hypotension and hypothermia. When coupled with the client being immobile on a noncompliant surface for an extended time period, hypothermia increases vulnerability for pressure ulcer development during surgery.*
- Many surgical clients have medical devices placed as a part of the surgical procedure. Avoid positioning the client on the medical device and perform frequent assessments of the skin under and around the device (NPIAP & EPUAP, 2019; Cooper et al, 2020). **EB**: *If a medical device is used for a prolonged period of time it can create pressure or edema and cause friction/shearing resulting in reduced sensation, circulation, and alteration in the microclimate (Cooper et al, 2020).*

Positioning the Perioperative Client

- Ensure linens on the operating room table are free of wrinkles. **EBN:** *Wrinkles may cause pressure/injury to the skin if the client is unable to move for prolonged periods of time. Layers of linens or blankets between the client and the support surface decrease the pressure-redistributing effect of the support surface (Van Wicklin, 2019).*
- Lock the operating room table, cart, or bed and stabilize the mattress before transfering/positioning the client. Monitor the client while on the operating room table at all times. **EBN:** *Studies showed that a lack of clear communication about who should be watching the client has contributed to falls (Van Wicklin, 2019).*
- Lift rather than pull or slide the client when positioning to reduce the incidence of skin injury from shearing and/or friction. **EB/EBN:** *Sliding or pulling the client can cause shearing force and/or friction (NPIAP & EPUAP, 2019; Van Wicklin, 2019).*
- Ensure that appropriate numbers of personnel are present to assist in positioning the client. **EBN:** *A minimum of two people should assist an awake client to transfer from a cart/bed to the operating room table: one person on the stretcher side to assist the client onto the table and a second person on the far side of the table to prevent the client from falling off. A minimum of four persons are necessary when transferring/positioning an anesthetized, unconscious, obese, or weak client (Van Wicklin, 2019).*
- Recognize that, optimally, clients (especially those with limited range of motion/mobility) should be asked to position themselves under the nurse's guidance before induction of anesthesia so that the nurse can verify that a position of comfort has been obtained.
- Ensure that nerves are protected by positioning extremities carefully. **EB/EBN:** *Nerves can be injured by stretching and compression, which is caused by a loss of protective muscle tone and pressure between two fixed points. Careful attention to proper body alignment and padding is necessary to prevent peripheral nerve injury (Van Wicklin, 2019; Bjøro et al, 2020).*
- Use slow and smooth movements during positioning *to allow the circulatory system to readjust.*
- Reassess the client after positioning and periodically during the procedure to maintain proper alignment and skin integrity. **EBN:** *Changes in position can expose or injure body parts (e.g., shearing, friction,*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

compression) that were originally protected, and the safety strap can shift and apply increased pressure. If possible, after 3 or 4 hours of surgery, the client should be checked, under the drapes, to make sure the client remains in alignment (Van Wicklin, 2019).

- Frequently assess the eyes and/or monitor intraocular pressure, especially when client is in the prone, Trendelenburg, or knee-chest position. **EBN:** *The cornea can easily be injured during surgery because of a decrease in lacrimation, failure of the eyes to fully close and/or improperly applied face masks, or prolonged prone positioning (Van Wicklin, 2019).*
- Position hips in proper alignment with knees flexed. Unaligned hips can cause pressure to the low back and hip joints. **EBN:** *Proper body alignment needs to be maintained to prevent nerve and pressure injuries (Van Wicklin, 2019).*
- Position the arms extended on arm boards so that they do not extend beyond a 90-degree angle. The arms should be at the level of the bed and should not be allowed to hang off the bed. Do not position arms at sides unless surgically necessary. **EBN:** *Positioning at less than a 90-degree angle, with elbows slightly flexed and hands supine, decreases the risk of a stretching injury to the brachial plexus and possible compression or occlusion injury to the subclavian and axillary arteries. When positioning arms at the sides is necessary, place the arms beneath the sheet and bring the sheet over the top of the arm and then tuck the sheet beneath the mattress so that the arm cannot fall off the mattress and hang over the metal edge of the table, where the surgical team could lean against it (Van Wicklin, 2019).*
- Protect the client's skin surfaces from injury by preventing pooling of preparative solutions, blood, irrigation, urine, and feces. **EBN:** *Prep solutions may change the pH of the skin and remove protective oils, making the skin more susceptible to pressure and friction. Pooling also increases the risk of maceration (Van Wicklin, 2019).*
- Keep the client appropriately covered and limit traffic in the room during the procedure. **EBN:***Reducing unnecessary exposure provides privacy and dignity for the client during positioning and helps prevent hypothermia (Van Wicklin, 2019).*
- When positioning the client prone, care should be taken to ensure the head and neck are properly positioned. In addition, 5- to 10-degree reverse Trendelenburg should be used, if possible, to reduce intraocular pressure and decrease facial edema. **EB/EBN:** *Inappropriate positioning of the head and neck in the prone position can lead to vertebral artery obstruction and possible stroke. Standard foam prone pillows should be used because they stabilize the neck in neutral, and the endotracheal tube can be positioned away from the face to decrease excessive pressure (Spruce, 2017; Van Wicklin, 2019).*
- Recognize that clients positioned in the lithotomy position should be kept in this position for as short a time as possible. **EBN:** *One research review suggested that the client's legs be removed from lithotomy positioning devices every 2 hours when the procedure is expected to last 4 hours or longer. Reported complications from extended time in this position include muscle contusion, compartment syndrome, and acute renal failure (Van Wicklin, 2019).*
- The lowest heel position should be used in the lithotomy position. **EBN:** *When possible, the legs should be at or lower than the level of the heart to prevent complications (Van Wicklin, 2019).*
- Maintain normal body alignment. **EBN:** *Misalignment, flexion, extension, and rotation may cause muscle and nerve damage and airway interference; pressure on the carotid sinus can cause arrhythmias; and restricted venous outflow can occur with extreme rotation of the head (Van Wicklin, 2019).*
- When applying body supports and restraint straps (safety belt), apply loosely and secure over waist or midthigh at least 2 inches above the knees, avoiding bony prominences by placing a blanket between the strap and the client. **EBN:** *Belts positioned directly over the knees cause compression of the peroneal nerve against the fibula (Van Wicklin, 2019).*
- Assess the client's skin integrity immediately postoperatively. **EB:** *Assess and document postoperative skin/tissue integrity focusing on areas with constant pressure during the procedure and limb function for nerve damage (Celik, Karayurt, & Ogce, 2019; NPIAP & EPUAP, 2019).*
- Ensure that complete, concise, accurate documentation of client assessment and use of positioning devices is in the client's medical record.

Geriatric

- Common age-related diseases include cardiovascular, diabetes, lung, renal, musculoskeletal, and neurodegenerative diseases. Progression of these diseases can lead to impaired systems and organs, leading to complications including anemia, malnutrition, and recurrent infection (Jaul et al, 2018).
- The skin of older adults (i.e., ≥65 years) is fragile and prone to shear injuries as the skin is less elastic; the dermis is thin and has less collagen, muscle, and adipose tissue than the skin of younger adults (Van

Wicklin, 2019). These changes leave the older adult's skin more susceptible to pressure, bruising, skin tears, infection, impaired thermoregulation, and slow healing (Van Wicklin, 2019). **EBN:** *Use of prophylactic dressings to bony prominences or other areas subjected to pressure, friction, and shear may be beneficial. Use of prophylactic dressings reduces the amount of shear delivered to skin through displacement and absorption of shearing forces (Van Wicklin, 2019).*

Pediatric

- Pressure injury sites in the pediatric client differ from those in the adult population due to differences in anatomic structure. **EBN:** *The occipital region is at increased risk for injury in infants and toddlers in the supine position due to disproportionately large head size (Van Wicklin, 2019).*
- Neonates are vulnerable to skin and pressure injuries because of an immature and underdeveloped epidermis and dermis (Broom, Dunk, & Mohamed, 2019). **EBN:** *The skin of children may be more resilient to normal and shear pressures than the skin of older adults because it is supported with sufficient collagen and elastin (Van Wicklin, 2019).*
- Neonates and children are at higher risk for nutritional deficiencies as a result of smaller appetites and dietary intake in combination with increased nutritional requirement necessary to meet growth needs (Van Wicklin, 2019).
- Use of pediatric- and neonatal-specific pressure injury risk assessment tools accounts for age-specific indicators. **EBN:** *Tools include the Braden Q Scale, Braden Q+P Scale, Glamorgan Scale, and Neonatal Skin Risk Assessment Scale (Van Wicklin, 2019).*

Client/Family Teaching and Discharge Planning

- Teach the client/family signs and symptoms of pressure injury, extremity nerve damage, compartment syndrome, and ocular injury based on surgical positioning. Early detection and treatment is beneficial.

Risk for Peripheral Neurovascular Dysfunction

Domain 11 Safety/projection Class 2

Physical injury

Krystal Chamberlain Tenure, MS, RN, CCRN, SCRN

NANDA-I

Definition

Susceptible to disruption in the circulation, sensation, and motion of an extremity, which may compromise health.

Risk Factors

To be developed

Associated Conditions

Bone fractures; burns; immobilization; mechanical compression; orthopedic surgery; trauma; vascular obstruction

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Circulation Status; Neurological Status: Spinal Sensorimotor Function; Tissue Perfusion: Peripheral

Example NOC Outcome with Indicators

Tissue Perfusion: Peripheral as evidenced by the following indicators: Radial or pedal pulse strength/Capillary refill in fingers or toes/Extremity skin temperature/Localized extremity pain/Numbness/Tingling/Skin color/Muscle strength/Skin integrity/Peripheral edema. (Rate the outcome and indicators of **Tissue Perfusion: Peripheral:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain circulation, sensation, and movement of an extremity within client's own normal limits
- Explain signs of neurovascular compromise

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Exercise Therapy: Joint Mobility; Peripheral Sensation Management

Example NIC Activities—Peripheral Sensation Management

Monitor for paresthesia: numbness, tingling, hyperesthesia, and hypoesthesia; Monitor for thrombophlebitis and deep vein thrombosis

Nursing Interventions and *Rationales*

- Recognize the risk factors that may result in peripheral neurovascular dysfunction. **EB:** *Conditions that diminish limb perfusion (e.g., tight-fitting dressings, casts, intraoperative positioning, edema, burns, trauma, snake or insect bites) could result in peripheral neurovascular dysfunction and/or compartment syndrome, an elevation of pressure within a compartment, leading to decreased tissue perfusion and cell death (Oak & Abrams, 2016; Schreiber, 2016). The nurse's proficient and timely assessment is critical in ensuring a positive client outcome (Schreiber, 2016).*

- Assess for the early onset of neurovascular dysfunction or compartment syndrome by performing the neurovascular assessment as ordered or as indicated by the client's condition, and report abnormal findings to the provider promptly. **EB:** *Early recognition of neurovascular dysfunction will minimize tissue necrosis and functional loss (Oak & Abrams, 2016). Historically, the "five Ps" of assessment, as outlined in the following list, have been used to identify compartment syndrome. However, pain is the most reliable finding and the other findings may be absent or late signs of compartment syndrome though may be helpful in the identification of vascular injury (Maher, 2016; Oak & Abrams, 2016).*
  - Pain: Assess severity (using an appropriate pain scale), quality, radiation, and relief by medications. **EB:** *Pain out of proportion to the injury that does not respond to opiates, and elicited with passive stretching of the compartment, is the earliest indicator and most reliable sign of compartment syndrome (Maher, 2016).*
  - Pulses: Assess the pulses distal to the injury and compare with the unaffected limb; use a 0-to-4 point scale (0 = absent and 4 = strong/bounding). **EB:** *Inequality of pulses is an abnormal finding that can indicate poor perfusion; pulses could still be present in the setting of compartment syndrome (Oak & Abrams, 2016; Schreiber, 2016).*
  - Pallor: Assess skin color and temperature changes below the injury site and compare with unaffected limb; assess capillary refill. **EB:** *Changes in temperature or color could indicate poor perfusion; consider the client's baseline skin tone. Skin that is shiny and pale suggests building pressure. Capillary refill time greater than 3 seconds can indicate abnormal perfusion (Schreiber, 2016).*
  - Paresthesia (change in sensation): Assess by lightly touching the skin proximal and distal to the injury; ask if the client has any unusual sensations such as hypersensitivity, tingling, prickling, decreased feeling, or numbness. **EB:** *Abnormal sensory findings may be related to nerve compression, compromised blood flow, and/or tissue ischemia (Maher, 2016; Schreiber, 2016).*
  - Paralysis: Ask the client to perform appropriate range-of-motion exercises in the unaffected and then the affected extremity. **EB:** *Loss of movement (paralysis) is a late sign of neurovascular dysfunction (Schreiber, 2016).*
  - In addition to the five Ps, assess for swelling or increase in compartment pressure by feeling the extremity; note new onset of firmness of the extremity. Intracompartmental pressures may also be measured with proprietary monitoring devices. **EB:** *Edema can contribute to neurovascular compromise, leading to muscle and nerve damage due to decreased perfusion and ischemia (Oak & Abrams, 2016; Schreiber, 2016).*
- Monitor appropriate application and function of corrective device (e.g., cast, splint, traction) as needed. **EB:** *Neurovascular compromise can result from restrictive pressure from devices or swelling of injured tissue (Oak & Abrams, 2016; Schreiber, 2016). After immobilization (casting or splinting), if pain worsens or there is any tingling or numbness, swelling, delayed capillary refill, or change in color of exposed digits, immediate evaluation is needed.*
- For prevention of deep vein thrombosis (DVT), nursing care of DVT, and pulmonary embolism, refer to the interventions on DVT prevention and treatment in the care plan for Ineffective Peripheral **Tissue** Perfusion.

Risk for Poisoning

Domain 11 Safety/protection Class 4 Environmental hazards

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to accidental exposure to, or ingestion of, drugs or dangerous products in sufficient doses, which may compromise health.

Risk Factors

External

Access to dangerous product; access to illicit drugs potentially contaminated by poisonous additives; access to pharmaceutical preparations; occupational setting without adequate safeguards

Internal

Excessive emotional disturbance; inadequate knowledge of pharmaceutical preparations; inadequate knowledge of poisoning prevention; inadequate precautions against poisoning; neurobehavioral manifestations; unaddressed inadequate vision

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Knowledge: Child Physical Safety, Medication, Personal Safety; Parenting Performance; Risk Control; Risk Control: Alcohol Use, Drug Use; Risk Detection; Safe Home Environment

Example NOC Outcome with Indicators

Knowledge: Child Physical Safety as evidenced by the following indicators: Appropriate activities for child's developmental level/Strategies to prevent medication misuse/Strategies to prevent exposure to toxic chemicals or substances. (Rate the outcome and indicators of **Knowledge: Child Physical Safety:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

P

Client Outcomes

Client Will (Specify Time Frame)

- Prevent inadvertent ingestion of or exposure to toxins or poisonous substances
- Explain and undertake appropriate safety measures to prevent ingestion of or exposure to toxins or poisonous substances
- Verbalize appropriate response to apparent or suspected toxic ingestion or poisoning

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Environmental Management: Safety, First Aid; Health Education; Medication Management; Surveillance; Surveillance: Safety

Example NIC Activities—Environmental Management: Safety

Identify safety hazards in the environment (e.g., physical, biological, chemical); Remove hazards from the environment, when possible

Nursing Interventions and *Rationales*

- When a client presents with possible/actual poisoning, follow the ABCs (airway, breathing and circulation) and administer oxygen if needed. **EB:** *Poisoning is a major cause of morbidity/mortality worldwide.*

Initial evaluation should include vital signs, mental status, pupil size, oxygenation, finger-stick glucose, and cardiac monitoring. Management is geared to supportive care, prevention of poison absorption, antidote use, and enhancement of elimination techniques (Chandran, 2019).

▲ When a client presents with possible poisoning, call the poison control center. **EB**: *The poison control hotline is 1-800-222-1222 or can be reached by texting POISON to 484848. Poison centers are a valuable tool for medical consultations. They are staffed by nurses, pharmacists, toxicologists, and other specialists in poisons and toxins who can recommend treatment advice (American Association of Poison Control Centers, 2021).*

● Obtain a thorough history of what was ingested, how much, and when, and ask to look at the containers. Note the client's age, weight, medications, medical conditions, and any history of vomiting, choking, coughing, or change in mental status. Also take note of any interventions performed before seeking treatment. **EB:** *The history is needed to confirm the diagnosis and is often unreliable when provided by clients with intentional ingestion. Additional information should be obtained from paramedics, police, family, and friends when possible (Chandran, 2019).*

▲ Note results of toxicology screens, arterial blood gases, blood glucose levels, and other ordered laboratory tests. **EB:** *When ingestion information is incomplete or inaccurate, laboratory tests may be needed to determine treatment (Chandran, 2019).*

● For suspected acetaminophen poisoning, obtain an accurate history of the time(s) of acetaminophen ingestion, the quantity, and the formulation of acetaminophen ingested. **EB:** *Acetaminophen poisoning is the most common cause of liver failure. Data collected will inform the timing of the serum acetaminophen level and hepatotoxicity risk. Treatment will include supportive care, prevention of absorption, and treatment with N-acetylcysteine (Saccomano, 2019).*

▲ Initiate prescribed treatment for poisoning promptly. The poison control center will specify any treatment or medications that need to be administered. **EB:** *Some poisoning deaths may be preventable. Substances ingested in preventable deaths have delayed gastrointestinal absorption or require metabolic activation to produce severe toxicity. This allows a time frame for recognition and successful intervention. Early poison center consultation may improve outcomes and decrease deaths (Srisuma et al, 2016).*

▲ Ensure that recommendations from the poison control center are clearly documented and readily accessible in the client's chart. **EB:** *The poison control center expertise provides specialized medical toxicology information needed to manage more serious exposures (Gummin et al, 2019).*

● Follow the "five rights" as guidelines when administering medications. **EB:** *The five traditional rights of medication administration are identified as the right client, the right drug, the right route, the right time, and the right dose (Hanson & Haddad, 2020).*

● Use a bar code scanning system for client identification whenever possible. **EBN:** *The implementation of the barcode administration showed statistically significant reduction in wrong medication, administration omission, wrong dose, and wrong order of administration errors (Macias et al, 2018).*

● Standardize use of abbreviations, acronyms, symbols, and dose designations and eliminate those that are prone to cause errors. **EB:** *The Institute for Safe Medication Practices (2021) has a list of Error-Prone Abbreviations (see https://www.ismp.org/recommendations/error-prone-abbreviations-list).*

● Be aware of the medications that look/sound alike and ensure that the correct medication is ordered and administered. **EB:** *The Institute for Safe Medication Practices (2019) has a list of Confused Drug Names containing look-alike and sound-alike (LASA) name pairs (see https://www.ismp.org/recommendations/confused-drug-names-list).*

● Identify all the client's current medications on admission to a health care facility and compare the list with the current ordered medications. Reconcile any differences in medications. Use the expertise of the pharmacy department if there is any uncertainty regarding the accuracy of the client's medications. Reconcile the list of medications if the client is transferred from one unit to another, when there is a handoff to the next provider of care, and when the client is discharged. **EB:** *Medication reconciliation is an important safety issue because of the number of people taking multiple medications and involves determining what medications the person should be taking, medications they are actually taking, and resolving discrepancies (Aronson, 2017).*

● Assess for possible interactions and adverse effects among prescribed medications and over-the-counter products with a computerized drug interaction checker. **EBN:** *A study found that drug interactions were minimized with tools to support nurses' clinical decision-making (Bueno et al, 2020).*

Pediatric

▲ Evaluate lead exposure risk and consult the health care provider regarding lead screening measures as indicated (public/ambulatory health). **EB:** *High levels of lead can cause anemia, multiorgan damage,*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

seizures, and death in children. Chronic low lead levels can result in physical, cognitive, and neurobehavioral impairment. Sources of lead exposure include lead industries, leaded gasoline, lead-based paint, water pipes, paint, dust, soil, and water. Children at risk for lead exposure include those living in deteriorating or renovated older homes with lead-based paint, living in areas with lead-based industry, and socioeconomic disadvantage (Nussbaumer-Streit et al, 2016).

- Provide multifaceted medication teaching to parents that includes an easy-to-read dosing handout, a teaching session, a teach-back method, and a standardized dosing device for liquid medications. **EB:** *A randomized controlled trial of parents in the emergency department found a 58% increase in reported safe dosing in the experimental group after a medication teaching intervention (Li et al, 2020).*
- Provide guidance for parents and caregivers regarding age-related safety measures, including the following (Safe Kids Worldwide, 2021):
  - Store household products safely out of child's reach and sight to prevent poisoning.
  - Keep all household cleaning products in their original containers. Shop for child-resistant containers.
  - Read and follow product labels.
  - Check home for products such as cleaning supplies, liquid laundry packets, personal care products, plants, pesticides, alcohol, and medicine.
  - Post Poison Help number in phone and visibly at home: 1-800-222-1222.

  EB: *Pediatric poisoning deaths most commonly come from ingestion of opioids, other analgesics, cardiovascular medications, antihistamines, and sedatives (Tadros et al, 2016).* **EB:** *A multicenter case-control study found that there were increased odds of poisoning in children ages 0 to 4 years when medicines were not locked away or stored out of reach and household products and medicines were not put away immediately after use (Kendrick et al, 2017).*
- Advise families that syrup of ipecac is no longer recommended to be kept and used in the home. **EB:** *The American Academy of Clinical Toxicology (AACT), the European Association of Poison Centres and Clinical Toxicologists (EAPCCT), and the American Academy of Pediatrics (AAP) do not recommend the use of ipecac syrup (Benzoni & Gibson, 2020).*
- Advise families that over-the-counter cough and cold suppressant medications are not recommended and are no longer considered safe for children 2 or younger. **EB:** *A study found that since the US Food and Drug Administration advised against the use of cough/cold medicines in children younger than 2 in 2008, there has been a decline in physician prescriptions of cough and cold medicines (Horton et al, 2019).*
- Recognize that some children may have been exposed to methamphetamines or the components used to make methamphetamines. **EB:** *Home-based methamphetamine manufacturing may represent significant hazards and exposures to those who manufacture the drug but also to others living in the home. Children are most susceptible to these hazards and these exposures may result in immediate and long-term adverse health effects (Wright, Edwards, & Walker, 2016).*
- Advise families to safely dispose of unused medications. **EB:** *A study found that most families do not practice all recommended safe management strategies for controlled medications (Engster et al, 2019).*

Geriatric

- Caution the client and family to avoid storing medications with similar appearances close to one another (e.g., nitroglycerin ointment near toothpaste or denture creams). Confusion and visual impairment can place the older person at risk of incorrectly identifying the contents. Place medications in a medication organizer that indicates when they are to be taken. Failing eyesight, the use of multiple drugs, and difficulty in remembering whether a medication was taken are among the causes of accidental poisoning in older persons. **EB:** *For both sexes, poisoning is a common, self-inflicted injury in clients admitted to hospital. Among seniors, there is concern regarding the recognition of intentional harm by self-induced poisoning (Skinner et al, 2016).*
- Perform medication reconciliation in all older clients entering the health care system and on discharge. **EB:** *A study evaluated the prevalence and nature of potentially inappropriate medications and found increased safety in older clients through reduction of the number of drugs prescribed (Aiezza et al, 2021).*
- Use the Screening Tool of Older People's Prescriptions (STOPP) and the Screening Tool to Alert Right Treatment (START) to promote safety, avoid omissions, and prevent inappropriateness in prescriptions. **EB:** *The STOPP criteria for frail older persons (>65 years) is largely associated with adverse drug events and recommends against taking medications to treat symptoms unassociated with selected illnesses (Nwadiugwu, 2020).*

Home Care

- The previous interventions may be adapted for home care use.
- Provide the client and/or family with information about the free poison control application webPOISONCONTROL. **EB:** *A study found that the webPOISONCONTROL application augmented traditional poison control services by providing automated, accurate online access to case-specific triage and first aid guidance for poison ingestions (Litovitz et al, 2016).*
- Identify poisonous substances in the immediate surroundings of the home, such as a garage or barn, including paints and thinners, fertilizers, rodent and bug control substances, animal medications, gasoline, and oil. Label with the name, a poison warning sign, and a poison control center number. Lock out of the reach of children. **EB:** *A hospital-based cross-sectional study found that household chemicals were involved in 54.25% of poisoning cases and 11.8% of poisoning cases occurred in the home surroundings (Saikia et al, 2020).*
- Identify the risk of toxicity from environmental activities such as spraying trees or roadside shrubs. Contact local departments of agriculture or transportation to obtain material safety data sheets or to prevent the activity in desired areas. **EB:** *Very young children, women who are of childbearing age or who are pregnant, and older adults are at greatest risk of poisoning (Ashgur et al, 2016).*
- To prevent carbon monoxide poisoning, instruct the client and family in the importance of using a carbon monoxide detector in the home and changing it every 6 months, having the home heating system serviced every year by a qualified technician, and ensuring proper installation and venting of all combustion equipment. Carbon monoxide results from fumes produced by portable generators, stoves, lanterns, gas ranges, running vehicles, or burning charcoal and wood, which can build up in enclosed or partially enclosed spaces and result in harm or death for people and animals exposed. **EB:** *Carbon monoxide poisoning may not be readily identified because many of the effects are similar to various childhood illnesses (Chang et al, 2017).*

Multicultural

- Prompt caregivers to take action to prevent lead poisoning. **EB:** *Lead knowledge in urban youth is limited and includes misinformation. Some youth demonstrated awareness of specific sources including paint, dust, and water but had limited awareness of prevention strategies (Bogar et al, 2017).*
- If children live in a high-lead environment, teach the need for handwashing before each meal, annual blood testing for lead levels, and avoidance of high-lead areas. **EB:** *Lead industries, leaded petrol, lead-based paint, water pipes, paint, dust, soil, and water are all sources of lead exposure for children (Nussbaumer-Streit et al, 2016).*

Client/Family Teaching and Discharge Planning

- The previous interventions may be adapted for teaching needs and discharge planning.
- Counsel the client and family members regarding the following points of medication safety:
  - Avoid sharing prescriptions.
  - Always use good light when preparing medication. Do not dispense medication during the night without a light on.
  - Read the label before you open the bottle, after you remove a dose, and again before you give it.
  - Always use child-resistant caps and lock all medications away from your child or confused older adult.
  - Give the correct dose. *Never* guess.
  - Do not increase or decrease the dose without calling the health care provider.
  - Always follow the weight and age recommendations on the label.
  - Avoid making conversions. If the label calls for 2 teaspoons and you have a dosing cup labeled only with ounces, do not use it.
  - Be sure the health care provider knows if you are taking more than one medication at a time.
  - Never let young children take medication by themselves.
  - Read and follow labeling instructions on all products; adjust dosage for age.
  - Avoid excessive amounts and/or frequency of doses. ("If a little does some good, a lot should do more.")

  EB: *Data from the Nationwide Emergency Department Sample (NEDS) from 2006 to 2012 show that there were 21,928 pediatric emergency department visits for prescription opioid poisonings. An increase in adult prescription opioid abuse contributes to unintentional ingestion of medications in children (Tadros et al, 2016).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

EB: *Unintentional poisoning is the fastest growing cause of childhood fatal injury. Per the Centers for Disease and Prevention (CDC), most of this increase is linked to the inappropriate use of prescription opioids (CDC, 2021).* **EB:** *Poisoning in children is common and places a significant burden on health care. Parents of poisoned children were more likely to not have safely stored or locked medicines (Kendrick et al, 2017).*

Post-Trauma Syndrome

Domain 9 Coping/stress tolerance Class 1 Post-trauma responses

Gail B. Ladwig, MSN, RN and Julianne E. Doubet, BSN, RN, EMT-B

NANDA-I

Definition

Sustained maladaptive response to a traumatic, overwhelming event.

Defining Characteristics

Aggressive behaviors; alienation; altered attention; altered mood; anxiety (00146); avoidance behaviors; compulsive behavior; denial; depressive symptoms; dissociative amnesia; enuresis; exaggerated startle response; expresses anger; expresses numbness; expresses shame; fear (00148); flashbacks; gastrointestinal irritation; headache; heart palpitations; hopelessness (00124); horror; hypervigilance; individuals with history of detachment; intrusive dreams; intrusive thoughts; irritable mood; neurosensory irritability; nightmares; panic attacks; rage; reports feeling guilty; repression; substance misuse

Related Factors

Diminished ego strength: environment not conducive to needs; exaggerated sense of responsibility; inadequate social support; perceives event as traumatic; self-injurious behavior; survivor role

At-Risk Population

Individuals displaced from home; individuals experiencing prolonged duration of traumatic event; individuals exposed to disaster; individuals exposed to epidemic; individuals exposed to event involving multiple deaths; Individuals exposed to event outside the range of usual human experience; individuals exposed to serious accident; individuals exposed to war; individuals in human service occupations; individuals suffering serious threat; individuals who witnessed mutilation; individuals who witnessed violent death; individuals whose loved ones suffered serious injuries; individuals whose loved ones suffered serious threats; individuals with destructed home; individuals with history of being a prisoner of war; individuals with history of being abused; individuals with history of criminal victimization; individuals with history of torture

Associated Conditions

Depression

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Cessation; Abuse Protection; Abuse Recovery: Emotional, Aggression Self-Control, Anxiety Self-Control, Grief Resolution, Impulse Self-Control; Self-Mutilation Restraint; Sleep

Example NOC Outcome with Indicators

Abuse Recovery: Emotional as evidenced by the following indicators: Trauma-induced psychoneurotic behaviors, conduct disorders, and learning difficulties. (Rate outcome and indicators of **Abuse Recovery: Emotional:** 1 = extensive, 2 = substantial, 3 = moderate, 4 = limited, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Return to pretrauma level of functioning as quickly as possible
- Acknowledge traumatic event and begin to work with the trauma by talking about the experience and expressing feelings of fear, anger, anxiety, guilt, and helplessness
- Identify support systems and available resources and be able to connect with them
- Return to and strengthen coping mechanisms used in previous traumatic event
- Acknowledge event and perceive it without distortions
- Assimilate event and move forward to set and pursue life goals

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Counseling; Support System Enhancement

Example NIC Activities—Counseling

Encourage expression of feelings; Assist client to identify strengths and reinforce them

Nursing Interventions and *Rationales*

- Observe for a reaction to a traumatic event in all clients regardless of age or sex. **EBN:** *Treatment, after a traumatic incident, is usually concentrated on stabilizing the client physically; what is not always addressed is the emotional and/or psychological damage that can follow a traumatizing event (Frank, Schroeter, & Shaw, 2017).*
- Use a trauma-informed approach with survivors. **EBN:** *Trauma-informed care addresses medical, legal, and psychosocial needs while acknowledging the connection between presenting symptoms and the individual's past trauma history. A trauma-informed framework emphasizes safety; trustworthiness and transparency; peer support; collaboration and mutuality; empowerment, voice, and choice; and cultural, historical, and gender issues (Emergency Nurses Association & International Association of Forensic Nurses, 2017).*
- After a traumatic event, assess for intrusive memories, avoidance and numbing, and hyperarousal. **EB:** *According to a study by Ellis and Zaretsky (2018), untreated posttraumatic stress disorder (PTSD) will impose lasting impairments for the client; these may include avoidance, vocational and social dysfunction, and other negative manifestations.*
- Use an open and nonthreatening body positioning and posture. **EBN:** *The use of nonthreatening body positioning and posture will help prevent the threat detection areas of the client's brain from taking over (Fleishman, Kamsky, & Sundborg, 2019).*
- Remain with the client and provide support during periods of overwhelming emotions. **EBN:** *Nurses must be approachable and prepared to listen to clients as they attempt to convey their feelings, even if they are negative in nature (Kukkonen & Sharifullin, 2017).*
- Help the individual to comprehend the trauma if possible. **EBN:** *Laughon and Lewis-O'Connor (2019) stress that as a nurse investigating client trauma, there is a need for a comprehensive approach that will give clients the opportunity to disclose only what information they choose, in a secure and supportive setting.*
- Use touch with the client's permission (e.g., a hand on the shoulder, holding a hand). **EBN:** *"Asking permission before you touch clients gives them a choice and empowers them to have control over their body and physical space," state Fleishman et al (2019) in their report regarding trauma-informed care.*
- Help the client regain previous sleeping and eating habits. **EB:** *In their pilot study of postdeployed US veterans with PTSD symptoms, Walters et al (2020) observed that the utilization of evidence-based sleep treatment should be included for full PTSD rehabilitation.*
- ▲ Provide the client pain medication if he or she has physical pain. **EB:** *In their study examining the link between PTSD and chronic pain, Fishbain et al (2017) found evidence that though the degree of PTSD may vary between types of chronic pain, there is a connection between the two.*
- ▲ Assess the need for pharmacotherapy and refer as needed. **EB:** *Health care providers may use medications for symptom relief in PTSD, including appropriate antidepressants and anxiolytics (Johnson, 2017).* **EBN:** *According to Kukkonen and Sharifullin (2017), nurses, in addition to the capability to propose psychotherapies and pharmacotherapies, must first generate trust and communication with their clients.*
- ▲ Refer for appropriate psychotherapy: cognitive therapy, exposure therapy, eye movement desensitization and reprocessing (EMDR), and cognitive-behavioral therapy (CBT). **EB:** *Shapiro and Brown (2019) found that EMDR and related treatments are beneficial, advanced, evidence-based therapies for PTSD.*
- Help the client use positive cognitive restructuring to reestablish feelings of self-worth. **EBN:** *Cognitive restructuring is another psychotherapeutic strategy that has been found useful in communicating to clients that adverse thoughts are a result of negative thinking (Kukkonen & Sharifullin, 2017).*
- Provide the means for the client to express feelings through therapeutic drawing. **EB:** *Because traumatic events are many times too difficult to describe in words, art therapy gives victims another avenue by which they can project their emotions (Ramirez, 2016).*

- Encourage the client to return to his or her normal routine as quickly as possible. **EB:** *According to Kendrick et al (2017), it is well documented that physical, psychological, and financial well-being develop when a client returns to work after an unintentional trauma.*
- Talk to and assess the client's social support after a traumatic event. **EBN:** *Nasirian et al (2018) found that the support of family, social, and work circles and their medical networks were most important to the physical and psychological recovery of trauma survivors.*

Pediatric

- Refer to nursing care plan Risk for **Post-Trauma** Syndrome.
- ▲ Carefully assess children exposed to disasters and trauma. Note behavior specific to developmental age. Refer for therapy as needed. **EB:** *According to Broaddus-Shea et al (2021), a medical history obtained from children and adolescent victims of trauma should be taken employing language personalized to their age and comprehension, which will aid in establishing trust and convey empathy; alliance with other protection agencies (e.g., child welfare, legal services, law enforcement) is also essential to the future well-being of the child or adolescent.*

Geriatric

- Carefully screen older adults for signs of PTSD, especially after a disaster. **EB:** *Older persons who have undergone an earlier in life trauma may react in a different manner than younger persons to a disaster; age alone does not presage psychological outcomes (Cherry et al, 2015).*
- Consider using the Impact of Event Scale—Revised (IES-R), which is an appropriate instrument to measure the subjective response to stress in the older population. **EBN:** *The use of the IES-R, although not diagnostic for PTSD, is an appropriate means of assessing an older adult client's response to a specific traumatic event (McCabe, 2019).*
- ▲ Monitor the client for clinical signs of depression and anxiety; refer to a health care provider for medication if appropriate. **EBN:** *In their review of articles concerning the nursing care of the institutionalized elderly with anxiety and depression, Manungkalit & Purnama Sari (2020) found that stress, especially PTSD, is frequently comorbid with depression and unresolved physical symptoms (somatization disorder).*
- Instill hope. **EB:** *The quality of hope has shown a significant correlation to the moderation of mental health problems (Sahranavard et al, 2018).*

Multicultural

- Assess the influence of cultural beliefs, norms, and values on the client's ability to cope with a traumatic experience. **EBN:** *Cultural sensitivity is the awareness of what is required to understand cultural diversity and in what ways culture may affect clients' values, beliefs, and attitudes (Brooks et al, 2019).*
- Acknowledge racial and ethnic differences at the onset of care. **EBN:** *In her study of cognitive assessment tools that were initially established for use within specific cultures, Sluder (2020) found that the use of these tools is not appropriate for all cultural groups and may lead to a false diagnosis.*
- ▲ Carefully assess refugees for PTSD and refer for treatment as appropriate. **EB:** *Countless refugees have been exposed to traumatic incidents, both in their homeland and again during their flight; this then results in an increased probability for the development of trauma-related syndromes (Hecker et al, 2018).*
- Use a family-centered approach when working with Latin, Asian, African American, and Native American clients. **EBN:** *Chauhan et al (2020), in their review of the literature concerning the health care of ethnic minorities, determined that client well-being can be augmented by developing cooperation with those family and friends who are supportive and will take a role in the client care process.*
- When working with Asian American clients, provide opportunities by which the family can save face. **EB:** *Understanding Asian American beliefs concerning the basis of mental illnesses can assist health care professionals in recognizing the feelings of shame and stigma that prevent this group from seeking mental health treatment (Bignall, Jacquez, & Vaughn, 2015).* **EBN:** *Health care providers must recognize common cultural practices and agree to the use of the recommended strategies that address the challenges of providing culturally appropriate, person-centered support for ailing South Asian clients and their families (Khosla et al, 2017).*
- Incorporate cultural traditions as appropriate. **EBN:** *Alegría et al (2016), in their research relating to the health care of ethnic-minority clients, found that the introduction of culturally mediated interventions resulted in the progressive improvement of health care for this diverse population.*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Home Care

▲ Assess family support and the response to the client's coping mechanisms. Refer the family for medical social services or other counseling, as necessary. **EBN:** *The hospitalization of a loved one after a traumatic event, plus the emerging responsibilities of caregiving, can be acutely stressful, often triggering a family crisis and serving as the basis of psychological distress (Newcomb & Hymes, 2017).*

● Assess the effect of the trauma on family and significant others and provide empathy and caring to them. **EBN:** *Donaldson-Andersen (2017) affirmed that nurses must continuously assess and reevaluate the needs of clients, and the client's loved ones, during a traumatic event and provide essential emotional and social support as needed.*

Client/Family Teaching and Discharge Planning

● Teach positive coping skills and avoidance of negative coping skills. **EB:** *Contractor et al (2020) found that previous research suggests that those with PTSD symptoms will present with deficits in positive internal experiences.* **EB:** *Mattson et al (2018), in their study of veterans with PTSD, propose that coping adapted clinical mediation could ease PTSD symptoms and advance positive growth after a traumatic experience.*

● Teach mindfulness strategies and encourage use when intrusive thoughts or flashbacks occur. **EB:** *The use of mindfulness has been linked with decreased symptoms in those experiencing PTSD. Acting with awareness and nonreactivity were the characteristics of mindfulness most commonly associated with the moderation of PTSD markers (Stephenson et al, 2017).*

● Refer the client to peer support groups. **EB:** *In a review of successful therapies for PTSD, Drebing et al (2018) observed that peer support groups, in combination with clinical treatments, resulted in better outcomes than either alone.*

● Consider the use of complementary and alternative therapies. **EB:** *Complementary and alternative medicine (CAM) for the treatment of PTSD is accepted internationally; CAM can include a variety of therapies (e.g., yoga, acupuncture, neurostimulation) (Song et al, 2020).*

P

Risk for Post-Trauma Syndrome

Domain 9 Coping/stress tolerance Class 1 Post-trauma responses

Gail B. Ladwig, MSN, RN and Julianne E. Doubet, BSN, RN, EMT-B

NANDA-I

Definition

Susceptible to sustained maladaptive response to a traumatic, overwhelming event, which may compromise health.

Risk Factors

Diminished ego strength; environment not conducive to needs; exaggerated sense of responsibility; inadequate social support; perceives event as traumatic; self-injurious behavior; survivor role

At-Risk Population

Individuals displaced from home; individuals experiencing prolonged duration of traumatic event; individuals exposed to disaster; individuals exposed to epidemic; individuals exposed to event involving multiple deaths; individuals exposed to event outside the range of usual human experience; individuals exposed to serious accident; individuals exposed to war; individuals in human service occupations; individuals suffering serious threat; individuals who witnessed mutilation; individuals who witnessed violent death; individuals whose loved ones suffered serious injuries; individuals whose loved ones suffered serious threats; individuals with destructed home; individuals with history of being a prisoner of war; individuals with history of being abused; individuals with history of criminal victimization; individuals with history of torture

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Associated Conditions

Depression

NOC (Nursing Outcomes Classification)

Refer to the care plan for **Post-Trauma** Syndrome for suggested NOC outcomes

Example NOC Outcome with Indicators

Risk Detection as evidenced by the following indicators: Recognizes signs and symptoms that indicate risk/Uses health care services congruent with need. (Rate the outcome and indicators of **Risk Detection:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify symptoms associated with posttraumatic stress disorder (PTSD) and seek help
- Acknowledge event and perceive it without distortions
- Identify support systems and available resources and be able to connect with them
- State that he/she is not to blame for the event

NIC (Nursing Interventions Classification)

Refer to the care plan for **Post-Trauma** Syndrome for suggested NIC interventions.

Nursing Interventions and *Rationales*

- Assess for PTSD in a client who has chronic/critical illness, anxiety, or personality disorder; was a witness to severe injury or death; or experienced sexual molestation. **EBN:** *Current literature validates that early identification and intervention in the treatment of traumatic stress is essential to optimal recovery for trauma clients (Frank, Schroeter, & Shaw, 2017).*
- Consider the use of a self-reported screening questionnaire. **EB:** *PTSD self-screens are questionnaires that may help to identify those who could have PTSD; positive responses might signal that a referral to a mental health professional is warranted (National Center for PTSD, 2017).*
- Assess for ongoing symptoms of posttraumatic stress such as dissociation, avoidance behavior, hypervigilance, and reexperiencing. **EB:** *The symptoms for individuals with PTSD can vary considerably, but they generally fall into these categories: reexperience, avoidance, negative changes in beliefs and/or feelings, and increased arousal (National Center for PTSD, 2017).*
- Assess for past experiences with traumatic events. **EBN:** *In their study of rural women with a history of trauma, Handley et al (2015) found that these clients may have other psychological and social repercussions, along with the development of PTSD.*
- Consider screening for PTSD in a client who is a high user of medical care. **EB:** *Prins et al (2016) found that PTSD is linked to greater health care use, medical debility, and tobacco and alcohol dependence.*
- ▲ Provide deployed combat veterans with previous history of low mental or physical health status before deployment with appropriate referral after deployment. **EB:** *Yang and Burr (2016), in their study of the well-being of older veterans exposed to combat, cited a previous study done of identical and fraternal twin combat veterans. It was surmised in that study that both environmental and genetic components played a role in combat veterans' negative mental and physical health outcomes.*
- Provide peer support to contact coworkers experiencing trauma to remind them that others in the organization are concerned about their welfare. **EB:** *A study by Bartone et al (2019) determined that there are lasting benefits in furnishing peer support; these may include the enhanced development of personal growth and a renewed positive awareness of the meaning of life.*
- Provide posttrauma debriefings. Effective posttrauma coping skills are taught, and each participant creates a plan for his or her recovery. **EB:** *Findings by Richins et al (2020) in their study implied that immediate posttrauma interventions can be successful in organizations if they are directed in accordance with evidence-based criteria and incorporated into the organizational system.*
- Provide posttrauma counseling and debriefings. **EB:** *In their study of veterans' health and wellness, Oster et al (2017) established a link between mental, physical, and social health and consequently encouraged a combined clinical approach to the veterans' problems.*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

P

- Consider exposure therapy for civilian trauma survivors after an assault or motor vehicle crash. **EB:** *According to Weisman and Rodebaugh (2018), exposure therapy is typically looked on as the benchmark for behavioral intercessions and clinical anxiety.*

▲ Assess for a history of life-threatening illness such as cancer and provide appropriate counseling. **EBN:** *Clients who are confronted by a critical illness often exhibit signs of apprehension and anxiety (Ford, 2016).*

- Children with cancer should continue to be assessed for PTSD into adulthood. **EBN:** *The mental and emotional distress caused by a child's cancer can linger and many of these clients, though cured, will continue to have problems involving neurological, physical, and social issues (Katzman & John, 2018).*
- Provide protection for a child who has witnessed violence or who has had traumatic injuries. Help the child acknowledge the event and express grief over the event. **EBN:** *Many asylum-seeking children have experienced past trauma, hospitalization, and health care encounters that may trigger traumatic memories and cause further distress (Flood & Coyne, 2019).*
- Assess for a medical history of anxiety disorders. **EBN:** *Evaluate the client for events that trigger anxiety and distress and help the client recognize and control these situations (Braga Mendonça et al, 2020).*

▲ Assess children of deployed parents for PTSD and provide appropriate referrals. **EB:** *Lucier-Greer et al (2016) found in their research that multiple parental deployments are a powerful indicator of detrimental outcomes for adolescents in military families.*

- Consider implementation of a school-based program for children to decrease PTSD after catastrophic events. **EBN:** *According to Cogan et al (2019), there is a demand for programs that guide the selection of evidence-based safety plans that reflect the developmental and the mental health needs of the school community.*

Geriatric and Multicultural

- Refer to the care plan for **Post-Trauma** Syndrome.

Home Care

▲ Evaluate the client's response to a traumatic or critical event. If screening warrants, refer to a therapist for counseling/treatment. **EB:** *Osofsky et al (2017) found that addressing life stressors is an important function in integrated client care.*

- Refer to the care plan for **Post-Trauma** Syndrome.

Client Family Teaching and Discharge Planning

- Provide education to explain that acute stress disorder symptoms may be common when preparing combatants for their role in deployment. Provide referrals if the symptoms persist. **EB:** *Because US military forces have been engaged in overseas conflicts since 2001, servicemen and servicewomen have faced stressors related to combat and long deployments. Most manage this stress successfully, but others struggle with mental health problems (Farmer et al, 2015).*

Readiness for Enhanced Power

Domain 9 Coping/stress tolerance Class 2 Coping responses

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

A pattern of participating knowingly in change for well-being, which can be strengthened.

Defining Characteristics

Expresses desire to enhance awareness of possible changes; expresses desire to enhance decisions that could lead to changes; expresses desire to enhance independence by taking action for change; expresses desire to enhance involvement in change; expresses desire to enhance knowledge for participation in change; expresses desire to enhance participation in choices for daily living; expresses desire to enhance participation in choices for health; expresses desire to enhance power

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health Beliefs: Perceived Control; Participation in Health Care Decisions; Personal Autonomy

Example NOC Outcome with Indicators

Health Beliefs: Perceived Control as evidenced by the following indicators: Belief that own actions and decisions control health outcomes/Perceived responsibility for health decisions/Efforts at gathering information. (Rate the outcome and indicators of **Health Beliefs: Perceived Control** as 1 = very weak, 2 = weak, 3 = moderate, 4 = strong, 5 = very strong [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Describe power resources
- Identify realistic perceptions of control
- Develop a plan of action based on power resources
- Seek assistance as needed

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Mutual Goal Setting; Self-Esteem Enhancement; Self-Responsibility Facilitation

Example NIC Activities—Mutual Goal Setting

Encourage the identification of specific life values; Identify with client the goals of care; Assist client in examining available resources to meet goals

Nursing Interventions and *Rationales*

- Assess the meaning of the event to the person. **EBN:** *Assessing meaning gives a voice to clients and makes it more likely that solutions reached will have meaning and be useful to the individual (Holmberg et al, 2019).*
- Establish a trusting relationship with the client. **EBN:** *A systematic review and synthesis of 61 studies revealed that individualized relational work by nursing staff could mitigate feelings of powerlessness in older hospitalized clients (Bridges et al, 2020).*
- Assist and encourage the client to identify sources of emotional support. **EBN:** *A study of parents found that gaining emotional support from others was a successful coping strategy to deal with feelings of powerlessness (Stevens & O'Connor-Von, 2016).*
- Provide support for client families to identify the balance between client care responsibilities and self-care. **EBN:** *A study found that by supporting client families and considering them as resources, family feelings of powerlessness can be reduced (Lindgren, Söderberg, & Skär, 2016).*
- Initiate and facilitate family health conversations between the client and their family. **EBN:** *Research findings showed that participation in family health conversations mediated consolation, helped identify family members' problems and suffering, and assisted in identifying their family's resources and strengths (Dorell & Sundin, 2016).*
- Provide the client with information and regular updates regarding their care. **EBN:** *A study found that powerlessness was a major component of client dissatisfaction that could be addressed by nursing rounds and continuous updates (Forsgärde, From Attebring, & Elmqvist, 2016).*
- Refer client to an empowerment support group. **EBN:** *A randomized controlled trial found that clients who participated in an empowerment support group showed significant increases in levels of empowerment and self-care behaviors (Hsiao et al, 2016).*

Pediatric

- Provide empowerment-based education for parents that includes a focus on caregiving knowledge, caring behaviors, self-efficacy, and indicators of the child's recovery. **EBN:** *A study of an empowerment-based health education program for parents caring for children with a congenital heart defect after corrective surgery showed parental improvement in caregiving knowledge, caring behaviors, and self-efficacy (Ni, Chao, & Xue, 2016).*
- Initiate problem-solving opportunities, empowering discussions, and reflection to help families take action to manage their child's illness. **EBN:** *A randomized clinical trial found that implementation of an asthma family empowerment program decreased parental stress, improved family functioning, and increased children's pulmonary function (Yeh et al, 2016).*
- Provide teaching so chronically ill children can learn about their illness, recommendations, identify their limitations, and adapt by changing their routines. **EB:** *A systematic review found that children with congenital heart disease gained a sense of control by learning to adapt to their limitations (Chong et al, 2018).*

Geriatric

- The preceding interventions may be adapted for use with older adults.
- Provide health education for older individuals that is tailored, interactive, structured, and continuous and incorporates motivational and encouragement techniques. **EB:** *A systematic review of the literature showed that use of specific educational interventions for older nursing home residents was an empowering strategy that increased self-efficacy and self-care (Shoberer et al, 2016).*

Multicultural

- The preceding interventions may be adapted for use with diverse clients.
- Provide support and educational interventions that are culturally tailored. **EB:** *A randomized control trial found that Latino families assigned to a culturally sensitive, cognitive-behavioral group intervention reported lower neuropsychiatric symptoms in their relative, less caregiver distress, a greater sense of caregiver self-efficacy, and less depressive symptoms over time (Gonyea, López, & Velásquez, 2016).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Home Care

- The preceding interventions may be adapted for use in home care.
- Provide caregivers with support, listen to their concerns, and advocate for their needs. **EBN:** *A qualitative study found that when nurses acted as advocates through dialogues and interactions, the family caregivers' feelings of powerlessness were decreased (Høgsnes et al, 2019).*

Powerlessness

Domain 9 Coping/stress tolerance Class 2 Coping responses

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

A state of actual or perceived loss of control or influence over factors or events that affect one's well-being, personal life, or the society (adapted from American Psychology Association).

Defining Characteristics

Delayed recovery; depressive symptoms; expresses doubt about role performance; expresses frustration about inability to perform previous activities; expresses lack of purpose in life; expresses shame; fatigue; loss of independence; reports inadequate sense of control; social alienation

Related Factors

Anxiety; caregiver role strain; dysfunctional institutional environment; impaired physical mobility; inadequate interest in improving one's situation; inadequate interpersonal relations; inadequate knowledge to manage a situation; inadequate motivation to improve one's situation; inadequate participation in treatment

regimen; inadequate social support; ineffective coping strategies; low self-esteem; pain; perceived complexity of treatment regimen; perceived social stigma; social marginalization

At-Risk Population

Economically disadvantaged individuals; individuals exposed to traumatic events

Associated Conditions

Cerebrovascular disorders; cognition disorders; critical illness; progressive illness; unpredictability of illness trajectory

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Depression Self-Control; Health Beliefs; Health Beliefs: Perceived Ability to Perform, Perceived Control, Perceived Resources; Participation in Health Care Decisions

Example NOC Outcome with Indicators

Health Beliefs: Perceived Control as evidenced by the following indicators: Perceived responsibility for health decisions/Beliefs that own decisions and actions control health outcomes. (Rate the outcome and indicators of **Health Beliefs: Perceived Control:** 1 = very weak belief, 2 = weak belief, 3 = moderately strong belief, 4 = strong belief, 5 = very strong belief [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State feelings of powerlessness and other feelings related to powerlessness (e.g., anger, sadness, hopelessness)
- Identify factors that are uncontrollable
- Participate in planning and implementing care; make decisions regarding care and treatment when possible
- Ask questions about care and treatment
- Verbalize hope for the future and sense of participation in planning and implementing care

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Cognitive Restructuring; Complex Relationship Building; Mutual Goal Setting; Self-Esteem Enhancement; Self-Responsibility Facilitation

Example NIC Activities—Self-Responsibility Facilitation

Encourage independence but assist client when unable to perform; Assist client to identify areas in which they could readily assume more responsibility

Nursing Interventions and *Rationales*

Note: Before implementation of interventions in the face of client powerlessness, nurses should examine their own philosophies of care to ensure that control issues or lack of faith in client capabilities will not bias the ability to intervene sincerely and effectively.

- Assess powerlessness with tools that are available for general and specific client groups:
  - Measure of Powerlessness for Adult Patients (de Almeida Lopes Monteiro da Cruz & Braga, 2006)
  - Personal Progress Scale–Revised, tested with women (Johnson, Worell, & Chandler, 2005)
  - Life Situation Questionnaire–Powerlessness subscale, tested with stroke caregivers (Larson et al, 2005)
  - Making Decisions Scale, tested in clients with mental illness (Hansson & Björkman, 2005)
  - Family Empowerment Scale, tested on parents of children with emotional disorders (Koren, DeChillo, & Friesen, 1992)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Establish a trusting relationship with the client. **EBN:** *A systematic review and synthesis of 61 studies revealed that individualized relational work by nursing staff could mitigate feelings of powerlessness in older hospitalized clients (Bridges et al, 2020).*
- Assist and encourage the client to identify sources of emotional support. **EBN:** *A study of parents found that gaining emotional support from others was a successful coping strategy to deal with feelings of powerlessness (Stevens & O'Connor-Von, 2016).*
- Engage with clients using respectful listening and questioning to develop an awareness of clients' most important concerns. **EB:** *Engaging clients will integrate clinician expertise with client needs and can diminish feelings of powerlessness (Sheridan et al, 2015).*
- Provide clients with a collaborative decision-making process. **EB:** *A study revealed that clients felt their choices were limited, due to the nature of their illness or pressure from other people, and described feeling powerless to influence decisions about their care (Morant et al, 2018).*
- Provide support for client families to identify the balance between client care responsibilities and self-care. **EBN:** *A study found that by supporting client families and considering them as resources, family feelings of powerlessness can be reduced (Lindgren, Söderberg, & Skär, 2016).*
- Use a rehabilitative behavioral learning model that assists clients to understand how the mechanisms of habit and ritual work to reinforce powerlessness in their lives. **EB:** *For clients with addiction, understanding the learning processes and mechanisms of powerlessness is an important part of recovery (Butler et al, 2015).*
- Provide the client with information and regular updates regarding their care. **EBN:** *A study found that powerlessness was a major component of client dissatisfaction that could be addressed by nursing rounds and continuous updates (Forsgärde, From Attebring, & Elmqvist, 2016).*
- Refer client to an empowerment support group. **EBN:** *A randomized controlled trial found that clients who participated in an empowerment support group showed significant increases in levels of empowerment and self-care behaviors (Hsiao et al, 2016).*
- Refer to the care plans for **Hopelessness** and **Spiritual** Distress.

Pediatric

- Provided empowerment-based educational preparation for parents that includes a focus on caregiving knowledge, caring behaviors, self-efficacy, and indicators of the child's recovery. **EBN:** *A study of an empowerment-based health education program for parents caring for children with a congenital heart defect after corrective surgery showed parental improvement in caregiving knowledge, caring behaviors, and self-efficacy (Ni, Chao, & Xue, 2016).*
- Initiate problem-solving opportunities, empowering discussions, and reflection to help families take action to manage their child's illness. **EBN:** *A randomized clinical trial found that implementation of an asthma family empowerment program decreased parental stress, improved family functioning, and increased children's pulmonary function (Yeh et al, 2016).*
- Provide teaching so chronically ill children can learn about their illness, recommendations, identify their limitations, and adapt by changing their routines. **EB:** *A systematic review found that children with congenital heart disease gained a sense of control by learning to adapt to their limitations (Chong et al, 2018).*

Geriatric

- The preceding interventions may be adapted for use with older adults.
- Initiate and facilitate family health conversations between older clients and their family. **EBN:** *Research findings showed that participation in family health conversations mediated consolation, helped identify family members' problems and suffering, and assisted in identifying their family's resources and strengths (Dorell & Sundin, 2016).*
- Provide health education for older individuals that is tailored, interactive, structured, and continuous and incorporates motivational and encouragement techniques. **EB:** *A systematic review of the literature showed that use of specific educational interventions for older nursing home residents was an empowering strategy that increased self-efficacy and self-care (Shoberer et al, 2016).*

Multicultural

- The preceding interventions may be adapted for use with diverse clients.

- Provide support and educational interventions that are culturally tailored. **EB:** *A randomized control trial found that Latino families assigned to a culturally sensitive, cognitive-behavioral group intervention reported lower neuropsychiatric symptoms in their relative, less caregiver distress, a greater sense of caregiver self-efficacy, and less depressive symptoms over time (Gonyea, López, & Velásquez, 2016).*

Home Care

- The preceding interventions may be adapted for use in home care.
- Provide caregivers with support, listen to their concerns, and advocate for their needs. **EBN:** *A qualitative study found that when nurses acted as advocates through dialogues and interactions, the family caregivers' feelings of powerlessness were decreased (Høgsnes et al, 2019).*

Client Family Teaching and Discharge Planning

- The preceding interventions may be adapted for teaching and discharge planning.

Risk for Powerlessness

Domain 9 Coping/stress tolerance Class 2 Coping responses

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to a state of actual or perceived loss of control or influence over factors or events that affect one's well-being, personal life, or the society, which may compromise health (adapted from American Psychology Association).

Risk Factors

Anxiety; caregiver role strain; dysfunctional institutional environment; impaired physical mobility; inadequate interest in improving one's situation; inadequate interpersonal relations; inadequate knowledge to manage a situation; inadequate motivation to improve one's situation; inadequate participation in treatment regimen; inadequate social support; ineffective coping strategies; low self-esteem; pain; perceived complexity of treatment regimen; perceived social stigma; social marginalization

At-Risk Population

Economically disadvantaged; individuals exposed to traumatic events

Associated Conditions

Cerebrovascular disorders, cognition disorders; critical illness; progressive illness; unpredictability of illness trajectory

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

See the care plan for **Powerlessness.**

Adult Pressure Injury

Domain 11 Safety/protection Class 2 Physical injury

JoAnn Coar, MSN, RN-BC, A-GNP-C, CWOCN

NANDA-I

Definition

Localized damage to the skin and/or underlying tissue of an adult, as a result of pressure, or pressure in combination with shear (European Pressure Ulcer Advisory Panel, 2019).

Defining Characteristics

Blood-filled blister; erythema; full thickness tissue loss; full thickness tissue loss with exposed bone; full thickness tissue loss with exposed muscle; full thickness tissue loss with exposed tendon; localized heat in relation to surrounding tissue; pain at pressure points; partial thickness loss of dermis; purple localized area of discolored intact skin; ulcer is covered by eschar; ulcer is covered by slough

Related Factors

External Factors

Altered microclimate between skin and supporting surface; excessive moisture; inadequate access to appropriate equipment; inadequate access to appropriate health services; inadequate availability of equipment for individuals with obesity; inadequate caregiver knowledge of pressure injury prevention strategies; increased magnitude of mechanical load; pressure over bony prominence; shearing forces; surface friction; sustained mechanical load; use of linen with insufficient moisture wicking property

Internal Factors

Decreased physical activity; decreased physical mobility; dehydration; dry skin; hyperthermia; inadequate adherence to incontinence treatment regimen; inadequate adherence to pressure injury prevention plan; inadequate knowledge of pressure injury prevention strategies; protein-energy malnutrition; smoking; substance misuse

Other Factors

Factors identified by standardized, validated screening tool

At-Risk Population

Individuals in aged care settings; individuals in intensive care units; individuals in palliative care settings; individuals in rehabilitation settings; individuals in transit to or between clinical care settings; individuals receiving home-based care; individuals with American Society of Anesthesiologists (ASA) Physical health status score ≥3; individuals with body mass index above normal range for age and gender; individuals with body mass index below normal range for age and gender; individuals with history of pressure injury; individuals with physical disability; older adults

Associated Conditions

Anemia; cardiovascular diseases; chronic neurological conditions; critical illness; decreased serum albumin level; decreased tissue oxygenation; decreased tissue perfusion; diabetes mellitus; edema; elevated C-reactive protein; hemodynamic instability; hip fracture; immobilization; impaired circulation; intellectual disability; medical devices; peripheral neuropathy; pharmaceutical preparations; physical trauma; prolonged duration of surgical procedure; sensation disorders; spinal cord injuries

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Intact Tissue Integrity: Skin and Mucous Membranes as evidenced by the following indicators: Skin intactness/Skin lesions absent/Tissue perfusion/Skin temperature. (Rate the outcome and indicators of **Tissue Integrity: Skin and Mucous Membranes:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

P

Client Outcomes

Client Will (Specify Time Frame)

- Report any altered sensation or pain at site of tissue impairment
- Skin, without redness over bony prominences and capillary refill of less than 6 seconds over areas of redness
- Be repositioned off of bony prominences frequently if risk for pressure injuries is high (e.g., Braden Scale score ≤18)
- Demonstrate understanding of plan to reduce pressure injury risk
- Describe measures to protect the skin

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Pain Management; Pressure Injury Care; Pressure Injury Prevention; Risk Identification; Skin Care: Topical Treatments; Skin Surveillance

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NIC Activities—Pressure Injury Care

Monitor color of skin, temperature, edema, erythema, moisture, and appearance of surrounding skin; Note characteristics of skin over bony prominences or under/in contact with medical devices

Nursing Interventions and *Rationales*

▲ The National Pressure Ulcer Advisory Panel (NPUAP) redefined the definition of a pressure ulcer, which is now referred to as pressure injuries, during the NPUAP 2016 Staging Consensus Conference in 2016. The new definitions more accurately define alterations in tissue integrity from pressure. Classify pressure injuries (NPUAP & European Pressure Ulcer Advisory Panel [EPUAP], 2016) using national guidelines and definitions (see http://www.npuap.org/resources/educational-and-clinical-resources/npuap-pressure-injury-stages/).

- ❍ **Pressure Injury:** A pressure injury is localized damage to the skin and underlying soft tissue usually over a bony prominence or related to a medical or other device. The injury can present as intact skin or an open ulcer and may be painful. The injury occurs as a result of intense and/or prolonged pressure or pressure in combination with shear. The tolerance of soft tissue for pressure and shear may also be affected by microclimate, nutrition, perfusion, comorbidities, and condition of the soft tissue (NPUAP & EPUAP, 2016).
- ❍ **Stage 1 Pressure Injury:** Nonblanchable erythema of intact skin. Area of localized nonblanchable erythema that may appear differently in darkly pigmented skin, and changes in sensation, temperature, or firmness may precede visual changes. Color changes do not include purple or maroon discoloration, which is more likely to indicate deep tissue pressure injury (NPUAP & EPUAP, 2016).
- ❍ **Stage 2 Pressure Injury:** Partial-thickness skin loss with exposed dermis. Partial-thickness skin loss with exposed dermis in which the wound bed is pink/red and moist and adipose (fat) and deeper tissues are not visible. Granulation tissue, slough, and eschar are not present. A stage 2 pressure injury may also present as an intact or ruptured blister. These injuries commonly result from adverse microclimate and shear in the skin over the pelvis and shear in the heel. This stage should not be used to describe moisture-associated skin damage (MASD) including incontinence-associated dermatitis (IAD), intertriginous dermatitis (ITD), medical adhesive–related skin injury (MARSI), or traumatic wounds (skin tears, burns, and abrasions) (NPUAP & EPUAP, 2016).
- ❍ **Stage 3 Pressure Injury:** Full-thickness skin loss. Full-thickness loss of skin, in which adipose is visible and granulation tissue and epibole (rolled wound edges) are often present and undermining/tunneling may occur. Slough and/or eschar may also be visible. Fascia, muscle, tendon, ligament, cartilage, and/or bone are not exposed. The depth of tissue damage varies by anatomical location, and areas of significant adiposity can develop deep wounds. If slough or eschar obscures the extent of tissue loss, this is an unstageable pressure injury (NPUAP & EPUAP, 2016).
- ❍ **Stage 4 Pressure Injury:** Full-thickness skin and tissue loss. Full-thickness skin and tissue loss with exposed or directly palpable fascia, muscle, tendon, ligament, cartilage, or bone, and slough and/or eschar may be visible. Epibole, undermining, and/or tunneling often occur and depth varies by anatomical location. If slough or eschar obscures the extent of tissue loss, this is an unstageable pressure injury (NPUAP & EPUAP, 2016).
- ❍ **Deep Tissue Pressure Injury:** Persistent nonblanchable deep red, maroon, or purple discoloration. Intact or nonintact skin with localized area of persistent nonblanchable deep red, maroon, or purple discoloration or epidermal separation revealing a dark wound bed or blood-filled blister. Pain and temperature change often precedes skin color changes. Discoloration may appear differently in darkly pigmented skin. This injury results from intense and/or prolonged pressure and shear forces at the bone–muscle interface. The wound may evolve rapidly to reveal the actual extent of tissue injury, or it may resolve without tissue loss. If necrotic tissue, subcutaneous tissue, granulation tissue, fascia, muscle, or other underlying structures are visible, this indicates a full-thickness pressure injury (unstageable, stage 3, or stage 4). Do not use deep tissue pressure injury to describe vascular, traumatic, neuropathic, or dermatological conditions (NPUAP & EPUAP, 2016).
- ❍ **Unstageable Pressure Injury:** Obscured full-thickness skin and tissue loss. Full-thickness skin and tissue loss in which the extent of tissue damage within the ulcer cannot be confirmed because it is obscured by slough or eschar. If slough or eschar is removed, a stage 3 or stage 4 pressure injury will

be revealed. Stable eschar (i.e., dry, adherent, intact without erythema or fluctuance) on the heel or ischemic limb should not be softened or removed (NPUAP & EPUAP, 2016).

- Routinely assess clients for risk of pressure injuries using a valid and reliable risk assessment tool (National Pressure Injury Advisory Panel [NPIAP] & European Pressure Injury Advisory Panel [EPIAP], 2019). A validated risk-assessment tool such as the Norton scale or Braden scale should be used to identify clients at risk for pressure-related skin breakdown (NPIAP & EPIAP, 2019). **EB:** *Targeting variables (e.g., Braden scale risk subscale categories, age, severity of illness) can focus assessment on particular risk factors (e.g., pressure, immobility, perfusion) and help guide the plan of prevention and care (Ratliff et al, 2017; NPIAP/EPIAP, 2019).*
- Pressure injury risk assessment should be completed on admission, daily, and after procedures or changes in the client's condition (Baranoski & Ayello, 2016; NPIAP & EPIAP, 2019).
- Inspect the skin daily, especially bony prominences and dependent areas, for pallor, redness, and breakdown. In addition to assessing pressure injury risk, client-specific interventions should be implemented to prevent tissue injury. Implement the following interventions to prevent tissue breakdown:
  - Turn and reposition all individuals at risk for pressure injury, unless contraindicated because of medical condition or medical treatments.
  - Position client properly; use pressure-redistributing surfaces based on the individual's needs (e.g., pillows, gel or foam cushions, reactive/nonreactive foam mattresses, alternating pressure mattress, air-fluidized surface) if indicated. Continue to turn and reposition the individual regardless of the support surface in use. Establish turning frequency based on the characteristics of the support surface and the individual's response (NPIAP & EPIAP, 2019).
  - Lift and move client carefully using a turn sheet and adequate assistance; keep bed linens dry and wrinkle-free.
  - Perform actions to keep client from sliding down in bed (e.g., bend knees slightly when head of bed is elevated 30 degrees or higher) to reduce the risk of skin surface abrasion and shearing. Use the 30-degree tilted side-lying position (alternately, right side, back, left side). Maintain the head of the bed as flat as possible. Avoid extended use of prone positioning unless the individual can tolerate this and his or her medical condition allows (NPIAP & EPIAP, 2019).
  - Select a seated posture that is acceptable for the individual and minimizes the pressure and shear exerted on the skin and soft tissues. Limit time in seated position and encourage pressure relieving maneuvers (NPIAP & EPIAP, 2019).
  - Keep client's skin clean. Thoroughly dry skin after bathing and as often as needed, paying special attention to skinfolds and opposing skin surfaces (e.g., axillae, perineum, beneath breasts). Pat skin dry rather than rub and use a mild soap for bathing. Avoid alkaline soaps and cleansers. Apply moisturizing lotion at least once a day (NPIAP & EPIAP, 2019).
  - Protect the skin from contact with urine and feces (e.g., keep perineal area clean and dry, apply a protective ointment or cream to perineal area).
  - Provide and encourage adequate daily fluid intake for hydration for an individual assessed to be at risk of or with a pressure injury (NPUAP & EPUAP, 2016). Adjust protein intake for individuals with or at risk for pressure injuries. This must be consistent with the individual's comorbid conditions and goals (NPIAP & EPIAP, 2019).
  - If the individual cannot be moved or is positioned with the head of the bed elevated over 30 degrees, place a polyurethane foam dressing on the sacrum (NPUAP & EPUAP, 2016). Use heel offloading device or polyurethane foam dressings on individuals at high risk for heel ulcers (NPUAP & EPUAP, 2016).
  - Consult with nutrition/dietary specialist to evaluate client's nutritional status.
  - Increase activity as allowed.

  EB: *Pressure injuries result in additional pain and treatment for the client and additional health care services and costs. A comprehensive assessment of the client's risk for pressure injuries and proactive interventions is necessary to reduce the risk for tissue injury (NPUAP & EPUAP, 2016; NPIAP & EPIAP, 2019).*
- Medical device–related pressure injuries (MDRPIs) result from the use of devices designed and applied for diagnostic or therapeutic purposes. The resultant pressure injury generally conforms to the pattern or shape of the device. The injury should be staged using the NPUAP pressure injury staging system and the etiology of the pressure injury noted to be caused by the device (NPUAP & EPUAP, 2016).
  - Assess the skin around and under medical devices routinely to identify signs of pressure-related injuries (NPIAP & EPIAP, 2019).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Common devices associated with pressure-related tissue injury include oxygen delivery and monitoring devices (e.g., face mask, nasal cannula, pulse oximetry, bilevel positive airway pressure [BiPAP] mask), feeding tubes (e.g., nasogastric, gastric, jejunal tubes), endotracheal devices (oral and/or nasal endotracheal tubes, tracheostomy tubes), urinary and bowel elimination equipment (indwelling urinary catheter, fecal containment catheter), and musculoskeletal appliances (cervical collar, splints, braces).
- Assess and evaluate the purpose and function of the medical device. Remove medical devices as soon as medically feasible (NPIAP & EPIAP, 2019).
- Assess proper fit of the medical device and securement to prevent tension, and assess the skin under the device regularly for pressure-related injury (NPIAP & EPIAP, 2019).
- Protect the skin below and around the device to reduce pressure. Use a prophylactic dressing under the medical device to protect skin (NPIAP & EPIAP, 2019).

EB: *Incorporate daily and frequent skin inspection around and under the medical device. See the NPIAP Best Practice flyer to help provide education about medical device–related pressure injuries (NPIAP & EPIAP, 2019).*

- **Mucosal Membrane Pressure Injury:** Mucosal membrane pressure injury is found on mucous membranes with a history of a medical device in use at the location of the injury. Due to the anatomy of the tissue these ulcers cannot be staged (NPUAP & EPUAP, 2016).
- Critically ill clients are at increased risk for pressure ulcers, often requiring frequent skin risk assessment and preventive interventions. **EB:** *Reposition all individuals with or at risk for pressure injuries on an individualized schedule unless contraindicated (NPIAP & EPIAP, 2019). Reposition in such a way that pressure is optimally removed from bony prominences and maximal pressure redistribution is achieved (NPIAP & EPIAP, 2019).*
- Efforts must be taken to disseminate evidence-based guidelines and ensure that health care providers, in all settings, are making every effort to identify individuals who are at risk for pressure injuries and implement preventive and treatment interventions (Ratliff et al, 2017). **EB:** *Consider optimizing work procedures at a professional level through the introduction of tailored staff education, and assess and maximize workforce characteristics to reduce pressure injury incidence (NPIAP & EPIAP, 2019).*
- A client at risk for skin, wound, and related complications can benefit from the expert knowledge and skill set of a certified wound, ostomy, continence nurse (Berke et al, 2019). See care plan for Impaired **Skin** Integrity for additional interventions if a pressure ulcer occurs.

Geriatric

- Consider the older client's cognitive status when assessing the skin and in developing a comprehensive plan of care to prevent pressure injuries (NPUAP & EPUAP, 2016; NPIAP & EPIAP, 2019).
- Aging skin, medications (e.g., steroids), and moisture place the older client at increased risk for pressure-associated skin breakdown. **EB:** *Assess the client for pressure injury (NPUAP & EPUAP, 2016) risk, skin tear, and moisture-associated skin breakdown. It is important to differentiate the cause of the older client's skin breakdown to effectively implement prevention and treatment strategies. An individual with continence-related issues is always at risk for skin or pressure-related injuries (Berke et al, 2019).*
- Clients over age 65 years are at higher risk for pressure injuries because they have reduced subcutaneous fat and capillary blood flow, as well as physiological skin changes, including decreased cohesion of the dermis and epidermis and reduced sensory function (Podd, 2018).
- Use atraumatic wound dressings to prevent and treat pressure injuries (NPUAP & EPUAP, 2016) to reduce further injury to a frail older client's skin (NPIAP & EPIAP, 2019).
- For older clients with continence concerns, develop and implement an individualized continence management program (NPIAP & EPIAP, 2019). **EB:** *Use skin barrier products and moisture wicking pads to reduce moisture-associated skin irritation that increases the risk for pressure injury development (NPUAP & EPUAP, 2016); use high-absorbency incontinence products to protect the skin; avoid the use of diapers except when the client is ambulating (NPIAP & EPIAP, 2019).*
- Regularly reposition the older client who is unable to reposition independently. Consider pressure redistribution support surface for clients assessed to be at high risk for pressure injuries (NPUAP & EPUAP, 2016; NPIAP & EPIAP, 2019).

Home Care

- The interventions described previously may be adapted for home care use.

- Instruct and assist the client and caregivers in how to assess the skin for excessive pressure. Provide written instructions for actions they can implement to reduce the risk of pressure injury development (NPUAP & EPUAP, 2016).
- Educate client and caregivers on proper nutrition and when to call the agency and/or health care provider with concerns.

▲ It may be beneficial to initiate a consultation in a case assignment with a wound, ostomy, continence nurse (or wounds specialist) to establish a comprehensive plan for pressure ulcer risk reduction for clients at high risk for skin breakdown.

Risk for Adult Pressure Injury

Domain 11 Safety/protection Class 2 Physical injury

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Adult susceptible to localized damage to the skin and/or underlying tissue, as a result of pressure, or pressure in combination with shear, which may compromise health (European Pressure Ulcer Advisory Panel, 2019).

Risk Factors

External Factors

Altered microclimate between skin and supporting surface; excessive moisture; inadequate access to appropriate equipment; inadequate access to appropriate health services; inadequate availability of equipment for individuals with obesity; inadequate caregiver knowledge of pressure injury prevention strategies; increased magnitude of mechanical load; pressure over bony prominence; shearing forces; surface friction; sustained mechanical load; use of linen with insufficient moisture wicking property

Internal Factors

Decreased physical activity; decreased physical mobility; dehydration; dry skin; hyperthermia; inadequate adherence to incontinence treatment regimen; inadequate adherence to pressure injury prevention plan; inadequate knowledge of pressure injury prevention strategies; protein-energy malnutrition; smoking; substance misuse

Other Factors

Factors identified by standardized, validated screening tool

At-Risk Population

Individuals in aged care settings; individuals in intensive care units; individuals in palliative care settings; individuals in rehabilitation settings; individuals in transit to or between clinical care settings; individuals receiving home-based care; individuals with American Society of Anesthesiologists (ASA) physical health

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

status score ≥3; individuals with body mass index above normal range for age and gender; individuals with body mass index below normal range for age and gender; individuals with history of pressure injury; individuals with physical disability; older adults

Associated Conditions

Anemia; cardiovascular diseases; chronic neurological conditions; critical illness; decreased serum albumin level; decreased tissue oxygenation; decreased tissue perfusion; diabetes mellitus; edema; elevated C-reactive protein; hemodynamic instability; hip fracture; immobilization; impaired circulation; intellectual disability; medical devices; peripheral neuropathy; pharmaceutical preparations; physical trauma; prolonged duration of surgical procedure; sensation disorders; spinal cord injuries

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

See the care plan for Adult **Pressure** Injury.

Child Pressure Injury Domain 11 Safety/protection Class 2 Physical injury

JoAnn Coar, MSN, RN-BC, A-GNP-C, CWOCN

NANDA-I

Definition

Localized damage to the skin and/or underlying tissue of a child or adolescent, as a result of pressure, or pressure in combination with shear (European Pressure Ulcer Advisory Panel, 2019).

Defining Characteristics

Blood-filled blister; erythema; full thickness tissue loss; full thickness tissue loss with exposed bone; full thickness tissue loss with exposed muscle; full thickness tissue loss with exposed tendon; localized heat in relation to surrounding tissue; pain at pressure points; partial thickness loss of dermis; purple localized area of discolored intact skin; ulcer is covered by eschar; ulcer is covered by slough

Related Factors

External Factors

Altered microclimate between skin and supporting surface; difficulty for caregiver to lift client completely off bed; excessive moisture; inadequate access to appropriate equipment; inadequate access to appropriate health services; inadequate access to appropriate supplies; inadequate access to equipment for children with obesity; inadequate caregiver knowledge of appropriate methods for removing adhesive materials; inadequate caregiver knowledge of appropriate methods for stabilizing devices; inadequate caregiver knowledge of modifiable factors; inadequate caregiver knowledge of pressure injury prevention strategies; increased magnitude of mechanical load; pressure over bony prominence; shearing forces; surface friction; sustained mechanical load; use of linen with insufficient moisture wicking property

Internal Factors

Decreased physical activity; decreased physical mobility; dehydration; difficulty assisting caregiver with moving self; difficulty maintaining position in bed; difficulty maintaining position in chair; dry skin; hyperthermia; inadequate adherence to incontinence treatment regimen; inadequate adherence to pressure injury prevention plan; inadequate knowledge of appropriate methods for removing adhesive materials; inadequate knowledge of appropriate methods for stabilizing devices; protein-energy malnutrition; water-electrolyte imbalance

Other Factors

Factors identified by standardized, validated screening tool

At-Risk Population

Children in intensive care units; children in long-term care facilities; children in palliative care settings; children in rehabilitation settings; children in transit to or between clinical care settings; children receiving home-based care; children with body mass index above normal range for age and gender; children with body mass index below normal range for age and gender; children with developmental issues; children with growth issues; children with large head circumference; children with large skin surface area

Associated Conditions

Alkaline skin pH; altered cutaneous structure; anemia; cardiovascular diseases; decreased level of consciousness; decreased serum albumin level; decreased tissue oxygenation; decreased tissue perfusion; diabetes mellitus; edema; elevated C-reactive protein; frequent invasive procedures; hemodynamic instability; immobilization; impaired circulation; intellectual disability; medical devices; pharmaceutical preparations; physical trauma; prolonged duration of surgical procedure; sensation disorders; spinal cord injuries

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Intact Tissue Integrity: Skin and Mucous Membranes as evidenced by the following indicators: Skin intactness/Skin lesions absent/Tissue perfusion/Skin temperature. (Rate the outcome and indicators of **Tissue Integrity: Skin and Mucous Membranes:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Report any altered sensation or pain at site of tissue impairment
- Skin, without redness over bony prominences and capillary refill of less than 6 seconds over areas of redness
- Be repositioned off of bony prominences frequently if risk for pressure injuries is high (e.g., Braden QD or Glamorgan scale score)
- Family/caregiver will demonstrate understanding of plan to reduce pressure injury risk
- Describe measures to protect the skin

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Pain Management; Pressure Injury Care; Pressure Injury Prevention; Risk Identification; Skin Care: Topical Treatments; Skin Surveillance

Example NIC Activities—Pressure Injury Care

Monitor color of skin, temperature, edema, erythema, moisture, and appearance of surrounding skin; Note characteristics of skin over bony prominences or under/in contact with medical devices

Nursing Interventions and *Rationales*

- Consider the impact of skin maturity, perfusion, and oxygenation and medical devices related to risk for pressure injury development in neonates and children (National Pressure Injury Advisory Panel [NPIAP] & European Pressure Injury Advisory Panel [EPIAP], 2019).
- Perform an age-appropriate pressure injury (National Pressure Ulcer Advisory Panel [NPUAP] & European Pressure Ulcer Advisory Panel [EPUAP], 2016) risk assessment using a valid and reliable tool. **EB/EB:** *The Braden QD and Glamorgan pediatric pressure ulcer risk assessment scales have been found to be*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

reliable and predictive in assessing pediatric-specific pressure injury risk assessment to assist with identification of pressure-related injury risk in the population from preterm to 21 years of age, in the acute care setting (Willock et al, 2016; Freundlich, 2017; Chamblee et al, 2018; Curley et al, 2018).

- Pressure injury risk assessment should be completed on admission, daily, and after procedures or changes in the client's condition (Baranoski & Ayello, 2016; Freundlich, 2017; NPIAP & EPIAP, 2019).

▲ NPUAP redefined the definition of a "pressure ulcer," which is now referred to as "pressure injuries," during the NPUAP 2016 Staging Consensus Conference in 2016. The new definitions more accurately define alterations in tissue integrity from pressure. Classify pressure injuries (NPUAP & EPUAP, 2016) using national guidelines and definitions (see http://www.npuap.org/resources/educational-and-clinical-resources/npuap-pressure-injury-stages/).

- **Pressure Injury:** A pressure injury is localized damage to the skin and underlying soft tissue usually over a bony prominence or related to a medical or other device. The injury can present as intact skin or an open ulcer and may be painful. The injury occurs as a result of intense and/or prolonged pressure or pressure in combination with shear. The tolerance of soft tissue for pressure and shear may also be affected by microclimate, nutrition, perfusion, comorbidities, and condition of the soft tissue (NPUAP & EPUAP, 2016).
- **Stage 1 Pressure Injury:** Nonblanchable erythema of intact skin. Area of localized nonblanchable erythema that may appear differently in darkly pigmented skin, and changes in sensation, temperature, or firmness may precede visual changes. Color changes do not include purple or maroon discoloration, which is more likely to indicate deep tissue pressure injury (NPUAP & EPUAP, 2016).
- **Stage 2 Pressure Injury:** Partial-thickness skin loss with exposed dermis. Partial-thickness skin loss with exposed dermis in which the wound bed is pink/red and moist and adipose (fat) and deeper tissues are not visible. Granulation tissue, slough, and eschar are not present. A stage 2 pressure injury may also present as an intact or ruptured blister. These injuries commonly result from adverse microclimate and shear in the skin over the pelvis and shear in the heel. This stage should not be used to describe moisture-associated skin damage (MASD) including incontinence-associated dermatitis (IAD), intertriginous dermatitis (ITD), medical adhesive–related skin injury (MARSI), or traumatic wounds (skin tears, burns, and abrasions) (NPUAP & EPUAP, 2016).
- **Stage 3 Pressure Injury:** Full-thickness skin loss. Full-thickness loss of skin, in which adipose is visible and granulation tissue and epibole (rolled wound edges) are often present and undermining/tunneling may occur. Slough and/or eschar may also be visible. Fascia, muscle, tendon, ligament, cartilage, and/or bone are not exposed. The depth of tissue damage varies by anatomical location, and areas of significant adiposity can develop deep wounds. If slough or eschar obscures the extent of tissue loss, this is an unstageable pressure injury (NPUAP & EPUAP, 2016).
- **Stage 4 Pressure Injury:** Full-thickness skin and tissue loss. Full-thickness skin and tissue loss with exposed or directly palpable fascia, muscle, tendon, ligament, cartilage, or bone, and slough and/or eschar may be visible. Epibole, undermining, and/or tunneling often occur and depth varies by anatomical location. If slough or eschar obscures the extent of tissue loss, this is an unstageable pressure injury (NPUAP & EPUAP, 2016).
- **Deep Tissue Pressure Injury:** Persistent nonblanchable deep red, maroon, or purple discoloration. Intact or nonintact skin with localized area of persistent nonblanchable deep red, maroon, or purple discoloration or epidermal separation revealing a dark wound bed or blood-filled blister. Pain and temperature change often precedes skin color changes. Discoloration may appear differently in darkly pigmented skin. This injury results from intense and/or prolonged pressure and shear forces at the bone–muscle interface. The wound may evolve rapidly to reveal the actual extent of tissue injury, or it may resolve without tissue loss. If necrotic tissue, subcutaneous tissue, granulation tissue, fascia, muscle, or other underlying structures are visible, this indicates a full-thickness pressure injury (unstageable, stage 3, or stage 4). Do not use deep tissue pressure injury to describe vascular, traumatic, neuropathic, or dermatological conditions (NPUAP & EPUAP, 2016).
- **Unstageable Pressure Injury:** Obscured full-thickness skin and tissue loss. Full-thickness skin and tissue loss in which the extent of tissue damage within the ulcer cannot be confirmed because it is obscured by slough or eschar. If slough or eschar is removed, a stage 3 or stage 4 pressure injury will be revealed. Stable eschar (i.e., dry, adherent, intact without erythema or fluctuance) on the heel or ischemic limb should not be softened or removed (NPUAP & EPUAP, 2016).

- Routinely assess clients for risk of pressure injuries using a valid and reliable risk assessment tool (NPIAP & EPIAP, 2019). A validated risk-assessment tool such as the Norton Scale or Braden Scale should be used

to identify clients at risk for pressure-related skin breakdown (NPIAP & EPIAP, 2019). **EB:** *Targeting variables (e.g., Braden scale risk subscale categories, age, severity of illness) can focus assessment on particular risk factors (e.g., pressure, immobility, perfusion) and help guide the plan of prevention and care (Ratliff et al, 2017; NPIAP & EPIAP, 2019).*

- Inspect the skin daily, especially bony prominences and dependent areas, for pallor, redness, and breakdown. In addition to assessing pressure injury risk, client-specific interventions should be implemented to prevent tissue injury. Implement the following interventions to prevent tissue breakdown:
  - ❍ Turn and reposition all individuals at risk for pressure injury, unless contraindicated because of medical condition or medical treatments.
  - ❍ Position client properly; use pressure-redistributing surfaces based on the individual's needs (e.g., pillows, gel or foam cushions, reactive/nonreactive foam mattresses, alternating pressure mattress, air-fluidized surface) if indicated. Continue to turn and reposition the individual regardless of the support surface in use. Establish turning frequency based on the characteristics of the support surface and the individual's response (NPIAP & EPIAP, 2019).
  - ❍ Lift and move client carefully using a turn sheet and adequate assistance; keep bed linens dry and wrinkle-free.
  - ❍ Perform actions to keep client from sliding down in bed (e.g., bend knees slightly when head of bed is elevated 30 degrees or higher) to reduce the risk of skin surface abrasion and shearing. Use the 30-degree tilted side-lying position (alternately, right side, back, left side). Maintain the head of the bed as flat as possible (NPIAP & EPIAP, 2019).
  - ❍ Select a seated posture that is acceptable for the individual and minimizes the pressure and shear exerted on the skin and soft tissues. Limit time in seated position and encourage pressure-relieving maneuvers (NPIAP & EPIAP, 2019).
  - ❍ Keep client's skin clean and moisturized. Thoroughly dry skin after bathing and as often as needed, paying special attention to skinfolds and opposing skin surfaces (e.g., axillae, perineum). Pat skin dry rather than rub and use a mild soap for bathing. Avoid alkaline soaps and cleansers. Apply moisturizing lotion at least once a day (NPIAP & EPIAP, 2019).
  - ❍ Protect the skin from contact with urine and feces (e.g., keep perineal area clean and dry, apply a protective ointment or cream to perineal area). Avoid diapers when possible. Apply skin protectant cream with each episode of cleansing skin of urine and feces (NPIAP & EPIAP, 2019).
  - ❍ Provide and encourage adequate daily fluid intake for hydration for an individual assessed to be at risk of or with a pressure injury (NPUAP & EPUAP, 2016). Adjust protein intake for individuals with or at risk for pressure injuries. This must be consistent with the individual's comorbid conditions and goals (NPIAP & EPIAP, 2019).
  - ❍ If the individual cannot be moved or is positioned with the head of the bed elevated over 30 degrees, place a pressure reduction pillow under the occiput and if appropriate a polyurethane foam dressing on the sacrum (NPUAP & EPUAP, 2016).
  - ❍ Implement automated nutrition/dietary specialist consultations to evaluate client's nutritional status.
  - ❍ Increase activity as allowed.

  EB: *Pressure injuries result in additional pain and treatment for the client and additional health care services and costs. A comprehensive assessment of the client's risk for pressure injuries and proactive interventions is necessary to reduce the risk for tissue injury (NPUAP & EPUAP, 2016; NPIAP & EPIAP, 2019).*
- Evaluate high-risk areas for pressure injury. Changes in growth influences at risk areas of the body for pressure injury areas. **EB:** *Body proportions also change as children grow. In younger infants and children, the occiput is the largest bony prominence and site of greatest risk for pressure injury. Ears are also a high-risk area for pressure injury (Freundlich, 2017).*
- Select an age-appropriate support surface for premature neonates and pediatric clients at high risk for pressure ulcers. **CEBN:** *A longitudinal study found that the use of continuous and reactive low-pressure mattresses reduced the observed incidence of pressure ulcers (García-Molina et al, 2012). Select a support surface to prevent occipital pressure ulcers for at-risk clients (NPIAP & EPIAP, 2019).*
- Medical device–related pressure injuries (MDRPIs) result from the use of devices designed and applied for diagnostic or therapeutic purposes. The resultant pressure injury generally conforms to the pattern or shape of the device. The injury should be staged using the NPUAP pressure injury staging system and the etiology of the pressure injury noted to be caused by the device (NPUAP & EPUAP, 2016).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Assess the skin around and under medical devices routinely to identify signs of pressure-related injuries (NPIAP & EPIAP, 2019).
- Common devices associated with pressure-related tissue injury include oxygen delivery and monitoring devices (e.g., face mask, nasal cannula, pulse oximetry), feeding tubes (e.g., nasogastric, gastric, jejunal tubes), endotracheal devices (oral and/or nasal endotracheal tubes, tracheostomy tubes), urinary and bowel elimination equipment (indwelling urinary catheter, fecal containment catheter), and musculoskeletal appliances (cervical collar, splints, braces). **EB:** *Children are at greatest risk of pressure injury associated with medical devices from oxygen devices, tracheostomy tubes and ties, and casts/immobilization devices (Freundlich, 2017; Cummins et al, 2019).*
- Assess and evaluate the purpose and function of the medical device. Remove medical devices as soon as medically feasible (NPIAP & EPIAP, 2019).
- Assess proper fit of the medical device and securement to prevent tension, and assess the skin under the device regularly for pressure-related injury (NPIAP & EPIAP, 2019).
- Protect the skin below and around the device to reduce pressure. Use a prophylactic dressing under the medical device to protect skin (NPIAP & EPIAP, 2019). **EB:** *Incorporate daily and frequent skin inspection around and under the medical device. See the NPIAP Best Practice flyer to help provide education about medical device–related pressure injuries (NPIAP & EPIAP, 2019)*

- **Mucosal Membrane Pressure Injury:** Mucosal membrane pressure injury is found on mucous membranes with a history of a medical device in use at the location of the injury. Due to the anatomy of the tissue these ulcers cannot be staged (NPUAP & EPUAP, 2016).
- Critically ill children are at increased risk for pressure injury, often requiring frequent skin risk assessment and preventive interventions. **EB:** *Reposition all individuals with or at risk for pressure injuries on an individualized schedule unless contraindicated (NPIAP & EPIAP, 2019). Reposition in such a way that pressure is optimally removed from bony prominences and maximal pressure redistribution is achieved (NPIAP & EPIAP, 2019).*
- Review evidence-based practice interventions to assess and implement nursing interventions to reduce pressure injury risk. **EB:** *Efforts must be taken to disseminate evidence-based guidelines and ensure that health care providers, in all settings, are making every effort to identify individuals who are at risk for pressure injuries and implement preventive and treatment interventions (Ratliff et al, 2017; Cummins et al, 2019).*
- Involve family/caregiver in education focused on reducing risks and management strategies for pressure injuries. **EB:** *Consider optimizing family/caregiver engagement and education aligned and taught by expert clinicians/wound, ostomy, continence nurse (Berke et al, 2019). Involving family/caregiver early in the presentation and management of pressure injury prevention is necessary in preparation of discharge planning (Nie, 2020).*
- Select an age-appropriate support surface for premature neonates and pediatric clients at high risk for pressure ulcers. **CEBN:** *A longitudinal study found that the use of continuous and reactive low-pressure mattresses reduced the observed incidence of pressure ulcers (García-Molina et al, 2012). Select a support surface to prevent occipital pressure ulcers for at-risk clients (NPIAP & EPIAP, 2019).*
- Engage the client/family/legal guardian in the development of a client-specific plan of care to reduce pressure-related risk for skin breakdown (NPIAP & EPIAP, 2019).
- Document risk assessment and interventions implemented to reduce the client's risk for pressure injury development (NPUAP & EPUAP, 2016).

Home Care

- The interventions described previously may be adapted for home care use.
- Instruct and assist the client and caregivers in how to assess the skin for excessive pressure. Provide written instructions for actions they can implement to reduce the risk of pressure injury development (NPUAP & EPUAP, 2016).
- Educate family/caregivers and client (age-appropriate instruction) on proper nutrition and when to call the agency and/or health care provider with concerns.

▲ Initiate a consultation in a case assignment with a wound, ostomy, continence nurse (or wounds specialist) to establish a comprehensive plan for pressure ulcer risk reduction for clients at high risk for skin breakdown.

Risk for Child Pressure Injury

Domain 11 Safety/protection Class 2 Physical injury

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Child or adolescent susceptible to localized damage to the skin and/or underlying tissue, as a result of pressure, or pressure in combination with shear, which may compromise health (European Pressure Ulcer Advisory Panel, 2019).

P

Risk Factors

External Factors

Altered microclimate between skin and supporting surface; difficulty for caregiver to lift patient completely off bed; excessive moisture; inadequate access to appropriate equipment; inadequate access to appropriate health services; inadequate access to appropriate supplies; inadequate access to equipment for children with obesity; inadequate caregiver knowledge of appropriate methods for removing adhesive materials; inadequate caregiver knowledge of appropriate methods for stabilizing devices; inadequate caregiver knowledge of modifiable factors; inadequate caregiver knowledge of pressure injury prevention strategies; increased magnitude of mechanical load; pressure over bony prominence; shearing forces; surface friction; sustained mechanical load; use of linen with insufficient moisture wicking property

Internal Factors

Decreased physical activity; decreased physical mobility; dehydration; difficulty assisting caregiver with moving self; difficulty maintaining position in bed; difficulty maintaining position in chair; dry skin; hyperthermia; inadequate adherence to incontinence treatment regimen; inadequate adherence to pressure injury prevention plan; inadequate knowledge of appropriate methods for removing adhesive materials; inadequate knowledge of appropriate methods for stabilizing devices; protein-energy malnutrition; water-electrolyte imbalance

Other Factors

Factors identified by standardized, validated screening tool

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

At-Risk Population

Children in intensive care units; children in long-term care facilities; children in palliative care settings; children in rehabilitation settings; children in transit to or between clinical care settings; children receiving home-based care; children with body mass index above normal range for age and gender; children with body mass index below normal range for age and gender; children with developmental issues; children with growth issues; children with large head circumference; children with large skin surface area

Associated Conditions

Alkaline skin pH; altered cutaneous structure; anemia; cardiovascular diseases; decreased level of consciousness; decreased serum albumin level; decreased tissue oxygenation; decreased tissue perfusion; diabetes mellitus; edema; elevated C-reactive protein; frequent invasive procedures; hemodynamic instability; immobilization; impaired circulation; intellectual disability; medical devices; pharmaceutical preparations; physical trauma; prolonged duration of surgical procedure; sensation disorders; spinal cord injuries

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

See the care plan for Child **Pressure** Injury.

Neonatal Pressure Injury

Domain 11 Safety/protection Class 2 Physical injury

JoAnn Coar, MSN, RN-BC, A-GNP-C, CWOCN

NANDA-I

Definition

Localized damage to the skin and/or underlying tissue of a neonate, as a result of pressure, or pressure in combination with shear (European Pressure Ulcer Advisory Panel, 2019).

Defining Characteristics

Blood-filled blister; erythema; full thickness tissue loss; full thickness tissue loss with exposed bone; full thickness tissue loss with exposed muscle; full thickness tissue loss with exposed tendon; localized heat in relation to surrounding tissue; maroon localized area of discolored intact skin; partial thickness loss of dermis; purple localized area of discolored intact skin; skin ulceration; ulcer is covered by eschar; ulcer is covered by slough

Related Factors

External Factors

Altered microclimate between skin and supporting surface; excessive moisture; inadequate access to appropriate equipment; inadequate access to appropriate health services; inadequate access to appropriate supplies; inadequate caregiver knowledge of appropriate methods for removing adhesive materials; inadequate caregiver knowledge of appropriate methods for stabilizing devices; inadequate caregiver knowledge of modifiable factors; inadequate caregiver knowledge of pressure injury prevention strategies; increased magnitude of mechanical load; pressure over bony prominence; shearing forces; surface friction; sustained mechanical load; use of linen with insufficient moisture wicking property

Internal Factors

Decreased physical mobility; dehydration; dry skin; hyperthermia; water-electrolyte imbalance

Other Factors

Factors identified by standardized, validated screening tool

● = Independent; ▲ = Collaborative; EBN = Evidence-Based Nursing; EB = Evidence-Based; ✱ = QSEN

At-Risk Population

Low birth weight neonates; neonates <32 weeks gestation; neonates experiencing prolonged intensive care unit stay; neonates in intensive care units

Associated Conditions

Anemia; decreased serum albumin level; decreased tissue oxygenation; decreased tissue perfusion; edema; immature skin integrity; immature skin texture; immature stratum corneum; immobilization; medical devices; nutritional deficiencies related to prematurity; pharmaceutical preparations; prolonged duration of surgical procedure; significant comorbidity

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Intact Tissue Integrity: Skin and Mucous Membranes as evidenced by the following indicators: Skin intactness/Skin lesions absent/Tissue perfusion/Skin temperature. (Rate the outcome and indicators of **Tissue Integrity: Skin and Mucous Membranes:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Intact skin; prevention of skin alterations
- Report any altered sensation or pain at site of tissue impairment
- Skin, without redness over bony prominences and capillary refill of less than 6 seconds over areas of redness
- Be repositioned off of bony prominences frequently if risk for pressure injuries is high
- Family/caregiver will demonstrate understanding of plan to reduce pressure injury risk
- Family/caregiver will describe measures to protect the skin

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Pain Management; Pressure Injury Care; Pressure Injury Prevention; Risk Identification; Skin Care: Topical Treatments; Skin Surveillance

Example NIC Activities—Pressure Injury Care

Monitor color of skin, temperature, edema, erythema, moisture, and appearance of surrounding skin; Note characteristics of skin over bony prominences or under/in contact with medical devices

Nursing Interventions and *Rationales*

- Gestational age influences the development of the skin and its function as a barrier. Epidermal maturation is complete at 34 weeks of age. Prematurely or critically ill infants are at a higher risk of skin alterations related to intrinsic and extrinsic factors (Broom et al, 2019). **EB:** *Consider the impact of skin maturity, perfusion, and oxygenation (National Pressure Injury Advisory Panel [NPIAP] & European Pressure Injury Advisory Panel [EPIAP], 2019). Intrinsic factors that increase the risk for skin injury include gestation, birth weight, skin integrity, immobility, impaired skin integrity, sepsis, and malnutrition (Broom et al, 2019).*
- Assess the presence of a medical device and pressure injury risk as well as illness severity and need for critical care in neonates and children (NPIAP & EPIAP, 2019). **EB:** *Medical devices account for a large percent of pressure injuries (Delmore et al, 2019).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Select medical devices that minimize tissue injury. Apply according to the manufacturer's recommendations, ensuring correct sizing and shape. Reposition devices regularly and remove as soon as they are no longer medically necessary. Apply prophylactic dressings under devices to reduce the risk of pressure injuries (NPIAP & EPIAP, 2019).
- Protect neonates against toxicity due to topical agents, including iodine, isopropyl ethyl and methyl alcohol, infection, and injury until the stratum corneum has reached maturity (Delmore et al, 2019).
- Routine skin assessment is essential as a lower gestational age is at a higher risk for skin injury (Broom et al, 2019).
- Assess for excessive moisture, especially in between skinfolds and dependent areas. **EB:** *Neonates skin may not be able to tolerate excessive moisture and is more likely to macerate and develop pressure injury (Broom et al, 2019; Johnson & Hunt, 2019).* **EB:** *Use of zinc oxide or petroleum-based products is recommended for prevention or alterations due to excess moisture (Delmore et al, 2019).*
- Risk assessment tools for high-risk neonates are limited; however, current best evidence has found the Braden QD and Glamorgan to be valid and reliable with assessing pressure injury risk in children and neonates. Clinicians should routinely perform an age-appropriate pressure injury (National Pressure Ulcer Advisory Panel [NPUAP] & European Pressure Ulcer Advisory Panel [EPUAP], 2016) risk assessment using a valid and reliable tool. **EB/EBN:** *The Braden QD and Glamorgan pediatric pressure ulcer risk assessment scales have been found to be reliable and predictive in assessing neonate- and pediatric-specific pressure injury risk assessment to assist with identification of pressure-related injury risk in the population from preterm to 21 years of age, in the acute care setting (Willock et al, 2016; Freundlich, 2017; Chamblee et al, 2018; Curley et al, 2018).*
- Avoid daily bathing of the skin, which can disrupt normal barrier function. **EB:** *Daily bathing can dry the skin, increasing the risk of injury* (Delmore et al, 2019).
- Avoid adhesives and products that increase adhesion, which may result in increased epidermal stripping (Delmore et al, 2019).
- Use support surfaces to alleviate poor tissue tolerance and shear and improve microclimate. **EB:** *Muscle and fat tissue structures are softer in neonates than in children and adults, increasing the risk of deformation injuries in the neonate (Delmore et al, 2019). Support surfaces do not take the place of regular turning and repositioning (NPIAP & EPIAP, 2019).*
- Involve family/caregiver in education focused on reducing risks and management strategies for pressure injuries. **EB:** *Involving family/caregiver early in the presentation and management of pressure injury prevention is necessary in preparation of discharge planning (Nie, 2020).*

Home Care

- The interventions described previously may be adapted for home care use.
- Instruct and assist the client and caregivers in how to assess the skin for excessive pressure. Provide written instructions for actions they can implement to reduce the risk of pressure injury development (NPIAP & EPIAP, 2019).
- Educate client and caregivers on proper nutrition and when to call the agency and/or health care provider with concerns.
- ▲ Initiate a consultation in a case assignment with a wound, ostomy, continence nurse (or wound specialist) to establish a comprehensive plan for pressure ulcer risk reduction for clients at high risk for skin breakdown (Berke et al, 2019).
- ▲ Collaboration with health care professionals, including medical, nursing, nutrition, and industry stakeholders, is imperative to improve outcomes in pressure injury prevention (Delmore et al, 2019; NPIAP & EPIAP, 2019).

NANDA-I

Definition

Neonate susceptible to localized damage to the skin and/or underlying tissue, as a result of pressure, or pressure in combination with shear, which may compromise health (European Pressure Ulcer Advisory Panel, 2019).

Risk Factors

External Factors

Altered microclimate between skin and supporting surface; excessive moisture; inadequate access to appropriate equipment; inadequate access to appropriate health services; inadequate access to appropriate supplies; inadequate caregiver knowledge of appropriate methods for removing adhesive materials; inadequate caregiver knowledge of appropriate methods for stabilizing devices; inadequate caregiver knowledge of modifiable factors; inadequate caregiver knowledge of pressure injury prevention strategies; increased magnitude of mechanical load; pressure over bony prominence; shearing forces; surface friction; sustained mechanical load; use of linen with insufficient moisture wicking property

Internal Factors

Decreased physical mobility; dehydration; dry skin; hyperthermia; water-electrolyte imbalance

Other Factors

Factors identified by standardized, validated screening tool

At-Risk Population

Low birth weight neonates; neonates <32 weeks gestation; neonates experiencing prolonged intensive care unit stay; neonates in intensive care units

Associated Conditions

Anemia; decreased serum albumin level; decreased tissue oxygenation; decreased tissue perfusion; edema; immature skin integrity; immature skin texture; immature stratum corneum; immobilization; medical devices; nutritional deficiencies related to prematurity; pharmaceutical preparations; prolonged duration of surgical procedure; significant comorbidity

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Ineffective Protection

Domain 1 Health promotion Class 2 Health management

Teri Hulett, RN, BSN, CIC, FAPIC

NANDA-I

Definition

Decrease in the ability to guard self from internal or external threats such as illness or injury.

Defining Characteristics

Altered sweating; anorexia; chilling; coughing; disorientation; dyspnea; expresses itching, fatigue; impaired physical mobility; impaired tissue healing; insomnia; leukopenia; low serum hemoglobin level; maladaptive stress response; neurosensory impairment; pressure injury; psychomotor agitation; thrombocytopenia; weakness

Related Factors

Depressive symptoms; difficulty managing complex treatment regimen; hopelessness; inadequate vaccination; ineffective health self-management; low self- efficacy; malnutrition; physical deconditioning; substance misuse

Associated Conditions

Blood coagulation disorders; immune system diseases; neoplasms; pharmaceutical preparations; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health-Promoting Behavior; Blood Coagulation; Endurance; Immune Status

Example NOC Outcome with Indicators

Immune Status as evidenced by the following indicators: Recurrent infections/Tumors/Weight loss. (Rate the outcome and indicators of **Immune Status:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

P

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of infection while in contact during contact with health care
- Remain free of any evidence of new bleeding as evident by stable vital signs
- Explain precautions to take to prevent infection including hand hygiene
- Explain precautions to take to prevent bleeding including fall prevention

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Bleeding Precautions; Infection Prevention; Infection Protection

Example NIC Activities—Infection Protection

Monitor for systemic and localized signs and symptoms of infection; Inspect skin and mucous membranes for redness, extreme warmth, or drainage

Nursing Interventions and *Rationales*

- Take temperature, pulse, and blood pressure (e.g., every 1–4 hours). **EBN:** *Changes in vital signs can indicate the onset of bleeding or infection. Temperatures taken by the tympanic and forehead methods have*

the highest and lowest accuracy for measuring body temperature, respectively. It is recommended to use the tympanic method for assessing a client's body temperature in the intensive care unit (ICU) because of high accuracy and acceptable precision (Asadian et al, 2016).

▲ Observe nutritional status (e.g., weight, serum protein and albumin levels, muscle mass, and usual food intake). Work with the dietitian to improve nutritional status if needed. **EB:** *Clients diagnosed with asthma, repeated respiratory infections, cancer, and/or immunocompromise should have a nutritional assessment.* **EB:** *Vitamin D influences the body's immune system by influencing the production of endogenous antimicrobial peptides and regulating the inflammatory cascade (Martineau et al, 2017).*

● Observe the client's sleep pattern; if altered, see Nursing Interventions and *Rationales* for Disturbed **Sleep** Pattern.

● Identify stressors in the client's life; stress can negatively affect the immune system. If stress is uncontrollable, see Nursing Interventions and *Rationales* for Ineffective **Coping.** **EB:** *Delirium is the most common surgical complication among older adults, with an incidence of 15% to 25% after major elective surgery and 50% after high-risk procedures such as hip-fracture repair and cardiac surgery. Among clients undergoing mechanical ventilation in the ICU, the cumulative incidence of delirium, when combined with stupor and coma, exceeds 75%. Delirium is present in 10% to 15% of older adults in the emergency department. The prevalence of delirium at the end of life approaches 85% in palliative care settings (Marcantonio, 2017).*

Prevention of Infection

▲ Monitor for and report any signs of infection (e.g., fever, chills, flushed skin, drainage, edema, redness, abnormal laboratory values, pain) and notify the health care provider promptly. **EBN:** *Although the white blood cell count may be in the normal range, an increased number of immature bands may be present (Shi et al, 2015).* **EBN:** *A neutropenic client with fever represents an absolute medical emergency (Klastersky et al, 2016). If the client's immune system is depressed, notify the health care provider of abnormal (high or low) temperature, even in the absence of other symptoms of infection.* **EB:** *Clients with depressed immune function are unable to mount the usual immune responses to the onset of infection; abnormal temperature (high or low) may be the only sign of infection. A neutropenic client with abnormal temperature (high or low) represents an absolute medical emergency.* **EBN:** *Febrile neutropenia is a medical emergency that requires urgent evaluation, the timely administration of empirical broad-spectrum antimicrobials, and careful monitoring to optimize client outcomes and mitigate the risk of complications (Braga et al, 2019).*

● If white blood cell count is severely decreased (i.e., absolute neutrophil count of less than 1000/mm^3), initiate the following precautions:
  ❍ Take vital signs every 2 to 4 hours.
  ❍ Complete a head-to-toe assessment twice daily, including inspection of oral mucosa, invasive sites, wounds, urine, and stool; monitor for onset of new reports of pain.

▲ Avoid any invasive procedures, including catheterization, injections, or rectal or vaginal procedures, unless absolutely necessary. **EBN:** *Immunocompromised clients are susceptible to bacterial, fungal, viral, and parasitic infections that healthy immune systems usually overcome. They are also more susceptible to complications from common infections (Bula-Rudas, 2020).*
  ❍ Consider warming the client before elective surgery. *Normothermia is associated with low postoperative infection rates (Moucha, 2016).*

▲ Administer granulocyte growth factor as ordered. **EB:** *Clients most likely to benefit from therapy are identified in the clinical guidelines for the use of granulocyte transfusions with indications to include clients with severe neutropenia meeting specific criteria per the guidelines. Clients who should not receive granulocyte therapy are identified, as well, in the guidelines (Estcourt et al. 2016).* **EB:** *Granulocyte macrophage colony-stimulating factor is mostly well tolerated, although some cancer and kidney disease clients have demonstrated significant complications such as leukopenia (McDowell, 2018).*
  ❍ Take meticulous care of all invasive sites; use chlorhexidine gluconate for cleansing. **EB:** *Use of chlorhexidine gluconate for vascular catheter site care reduces catheter-related bloodstream infections and catheter colonization (O'Grady et al, 2011).*
  ❍ Provide frequent oral care and nutritional evaluation. **EBN:** *The effects of chemotherapy or radiation can cause changes in taste and smell. Self-reported taste and smell alterations are prevalent in up to 86% of cancer clients. In some clients, taste and smell alterations may continue well after their cancer treatment has been completed. Such disorders can increase distress, reduce appetite, and contribute toward poor nutritional status. Both adult and child cancer clients should be referred for nutritional consultation (Cohen et al, 2016).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- ❍ Follow standard precautions, especially performing hand hygiene, to prevent health care–associated infections. **EBN:** *Hands of health care workers are the most common cause of health care–associated infections (Boyce et al, 2011).*

▲ Refer for appropriate prophylactic antifungal treatment and avoid pathogen exposure (through air filtration, regular hand hygiene, and avoidance of plants and flowers). **CEB:** *Practical measures can be taken to avoid exposing the client to respiratory pathogens (Siegel et al, 2007).* **EB:** *Viruses are the second most common cause of severe respiratory infections in the immunocompromised client. Invasive fungal infections* (Aspergillus, Mucorales, *and* Pneumocystis jirovecii) *account for about 15% of severe respiratory infections. Parasites rarely cause severe acute infections in the immunocompromised client (Azoulay et al, 2020).*

- ❍ Have the client wear a mask when leaving the room. **EB:** *Hospital construction and renovation activities are an ever-constant phenomenon in health care facilities, causing dust contamination and possible dispersal of fungal spores. Fungal outbreaks still occur in health care settings, especially among clients with hematological malignancies and those who are immunocompromised. The causative pathogens of these outbreaks are usually* Aspergillus *species, but* Zygomycetes *and other fungi were occasionally reported. The overall mortality of construction/renovation-associated fungal infection was approximately 50%. Protective measures include relocating high-risk clients away from construction areas (Kanamori et al, 2015). To prevent health care–acquired pulmonary aspergillosis during hospital construction, at risk (neutropenic) clients should wear N-95 (fit-tested) protective masks if it is necessary to transport them through or near to the construction zone (Aspergillosis Subcommittee of the Health Protection Surveillance Centre Scientific Advisory Committee, 2018). Limit and screen visitors to minimize exposure to contagion.*
- ❍ Help the client bathe daily.
- ❍ Practice food safety: a neutropenic diet may not be necessary. **EBN:** *The rationale behind the neutropenic diet is to limit the bacterial load delivered to the gut. Fresh fruits and vegetables harbor organisms, and the ingestion of contaminated foods is believed to serve as a source of pathogenic bacteria, which may cause potentially life-threatening infections. Cooking foods destroys bacteria, rendering the cooked foods safe. Multiple studies have been done that do not support the benefit of the neutropenic diet. The inefficacy of the neutropenic diet may be attributed to the fact that the organisms on fresh fruits and vegetables are part of the normal gut flora. Unnecessary dietary restrictions can place clients at further risk of inadequate intake and malnutrition. Maintaining nutrition in this client population is already a challenge, and the restriction of a wide variety of food items (fresh fruits, vegetables, dairy, certain meats, and eggs) can cause malnutrition, low client satisfaction, and poor quality of life (Wolfe et al, 2018).*
- ❍ Ensure that the client is well nourished. Provide food with protein and consider vitamin supplements. If appetite is suppressed, institute a dietary referral. Keep track of serum albumin levels and transferrin and prealbumin levels. **EB:** *Initiate a dietitian-driven comprehensive nutrition assessment, including a food and nutrition-related history, anthropometric measurements, biochemical data, medical tests and procedures, nutrition-focused physical assessment, medical history, and treatment plan, which will be used to develop interventions (National Cancer Institute, 2021).*
- ❍ Help the client cough and practice deep breathing regularly. Maintain an appropriate activity level.
- ❍ Obtain a private room for the client. Use high-energy particulate air filters if available and appropriate. **EB:** *Published data support placing allogeneic hematopoietic stem cell transplant (HSCT) clients in a protective environment. Communicate with infection prevention and facilities management to ensure appropriate environmental controls are in place, on, and functioning to confirm the client is in a protective environment (Siegel et al, 2007).*

▲ Nurses play a pivotal role in the early identification and management of sepsis. Early identification is key to survival. Identifying abnormal vital signs is the first step in early sepsis recognition. If early signs of sepsis are identified, immediately notify the health care provider. **EB:** *Elevated heart rate, hypotension, increased respiratory rate, and elevated temperature are early sepsis indicators (Kleinpell et al, 2019).*

- ● Refer to care plan for Risk for **Infection**.
- ● Refer to care plan for Readiness for Enhanced **Nutrition** for additional interventions.

Pediatric

- ● Skin-to-skin contact (SSC) is the practice of placing a diapered infant onto the bare chest of the mother so that the mother and infant are in direct SSC contact with each other. In resource-rich countries, SSC has been motivated by a push to humanize a process that has become a medical experience. SSC has been a process to facilitate infant transition to extrauterine life. **EB:** *Evidence supports the benefit of SSC for preterm infants (<37 weeks gestation) targeted at temperature regulation and increased cardiorespiratory*

stability. Evidence supports the benefit to the breastfeeding mother with increased maternal milk volume and promoting exclusive breastfeeding and duration in the preterm infant (Campbell-Yeo et al, 2015). **EBN:** *In reviewing the entire hospitalization, SSC is associated with decreased likelihood of infection, severe illness, and death. Additional evidence supports homeostasis (temperature regulation, cardiorespiratory stability), and positive effects on sleep, neurodevelopment, and growth (Campbell-Yeo et al, 2015).*

- Assess postoperative fever in pediatric oncology clients promptly. **EB:** *Fever is a common sign that suggests infection in children. Signs and symptoms are often absent or minimized in the child with cancer because of inability to evoke an inflammatory response. Chemotherapy agents and radiation therapy cause myelosuppression. When the myelosuppressive effect is severe enough, the child becomes predisposed to infection. Because of high mortality rates associated with untreated infection, all febrile children with cancer should be evaluated immediately for neutropenia. If neutropenic, the child is at risk for a life-threatening infection until proven otherwise (Texas Children's Hospital EBOC, 2016).*

Geriatric

▲ If not contraindicated, encourage exercise to promote improved quality of life in older adults. **EB:** *A study of healthy adults women over 60 years and older suggested that the effects of resistance-type exercise training can counteract the loss of muscle mass and strength with aging (Braverman, 2019). Give older clients with imbalanced nutrition a vitamin D supplement to reduce risk of fracture.* **EB:** *Vitamin D deficiency has been correlated with increased risk and greater severity of infection, particularly of the respiratory tract. Vitamin D influences the body's immune system by influencing the production of endogenous antimicrobial peptides and regulating the inflammatory cascade (Dankers et al, 2017).*

Prevention of Bleeding

▲ Immune thrombocytopenia (ITP), previously known as idiopathic thrombocytopenic purpura, is an autoimmune disorder characterized by a severe reduction in peripheral blood platelet count. Bleeding events are often unpredictable, and clients with ITP may not exhibit bleeding beyond bruising and petechiae. However, more serious mucosal bleeding may occur, including menorrhagia, epistaxis, gastrointestinal hemorrhage, hematuria, or intracranial hemorrhage (Khan et al, 2017; Neunert et al, 2019). Monitor the client's risk for bleeding; evaluate results of clotting studies and platelet counts. **EB:** *Laboratory studies give a good indication of the seriousness of the bleeding disorder.*

- Watch for hematuria, melena, hematemesis, hemoptysis, epistaxis, bleeding from mucosa, petechiae, and ecchymoses. **EBN:** *Severe bleeding is reported in 9.5% of adults and 20.2% of children. Adults with ITP had a 1.3- to 2.2-fold higher mortality rate than the general population due to cardiovascular disease, infection, and bleeding (Neunert et al, 2019).*

▲ Give medications orally or intravenously only; avoid giving intramuscularly, subcutaneously, or rectally.

- Apply pressure for a longer time than usual to invasive sites, such as venipuncture or injection sites. Additional pressure is needed to stop bleeding of invasive sites in clients with bleeding disorders.
- Take vital signs often; watch for changes associated with fluid volume loss. **EB:** *Excessive bleeding causes decreased blood pressure and increased pulse and respiratory rates (Johnson & Burns, 2020).*
- Monitor menstrual flow if relevant; have the client use pads instead of tampons. **EB:** *Menstruation can be excessive in clients with bleeding disorders. Adolescents presenting with heavy menstrual bleeding at or near menarche assessment should include bleeding disorders (Adeyemi-Fowode et al, 2019).*
- Have the client use a moistened toothette or a very soft child's toothbrush instead of an adult toothbrush. Follow the dentist's recommendation for flossing and appropriate rinses to use. Control gum bleeding by applying pressure to gums with gauze pad soaked in ice water. **EB:** *These actions help prevent trauma to the oral mucosa, which could result in bleeding (National Institute of Dental and Craniofacial Research [NIDCR], 2018).*

▲ To decrease risk of bleeding, avoid administering salicylates or nonsteroidal antiinflammatory drugs (NSAIDs) if possible. **CEB:** *Gastrointestinal bleeding caused by NSAIDs, acetylsalicylic acid, or warfarin was the most common adverse drug reaction (ADR) that resulted in hospital admission and represented 40% of all ADRs (12 of 30), according to the World Health Organization (WHO) causality criteria (Tennant, 2015).*

Home Care

- Some of the interventions previously described may be adapted for home care use.

▲ The Patient-Centered Medical Home (PCMH) model facilitates a team-based approach to care, wherein providers coordinate care across all elements of the larger health care system (Frasso et al, 2017). Consider using

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

a nurse-led PCMH for monitoring high-need, high-cost clients (Breland et al, 2016). **EBN:** *The PCMH model supports team-based coordination of care and client self-management capacity in an effort to improve quality of care and associated health outcomes. Nurse-led practices have shown promise in alleviating the US demand for primary care and have been identified as practice models for improving quality of care. Nurse-led centers emphasize the holistic model of care and integrate an understanding of the social determinants of health. Additionally, nurse-led centers often use the client–provider team approach to care, which promotes client autonomy and supports shared decision-making—all key constructs in the PCMH model (Frasso et al, 2017).*

- End-of-life (EOL) care is defined as care that helps those with advanced, progressive, incurable, and serious illness to live as well as possible until they die. EOL care in the United States is provided through palliative and hospice medicine. Both hospice and palliative care focus on ensuring the best possible quality of life for individuals with serious illness and their families by providing support, symptom management, and comfort care. Palliative care need depends on the psychosocial, spiritual, and physical necessities of each client rather than the diagnosis. Caution should be used when assessing need for palliative care; the diagnosis should not be the primary trigger but instead use of a provider tool consisting of three elements: nutritional decline, disease progression, and functional decline. Building trust and shared decision making among the health care team, client, and family are pivotal in all palliative care conversations. Seriously ill clients have a high symptom burden, depending on their diagnosis (Cruz-Oliver, 2017). **EB:** *Develop with the client, family, and health care providers a multiprofessional plan of care to address immediate and anticipated needs of the client, including nausea, pain, fatigue, anorexia, breathlessness, and spiritual needs (Cruz-Oliver, 2017).*

Client/Family Teaching and Discharge Planning

Depressed Immune Function

- Discharge planning should start at admission. Key elements to focus on when providing discharge teaching to clients and their families to promote a successful transition from acute care to self-management at home are to develop health knowledge, provide resources, and promote self-efficacy. Identify clients' needs to provide tailored, individual support and education. Teach the client and family how and when to take the client's temperature and provide temperature parameters so the client/family knows when to call the provider (Pollack et al, 2016). **EBN:** *Identify clients' needs to provide client-specific, tailored individual support. Assess the client's ability to effectively participate in discharge teaching. Provide client-specific parameters, including when the client/family should notify provider. Provide discharge instruction in writing and provide community resource and follow-up contact information to client and family (Pollock et al, 2016).*
- Teach precautions to use to decrease the chance of infection. Teach/reinforce appropriate self-care, including good hand hygiene, personal hygiene, and ensuring a safe environment. Teach the client to avoid crowds and contact with persons who have infections. Teach the need for good nutrition, avoidance of stress, and adequate rest to maintain immune system function. **CEBN:** *Approaches to avoiding infection at home for the client with neutropenia include good hand hygiene and careful management of food, drink, and the client's environment (Braga et al, 2019; Bula-Rudas, 2020).*

Bleeding Disorder

- Teach the client to wear a medical alert bracelet and to notify all health care personnel of the bleeding disorder. **CEB:** *Emergency identification schemes such as medical alert bracelets use emblems that alert health care professionals to potential problems and can ensure appropriate and prompt treatment (National Hemophilia Foundation, Medical and Scientific Advisory Council [MASAC], 2019).*
- Teach the client and family the signs of bleeding, precautions to take to prevent bleeding, and action to take if bleeding begins. Caution the client to avoid taking over-the-counter medications without the permission of the health care provider. Medications containing salicylates can increase bleeding.
- Teach the client to wear loose-fitting clothes and avoid physical activity that might cause trauma.

Rape-Trauma Syndrome

Domain 9 Coping/stress tolerance Class 1 Post-trauma responses

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Sustained maladaptive response to a forced, violent, sexual penetration against the victim's will and consent.

Defining Characteristics

Aggressive behaviors; altered interpersonal relations; anger behaviors; anxiety (00146); cardiogenic shock; confusion; denial; depressive symptoms; difficulty with decision-making; disordered thinking; expresses anger; expresses embarrassment; expresses shame; fear (00148); humiliation; hypervigilance; loss of independence; low self-esteem; mood variability; muscle spasm; muscle tension; nightmares; paranoia; perceived vulnerability; phobic disorders; physical trauma; powerlessness (00125); psychomotor agitation; reports altered sleep-wake cycle; reports feeling guilty; self-blame; sexual dysfunction (00059); substance misuse; thoughts of revenge

Related Factors

To be developed

At-Risk Population

Individuals who experienced rape; individuals with history of suicide attempt

Associated Conditions

Depression; dissociative identity disorder

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Cessation; Abuse Protection; Abuse Recovery: Emotional, Sexual, Coping; Impulse Self-Control; Self-Mutilation Restraint

Example NOC Outcome with Indicators

Abuse Recovery: Sexual as evidenced by the following indicators: Acknowledgment of right to disclose abusive situation/Expression of right to have been protected from abuse. (Rate the outcome and indicators of **Abuse Recovery: Sexual:** 1 = none, 2 = limited, 3 = moderate, 4 = substantial, 5 = extensive [see Section I].)

R

Client Outcomes

Client Will (Specify Time Frame)

- Share feelings, concerns, and fears
- Recognize that the rape or attempt was not client's own fault
- State that, no matter what the situation, no one has the right to assault another
- Describe medical/legal treatment procedures and reasons for treatment
- Report absence of physical complications or pain
- Identify support resources and attend psychotherapy/group assistance in coping with the trauma and effects of the traumatic experience
- Function at same level as before crisis, including sexual functioning
- Recognize that it is normal for full recovery to take a minimum of 1 year

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Abuse Protection Support; Counseling; Crisis Intervention; Sexual Counseling; Infection Protection; Rape-Trauma Treatment

Example NIC Activities—Rape-Trauma Treatment

Explain rape protocol and obtain consent to proceed through protocol; Implement crisis intervention counseling

Nursing Interventions and *Rationales*

- Use a trauma-informed approach with survivors of sexual assault. **EBN:** *Trauma-informed care addresses medical, legal, and psychosocial needs while acknowledging the connection between presenting symptoms and the individual's past trauma history. A trauma-informed framework emphasizes safety; trustworthiness and transparency; peer support; collaboration and mutuality; empowerment, voice, and choice; and cultural, historical, and gender issues (Emergency Nurses Association & International Association of Forensic Nurses, 2017).*
- Introduce yourself and your role in all interactions. **EBN:** *The client's understanding of who the nurse is and the nurse's role in their care can make the client feel empowered and more actively engaged (Fleishman, Kamsky, & Sundborg, 2019).*
- Escort the client to a treatment room immediately on arrival to the emergency department. Stay with the client and provide access to a community-based advocate. **EB:** *Timely care will assist survivors of sexual assault to feel safe, avoid anxiety, and avoid retraumatizing (Menschner & Maul, 2016).*
- Assure the client of confidentiality. **EB:** *According to Ogunwale and Oshiname (2017), rape is a traumatic experience, which has known physical and psychosocial destructive effects, but survivors rarely seek support to escape being stigmatized.*
- Provide a sexual assault response team (SART), if available, that includes a sexual assault nurse examiner (SANE), rape counseling advocate, and representative of law enforcement for best possible outcomes. **EB:** *According to a study by Patterson and Tringali (2015), a team of forensic nurses and survivor advocates partner together to provide treatment not only for the necessary physical and medical requirements of sexual assault survivors but also for dealing with the complex legal and mental health needs that necessitate follow-up.*
- Use an open and nonthreatening body positioning and posture. **EBN:** The use of nonthreatening body positioning and posture will help prevent the threat detection areas of the client's brain from taking over (*Fleishman, Kamsky, & Sundborg, 2019*).
- Use open-ended questions to document the client's chief complaint and request an event history of the sexual assault in his or her own words. **EBN:** *Participants felt cared for and emotionally supported when they were probed about what had happened to them (Selenga & Jooste, 2015).*
- Use the sexual assault evidence collection kits that have been reviewed by the SART members and provided by your state to collect adequate and accurate evidence for analysis by a forensic laboratory. **EB:** *The health care provider who examines survivors of sexual assault must be responsible for acting in accordance with state and local statutory or policy requirements for the use of evidence-gathering kits (American College of Obstetrics and Gynecology [ACOG], 2019).*
- Before proceeding with a medical forensic examination, consent for the medical evaluation and for evidence collection and release must be obtained from the sexual assault client. **EB:** *Consent is a legal need that is a critical component of the forensic examination as the client's clothing may be kept for evidential purposes and photographs may be taken to document the client's injuries (ACOG, 2019).*
- Ask permission before you touch the client. **EBN:** *Asking a client for permission before touching provides choice and empowers them to have control over their body and physical space (Fleishman, Kamsky, & Sundborg, 2019).*
- Provide anticipatory guidance by explaining every step of the physical examination and nursing care to the client before performing and check for understanding. **EBN:** *Sexual assault clients should receive consistent, objective, immediate care, and information about the collection of evidence and protocols for evidence collection (Emergency Nurses Association & International Association of Forensic Nurses, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Observe for signs of physical injury. **CEB:** *Locations to assess for genital injuries would include tears or abrasions of the posterior labia, abrasion or bruising of the labia minora and fossa navicularis, and ecchymosis or tears of the hymen; document these injuries as evidence for any future legal proceedings (Linden, 2011).*
- Inform client of the risk of pregnancy and sexually transmitted infections (STIs) and offer available treatments. **EB:** *Survivors of sexual assault should be advised that they are at risk for pregnancy and STIs; as survivors of sexual assault, they should be monitored and offered emergency contraception and STI prophylaxis (ACOG, 2019).*
- Assess sexual assault clients for health problems related to human sex trafficking: infectious diseases; noninfectious diseases (malnutrition, dental problems, and skin problems); reproductive health problems; substance abuse; mental health problems; and violence. **EB:** *Nurses are positioned to recognize the health problems associated with sex trafficking and can assist clients to access appropriate care (Roney & Villano, 2020).*
- Provide reassurance that the sexual violence was not the client's fault. **EB:** *Shortly after a sexual assault, clients need acknowledgment from care providers that the violence was real and not their fault (Hutschemaekers et al, 2019).*
- Emphasize the client's resilience and strengths. **EB:** *The skills and strategies the client has used previously can facilitate coping (Machtinger et al, 2019).*
- Encourage the client to verbalize his or her feelings. **EBN:** *Research by Thomas, Tilley, and Esquibel (2015) indicated that survivors want nonjudgmental attitudes from health care providers, acknowledgment of the violence they have suffered, and acknowledgment that their stories are heard and believed.*
- Assess to determine whether physically abused women are also survivors of sexual assault. **EBN:** *According to a study by Santos de Oliveira et al (2016), there is a need for primary care professionals to focus on women who are involved in relationships in which they experience sexual violence.*

▲ Encourage the client to report the sexual assault to a law enforcement agency. **EB:** *Sexual assault survivors often feel apprehensive about involvement in the criminal justice system; therefore many do not report their sexual assault to law enforcement (Patterson & Tringali, 2015).*

▲ Refer the client for cognitive behavioral therapy (CBT). **EB:** *A randomized clinical trial of a CBT-based, telepsychology-delivered interactive program for rape survivors showed a large reduction in post-test posttraumatic stress disorder (PTSD) symptoms (Littleton & Grills, 2019).*

▲ Stress the necessity of follow-up care with counselors, mental health specialists, and medical subspecialists as appropriate. **EB:** *Follow-up with appropriate referrals is crucial in physical and emotional healing (Hovelson, Scheiman, & Pearlman, 2016).*

Male Rape

- Some of the interventions described previously may be adapted for use with male clients.
- Assist male survivors of sexual assault to identify and verbalize their victimization experiences as rape. **EB:** *Male survivors are less likely to conceptualize their victimization experiences as rape than women, which may impede their recovery (Reed et al, 2020).*

Geriatric

- Some of the interventions described previously may be adapted for use with older clients.
- Build a trusting relationship with the client. **EBN:** *A person-centered communication style by the nurse can have positive outcomes in the client–nurse relationship (Selenga & Jooste, 2015).*
- All examinations should be done on older adults as they would be done on any adult client after sexual assault, with modifications for comfort if necessary. **EB:** *All sexual assault clients should receive consistent, objective, immediate medical care, as well as options for the collection of evidence by emergency nurses and physicians knowledgeable of jurisdictional guidelines and protocols for evidence collection (Emergency Nurses Association & International Association of Forensic Nurses, 2017).*
- Assess for mobility limitations and cognitive impairment. **EB:** *Providing support is complicated by challenges associated with aging bodies and cognitive impairments (Bows, 2018).*
- Explain and encourage the client to report sexual abuse. **EBN:** *It is of the utmost importance that the client's wishes, feelings, and beliefs are taken into consideration before any action is taken (Andrews, 2017).*
- Observe for psychosocial distress. **EBN:** *The elderly are often isolated and mistreated, leaving them insecure and vulnerable and without support of family and/or friends (Carvalho Sena Damasceno, de Sousa, & Batista Moura, 2016).*

Pediatric

- Some of the interventions described previously may be adapted for use with child and adolescent populations.
- For minors, follow state-mandated reporting laws and report to Child Protective Services. **EBN:** *Minors who present with sexual assault injuries may also be experiencing neglect, as well as physical, sexual, or emotional abuse (Roney & Villano, 2020).*
- Use language that is tailored to the age and abilities of the child or adolescent. **EB:** *It is necessary to obtain medical history and information in ways that avoid retraumatizing the individual (Broaddus-Shea et al, 2021).*
- Assess adolescent sexual assault clients for health problems related to human sex trafficking: infectious diseases; noninfectious diseases (malnutrition, dental problems, and skin problems); reproductive health problems; substance abuse; mental health problems; and violence. **EB:** *Minor clients being trafficked may not openly identify themselves as victims; therefore nurses and other health care professionals must be aware of the signs and symptoms of trafficking (Roney & Villano, 2020).*

Multicultural

- Some of the interventions described previously may be adapted for use with diverse clients.
- Assess how an individual's culture affects how they perceive trauma, safety, and privacy. **EB:** *A safe environment will promote client engagement (Menschner & Maul, 2016).*
- Provide information and referrals for follow-up care that recognize and address the unique needs of sexual and gender minority clients. **EB:** *Integrated and coordinated follow-up services are the goal for all sexual assault survivors (Hendriks et al, 2018).*

Home Care

- Some of the interventions described previously may be adapted for home care use.
- Assist the client with assessing the home setting for safety and/or selecting a safe living environment. **EB:** *Survivors of sex trafficking identified the need for a safe place away from their pimp so that they can work through the immediate impact of their experiences (Rajaram & Tidball, 2018).*

▲ Ensure that the client has systems in place for long-term support. **EBN:** *When treating a survivor of sexual assault, the health care provider should not only treat the survivor's physical injuries but understand and support the emotional needs of the survivor and follow up with them during the period of recovery (Dos Reis, Baena de Moraes Lopes, & Duarte Osis, 2017).*

▲ Assess for other client vulnerabilities, such as mental health issues or addiction, and refer the client to social agencies for implementation of a therapeutic regimen. **EB:** *Those who have the dual diagnosis of addiction and mental illness are highly prone to sexual victimization, and actions should be taken to reduce their vulnerability (de Waal, Decker, & Goudriaan, 2017).*

Client/Family Teaching and Discharge Planning

- Provide teaching about the emotional and physical aftermath of sexual trauma. **EBN:** *Initial reactions may include generalized physical pain, disturbances in eating and sleeping patterns, and feelings of shame, fear, anxiety, or anger. Later responses may include phobias, flashbacks, nightmares, physical symptoms, and PTSD (Wisner, 2019).*
- Screen the client for suicide risk and refer to appropriate services. **EBN:** *Study results indicated that it was valuable to screen all sexual assault clients for suicide risk as it promoted client safety and promoted the emotional healing process (Cochran, 2019).*

Ineffective Relationship

Domain 7 Role relationship Class 3 Role performance

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

R

NANDA-I

Definition

A pattern of mutual partnership that is insufficient to provide for each other's needs.

Defining Characteristics

Delayed attainment of developmental goals appropriate for family life-cycle stage; expresses dissatisfaction with complementary interpersonal relations between partners; expresses dissatisfaction with emotional need fulfillment between partners; expresses dissatisfaction with idea sharing between partners; expresses dissatisfaction with information sharing between partners; expresses dissatisfaction with physical need fulfillment between partners; imbalance in autonomy between partners; imbalance in collaboration between partners; inadequate mutual respect between partners; inadequate mutual support in daily activities between partners; inadequate understanding of partner's compromised functioning; partner not identified as support person; reports unsatisfactory communication with partner

Related Factors

Ineffective communication skills; stressors; substance misuse; unrealistic expectations

At-Risk Population

Individuals experiencing developmental crisis; individuals with history of domestic violence; individuals with incarcerated intimate partner

Associated Conditions

Cognitive dysfunction in one partner.

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Family Functioning/Integrity; Role Performance; Social Support

Example NOC Outcome with Indicators

Family Integrity as evidenced by the following indicators: Members share thoughts, feelings, interests, concerns/Members communicate openly and honestly with one another/Members encourage individual autonomy and independence/Members assist one another in performing roles and daily tasks. (Rate the outcome and indicators of **Family Integrity:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Family/Client Will (Specify Time Frame)

- Share thoughts and feelings with each other
- Communicate openly with each other
- Assist in performing family roles and tasks
- Provide support for each other
- Obtain appropriate assistance

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Family Integrity Promotion; Role Enhancement

Example NIC Activities—Family Integrity Promotion

Facilitate a tone of togetherness within/among the family; Encourage family to maintain positive relationships; Facilitate open communication among family members

Nursing Interventions and *Rationales*

- Assess communication patterns concerning role and satisfaction within the relationship, including elements associated with intimacy. **EB:** *A recent study found that underlying chronic pain was a predominant factor that adversely affected communication and family roles between partners (Signs & Woods, 2020).*
- Assess relationship quality using the Relationship Flourishing Scale. **EB:** *The Relationship Flourishing Scale is a 12-item measure of eudaimonic relationship quality that assesses meaning, personal growth, relational giving, and goal sharing* (*Fowers et al, 2016*).
- Focus on helping couples maintain or develop marital closeness, especially during times of extreme stress. **EB:** *A review found that marital closeness and verbalization of stress were protective factors that may prevent relationship breakdown (Albuquerque, Pereira, & Narciso, 2016).*
- Assess the presence of stressors; physical, emotional, and behavioral health; and physical health status of the couple. **EB:** *The biobehavioral family model suggests that there is an interactive synergy between a partnership and family associated with family emotional climate, biobehavioral reactivity, and disease activity.*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

How individuals react to each dynamic can positively or adversely influence the perceived satisfaction in the relationship (*Priest, 2019*).

- Explore the couple's perceptions of the impact of illness on the relationship. **EB:** *A study that explored psychophysiological variables on the relationship, including intimacy, found that depressive symptoms, anxiety, and diseases with chronic inflammation adversely affected the relationship; however, severity of illness appeared to strengthen the partnership* (*Priest, Roberson, & Woods, 2019*).
- Assist couples to identify sources of their own perceived dyadic empathy in the relationship. **EB:** *A study exploring empathy among partners found that for new parents who reported greater dyadic empathy, both partners reported higher sexual satisfaction and relationship adjustment* (*Rosen, Mooney, & Muise, 2017*).
- Assist clients to identify sources of gratitude in their relationships. **EB:** *Sharing feelings of gratitude was predictive of both one's own and one's spouse's relationship satisfaction* (*Hogan & Gordon, 2020*).
- Encourage couples to engage in reappraisal of conflict in their relationship. **EB:** *Reappraisal of conflict has been found to protect partners against declines in marital quality over time (Finkel et al, 2013*).
- Encourage the use of positive relational humor and humor evaluation between partners. **EB:** *Relational humor, which is created and shared between partners, and humor evaluation, which is one partner's judgment of the other partner's sense of humor, were both strongly associated with relationship satisfaction in a meta-analysis* (*Hall, 2017*).
- Provide support resources to provide military members and their families with assistance in preparation for deployments and education about the importance of maintaining communication during deployment. **EBN:** *Veterans who have been deployed report that dedicated resources are needed to successfully reestablish their social connections with family and reclaim their place within the family* (*Messecar, 2017*).
- Provide resources to military family members with posttraumatic stress disorder (PTSD). **EB:** *A study of combat veterans found that PTSD symptoms interfere with relationship functioning, specifically communication, intimacy, problem solving, and low self-esteem in the relationship. Involving the partner in PTSD therapy was found to improve the relationship* (*Malaktaris et al, 2019*).
- Encourage couples to participate together in leisure activities. **EB:** *A study of persons with physical disabilities found that social and physical activities improved communication and coping skills (Han et al, 2019*). **EB:** *A study of cancer survivors and their partners found that light-intensity ballroom dancing intervention improved the quality of life and the relationship with loved ones (Pisu et al, 2017*).
- Openly explore communication and satisfaction in the same-sex relationship without bias. **EB:** *Research is demonstrating that the elements of satisfaction in relationships are similar between opposite- and same-sex partners. The Rainbow Couples Relationship Standards Scale (Rainbow CRSS) measures elements that bond couples such as expression of love, caring, intimacy, family relationships, and harmony and religion (Baker & Halford, 2020*).
- Refer to care plans Readiness for Enhanced **Relationship**, Readiness for Enhanced **Family** Processes, and Readiness for Enhanced Family **Coping.**

Geriatric

- Assess geriatric spousal caregivers for positive and negative consequences of providing medical care. **EB:** *A study found that spouses who assist with more health-related tasks feel they are directly benefitting their partner, which further enhances perceptions of gains and promotes positive feelings among spousal caregivers (Park, 2017).*
- Assess intimacy and sexuality of older adults **EB:** *A study of older adults found that intimacy evolved with aging but remained important with overall quality of life and satisfaction in the relationship. Intimate behaviors were not limited to intercourse but more frequently included kissing, cuddling, and touch (Skalacka & Germyski, 2019).*
- Facilitate and increase opportunities for social connectedness for older individuals through the use of technology training. **EBN:** *A study demonstrated that computer training at a senior citizens club helped participants build group cohesion and form tiered connections with partners, family, and friends with whom they no longer live (Burmeister et al, 2016).*

Multicultural

- Assess relationship dynamics without bias as to race, gender identity, or ethnicity. **EB:** *A study of Asian Americans found that this population values primacy of family goals over individual wishes and is more likely to engage in intimate/sexual relationship within the context of marriage. Asian Americans reported being more reluctant to obtain sexual and reproductive care associated with cultural beliefs (Okazaki, 2002*).

- Use culturally tailored cognitive behavioral techniques to promote communication, problem solving, self-disclosure, empathic response skills, and sexual education and counseling. **EB:** *A review of 39 studies found that interventions to promote communication, problem solving, self-disclosure, empathic responses, and sexual education could enhance marital intimacy and strengthen family bonds and stability. Health care providers need to individualize interventions that are appropriate to the couple's characteristics and their relationship* (*Kardan-Souraki et al, 2016*).

Readiness for Enhanced Relationship

Domain 7 Role relationship Class 3 Role performance

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

A pattern of mutual partnership to provide for each other's needs, which can be strengthened.

Defining Characteristics

Expresses desire to enhance autonomy between partners; expresses desire to enhance collaboration between partners; expresses desire to enhance communication between partners; expresses desire to enhance

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

emotional need fulfillment for each partner; expresses desire to enhance mutual respect between partners; expresses desire to enhance satisfaction with complementary interpersonal relationship between partners; expresses desire to enhance satisfaction with emotional need fulfillment for each partner; expresses desire to enhance satisfaction with idea sharing between partners; expresses desire to enhance satisfaction with information sharing between partners; expresses desire to enhance satisfaction with physical need fulfillment for each partner; expresses desire to enhance understanding of partner's functional impairment

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Family Functioning/Integrity; Role Performance; Social Support

Example NOC Outcome with Indicators

Family Integrity as evidenced by the following indicators: Members share thoughts, feelings, interests, concerns/Members communicate openly and honestly with one another/Members encourage individual autonomy and independence/Members assist one another in performing roles and daily tasks. (Rate the outcome and indicators of **Family Integrity:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Family/Client Will (Specify Time Frame)

- Share thoughts and feelings with each other
- Communicate openly with each other
- Assist in performing family roles and tasks
- Provide support for each other
- Obtain appropriate assistance

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Family Integrity Promotion; Role Enhancement

Example NIC Activities—Family Integrity Promotion

Facilitate a tone of togetherness within/among the family; Encourage family to maintain positive relationships; Facilitate open communication among family members

Nursing Interventions and *Rationales*

- Assess the ways in which the relationship has been altered (e.g., communication, sexuality, intimacy) from both partner's perspective. **EB:** *A review found that when involving both partners in marital interventions, it is necessary to assess both views of the relationship (Albuquerque, Pereira, & Narciso, 2016).*
- Assess relationship quality using the Relationship Flourishing Scale. **EB:** *The Relationship Flourishing Scale is a 12-item measure of eudaimonic relationship quality that assesses meaning, personal growth, relational giving, and goal sharing (Fowers et al, 2016).*
- Focus on helping couples maintain or develop marital closeness. **EB:** *A review found that marital closeness is a protective factor that may prevent relationship breakdown (Albuquerque, Pereira, & Narciso, 2016).*
- Assist couples to identify sources of their own perceived dyadic empathy in the relationship. **EB:** *A study found that for new parents who reported greater dyadic empathy, both partners reported higher sexual satisfaction and relationship adjustment (Rosen, Mooney, & Muise, 2017).*
- Assist clients to identify sources of gratitude in their relationships. **EB:** *A study found that individual gratitude was predictive of both one's own and one's spouse's relationship satisfaction (Hogan & Gordon, 2020).*
- Encourage couples to engage in reappraisal of conflict in their relationship. **EB:** *A study demonstrated that a reappraisal of conflict in their marriages protected participants against declines in marital quality over time (Finkel et al, 2013).*

- Encourage the use of positive relational humor and humor evaluation between partners. **EB:** *Relational humor, which is created and shared between partners, and humor evaluation, which is one partner's judgment of the other partner's sense of humor, were both strongly associated with relationship satisfaction in a meta-analysis (Hall, 2017).*
- Provide support resources to provide military members and their families with assistance in preparation for deployments and education about the importance of maintaining communication during deployment. **EBN:** *Veterans who have been deployed report that dedicated resources are needed to successfully reestablish their social connections with family and reclaim their place within the family (Messecar, 2017).*
- Encourage couples to participate together in leisure activities such as dance. **EB:** *This study demonstrated that a light-intensity ballroom dancing intervention improved the life of cancer survivors and the relationship with loved ones (Pisu, Demark-Wahnefried, & Kenzik, 2017).*
- Refer to care plans Readiness for Enhanced **Family** Processes and Readiness for Enhanced Family **Coping.**

Pediatric

- Encourage guidance and information on communication for parents of seriously ill children. **EBN:** The findings of this study suggested that parents are an important focus of care, and enhancing couples' communication is a way to address changes in marital relationships (Machado Silva-Rodrigues et al, 2016).
- Encourage young children to express gratitude. **EB:** *A study found that expressions of gratitude positively affected preschool children's prosocial behavior (Shoshani et al, 2020).*

Geriatric

- Assess geriatric spousal caregivers for positive and negative consequences of providing medical care. **EB:** *A study found that more medical/nursing tasks were linked to greater caregiving gains. Spouses who assist with more medical/nursing tasks feel they are directly benefitting their partner, which further enhances perceptions of gains and promotes positive feelings among spousal caregivers (Park, 2017).*
- Assess sexuality needs and support consensual sexual expression. **EB:** *Older adult participants in an Australian study made suggestions related to the visibility and normalization of sex in later life, cultural representations of sex and older people, and the need to provide sex-positive aged care and retirement home facilities (Fileborn et al, 2017).*
- Facilitate and increase opportunities for social connectedness for older individuals through the use of technology training. **EBN:** *A study demonstrated that computer training at a senior citizens club helped participants build group cohesion and form tiered connections with partners, family, and friends with whom they no longer live (Burmeister et al, 2016).*

Multicultural

- Provide a relationship-focused intervention to enhance communication for multicultural couples. **EB:** *A Korean study found that a relationship-focused communication intervention improved couples' abilities to communicate effectively and to resolve conflicts, and it enhanced intimacy (Kim et al, 2016).*
- Use culturally tailored cognitive behavioral techniques to promote communication, problem-solving, self-disclosure, empathic response skills, and sexual education and counseling. **EB:** *A review of 39 studies found that interventions to promote communication, problem-solving, self-disclosure, empathic responses, and sexual education could enhance marital intimacy and strengthen family bonds and stability. Health care providers need to individualize interventions that are appropriate to the couple characteristics and their relationship (Kardan-Souraki et al, 2016).*

Risk for Ineffective Relationship

Domain 7 Role relationship Class 3 Role performance

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to developing a pattern that is insufficient for providing a mutual partnership to provide for each other's needs.

Risk Factors

Inadequate communication skills; stressors; substance misuse; unrealistic expectations

At-Risk Population

Individuals experiencing developmental crisis; individuals with history of domestic violence; individuals with incarcerated intimate partner

Associated Conditions

Cognitive dysfunction in one partner

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* and References

Refer to care plan for Ineffective **Relationship**.

Impaired Religiosity

Domain 10 Life Principles Class 3 Value/belief/action congruence

Barbara Baele Vincensi, PhD, RN, FNP-BC and Mary E. Desmond, PhD, RN, MA, MSN, AHN-BC

NANDA-I

Definition

Impaired ability to exercise reliance on beliefs and/or participate in rituals of a particular faith tradition.

Defining Characteristics

Desires to reconnect with belief pattern; desires to reconnect with customs; difficulty adhering to prescribed religious beliefs; difficulty adhering to prescribed religious rituals; expresses distress about separation from faith community; questions religious beliefs; questions religious customs

Related Factors

Anxiety; cultural barrier to practicing religion; depressive symptoms; environmental constraints; fear of death; inadequate social support; inadequate sociocultural interaction; inadequate transportation; ineffective caregiving; ineffective coping strategies; insecurity; pain; spiritual distress

At-Risk Population

Hospitalized individuals; individuals experiencing end of life crisis; individuals experiencing life transition; individuals experiencing personal crisis; individuals experiencing spiritual crisis; individuals with history of religious manipulation; older adults

Associated Conditions

Depression; impaired health status

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Client Satisfaction: Cultural Needs Fulfillment

Example NOC Outcome with Indicators

Client Satisfaction: Cultural Needs Fulfillment as evidenced by the following indicators: Respect for religious beliefs/Respect for cultural health behaviors/Incorporation of cultural beliefs in health teaching/Respect for personal values. (Rate each indicator of **Client Satisfaction: Cultural Needs Fulfillment:** 1 = not at all satisfied, 2 = somewhat satisfied, 3 = moderately satisfied, 4 = very satisfied, 5 = completely satisfied [see Section I].)

R

Client Outcomes

Client Will (Specify Time Frame)

- Express satisfaction with the ability to express religious practices
- Express satisfaction with access to religious materials and rituals
- Demonstrate balance between religious practices and healthy lifestyles
- Avoid high-risk, controlling religious relationships that inflict physical, sexual, or emotional harm and/or exploitation

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Religious Ritual Enhancement; Culture Brokerage; Religious Addiction Prevention

Example NIC Activities—Religious Ritual Enhancement

Encourage the use of and participation in usual religious rituals that are not detrimental to health

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Nursing Interventions and *Rationales*

Adults

- Recognize when clients integrate religious practices into their life. **EB:** *In a prospective study of 110 clients before, during, and after chemotherapy Kaliampos and Roussi (2017) found that use of religious coping significantly predicted a positive affect 7 months later.*
- Assist clients to work around or overcome barriers to participating in their usual religious rituals or practices that support coping. **EBN:** *In a cross-sectional descriptive study (Akgül & Karadağ, 2016) fecal ostomies were found to be a barrier to incorporating specific religious practices of salat, fasting, and pilgrimage in the lives of 150 Muslims postoperatively, providing an opportunity for nurses to assist clients in meeting their religious needs through adaptation or facilitation around this barrier.*
- Encourage the use of prayer or meditation as appropriate. **EBN:** *In a qualitative study by Woods-Giscombé and Gaylord (2014) with 15 African American participants who had mindfulness meditation experience mindfulness meditation was helpful in managing stress and it also had several concepts in common with African American religious concepts, suggesting that this type of meditation could be used within a religious framework with this population.*
- Promote family coping using religious practices to help cope with loss, as appropriate. **EBN:** *In a longitudinal qualitative study by Nilmanat et al (2015) of 15 Thai clients dying of cancer, three themes emerged to help cope with the dying process: surrounded by love from family, moving beyond suffering, and reconnecting to religious faith to counter suffering.*
- Refer to a religious leader, professional counseling, or support group as needed. **EB:** *A cross-sectional survey by Ghesquiere et al (2015) of 591 hospices in the United States found that complicated grief or depression related to death can be assessed and managed by most hospices in varying degrees with the use of multiprofessional teams, support groups, individual counseling, or group therapy.* **EBN:** *In a descriptive study by Brelsford et al (2016) of 52 neonatal intensive care unit (NICU) parents, family cohesiveness decreased with the use of negative religious and spiritual coping, providing an indicator to nurses of a need for potential referral or support.*

End-of-Life Care

- Refer to a religious leader, professional counseling, or support group as needed. **EB:** *A cross-sectional survey by Ghesquiere et al (2015) of 591 hospices in the United States found that complicated grief or depression related to death can be assessed and managed by most hospices in varying degrees with the use of multiprofessional teams, support groups, individual counseling, or group therapy.*

✱ Implement QSEN competencies and evidence-based practice in providing end-of-life (EOL) care. **EBN:** *Using mixed methods, Lindemulder et al (2018) evaluated BSN students' incorporation of QSEN competencies related to teamwork, collaboration, person-centered care, spiritual/religious care, professionalism, and safety during an EOL simulation scenario and found significantly improved students pre– to post–self-assessment scores on all the above items.*

Maternal–Child Health

- Provide support for pregnant client's religiosity to promote health-seeking behaviors. **EBN:** *Cyphers et al (2017) found significant correlations between pregnant women and their use of religiosity to promote health-seeking behaviors during pregnancy.*

Sexual Minority Individuals (Lesbian, Gay, Bisexual, Transgender, Queer)

- Provide support using religiosity with caution. **EB:** *Brewster et al (2016) found that religious coping strategies may or may not promote psychological well-being or relieve psychological symptoms of distress caused by internalization of specific thoughts and experiences in a sample of self-identified sexual minority participants (n = 143), in which sexual discrimination and harassment had occurred within and outside of the religious/church establishment; therefore, promotion of religious coping or practices for this minority should be approached carefully.*

Pediatric

- Provide spiritual care for children based on developmental level. **EB:** *When nurses are comfortable providing spiritual care, they can implement numerous spiritual care activities and intervention to meet the spiritual needs of the child and family. After determining the child's spiritual beliefs and spiritual needs, a plan of care is developed based on the child's developmental age (Fowler, 1987).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

R

- **Parents:** Incorporate religious traditions and faith practices for parents with hospitalized and chronically ill children. **EB:** *A qualitative study indicated that religion was a positive coping mechanism for parents with infants in the neonatal intensive care unit (NICU) (Huenink & Porterfield, 2017).* **EBN:** *In a quantitative descriptive study, parents of children with cancer demonstrated an increase in their religious faith (Wiener et al, 2016).* **EBN:** *Additional relevant research can be found in Wang et al (2019).*

Geriatric

- Promote established religious practices in older adults. **EB:** *In a systematic review by Agli et al (2015), encouraging spiritual and religious practices in older adults with dementia increased positive coping strategies, cognitive function, and quality of life.* **EBN:** *Using a pre-post control group with 66 older clients admitted to an ICU, Elham et al (2015) found a significant inverse relationship between groups regarding spiritual well-being and anxiety when client concerns were met after an adequate assessment of spiritual/religious needs was completed and interventions implemented by nurses.*

Multicultural

Promote religious practices that are culturally appropriate:

- **African American.** **EB:** *Salas-Wright et al (2015) found an inverse relationship between religious involvement and violent and nonviolent antisocial behaviors in adolescent African American females living in high-risk communities.* **EB:** *In a cross-sectional survey of 1013 African American women, Ludema et al (2015) found that those who highly identified with organized religion, nonorganized religion, and spirituality had less risky sexual behaviors for potential HIV exposure than those who had no affiliation.* **EBN:** *Additional relevant research can be found in Woods-Giscombé and Gaylord (2014).*
- **Hispanic.** **EB:** *Rivera-Hernandez (2016)* found a positive relationship between religiosity with diabetes care and blood sugar control in a sample of 2216 Hispanic individuals 50 years and older living in Mexico.
- **Jordanian.** **EBN:** *Using a cross-sectional and correlational design, Musa et al (2016) found that spiritual well-being and religiosity had a positive correlation with self-rated health in a convenience sample of 340 Jordanian Arab Christians who make up only 3% of the population of this country.*
- **Muslim.** **EBN:** *In a cross-sectional descriptive study (Akgül & Karadağ, 2016) fecal ostomies were found to be a barrier to incorporating specific religious practices of salat, fasting, and pilgrimage in the lives of 150 Muslims postoperatively, providing an opportunity for nurses to assist clients in meeting their religious needs through adaptation or facilitation around this barrier.*

Multiprofessional

- Refer to a religious leader, professional counseling, or support group as needed. **EB:** *A cross-sectional survey by Ghesquiere et al (2015) of 591 hospices in the United States found that complicated grief or depression related to death can be assessed and managed by most hospices in varying degrees with the use of transdisciplinary teams, support groups, individual counseling, or group therapy.*

Readiness for Enhanced Religiosity

Domain 10 Life principles Class 3 Value/belief/action congruence

Barbara Baele Vincensi, PhD, RN, FNP-BC and Mary E. Desmond, PhD, RN, MA, MSN, AHN-BC

NANDA-I

Definition

A pattern of reliance on religious beliefs and/or participation in rituals of a particular faith tradition, which can be strengthened.

Defining Characteristics

Expresses desire to enhance connection with a religious leader; Expresses desire to enhance forgiveness; Expresses desire to enhance participation in religious experiences; Expresses desire to enhance participation in religious practices; Expresses desire to enhance religious options; Expresses desire to enhance use of religious material; Expresses desire to reestablish belief patterns; Expresses desire to reestablish religious customs

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Client Satisfaction: Cultural Needs Fulfillment

Example NOC Outcome with Indicators

Client Satisfaction: Cultural Needs Fulfillment as evidenced by the following indicators: Respect for religious beliefs/Respect for cultural health behaviors/Incorporation of cultural beliefs in health teaching/Respect for personal values. (Rate each indicator of **Client Satisfaction: Cultural Needs Fulfillment:** 1 = not at all satisfied, 2 = somewhat satisfied, 3 = moderately satisfied, 4 = very satisfied, 5 = completely satisfied [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Express satisfaction with the ability to express religious practices
- Express satisfaction with access to religious materials and rituals
- Demonstrate balance between religious practices and healthy lifestyles
- Avoid high-risk, controlling religious relationships that inflict physical, sexual, or emotional harm and/or exploitation

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Religious Ritual Enhancement; Culture Brokerage; Religious Addiction Prevention

Example NIC Activities—Religious Ritual Enhancement

Encourage the use of and participation in usual religious rituals that are not detrimental to health

Nursing Interventions and *Rationales*

Adults

- Encourage centering prayer or other forms of meditation to promote mental and spiritual health. **EB:** *In a small sample, centering prayer demonstrated positive effects on emotional and spiritual health (Fox et al, 2016).* **EB:** *A prospective study found religious coping, including prayer used during chemotherapy, predicted a positive affect 7 months later (Kaliampos & Roussi, 2017).*

Disabled

- Use prayer as a coping mechanism for those with disabilities. **EB:** *Hodge and Reynolds (2019) found, in a cross-sectional exploratory study, that those with disabilities are more likely to pray several times a day as compared to those without disabilities.*

Maternal–Child Health

- Provide support for pregnant client's religiosity to promote health-seeking behaviors. **EBN:** *Cyphers et al (2017) found significant correlations between pregnant women and their use of religiosity to promote health-seeking behaviors during pregnancy.*

Sexual Minority Individuals (Lesbian, Gay, Bisexual, Transgender, Queer)

- Encourage the use of religion to decrease stigma and improve quality of life (QOL) for HIV-positive men. **EBN:** *A cross-sectional observational study of men having sex with men (MSM) by Desyani et al (2019) found a negative relationship (p = 0.007) between stigma and QOL and a positive relationship (p = 0.000) between religiosity and QOL, indicating the potential use of religiosity to improve QOL in MSM who are HIV positive.*

Uninsured/Low Income

- Explore the use of a faith community nurse to provide wellness services and care monitoring. **EB:** *Faith Community Nursing is a nursing specialty focusing on integration of faith and health while providing wellness care within faith communities and outreach into the surrounding community (Morris, 2015; Young et al, 2015).*

Veterans

- Encourage the use of religion to help decrease sleep disturbances in veterans. **EB:** *A cross-sectional study on combat casualty exposed veterans found that religious salience and attendance was a buffering element to sleep disturbances (White et al, 2018).*

End-of-Life Care

✱ Implement QSEN competencies and evidence-based practice in providing end-of-life (EOL) care. **EBN:** *Using mixed methods,* Lindemulder et al (2018) *evaluated BSN students' incorporation of QSEN*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

competencies related to teamwork, collaboration, person-centered care, spiritual/religious care, professionalism, and safety during an EOL simulation scenario and found significantly improved students pre– to post–self-assessments scores on all the above items.

▲ Refer to a religious leader, professional counseling, or support group as needed. **EB:** *A cross-sectional survey by* Ghesuiere et al (2015) *of 591 hospices in the United States found that complicated grief or depression related to death can be assessed and managed by most hospices in varying degrees with the use of a multiprofessional team, support groups, individual counseling, or group therapy.*

Pediatric

- Provide spiritual care for children based on developmental level. **EB:** *When nurses are comfortable providing spiritual care, they can implement numerous spiritual care activities and intervention to meet the spiritual needs of the child and family. After determining the child's spiritual beliefs and spiritual needs, a plan of care is developed based on the child's developmental age (Fowler, 1987).* **EBN:** *In a meta-synthesis on children living with chronic disease by Bakker et al (2018), children ages 0 to 18 found comfort and strength in their relationship with God, used their religious beliefs to cope, and reported their spiritual experiences using religious terminology.*
- **Parents:** Incorporate religious traditions and faith practices for parents with hospitalized and chronically ill children. **EB:** *A qualitative study indicated that religion was a positive coping mechanism for parents with infants in the neonatal intensive care unit (NICU) (Huenink & Porterfield, 2017).* **EBN:** *In a quantitative descriptive study, parents of children with cancer demonstrated an increase in their religious faith (Wiener et al, 2016).* **EBN:** *Additional relevant research can be found in Wang et al (2019).*
- **School-Age Children:** Encourage faith community involvement and religious attendance with parent(s). **EBN:** *In a meta-synthesis by Bakker et al (2018) on children living with chronic disease, children ages 0–18 found comfort and strength in their relationship with God, used their religious beliefs to cope, and described spiritual experiences using religious terminology.*
- **School-Age Children:** Encourage children to participate in faith community health programs. **EBN:** *An ethnographic study indicated that faith communities provide a forum for healthy nutrition as part of the faith culture (Opalinski et al, 2017).*
- **African American Children:** Incorporate faith traditions in coping with chronic disease. **EBN:** *In an ethnographic study of African American parents of children with autism, religious faith in God was a positive theme and can support culturally congruent health care (Burkett et al, 2017).*
- **Latino Children:** Incorporate faith traditions among clients and families in pediatric settings. **EBN:** *In an ethno-nursing study with Latino families and providers of care on a medical-surgical unit, a culturally competent model was developed with findings indicating five care factors as most valuable: family, faith, communication, care integration, and meeting basic needs (Mixer et al, 2015).*
- **Adolescents:** Encourage prayer, particularly within the African American community. **EBN:** *Qualitative research indicates that urban African American youth have multifaceted dimensions of their spirituality, including the role of prayer in their lives, an unwavering faith in a higher power, and the importance of giving back to their communities (Dill, 2017).*
- **Adolescents/Young Adults:** Encourage religious coping in the adolescent/young adult population. **EB:** *A secondary analysis using a national database found a significant difference (p = 0.001) between females' and males' risk perception scores of marijuana use and total religiosity scores, suggesting that religiosity has an indirect effect on marijuana use; females were more religious with a higher risk perception score than males, and less likely to use the drug (Hai et al, 2018).*

Geriatric

- Encourage listening to religious music. **EB:** *A national quantitative study found that frequency of listening to religious music was associated with decreases in death anxiety and increases in life satisfaction, self-esteem, and sense of control (Bradshaw et al, 2015).*

Multicultural

- **African American:** Collaborate with faith communities to promote wellness. Also, incorporate faith traditions in coping with chronic disease. **EB:** *In a qualitative participatory action study with church leaders, findings indicated feelings of distrust of the medical system with a preference for self-management and suggested incorporating a religious orientation to rebuild trust within the African American community (Lew*

et al, 2015). **EBN:** *In an ethnographic study of African American parents of children with autism, religious faith in God was a positive theme and can support culturally congruent health care (Burkett et al, 2017).*

- **Latino:** Incorporate faith traditions among clients and families in pediatric settings. **EBN:** *In an ethnonursing study with Latino families and providers of care on a medical-surgical unit, a culturally competent model was developed with findings indicating five care factors as most valuable: family, faith, communication, care integration, and meeting basic needs (Mixer et al, 2015). Collaborate with faith communities to promote wellness. A cross-sectional study by Sanchez et al (2019) identified the importance of religious capital, which promoted health through social support, as useful in decreasing immigration stress, especially among undocumented immigrants.*
- **Thai:** Encourage both religious and spiritual coping strategies to help cope. **EBN:** *The Thai people were found to be both religious and spiritual, using coping strategies from both areas to help manage concerns and to explain the development of kidney disease in a qualitative study by Yodchai et al (2017).*

Multiprofessional

▲ Chaplain referral when individuals engage in religious coping mechanisms. **EB:** *When individuals engage in religious coping, additional religious struggles follow, which may benefit from chaplain expertise to promote well-being (Fox et al, 2016).* **EB:** *A cross-sectional survey by Ghesuiere et al (2015) of 591 hospices in the United States found that complicated grief or depression related to death can be assessed and managed by most hospices in varying degrees with the use of a multiprofessional team, support groups, individual counseling, or group therapy.*

Risk for Impaired Religiosity

Domain 10 Life principles Class 3 Value/belief/action congruence

Mary Beth Flynn Makic, PhD, RN, CCNS, CCRN-K, FAAN, FNAP, FCNS

NANDA-I

Definition

Susceptible to an impaired ability to exercise reliance on religious beliefs and/or participate in rituals of a particular faith tradition, which may compromise health.

Risk Factors

Anxiety; cultural barrier to practicing religion; depressive symptoms; environmental constraints; fear of death; inadequate social support; inadequate sociocultural interaction; inadequate transportation; ineffective caregiving; ineffective coping strategies; insecurity; pain; spiritual distress

At-Risk Population

Hospitalized individuals; individuals experiencing end of life crisis; individuals experiencing life transition; individuals experiencing personal crisis; individuals experiencing spiritual crisis; Individuals with history of religious manipulation; older adults

Associated Conditions

Depression; impaired health status

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales*, and References

Refer to care plan for Impaired **Religiosity.**

R

Relocation Stress Syndrome

Domain 9 Coping/stress tolerance Class 1 Post-trauma responses

Margaret M. Egan-Touw, DNP, RN, CNE

NANDA-I

Definition

Physiological and/or psychosocial disturbance following transfer from one environment to another.

Defining Characteristics

Anger behaviors; anxiety (00146); decreased self concept; depressive symptoms; expresses anger; expresses frustration; fear (00148); increased morbidity; increased physical symptoms; increased verbalization of needs; loss of identity; loss of independence; low self-esteem; pessimism; preoccupation; reports altered sleep-wake cycle; reports concern about relocation; reports feeling alone; reports feeling insecure; reports feeling lonely; social alienation; unwillingness to move

Related Factors

Communication barriers; inadequate control over environment; inadequate predeparture counseling; inadequate social support; ineffective coping strategies; powerlessness; situational challenge to self-worth; social isolation

At-Risk Population

Individuals facing unpredictability of experience; individuals who move from one environment to another; individuals with history of loss

Associated Conditions

Depression; diminished mental competency; impaired health status; impaired psychosocial functioning

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Relocation Adaptation; Anxiety Self-Control; Child Adaptation to Hospitalization; Coping; Depression Level; Depression Self-Control; Loneliness Severity; Psychosocial Adjustment: Life Change, Quality of Life; Stress Level

Example NOC Outcome with Indicators

Relocation Adaptation as evidenced by the following indicators: Recognizes reason for change in living environment/Participates in decision-making in new environment/Expresses satisfaction with daily routine/Expresses satisfaction with level of independence/Compares care needs with available resources/Expresses satisfaction with social relationships/Expresses satisfaction with variety of food/Expresses satisfaction with food preparation/Expresses satisfaction with retained personal belongings/Expresses satisfaction with living arrangements/Exhibits positive mood/Appears content/Respects others' rights/Maintains positive relationships with family/Maintains positive relationships with friends/Maintains positive relationships with others in new environment/Participates in social activities/Seeks information to reduce anxiety/Plans coping strategies for stressful situations/Uses effective coping strategies/Uses relaxation techniques to reduce anxiety/Maintains social relationships/Maintains adequate sleep/Controls anxiety response. (Rate the outcome and indicators of **Relocation Adaptation:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Recognize and know the name of at least one staff member or new neighbor within 1 week of relocating
- Engage at least one staff member of new neighbor in a conversation within 2 weeks of relocating
- Express concern about move when encouraged to do so during individual contacts within 24 hours of awareness of impending relocation
- Perform activities of daily living (ADLs) in safe manner
- Proactively ask for assistance with ADLs
- Maintain previous mental and physical health status (e.g., nutrition, elimination, sleep, social interaction, physical activity) within 2 months of relocating

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Anxiety Reduction; Coping Enhancement; Discharge Planning; Hope Instillation; Self-Responsibility Facilitation; Animal-Assisted Therapy; Art Therapy; Music Therapy; Massage; Mood Management; Active Listening

Example NIC Activities—Anxiety Reduction

Stay with client to promote safety and reduce fear; Provide objects that symbolize safeness to the client; Orient to the new setting and personnel daily; Encourage sharing life experiences with peers and staff; Promote autonomy.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Nursing Interventions and *Rationales*

- Orientation to the new environment is a proactive means that alleviates anxiety and increases confidence. **EBN:** *Orientation before the move can serve as a means to reduce fear and anxiety associated with the newness of the move (Luo, Chen, & Lian, 2020). The authors proposed guidelines to facilitate optimal adjustment and autonomy inclusive for structured and free-style exploration by the resident to familiarize oneself with the new setting.*
- Be aware that relocation to retirement communities may be a positive change. **EBN:** *The elderly, when facing moving from the marital home into a structured residential facility, verbalized and demonstrated confidence and self-satisfaction when identified as the primary decision-maker regarding the move. This was reinforced on arrival at the facility. A cross-sectional study of older individuals relocating to retirement communities found older individuals experienced less stress when they had a greater role in the decision-making associated with the relocation, positive cognitions, and adjustment resources (Peck & Jacob, 2019).*
- Begin relocation planning as early in the decision-making process as possible. **EBN:** *Having a well-organized proactive plan for the move with support and advocacy through the planning and decision-making process may reduce anxiety and alleviate fear(s) (Peck & Jacob, 2019; Luo, Chen, & Lian, 2020).*
- Obtain a history, including the reason for the move, the client's usual coping mechanisms, history of losses, and family and financial support for the client. **EBN:** *A complete history helps the nurse determine the type of support needed and appropriate interventions to reduce relocation stress. Getting to know the resident's premove lifestyle will help identify quality of life and safety concerns that will enable to receiving facility to plan accordingly (Ryman et al, 2018; Luo, Chen, & Lian, 2020).*
- Identify to what extent the client can participate in the relocation decision-making process and advocate for this participation. **EBN:** *As the population of those over 60 increases, one can anticipate nursing taking a more proactive role in the planning and education of individuals facing moving into continuing care facilities (Ryman et al, 2018). Engaging older adults in the decision-making process is likely to enhance the level of adjustment after the relocation and promote psychological well-being (Hertz et al, 2016; Peck & Jacob, 2019).* **EB:** *A study of highly dependent older adults who were relocated found that the subjects had a higher use of new antidepressant agents and new antibiotic orders, suggesting the need for vigilant planning to reduce the stress of the move (Mello & O'Connor, 2016).*
- Assess client's readiness to relocate and relocation self-efficacy. **EB:** *Relocation is a complex process that requires careful consideration and planning before the move (prelocation) and adjustment to the new home after the move (postrelocation) to promote the older client's adjustment (Hertz et al, 2016; Ryman et al, 2018; Luo, Chen, & Lian, 2020).*
- Consult an evidence-based practice guide for relocation. **EBN:** *Researchers compiled the latest findings to develop a protocol to assist in relocating older adults (Hertz et al, 2016; Luo, Chen, & Lian, 2020).*
- Assess family members' perceptions of client's ability to participate in relocation decisions. Particularly in incidences of neurocognitive impairment such as dementia, be attentive to health care workers' involvement in making the decision to relocate. They may need support and encouragement through the process. **EB:** *Health care workers were found to be highly stressed during the relocation decision-making process and "walking a tightrope" between the older adult's needs and those of the person's family members (Canham et al, 2018).*
- Consider the cultural and ethnic values of the client and family as much as possible when choosing roommates, foods, and other aspects of care. **EB:** *Inclusion of culturally and ethnically sensitive foods during meals and leisure activities where snacks are an expectation can promote inclusion and thereby facilitate adjustment to the new facility. Nurses need to be aware of the differences in values and practices of different cultures and ensure that they provide culturally appropriate care that is respectful of individual and familial caregivers' beliefs (Lee et al, 2017; Lin & Yen, 2018; Shekriladze, Javakhishvili, & Tchanturia, 2019; Luo, Chen, & Lian, 2020).*
- Promote clear communication between all participants involved in the relocation process. **EB:** *A narrative study exploring older client's transitions found that communication and exploring unspoken fears helped reduce concerns of loss of control and uncertainty (Lee et al, 2017; Lin & Yen, 2018; Luo, Chen, & Lian, 2020).*
- Observe the following procedures if the client is being transferred to an extended care or assisted living facility:
  - Facilitate the client's participation in decisions and choice of placement, and arrange a preadmission visit if possible.
  - If the client cannot visit the new facility, arrange for a visit or telephone call by a member of the staff to welcome the client and show a videotape or at least provide pictures of the new care facility.

- ❍ Have a familiar person accompany the client to the new facility. This lessens client and family anxiety, confusion, and dissatisfaction.
- ❍ Encourage the resident and/or caregiver to write a journal regarding thoughts and feelings about the relocation.
- ❍ Continue to assess caregiver psychological distress during a 6-month period after relocation. Caregivers experience guilt and distress because of the responsibility of moving their loved one.

EB: *The adjustment period for the resident as well as the caregiver is usually 3 to 6 months after relocation. Caregivers may begin to identify conflicted feelings and work on resolution during this time and need support* (*Lee et al, 2017*).

- Identify previous routines for ADLs. Try to maintain as much continuity with the previous schedule as possible. **EB:** *Continuity of client's everyday personal care by care aides that is both empathetic and nurturing is perceived as supportive and compassionate and eases relocation stress (Andersen & Spiers, 2016).*
- Bring in familiar items from home (e.g., pictures, clocks, afghans). **EB:** *Familiarity eases transition, reinforces one's identity, and symbolizes safeness* (*Wiles et al, 2012*; *Iecovich, 2014*).
- Establish the way the client would like to be addressed (Mr., Mrs., Miss, first name, or calling name/nickname). **EB:** *Calling clients by their desired name shows respect and acknowledgement of their individuality.*
- Thoroughly orient the client and the family to the new environment and routines; repeat directions as needed. **EB:** *Providing honest answers to client questions and supporting the individual adjustment to the new location will be necessary for at least 6 months until the client feels at home* (*Hertz et al, 2016*; *Luo, Chen, & Lian, 2020*).
- Spend one-to-one time with the client. Allow the client to express feelings and convey acceptance of them; emphasize that the client's feelings are real and individual and that it is acceptable to be sad or angry about moving. **EB:** *Interventions should recognize personal values; allow adequate time to listen to and respect the views and needs of the older adult* (*Hertz et al, 2016*; *Luo, Chen, & Lian, 2020*).
- Allocate an attentive staff member to help the client adjust to the move. Assign the same staff members to the client for care if the therapeutic relationship is compatible with client needs; maintain consistency in the staffing personnel with whom the client interacts on a daily basis.
- Encourage the client to verbalize one positive aspect of the new living situation each day. Helping the client to focus on the positive aspects of the move can facilitate adaptation and adjustment by reframing one's attitude in a positive fashion. **EBN:** *Assisting clients to focus on positive thinking has been found to promote their ability to manage daily activities and adapt to change. Clients with greater resourcefulness have been found to be able to adapt to challenging situations in a more constructive and successful manner (Luo, Chen, & Lian, 2020).*
- Ask the client to verbalize one positive aspect of the new living situation each day. **EB:** *Helping the client focus on the positive aspects of the move can help change attitude and reframe the situation in a positive fashion (Hertz et al, 2016).*
- Monitor the client's well-being and provide appropriate interventions for problems with social interaction, nutrition, sleep, new onset of infection, or elimination problems. **EB:** *Older clients and lower socioeconomic status are associated with greater risk of maladjustment after relocation (Hertz et al, 2016). A study found a significant increase in morbidity before and after transfer. Residents who transferred had increased rates of illness and greater antibiotic and antidepressant medication prescription rates in the months before and after relocation (Mello & O'Connor, 2016; Costlow & Parmelee, 2019).*
- If the client is being transferred within a facility, have staff members from the new unit visit the client and the family, if possible, before transfer.
- Work with the caregivers and family members, helping them work with and adjust to the stages of "making the best of it," "making the move," and "making it better." **EBN:** *Provide opportunities for family to visit, encourage engagement in facility social events, and provide electronic access for the client to maintain ties with loved ones and friends (Hertz et al, 2016; Lee et al, 2017).*
- If a client is being transferred from the intensive care unit (ICU), have previous staff make occasional visits until the client is comfortable in the new surroundings. Ensure that the family is told relevant information. **EB:** *Providing an individualized transfer plan from the ICU to the medical-surgical unit that addresses client and family questions before transfer reduces relocation stress (Dale et al, 2020; Won & Son, 2020).*
- Watch for coping problems (e.g., withdrawal, regression, angry behavior, impaired sleeping, refusal to eat, flat affect, anxiety) and intervene immediately. **EB:** *Loss of independence with transfer to a nursing home may manifest in anxiety, anger, and depression (Dale et al, 2020; Won & Son, 2020).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Encourage the client to express grief for the loss of former residence and of interpersonal relationships and explain that it is normal to feel sadness over change and loss. **EB:** *Acknowledging and verbalizing feelings of grief can help alleviate the heartache and promote healing (Costlow & Parmelee, 2019).*
- Assess the client's psychological needs along with physiological needs. **EB:** *Although physical care needs may predicate the relocation, meeting psychosocial care needs must be individualized via thorough assessment (Hertz et al, 2016; Luo, Chen, & Lian, 2020).*
- Encourage clients to take a proactive role in their care as much as is possible inclusive of autonomous decision-making (e.g., arrangement of the furniture in the residence, choice of roommate, bathing routines). **EB:** *Autonomy facilitates making choices that help prevent feelings of powerlessness that may lead to depression (Hertz et al, 2016; Peck & Jacob, 2019).*

Pediatric

- Assess family history and contact information from children relocated to rescue shelters. **EB:** *Efforts have been made to develop systematic processes to reunite children who are separated from families during disasters. Current guidelines established by the Federal Emergency Management Agency (FEMA), the Red Cross, the Centers for Disease Control and Prevention (CDC), and the National Center for Missing and Exploited Children focus on providing effective, efficient action through the following:*
  - *A shared understanding of local and national resources and capabilities*
  - *Collaboration, coordination, effective communication for children with disabilities and other access and functional needs, and needs assessments during disasters*
  - *Shared operational procedures and technologies (FEMA et al, 2013; Miller et al, 2019)*
- Be aware that community relocation may be beneficial for children and assess community and academic resources of new location (Miller et al, 2019).
- Provide support for a child and family who must relocate to be near a higher acuity health care facility such as a transplant center (Søndergaard et al, 2016).
- In situations of familial discord such as divorce, recommend alternative dispute resolution versus traditional litigated settlement. **EBN:** *This nonadversarial approach may mitigate some of the loss of trust and trauma experienced by children of divorce (Søndergaard et al, 2016).*
- Assess presence of allergies before and after relocation.
  - If the client is an adolescent, try to avoid a move in the middle of the school year, find a newcomers' club for the adolescent to join, and refer for counseling if needed. **EB:** *Most adolescents who relocate suffer a brief period of loss of companionship and intimacy with close friends (McBride, 2015; Miller et al, 2019).*
- Assess adolescents' perceptions of their acceptance by peers. **EB:** *Poor perceptions of peer acceptance have been related to less initiation of social interactions in new settings (McBride, 2015).*
- Help parents recognize that relocation stress syndrome may persist for prolonged periods (e.g., 2 years), especially in adolescents. **EB:** *Adolescents were found to commonly express their ideology of the relocation* (*McBride, 2015*).
- Be aware that adolescents may cope with the transition by exerting control in particular domains. **EBN:** *Adolescents may be at risk of developing eating disorders after a major transition (McBride, 2015).*
- The effects of frequent relocation may not manifest immediately and may have long-term effects on physical and mental health. **EBN:** *Longitudinal analysis found that frequent relocation in adolescence was associated with higher rates of stress and physical exhaustion in adulthood* (*McBride, 2015*; *Søndergaard et al, 2016*).

Geriatric

- Monitor the need for transfer and relocate only when medically or psychologically necessary. **EB:** *Older adults often experience loss of physical and psychological well-being following relocation (Lee et al, 2017).*
- Implement discharge planning early and engage the older adult in the planning and decision-making process about relocation. **EB:** *Engaging the older adult in decision-making is key to successful relocation (Hertz et al, 2016; Luo, Chen, & Lian, 2020).*
- Use technologies, such as sensing devices, to measure average in-home gait speed (AIGS) as a predictor of fall risk. **EBN:** *AIGS was found to be a more reliable and valid predictor of fall risk than traditional physical performance assessments (Stone et al, 2015).*
- Implement a registered nurse (RN) care coordination care planning model to restore older adults' health, maintain their independence, and reduce care costs. **EBN:** *RN care coordination was found to significantly*

and positively affect older adult outcome variables and to result in lesser costs of care (Lee et al, 2017; Dale et al, 2020).

- After the transfer, assess the client's mental status. Document and observe for any new onset of confusion. Confusion can follow relocation because of the overwhelming stress and sensory overload. **EB:** *Elderly women are more at risk for experiencing moderate to severe anxiety when compounded with loneliness. Many have outlived their spouses and friends, which highlights the sense of isolation (Wiyono, Sukartini, & Mundakir, 2018).*
- Facilitate visits from companion animals. **EB:** *Pet therapy has been found to improve depressive symptoms and cognitive function in residents of long-term care facilities with mental illness (Ambrosi et al, 2019)*

Client/Family Teaching and Discharge Planning

- Teach family members about symptoms of relocation stress syndrome. Encourage them to monitor for signs of the syndrome.
- Help significant others learn how to support the client in the relocation process by setting up social engagements such as a schedule of visits, arranging for holidays, bringing familiar items from home, and establishing a system for contact when the client needs support. **EBN:** *Social support of family and friends was significantly related to relocation adjustment (Hertz et al, 2016).*
- Assist family members and the relocating older adult to use Internet/webcam technology for interaction to supplement in-person visits. **EB:** *When older adults in a care facility have less than one visitor per week, interaction can be supplemented with technological "visits" (Hertz, 2016).*

Risk for Relocation Stress Syndrome

Domain 9 Coping/stress tolerance Class 1 Post-trauma responses

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Susceptible to physiological and/or psychosocial disturbance following transfer from one environment to another, which may compromise health.

Risk Factors

Communication barriers; inadequate control over environment; inadequate predeparture counseling; inadequate social support; ineffective coping strategies; powerlessness; situational challenge to self-worth; social isolation

At-Risk Population

Individuals facing unpredictability of experience; individuals who move from one environment to another; individuals with history of loss

Associated Conditions

Diminished mental competency; impaired health status; impaired psychosocial functioning

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for **Relocation** Stress Syndrome.

Impaired Resilience

Domain 9 Coping/stress tolerance Class 2 Coping responses

Gail B. Ladwig, MSN, RN and Julianne E. Doubet, BSN, RN, EMT-B

NANDA-I

Definition

Decreased ability to recover from perceived adverse or changing situations, through a dynamic process of adaptation.

Defining Characteristics

Decreased interest in academic activities; decreased interest in vocational activities; depressive symptoms; expresses shame; impaired health status; inadequate sense of control; ineffective coping strategies; ineffective integration; low self-esteem; renewed elevation of distress; reports feeling guilty; social isolation

Related Factors

Altered family relations; community violence; disrupted family rituals; disrupted family roles; dysfunctional family processes; inadequate health resources; inadequate social support; inconsistent parenting; ineffective family adaptation; multiple coexisting adverse situations; perceived vulnerability; substance misuse

At-Risk Population

Economically disadvantaged individuals; individuals experiencing a new crisis; individuals experiencing chronic crisis; individuals exposed to violence; individuals who are members of an ethnic minority; individuals whose parents have mental disorders; individuals with history of exposure to violence; individuals with large families; mothers with low educational level; women

Associated Conditions

Intellectual disability; psychological disorder

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Resiliency; Coping; Decision-Making; Self-Esteem

Example NOC Outcome with Indicators

Personal Resiliency as evidenced by the following indicators: Adapts to adversities as challenges. (Rate the outcome and indicators of **Personal Resiliency:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate reduced or cessation of drug and alcohol usage
- State effective life events on feelings about self
- Seek help when necessary
- Verbalize or demonstrate cessation of abuse
- Adapt to unexpected crises or challenges
- Verbalize positive outlook on illness, family, situation, and life
- Use available resources to meet coping needs
- Identify role models
- Identify available assets and resources
- Be able to verbalize meaning of one's life

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Resiliency Promotion; Coping Enhancement; Counseling; Emotional Support; Self-Esteem Enhancement; Support Group; Support System Enhancement

Example NIC Activities—Resiliency Promotion

Encourage positive health-seeking behaviors; Facilitate family communication

Nursing Interventions and *Rationales*

- Encourage positive, health-seeking behaviors. **EB:** *Johansson et al (2016) concluded, in their study of diabetic health, that caregivers should establish an atmosphere of open learning that generates interactions in a climate that establishes and encourages contemplation to promote health and well-being.*
- Ensure access to biological, psychological, and spiritual resources. **EB:** *Tay and Lin (2020) characterize psychological resistance as an evolving response to stress that is adaptable, is durable, and can be fostered and maintained by the influence of "biological, psychological, spiritual, and social factors."*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Foster cognitive skills in decision-making. **EB:** *Client's comprehension of pertinent information is an essential part of the standard that allows for informed decisions (Gerstenecker et al, 2015).*
- Assist client in cognitive restructuring of negative thought processes. **EB:** *Ayoningtyas et al (2019) found that group counseling, with exercises in both cognitive restructuring and self-instruction techniques, strengthened career decision-making capabilities.*
- Facilitate supportive family environments and communication. **EBN:** *Family caregivers of clients with cancer may find themselves subjected to struggles with physical, mental, and spiritual problems, which if ignored could put strain on the whole family (Borji et al, 2017).*
- Promote engagement in positive social activities. **EB:** *In their study of persons with learning disabilities, Howarth et al (2016) ascertained that taking part in various social activities provided a key opportunity for individuals to expand their social connections.*
- Assist client to identify strengths and reinforce these. **EBN:** *According to Strandis and Bonds (2017), a positive nurse–client relationship aids the client in recognizing their innate ability to maintain their own health and well-being.*
- Help the client identify positive emotions during adverse situations. **EBN:** *Terrill et al (2017) found that a concentration on positive emotions can introduce strength-based processes in end-of-life care.*
- Build on supportive counseling and therapy. **EBN:** *Education and counseling are important interventions in client care, but clients can also gain a feeling of well-being and control using their own inner strengths and methods of coping (Sadruddin et al, 2017).*
- Identify protective factors such as assets and resources to enhance coping. **EBN:** *The reinforcement of beneficial protective influences can improve the resilience of elderly people and facilitate their abilities to deal with possible crises quickly and productively (Yang-Tzu et al, 2019).*
- Provide positive reinforcement and emotional support during the learning process. **EBN:** *Families caring for family members with dementia face a multitude of problems; dementia specialists found that by using video diaries provided by caregivers, they were able to evaluate and then provide personalized care counseling (Sohyun et al, 2019).*
- Encourage mindfulness, a conscious attention, and awareness of self. **EBN:** *Key elements that promote the alleviation of stress and encourage resilience are mindfulness and meditation (Savel & Munro, 2017).*
- Educate and encourage the use of stress-reduction techniques. **EB:** *The use of stress reduction interventions such as relaxation music, mindful meditation, and other relaxation techniques has been accepted and considered valuable as related treatments (Hwang & Bunt, 2020).*
- Enhance knowledge and use of self-care strategies. **EBN:** *In their study of heart failure clients and self-care, Awoke et al (2019) found that nurses have distinctive skills required to direct educational programs that advance positive health effects.*

Pediatric

- The preceding interventions may be adapted for the pediatric client.
- Promote nurturing, supportive relationships with family. **EB:** *According to the National Scientific Council on the Developing Child (2015), "Supportive relationships with adults help children develop resilience, or the set of skills needed to respond to adversity and thrive."*
- Facilitate health and well-being opportunities. **EB:** *Fostering resilience in pediatric clients is an opportunity to cultivate the health and welfare of succeeding generations and subsequently enrich national productivity (Traub & Boynton-Jarrett, 2017).*
- Promote the development of positive mentor relationships. **EB:** *DeWit et al (2016) found, in their study of supported mentoring, that girls and boys involved in long-term, supported mentoring connections experienced beneficial outcomes.*

▲ Consider referral to appropriate community resource for children who have had adverse childhood experiences. **EB:** *Curtis (2018), in his study of strength in families, found that the data he collected support counseling programs that concentrate on positive family dynamics to foster strengths.*

Readiness for Enhanced Resilience

Domain 9 Coping/stress tolerance Class 2 Coping responses

Gail B. Ladwig, MSN, RN and Julianne E. Doubet, BSN, RN, EMT-B

R

NANDA-I

Definition

A pattern of ability to recover from perceived adverse or changing situations, through a dynamic process of adaptation, which can be strengthened.

Defining Characteristics

Expresses desire to enhance available resources; expresses desire to enhance communication skills; expresses desire to enhance environmental safety; expresses desire to enhance goal setting; expresses desire to enhance interpersonal relations; expresses desire to enhance involvement in activities; expresses desire to enhance own responsibility for action; expresses desire to enhance positive outlook; expresses desire to enhance progress toward goal; expresses desire to enhance psychological resilience; expresses desire to enhance self-esteem; expresses desire to enhance sense of control; expresses desire to enhance support system; expresses desire to enhance use of conflict management strategies; expresses desire to enhance use of coping skills; expresses desire to enhance use of resources

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Resiliency; Family Resiliency; Quality of Life

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Example NOC Outcome with Indicators

Personal Resiliency as evidenced by the following indicator: Adapts to adversities and challenges. (Rate the outcome and indicators of **Personal Resiliency:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Adapt to adversities and challenges
- Communicate clearly and appropriately for age
- Take responsibility for own actions
- Make progress towards goals
- Use effective coping strategies
- Express emotions

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Resiliency Promotion; Self-Efficacy Enhancement; Counseling; Emotional Support

Example NIC Activities—Self-Efficacy Enhancement

Explore individual's perception of his or her capability to perform the desired behavior

Nursing Interventions and *Rationales*

- Listen to and encourage expressions of feelings and beliefs. **EBN:** *Listening is the skill of demonstrating interest and sensitivity to another but understanding that wanting to be listened to is also a universal desire (Duarte-Quilao, 2019).*
- Establish a therapeutic relationship based on trust and respect. **EBN:** *A vital element of nursing practice is the formation of a positive and trusting therapeutic relationship that paves the way for effective client care (Fao et al, 2017).*
- Assist client in rating current level of resilience. **EBN:** *Maurović and colleagues (2020) link family resilience to the philosophies of individual resilience and community resilience; this connection may pose not only challenges but also solutions.*
- Facilitate supportive family environments and communication. **EB:** *A study by Waters (2020) suggests that introducing positive practices in family interactions, with the goal of change in family relationship dynamics, may help modify divisive family elements.*
- Assist client to identify and reinforce strengths. **EBN:** *A sound nurse–client relationship has the potential to identify the client's personal strengths and to encourage their use in the management of the client's own health care (Strandås & Bondas, 2018).*
- Enhance skills associated with social and executive functioning. **EB:** *Executive functioning is a term used to describe high-level intellectual activities that may include "planning, working memory, inhibition, mental flexibility." These functions facilitate the manner in which people control and adjust their goal-targeted activities (Cropley et al, 2016).*
- Provide positive reinforcement and emotional support during implementation of nursing care. **EBN:** *In their study concerning the introduction of self-care guidelines for clients who have had a permanent pacemaker placed, researchers found that the guidelines had beneficial effects not only in enhancing the clients' self-care management but also in augmenting all aspects of nursing sensitive clients' outcomes (Ebada et al, 2017).*
- ▲ Facilitate the engagement with mentorship and volunteer opportunities. **EB:** *Volunteering is consistently recognized as a positive factor in enriching one's sense of purpose and meaning (Johnson, 2017).*
- Determine how family behavior affects the client. **EBN:** *As the family is usually the most dedicated support system for clients, it is essential that the nurse evaluate the family's circumstances and then subsidize the family's decision-making abilities (Judha, 2019).* **EB:** *Family can be instrumental in fostering resilience when faced with adverse difficulties (Theiss, 2018).*

- Promote use of mindfulness and other stress-reduction techniques. **EB:** *In their study of the use of mindfulness-based stress reduction (MBSR) in Parkinson's disease, McClean et al (2017) noted that the use of MBSR as an intervention has increased and improved outcomes in a mix of long-term conditions, including stress and depression.*

Pediatric

- The preceding interventions may be adapted for the pediatric client.
- Encourage the promotion of protective factors by fostering the seeking of opportunities to improve cognitive abilities, such as tutoring and other resources; the development of positive and supportive relations such as family, community members, or mentors; and the improvement of general health. **EB:** *According to Lehrer et al (2017), adolescents who experience positive emotions and receive social support will develop an increased sense of well-being.*

Multicultural

- Use teaching strategies that are culturally and age appropriate. **EBN:** *Lee et al (2020), in their study of nurses' cultural competence capabilities, realized that it is necessary for nurses to distinguish cultural variances and utilize unique communication skills to deliver client-centered nursing care to those from diverse backgrounds.*

Risk for Impaired Resilience

Domain 9 Coping/stress tolerance Class 2 Coping responses

Gail B. Ladwig, MSN, RN and Julianne E. Doubet, BSN, RN, EMT-B

NANDA-I

Definition

Susceptible to decreased ability to recover from perceived adverse or changing situations, through a dynamic process of adaptation, which may compromise health.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Risk Factors

Altered family relations; community violence; disrupted family rituals; disrupted family roles; dysfunctional family processes; inadequate health resources; inadequate social support; inconsistent parenting; ineffective family adaptation; multiple coexisting adverse situations; perceived vulnerability; substance misuse

At-Risk Population

Economically disadvantaged individuals; individuals experiencing a new crisis; individuals experiencing chronic crisis; individuals exposed to violence; individuals who are members of an ethnic minority; individuals whose parents have mental disorders; individuals with history of exposure to violence; individuals with large families; mothers with low educational level; women

Associated Conditions

Intellectual disability; psychological disorder

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Resiliency; Family Resiliency; Knowledge: Health Resources

Example NOC Outcome with Indicators

Personal Resiliency as evidenced by the following indicator: Takes responsibility for own actions. (Rate the outcome and indicators of **Personal Resiliency:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify available community resources
- Propose practical, constructive solutions for disputes
- Identify and access community resources for assistance
- Accept assistance with activities of daily living from family and friends
- Verbalize an enhanced sense of control
- Verbalize meaningfulness of one's life

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Resiliency Promotion; Assertiveness Training; Values Clarification; Parenting Promotion

Example NIC Activities—Resiliency Promotion

Encourage family involvement with child's schoolwork and activities; Assist family in providing atmosphere conducive to learning

Nursing Interventions and *Rationales*

- Determine how family behavior affects client. **EBN:** *The model of resilience is based on the presupposition that individuals and families are connected to each other and their community and have collective strengths, which will help them compensate for their adversity (Deist & Greeff, 2015).*
- Help the client to identify personal rights, responsibilities, and conflicting norms. **EBN:** *According to Salmond and Echevarria (2017), in their study of nursing in a rapidly shifting health care milieu, the end results of comprehensive health care are subject to a series of considerations beyond that of the clinical, such as environment, social and economic conditions, and the client's own health maintenance behaviors.*

- Encourage consideration of values underlying choices and consequences of the choice. **EBN:** *A study found that acceptance of responsibility must take place before one can make lifestyle choices and/or feel satisfaction for these choices (Finderup et al, 2016).*
- Help the client practice conversational and social skills. **EBN:** *When it is evident that a client's active participation in self-care is diminished, the next step is to incorporate a facilitator in the process (du Pon et al, 2019).*
- Assist client to prioritize values. **EBN:** *Evidence-based practice merges cutting-edge research with clinical proficiency and client values to implement objective interventions for favorable client outcomes and improvement in quality of life (Butcher, 2016).*
- Foster an accepting, nonjudgmental atmosphere. **EB:** *The results of a study by Usaite and Cameron (2015) found that active participation in pleasurable but structured pastimes can enrich the lives of children and their families by promoting "a positive sense of self, constructive relationships, roles, routines and responsibilities."*
- Help to identify self-defeating thoughts. **EBN:** *McRae (2016) writes, in her article concerning emotional regulation, that a commonly used approach to help manage a client's emotional insecurity is cognitive appraisal; this strategy involves shifting the manner in which the client envisages a past stressful situation and then generates a positive modification to the negative stressor.*
- ▲ Refer to community resources/social services as appropriate. **EB:** *Social support is assistance provided by others in the community that promotes and maintains a client's well-being and resilience* (*Fuentes-Peláez et al, 2016*).
- ▲ Help clarify problem areas in interpersonal relationships. **EB:** *It is well established that appropriate communications are not only connective but also indispensable in interpersonal relationships: communication competencies are key to the construction of social connections* (*Trancă & Neagoe, 2018*).
- ▲ Promote a sense of an individual's autonomy and control over choices to be made in one's environment. **EBN:** Meeting one's psychological needs and goals is thought to contribute to a sense of well-being and to support autonomy, especially in the selection of beneficial options that can influence "value, self-respect, and dignity" (*Liu et al, 2020*).
- ▲ Identify and enroll high-risk families in follow-up programs. **EBN:** Programs aimed at community health are offered by local agencies to assist in the adjustment of attitudes toward culture and relationships and by fostering affirmative means of communication in schools, peer groups, and families (*Horner, 2017*).

Parental Role Conflict

Domain 7 Role relationship Class 3 Role performance

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Parental experience of role confusion and conflict in response to crisis.

Defining Characteristics

Anxiety; disrupted caregiver routines; expresses fear; expresses frustration; perceived inadequacy to provide for child's needs; perceived loss of control over decisions relating to child; reluctance to participate in usual caregiver activities; reports concern about change in parental role; reports concern about family; reports feeling guilty

Related Factors

Interruptions in family life due to home treatment regimen; intimidated by invasive modalities; intimidation by restrictive modalities; parent–child separation

At-Risk Population

Individuals living in nontraditional setting; individuals undergoing changes in marital status; parents with child requiring home care for special needs

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Caregiver Emotional Health; Caregiver Well-Being; Caregiver Lifestyle Disruption; Coping; Parenting Performance; Role Performance; Family Coping

Example NOC Outcome with Indicators

Family Coping as evidenced by the following indicators: Establishes role flexibility/Manages family problems/Uses family-centered stress reduction activities. (Rate the outcome and indicators of **Family Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Express feelings and perceptions regarding effects of illness, disability, and/or hospitalization on parental role
- Participate in hospital and home care as much as able given the availability of resources and support systems
- Exhibit assertiveness and responsibility in active family decision-making regarding care of the child
- Describe and select available resources to support parental management of the needs of the child and family

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Caregiver Support; Counseling; Decision-Making Support; Family Process Maintenance; Family Therapy; Parenting Promotion; Role Enhancement

Example NIC Activities—Role Enhancement

Teach new behaviors needed by client/parent to fulfill a role; Serve as role model for learning new behaviors as appropriate

Nursing Interventions and *Rationales*

- Assess and support parent's previous coping behaviors. **EBN:** *Understanding what experience a parent has with coping will enable the nurse to support the parents in the current situation (Senger et al, 2016).*
- Assess for the following signs of parental burnout: exhaustion in one's parental role, contrast with previous parental self, feelings of being fed up with one's parental role, and emotional distancing from one's children. **EB:** *A study to measure parental burnout identified the four dimensions of parental burnout syndrome as exhaustion in one's parental role, contrast with previous parental self, feelings of being fed up with one's parental role, and emotional distancing from one's children (Roskam, Brianda, & Mikoljczak, 2018).*
- Determine parent/family sources of stress, using the Parental Stress Scale. **CEB:** *The Parental Stress Scale is a valid and reliable self-report scale that contains 18 items representing pleasure or positive themes of parenthood (Berry & Jones, 1995).*
- Evaluate the family's perceived strength of its social support system. Encourage the family to use social support. **EB:** *A study of African American mothers found that social support moderated the relationship between parental stress and child behavior (Royal et al, 2017).*
- Determine the older childbearing woman's support systems and expectations for motherhood. **EBN:** *Supporting mothers during their transition into parenthood can assist with the bonding of the mother and the infant (Gilmer et al, 2016).*
- Use family-centered care and role modeling for holistic care of families. **EBN:** *Incorporating family-centered care helps enhance the parents' role in caring for their child (Cady et al, 2015).*
- ▲ Maintain parental involvement in shared decision-making regarding care by using the following steps: incorporate parents' information concerning the child's typical routines, behaviors, fears, likes, and dislikes; provide clear and direct firsthand information concerning the child's condition and progress; normalize the home/hospital environment as much as possible; and collaborate in care by providing choices when possible. **EB:** *A study found that parental involvement in decision-making was related to clinician communication and information sharing (Links et al, 2020).*
- Seek and support parental participation in care. **EBN:** *Nurses can support parents' participation in their child's care through a family-friendly environment, counseling, and good communication (Palomaa, Korhonen, & Pölkki, 2016).*
- ▲ Inform parents of financial resources, respite care, and home support to assist them in maintaining sufficient energy and personal resources to continue caregiving responsibilities. **EB:** *There can be a financial burden on parents of children with chronic illness and a need to help the family identify their resources (Stewart et al, 2016).*
- Provide family-centered care: allow parents to touch and talk to the child, and assist in the handling of medical equipment; offer open visiting hours; promote family presence at the bedside; promote open communication; provide for privacy. **EBN:** *Family-centered care can support family involvement with a child's care and decrease the stress associated with a child's hospitalization (Coats et al, 2018).*
- Refer parents to available telephone and/or Internet support groups. **EB:** *A study found that peer support meetings moderated by resource parents provided a unique and useful means to support NICU parents (Dahan et al, 2020).*
- Involve new mother's partner or parents in clinical encounters and invite family members to discuss their expectations and parenting experiences. **EBN:** *Health care providers realize the importance of family-centered care of the infant to help the mother and her partner care for the infant (Dzubaty, 2016).*

Multicultural

- Acknowledge racial/ethnic differences at the onset of care. **EBN:** *Providing culturally competent care is important to health care equality, and it is important for nurses to understand the importance of identifying the cultural differences that their clients will require (Dzubaty, 2016).*
- Assess for the influence of cultural beliefs, norms, and values on the client's perceptions of the parental role. **EBN:** *Understanding the cultures and beliefs of parents can enhance the interactions between nurse and family and assist the nurse to better care for the child and their family (Xiong et al, 2016).*
- Acknowledge that value conflicts arising from acculturation stresses may contribute to increased anxiety and significant conflict with the parental role. **EB:** *Study results suggest that lower acculturation conflict is associated with higher perceptions of general parenting competence for both Asian and Latin American parents (Kiang, Glatz, & Buchanan, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

▲ Refer parents of young children in specific cultural communities to support programs. **EBN:** *Parents and children benefit when a support group is incorporated into the care (Thomson-Salo et al, 2017).*

Home Care

- The interventions described previously may be adapted for home care use.
- Assess family preference for prenatal and postpartum visits; assist new parents to renegotiate parenting roles and responsibilities with coparenting. **EB:** *A cross-sectional survey of postpartum clients found that current prenatal and postpartum care delivery does not match clients' preferences for the number of visits or between-visit contacts. Clients also expressed openness to alternative models of prenatal care, including remote monitoring (Peahl et al, 2020).*

Client/Family Teaching and Discharge Planning

- Offer family-led education interventions to improve participants' knowledge about their condition and its treatment and decrease their information needs. **EBN:** *A study of caregivers found an association between the Stress-related Vulnerability Scale (SVS) and the perception of the usefulness of health care education (Di Stasio et al, 2020).*
- Encourage children and parent involvement in bereavement support groups, as an adjunct to grief therapy. **EB:** *A systematic review found that online support groups may be a useful adjunct to, but not an alternative to, grief therapy or counseling (Robinson & Pond, 2019).*

▲ Refer to a parenting program to facilitate learning of parenting skills. **EBN:** *A study of foster parents showed that participation in parenting programs increased levels of skills and knowledge following training than did those in the control group (Solomon, Niec, & Schoonover, 2017).*

- Teach the client about available community resources (e.g., therapists, ministers, counselors, self-help groups). **EBN:** *Community-based resources can support caregivers and ensure that they can identify needed services (Tallon et al, 2017).*

Ineffective Role Performance

Domain 7 Role relationship Class 3 Role performance

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

A pattern of behavior and self-expression that does not match the environmental context, norms, and expectations.

Defining Characteristics

Altered pattern of responsibility; altered perception of role by others; altered role perception; altered role resumption; anxiety; depressive symptoms; domestic violence; harassment; inadequate confidence; inadequate external support for role enactment; inadequate knowledge of role requirements; inadequate motivation; inadequate opportunity for role enactment; inadequate self-management; inadequate skills; inappropriate developmental expectations; ineffective adaptation to change; ineffective coping strategies; ineffective role performance; perceived social discrimination; pessimism; powerlessness; reports social discrimination; role ambivalence; role denial; role dissatisfaction; system conflict; uncertainty

Related Factors

Altered body image; conflict; fatigue; inadequate health resources; inadequate psychosocial support system; inadequate rewards; inadequate role models; inadequate role preparation; inadequate role socialization; inappropriate linkage with the health care system; low self-esteem; pain; role conflict; role confusion; role strain; stressors; substance misuse; unaddressed domestic violence; unrealistic role expectations

R

At-Risk Population

Economically disadvantaged individuals; individuals with developmental level inappropriate for role expectation; individuals with high demand job role; individuals with low educational level

Associated Conditions

Depression; neurological defect; personality disorders; physical illness; psychosis

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Psychosocial Adjustment: Life Change; Role Performance

Example NOC Outcome with Indicators

Role Performance as evidenced by the following indicators: Knowledge of role transition periods/Reported comfort with role changes. (Rate the outcome and indicators of **Role Performance:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Client Outcomes

Client Will (Specify Time Frame)

- Identify realistic perception of role
- State personal strengths
- Acknowledge problems contributing to inability to perform usual role
- Accept physical limitations regarding role responsibility and consider ways to change lifestyle to accomplish goals associated with role performance
- Demonstrate knowledge of appropriate behaviors associated with new or changed role
- State knowledge of change in responsibility and new behaviors associated with new responsibility
- Verbalize acceptance of new responsibility

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Role Enhancement

Example NIC Activities—Role Enhancement

Assist client to identify behaviors needed for role development; Assist client to identify positive strategies for managing role changes

Nursing Interventions and *Rationales*

- Assess the client's level of resilience and implement nursing actions that increase client resilience and sense of coherence. **EBN:** *A study of individuals with chronic obstructive pulmonary disease indicated that high levels of a sense of coherence and resilience were negatively associated with symptoms of anxiety and depression and perceived illness-specific disability (Keil et al, 2017).*
- Assess the effect of uncertainty on the client's role and provide support and education. **EBN:** *A study of caregivers with hospitalized children showed that levels of uncertainty and stress decreased and role performance improved after an educational intervention (Jeong & Kwon, 2017).*
- Assess the client's social support system. **EB:** *A study showed that clients with good social support are more likely to change their lifestyle and make more changes (Clementi et al, 2016).*
- Assess for the presence of shame related to current health situation. **EBN:** *A Greek study of intensive care unit (ICU) families found that family members who live with the client and have low educational levels are prone to feel shame, which could interfere with coping and caregiving (Koulouras et al, 2017).*
- Assess for the characteristics of role stress. **EB:** *A study showed that a lack of role clarity was significantly linked to emotional exhaustion (Portoghese et al, 2017).*
- Assess male military members for gender role stressors with the Male Gender Role Stressor Inventory (MGRSI). **EB:** *Research piloting the MGRSI found that honor, strength, and achievement were the most commonly reported sources of male gender role stress and may be associated with suicidal behaviors (Sterling et al, 2017).*
- Ask the client what they need to feel prepared for the tasks and demands of their role. **EBN:** *A study of family caregivers found the need for services to address emotional needs and resources to mitigate the stress of caregiving (Muliira, Kizza, & Nakitende, 2019).*
- Support the client's spirituality practices. **EB:** *Spiritual care was found to reduce care strain in caregivers of elderly clients with Alzheimer's disease (Mahdavi et al, 2017).*
- Refer to the care plans for Readiness for Enhanced Family **Coping,** Readiness for Enhanced **Decision-Making,** Ineffective **Home** Maintenance Behaviors, Impaired **Parenting,** Risk for **Loneliness,** Readiness for Enhanced Community **Coping,** Readiness for Enhanced **Self-Care,** and Ineffective **Sexuality** Pattern.

Pediatric

▲ Provide parents of disabled children with information about and referrals to educational and social resources available to assist their child. **EB:** *A longitudinal study found that parents' educational expectations shape academic development and changes in self-concept among young people with different types of disabilities (McCoy et al, 2016).*

- Provide parents with information about mindfulness-based interventions (MBIs) to enhance coping when the role change is associated with a critically and chronically ill child. **EB:** *Research found that MBI is a culturally adaptable, acceptable, and effective method to improve quality of life and positive stress reappraisal coping in parents of children with autism spectrum disorder (Rayun & Ahmad, 2016).*

Geriatric

- Assess older adults' choices regarding their care and enable them to live as they wish and receive the help they want by carefully listening to their stories. **EB:** *A study found that complementing standardized assessment data with informal interviews provided information that older adults and their families believed was important to their care (Lafortune et al, 2017).*
- Assess older adults for a sense of competence in their daily life. **EB:** *A French study showed that increased competence was associated with a decrease in depressive symptoms and apathy (Souesme et al, 2016).*
- Provide support and practice for older adults to use technology. **EB:** *A study found that participants used information and communication technology (ICT) to connect with friends and family. ICT use predicted higher well-being across outcomes (Sims et al, 2017).*
- Support the client's spiritual beliefs and activities and provide appropriate spiritual support persons. **EB:** *Spiritual care was found to reduce care strain in caregivers of elderly clients with Alzheimer's disease (Mahdavi et al, 2017).*

Multicultural

- Assess for the influence of cultural beliefs, norms, values, and expectations on the individual's role. **CEB:** *The individual's role may be based on cultural perceptions (Leininger & McFarland, 2002).*
- Negotiate with the client regarding the aspects of their role that can be modified and still honor cultural beliefs. **CEB:** *Give-and-take with the client will lead to culturally congruent care (Leininger & McFarland, 2002).*
- Identify perceived barriers to family to use support groups or other service programs to assist with role changes. **EB:** *A systematic review identified that assessment for support resources, home care, or community assistance was needed before discharge and at routine intervals throughout the care situation (Greenwood et al, 2015).*
- The preceding interventions may be adapted for home care use.

Client/Family Teaching and Discharge Planning

▲ Refer client to comprehensive services to assist with transition needs at discharge. **EB:** *A study found no 30-day rehospitalizations for participants in the Kentucky Care Coordination for Community Transitions (KCT-T-3) program, which provided access to medical, social, and environmental services to support community transitions* (*Kitzman et al, 2017*).

- Provide educational materials to family members on client behavior management plus caregiver stress-coping management. **EB:** *Research has identified that multiple components to provide education, support, counseling, care continuity, and linkage to community resources to ease transitions can improve caregiver health and coping (Naylor et al, 2017).*
- Help the client identify resources for assistance in caring for a disabled or aging parent (e.g., adult day care, nursing home placement). **EB:** *A systematic review identified that assessment for support resources, home care, or community assistance was needed before discharge and at routine intervals throughout the care situation (Greenwood et al, 2015).*

Sedentary Lifestyle

Domain 1 Health promotion Class 1 Health awareness

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

An acquired mode of behavior that is characterized by waking hour activities that require low energy expenditure.

Defining Characteristics

Average daily physical activity is less than recommended for age and gender; chooses a daily routine lacking physical exercise; does not exercise during leisure time; expresses preference for low physical activity; performs majority of tasks in a reclining posture; performs majority of tasks in a sitting posture; physical deconditioning

Related Factors

Conflict between cultural beliefs and health practices; decreased activity tolerance; difficulty adapting areas for physical activity; exceeds screen time recommendations for age; impaired physical mobility; inadequate interest in physical activity; inadequate knowledge of consequences of sedentarism; inadequate knowledge of health benefits associated with physical activity; inadequate motivation for physical activity; inadequate resources for physical activity; inadequate role models; inadequate social support; inadequate time management skills; inadequate training for physical exercise; low self-efficacy; low self-esteem; negative affect toward physical activity; pain; parenting practices that inhibit child's physical activity; perceived physical disability; perceived safety risk

At-Risk Population

Adolescents; individuals aged ≥ 60 years; individuals living in urban areas; individuals living with a partner; individuals with high educational level; individuals with high socioeconomic status; individuals with significant time constraints; married individuals; women

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Ambulation; Activity Tolerance; Endurance; Exercise Participation; Health Promoting Behavior; Lifestyle Balance; Personal Health Status; Physical Fitness; Exercise Promotion

Example NOC Outcome with Indicators

Ambulation as evidenced by the following indicators: Walks with effective gait/Walks at moderate pace/Walks up and down steps/Walks moderate distance. (Rate the outcome and indicators of **Ambulation:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Engage in purposeful moderate-intensity cardiorespiratory (aerobic) exercise for 30 to 60 minutes/day on 5 or more days per week for a total of 2 hours and 30 minutes (150 minutes) per week
- Increase exercise to 20 minutes/day (>150 minutes/week); light to moderate intensity exercise may be beneficial in deconditioned persons
- Increase pedometer step counts by 1000 steps per day every 2 weeks to reach a daily step count of at least 7000 steps per day, with a daily goal for most healthy adults of 10,000 steps per day
- Perform resistance exercises that involve all major muscle groups (legs, hips, back, chest, abdomen, shoulders, and arms) performed 2 to 3 days/week
- Perform flexibility exercise (stretching) for each of the major muscle-tendon groups 2 days/week for 10 to 60 seconds to improve joint range of motion; greatest gains occur with daily exercise
- Engage in neuromotor exercise 20 to 30 minutes/day including motor skills (e.g., balance, agility, coordination, and gait), proprioceptive exercise training, and multifaceted activities (e.g., Tai chi and yoga) to improve and maintain physical function and reduce falls in those at risk for falling (older persons)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Exercise Therapy: Ambulation; Joint Mobility; Positioning; Exercise Promotion; Activity Therapy; Energy Management

Example NIC Activities—Exercise Therapy: Ambulation

Assist the client to use footwear that facilitates walking and prevents injury; Instruct in availability of assistive devices, if appropriate

Nursing Interventions and *Rationales*

- Assess the client with the American College of Sports Medicine (ACSM, 2018) guidelines for exercise preparticipation health screening before implementing physical activity interventions. **EB:** *The ACSM exercise guidelines focus on assessing (1) the individual's current level of physical activity; (2) presence of signs or symptoms of and/or known cardiovascular, metabolic, or renal disease; and (3) desired exercise intensity. The ACSM algorithm referred a smaller proportion of adults for preparticipation medical clearance than previously used screening tools. This lower referral proportion may mitigate the barrier of medical clearance from exercise participation (Whitfield et al, 2017).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Observe the client for sedentary behaviors such as prolonged sitting, physical inactivity, and prolonged sleep. **EB:** *Prolonged sitting, physical inactivity, and prolonged sleep were identified as lifestyle health risk behaviors in an Australian study (Ding et al, 2015).*
- Recommend the client enter an exercise program with an active person who supports exercise behavior (e.g., friend or exercise buddy). **EB:** *A 12-week pilot controlled trial of a physical activity buddy program found that the active buddy group (p = 0.005) showed significantly higher step changes than the inactive buddy group (Choi, 2017).*
- Recommend the client use a mobile fitness application for customizing, cueing, tracking, and analyzing an exercise program. **EB:** *A 3-year university community engagement study reported that a combination of coaching and wrist-worn activity tracker reduced general sitting time (Kiessling et al, 2017).*
- Encourage prescriptive resistance exercise of each major muscle group (hips, thighs, legs, back, chest, shoulders, and abdomen) using a variety of exercise equipment. **EB:** *Equipment such as free weights, bands, stair climbing, or machines should be used 2 to 3 days/week. Involve the major muscle groups for 8 to 12 repetitions to improve strength and power in most adults, 10 to 15 repetitions to improve strength in middle-aged and older persons starting exercise, and 15 to 20 repetitions to improve muscular endurance. Intensity should be between moderate (5 to 6) and hard (7 to 8) on a scale of 0 to 10 (ACSM, 2018).*
- Encourage gradual progression of greater resistance, more repetitions per set, and/or increasing frequency. **EB:** *A study found that a global progressive resistance strength training program was effective for improving the functional capacity of clients with rheumatoid arthritis (Lourenzi et al, 2015).*
- Encourage pregnant clients to engage in regular physical activity. **EB:** *A study reported that pregnant women spend the majority of their day engaged in sedentary behaviors with more sedentary behaviors on weekdays and during evening hours (Odabasic et al, 2018).*

▲ Assess the client for depression and refer for counseling and follow-up as appropriate. **EB:** *A study reported data indicating that depression may be a barrier to health-promoting behavior in middle-aged and older women with hypertension or heart disease (Cramer et al, 2020).*

Multicultural

- Assess for reasons why the client would be unable to participate in regular physical activity; address reasons and refer to resources as needed. **EB:** *A systematic integrative literature review to identify barriers to physical activity among African American women found intrapersonal barriers (lack of time, knowledge, and motivation; physical appearance concerns; health concerns; monetary cost of exercise facilities; and tiredness/fatigue), interpersonal barriers (family/caregiving responsibilities; lack of social support; and lack of a physical activity partner), and environmental barriers (safety concerns; lack of facilities; weather concerns; lack of sidewalks; and lack of physically active African American role models) (Joseph et al, 2015).*
- Assess for clients' perceptions of the neighborhood they reside in. **EB:** *A study found that negative neighborhood environment perceptions were associated with greater sedentary time for individuals living in lower socioeconomic areas (Ahuja et al, 2017).*
- Encourage and support spiritual practices. **EB:** *A study by Silfee et al (2017) found that Latino adults who are more spiritual are also less sedentary, and this association was stronger in men than women.*
- Encourage participation in group physical activity programs. **EBN:** *Results of a physical activity study suggest that a team-based exercise training program may assist in overcoming sedentary behavior for African American women (Piacentine et al, 2018).*

Pediatric

- Assess the child's current activity status using the Pediatric Inactivity Triad (Faigenbaum et al, 2018). **EB:** *Components of the Pediatric Inactivity Triad include (1) exercise deficit disorder (less than 60 minutes of recommended physical activity daily), (2) pediatric dynapenia (decreased muscle strength and power), and (3) physical illiteracy (low competence and confidence). Addressing these components collectively will enhance effective change (Faigenbaum et al, 2018).*
- Assess parent's perceptions of children's screen time and active play. **EB:** *A study identified that parental perceptions of the benefits and risks of screen time and active play were not always consistent with current research (Hinkley & McCann, 2018).*
- Children and adolescents should participate in 60 minutes (1 hour) or more of physical activity daily.
  - ❍ Aerobic: Sixty or more minutes a day should be either moderate-intensity or vigorous-intensity aerobic physical activity and should include vigorous-intensity physical activity at least 3 days a week.

- Muscle-strengthening: As part of daily physical activity, children and adolescents should include muscle-strengthening physical activity on at least 3 days of the week.
- Bone-strengthening: As part of daily physical activity, children and adolescents should include bone-strengthening physical activity on at least 3 days of the week.
- Providing activities that are age appropriate, are enjoyable, and offer variety will encourage young people to participate in physical activities (U.S. Department of Health and Human Services, 2018).

- Assist families to develop family-based interventions to increase child physical activity. **EB:** *A meta-analysis of family-based interventions found a small effect on physical activity when interventions were tailored to the ethnicity, motivation, and time constraints of the family; combined goal-setting and reinforcement techniques were used; educational strategies were used to increase knowledge as needed; and consideration of the family psychosocial environment (Brown et al, 2016).*
- Encourage parents and caregivers to adhere to the following American Academy of Pediatrics guidelines for children's media use (Chassiakos et al, 2016):
  - For children younger than 18 months, avoid use of screen media other than video-chatting.
  - Parents of children 18 to 24 months of age who want to introduce digital media should choose high-quality programming and watch it with their children to help them understand what they are seeing.
  - For children ages 2 to 5 years, limit screen use to 1 hour/day of high-quality programs. Parents should co-view media with children to help them understand what they are seeing and apply it to the world around them.
  - For children ages 6 and older, place consistent limits on the time spent using media, and the types of media, and make sure media does not take the place of adequate sleep, physical activity, and other behaviors essential to health.
  - Designate media-free times together, such as dinner or driving, and media-free locations at home, such as bedrooms.
  - Have ongoing communication about online citizenship and safety, including treating others with respect online and off-line.
  - Encourage parents and caregivers to create their personalized family media plan (see https://www.healthychildren.org/English/media/Pages/default.aspx) (American Academy of Pediatrics, 2021).

Geriatric

- Use valid and reliable criterion-referenced standards for fitness testing (e.g., Senior Fitness Test) designed for older adults that can predict the level of capacity associated with maintaining physical independence into later years of life (e.g., get up and go test). **EB**: *Interventions can subsequently be designed to target weak areas and therefore help reduce the risk of immobility and dependence (Bhattacharya, Deka, & Roy, 2016).*
- Recommend the client begin a regular exercise program, even if generally active. **EB:** *A meta-analysis of the association between time in sedentary behavior and hospitalizations, mortality, cardiovascular disease, cancer, and diabetes found prolonged sedentary time associated as an independent risk factor for poor health outcomes despite engagement in physical activity (Biswas et al, 2015).*
- Implement progressive resistance training plus balance exercise for older adults as indicated. **EB:** *A cluster randomized controlled trial showed that the Sunbeam Program of progressive resistance training in conjunction with balance exercise significantly reduced the rate of falls and improved physical performance in clients of residential care (Hewitt et al, 2018).*
- Before surgery, refer clients to a personalized "prehabilitation" program that includes a warm-up followed by aerobic, strength, flexibility, neuromotor, and functional task work. **EB:** *A study of major surgery clients assigned to personalized prehabilitation programs showed enhanced aerobic capacity and reduction in post-operative complications by 51% (Barbaren-Garcia et al, 2018).*

Home Care

- The preceding interventions may be adapted for home care use.

▲ Assess home environment for factors that create barriers to mobility. Refer to physical and occupational therapy services if needed to assist the client in restructuring home environment and daily living patterns.

Client/Family Teaching and Discharge Planning

- Provide teaching to clients and family to increase awareness of the health benefits of reducing sedentary behavior. **EB:** *A qualitative study found that clients placed little importance on reducing sedentary behavior,*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

were unconvinced of the health benefits of reducing sedentary behavior, did not perceive themselves to be sedentary, and did not associate nonsedentary behaviors with enjoyment and relaxation (Biswas et al, 2018).

- Consider using motivational interviewing techniques when working with both children and adult clients to increase their activity. **EB:** *A study to increase physical activity among clients with rheumatoid arthritis found that at posttreatment and 6-months follow-up, significantly more clients met current physical activity recommendations (Knittle et al, 2015).*

Readiness for Enhanced Self-Care

Domain 4 Activity/rest Class 5 Self-care

Ruth A. Wittmann-Price, PhD, RN, CNS, CNE, CNEcl, CHSE, ANEF, FAAN

NANDA-I

Definition

A pattern of performing activities for oneself to meet health-related goals, which can be strengthened.

Defining Characteristics

Expresses desire to enhance independence with health; expresses desire to enhance independence with life; expresses desire to enhance independence with personal development; expresses desire to enhance independence with well-being; expresses desire to enhance knowledge of self-care strategies; expresses desire to enhance self-care

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Adherence Behavior; Health-Seeking Behavior; Self-Care Status

Example NOC Outcome with Indicators

Health-Seeking Behavior as evidenced by the following indicators: Completes health-related tasks/ Performs self-screening/Obtains assistance from health professionals. (Rate the outcome and indicators of **Health-Seeking Behavior:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Evaluate current levels of self-care as optimum for abilities
- Express the need or desire to continue to enhance levels of self-care
- Seek health-related information as needed
- Identify strategies to enhance self-care
- Perform appropriate interventions as needed
- Monitor level of self-care
- Evaluate the effectiveness of self-care interventions at regular intervals

NIC (Nursing Interventions Classification)

S

Suggested NIC Interventions

Coping Enhancement; Energy Management; Learning Facilitation; Multidisciplinary Care Conference; Mutual Goal Setting; Self-Care Assistance

Example NIC Activity—Self-Care Assistance

Encourage person to perform normal activities of daily living to level of ability

Nursing Interventions and *Rationales*

- For assessment of self-care, use a valid and reliable screening tool if available for specific characteristics of the person, such as arthritis, diabetes, stroke, heart failure (HF), or dementia. **EBN:** *Bryant (2017) developed a Self-Care to Success toolkit that supports nurse practitioners to empower clients with HF and promote self-care behaviors (SCBs) successfully.* **EBN:** *Powell and Deroche (2020) researched how clients* (n = 500) *with chronic illnesses used electronic health care portals to assist with self-care and found overall low usage among registered users. Clients were more likely to use the electronic portal if they had HF and were located a distance from their provider's practice.*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Support the person's awareness that enhanced self-care is an achievable, desirable, and positive life goal. **EBN:** *Kauric-Klein, Peters, and Yarandi (2017) examined how educational sessions and individual counseling affected blood pressure self-efficacy and self-care outcomes in adults* (n = *118) receiving hemodialysis and found that self-efficacy was related to SCBs such as decreased salt intake, lower weight gain, increased adherence to medications, and fewer missed appointments.* **EB:** *Fletcher et al (2020) studied partners' awareness of self-care needs when the new mothers of their babies had severe mental illness (SMI). The researchers provided text information to partners about self-care, baby care, and partner care. The results demonstrated that partners of new mothers with SMI increased in knowledge and awareness about caring for themselves and their family's needs.*
- Show respect for the person, regardless of characteristics and/or background. **EBN:** *Marzband and Zakayi (2017) explored the concept of self-care in Islamic texts and found that self-care is participating in responsible activities to God for health promotion, preventive disease, and treatment. Self-care included physical, mental, spiritual, and social dimensions.* **EB:** *By conducting a cross-sectional descriptive correlational study, Miano et al (2020) investigated how adolescents and young adults (AYA) with cancer view self-care in relation to decision-making. Most AYA clients preferred an "active collaborative" role (39%) or a "shared decision-making" role (34%).*
- Promote trust and enhanced communication between the person and health care providers. **EBN:** *Chen (2020) studied the effects of low literacy on the health-seeking behaviors of older adults and found that it delayed treatment, had negative effects on client–provider communication, and decreased the use of preventive services.* **EBN:** *Researchers studied the client–provider relationships (communication, integration, collaboration, and empowerment) in pregnant clients* (n = *139) in relation to better client self-care and women's perceptions of better communication, collaboration, and empowerment from their midwives, which were associated with more frequent SCBs (Nicoloro-Santa Barbara et al, 2017).*
- Promote opportunities for spiritual care and growth. **EBN:** *Salamizadeh, Mirzaei, and Ravari (2017) studied the effects of a spiritual care educational intervention with caretakers* (n = *60) of Alzheimer's clients using a random group pretest–posttest method and concluded that spiritual care enhanced the self-efficacy of the caregivers.* **EB:** *Agarwal et al (2020) used interpretive phenomenological analysis to understand the effects of a spiritually focused meditation practice on clients with breast cancer. The research discovered that the self-care practice promoted a positive state of mind, self-awareness, awareness of God's healing power, spiritual support, and spiritual growth.*
- Promote social support through facilitation of family involvement. **EB:** *Morgan et al (2017) performed a literature review regarding social support for self-management for clients to manage their chronic condition(s) and found the two elements that were most important for self-care were commitment and empowerment.*
- Provide opportunities for ongoing group support through establishment of self-help groups on the Internet. **EB:** *A mixed-methods study was conducted by Bradley et al (2020) about homeless families* (n = *15) with children ages 2 to 11. They used a peer-teaching program that increased parenting knowledge and practices and improved child behavioral difficulties. The program did not change social support perceptions but improved family self-care.*
- Help the person identify and reduce the barriers to self-care. **EB:** *Lim et al (2020) used a mixed-method study to identify the barriers and the facilitators to regular physical exercise for prediabetic clients* (n = *433). Barriers to physical exercise self-care were lack of knowledge, medical conditions, lack of family participation, extended sitting, and lack of time.* **EB:** *Novak et al (2020) studied the barriers that diabetic clients have to self-care. The researchers studied the clients' lived experience of managing diabetes and how the work of self-care is embedded in the other routines of everyday living. The researchers found that everyday objects and spaces were instrumental in the incorporation of diabetic self-care into daily routines.*
- Provide literacy-appropriate education for self-care activities. **EBN:** *Lelorain et al (2017) studied health care professionals' perception of therapeutic client education for promoting self-care and found that nurses often lack skills and knowledge and are disillusioned about the effectiveness of therapeutic client education, and that person-centered care is needed in many places to promote education that can increase self-care.* **EBN:** *Hu et al (2020) examined the reliability and validity of the Spoken Knowledge in Low Literacy in Diabetes (SKILLD) scale in measuring diabetes knowledge among Hispanics with type 2 diabetes (T2DM) and found that it was reliable and valid for T2DM Spanish-speaking patents with low literacy ability.*
- Facilitate self-efficacy by ensuring the adequacy of self-care education. **EBN:** *Researchers used a correlation (a descriptive design to examine the relationship between glycemic control and SCBs in clients with type 2 diabetes) and found that clients with poor glycemic control had poorer self-efficacy and SCBs (D'Souza*

et al, 2017). **EBN:** *Rhee et al (2020) examined the relationship of three measures of self-efficacy in asthmatic adolescent clients* (n = *371). The researchers compared the three measures to variables of self-care (quality of life, medication adherence, asthma control, asthma knowledge, and attitudes) and found that the Asthma* Self-Efficacy *scale (ASE) was the best scale to evaluate self-efficacy for this population.*

- Provide alternative mind–body therapies such as reiki, guided imagery, yoga, and self-hypnosis. **EBN:** *Orellana-Rios et al (2017) piloted an "on the job" mindfulness and compassion-oriented meditation training for multiprofessional team members* (n = *27) designed to reduce distress, foster resilience, and strengthen a prosocial motivation in the clinical encounter. Improvements were realized in two burnout components (emotional exhaustion and personal accomplishment) and overall improvement of self-care.* **EB:** *Researchers used cognitive behavioral therapy and adherence counseling with HIV clients. Depressive symptoms were unchanged, but adherence to therapy improved at both 4 and 8 months after treatment (Safren et al, 2020).*
- Promote the person's hope to maintain self-care. **EB:** *Anderson, Turner, and Clyne (2017) developed a self-management intervention called the Help to Overcome Problems Effectively (HOPE: MS) to improve the physical and psychological well-being of people living with multiple sclerosis (MS) and found that the HOPE: MS was helpful and useful to clients living with MS and covered the parameters needed to identify self-care needs.* **EBN:** *Armstrong and Murtaugh (2020) studied clients with traumatic brain injury (TBI) and found that throughout their care (trauma, intensive, acute, and rehabilitation) that the multiprofessional team played a pivotal role in providing hope through specific individualized interventions.*

Pediatric

- Assess and evaluate a child's level of self-care and adjust strategies as needed. **EBN:** *Burgess et al (2020) completed a longitudinal study of children* (n = *71) with cerebral palsy (CP) and their self-care trajectories. The study demonstrated that self-care for many levels increased in children 8 to 12 years old, but it was very dependent on the level of functioning of the child with CP and actually decreased in children who had more limited functioning.* **EB:** *Burns-Nader, Joe, and Pinion (2017) studied using computer tablets with children who were burned during treatments, and nurses reported significantly less pain and anxiety for the tablet distraction group compared with the control group.*
- Assist families to engage in and maintain social support networks. **EB:** *Pumar-Méndez et al (2017) interviewed stakeholders* (n = *90) in six countries about the support for self-care for clients with chronic illness (SSSC) and investigated the stakeholders' roles. The stakeholders described the ideal SSSC as inclusive, interdependent, and person-centered and needed support was from clients, governments, health care professionals, associations, private companies, and the media. The recommendations were to continue to promote SSSC with stakeholders and health professionals to improve care.* **EBN:** *Murfield et al (2020) completed an integrative review about family caregivers of older adults and focused on self-compassion. They noted that self-compassion as a part of self-care increased with the caregivers' ability to cope.*
- Encourage activities that support or enhance spiritual care. **EBN:** *O'Shea et al (2017) completed a qualitative descriptive study about meeting the physical, emotional, and spiritual needs of parents with seriously ill children and found there was a need among providers to enhance both basic education and advanced skills in pediatric palliative and end-of-life care education statewide.* **EB:** *Jenkins et al (2020) completed a qualitative analysis of participants* (n = *6) in leadership roles and revealed, through focus group interviews, themes that permeate leadership roles. The themes included taking responsibility for others; taking responsibility for self-care; addressing stigma in the workplace; and having a spiritual calling to help.*

Multicultural

- Identify cultural beliefs, values, lifestyle practices, and problem-solving strategies when assessing the client's level of self-care. **EBN:** *Chen et al (2020) studied Taiwanese clients* (n = *62) with HF for readiness to participate in self-care. The researchers implemented a predischarge educational program and followed up 1 year after discharge to examine self-care behaviors, readmission, sleep quality, and depression in clients with HF. The results demonstrated a significant increase in self-care 1 year after discharge by instituting a predischarge educational program.* **EBN:** *Researchers studied the COM-B model (consisting of capability, opportunity, and motivation) to explore SCBs and examine the self-care confidence on Chinese clients* (n = *321) with chronic HF and found that Chinese clients have poor SCBs caused by lack of confidence, functional capacity, knowledge, and health literacy (Zou et al, 2017).*
- Recognize the effect of culture on SCBs. **EB:** *Researchers studied the elements that affect self-care in HF clients* (n = *226) in Jordan by looking at knowledge, sociodemographics, and SCBs. Results revealed that*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

knowledge, income, and educational levels; shorter duration of disease; fewer people living at home; older age; and being unemployed were significant predictors of low self-care scores (Tawalbeh et al, 2017). **EBN:** *Dehghani, Khoramkish, and Isfahani (2019) used content analysis from interviews to study Iranian clients with MS* (n = *14) and their self-care abilities. The Iranian participants with MS identified the following self-care challenges: (1) confrontation to physical, emotional, psychological, and behavioral changes; (2) fear of becoming crippled; (3) tolerance of financial burden of the disease; and (4) confrontation to cultural social beliefs.*

- Provide culturally competent care. **EBN:** *Labore et al (2017) culturally explored the meaning of transition to self-care in sickle cell disease clients using an existential framework, and meaning was found in lived time, space, body, and human relationship.* **EBN:** *Kes and Gökdoğan (2020) developed a Turkish version of the Hypertension Self-Care Profile and examined its reliability and validity. The nurse researchers studied the tool with 200 people to determine whether the translation of the scale remained valid and reliable to use with the Turkish population.*
- Support independent self-care activities. **EBN:** *Teppala et al (2017) studied postacute rehabilitation for clients with hip fracture by examining the variation in mobility and self-care using a retrospective cohort study and found variation in discharge mobility and self-care related to health care organization differences.* **EBN:** *Mackintosh et al (2020) completed a descriptive analysis of women's* (n = *632) use and experiences of digital resources for self-diagnosis and help seeking and found that over half the participants experienced concerns about themselves or their baby and accessed online information, noting that digital self-monitoring is increasingly integral to women's self-care during pregnancy.*

Home Care

- The nursing interventions described previously may also be used in home care settings. Provide clients with information about digital resources and health applications. **EBN:** *Göransson et al (2020) investigated a home care electronic application (app) among older persons* (n = *17) to help maintain their health. The results demonstrated that the app provided a sense of security about self-care but without maintaining the app's educational information it decreased afterward.*
- Assist individuals and families to identify self-care activities for prevention of exacerbations of chronic illness symptoms to avoid rehospitalization. **EB:** *Toukhsati et al (2019) completed a meta-analysis study about self-care activity for HF clients in relation to rehospitalizations. The researchers found a variety of educational and behavioral interventions developed by health care providers to encourage and support client self-care.*
- Use educational guidelines for stroke survivors. **EB:** *Atler et al (2017) completed a study about yoga as an intervention in poststroke clients* (n = *13), and five themes were identified from qualitative analysis: (1) improved abilities, (2) gained new knowledge, (3) enhanced engagement in activities, (4) improved relaxation, and (5) increased confidence.* **EBN:** *Wales, Dunford, and Davis (2020) studied children who had strokes and their ability for self-care. The researchers found that rehabilitation therapy was important for gaining self-care independence.*
- Ensure appropriate multiprofessional communication to support client safety. **EB:** *Weiss, Robertson, and Goebel (2019) completed a pilot project to develop a self-management tool for elderly clients in the community in order for them to understand when they needed to "take action" and call a provider. An multiprofessional palliative care team developed the tool and participants rated the tool as easy to understand and helpful in recognizing and reporting symptoms.*
- For public safety, health care professionals and consumers should participate in decision-making when managing reflux-related symptoms in the self-care setting. **EB:** *Johnson et al (2017) explored the consensus of an expert panel related to over-the-counter (OTC) proton pump inhibitors (PPIs) for gastroesophageal reflux disease and found that although OTC PPIs would probably not mask gastric cancer or affect bone density,* Clostridioides difficile *infection, or cardiovascular adverse events, they may be associated with slightly increased risks for infectious diarrhea, certain idiosyncratic reactions, and cirrhosis-related spontaneous bacterial peritonitis.*
- Enhance individual and family coping with chronic illnesses. **EBN:** *Kim and Kim (2017) studied elements that affected health-related quality of life (HRQOL) in elderly clients* (n = *365) with diabetes and found that gender (male) and depression were negatively correlated with diabetic self-care.* **EB:** *Currow et al (2020) surveyed a large population of clients* (n = *2883) in the community with shortness of breath and found that chronic breathlessness was iteratively associated with lower mobility, interference with daily activities, and worse pain/discomfort. Decreased self-care and increased anxiety/depression were connected to the most*

severe breathlessness. Respondents who had chronic breathlessness for 2 to 6 years had the worst self-care scores.

- Encourage participation in a community care management program. **EBN:** *Merius and Rohan (2017) completed a literature review (n = 14) related to adult attrition from community programs on diabetes self-care and found that barriers for retention included transportation, family obligations, and scheduling conflicts.* **EB:** *Williamson and Ennals (2020) studied young people with mental illness in the community to focus on self-regulation. Qualitatively the researchers discovered that self-care for the young people and their families was dependent on the following themes: (1) knowing yourself; (2) understanding the "why": developing shared reasons for engaging in sensory modulation; (3) creating comfort; (4) creating connection; and (5) constantly learning.*

Client/Family Teaching and Discharge Planning

- Teach clients how to regularly assess their level of self-care.
- Instruct clients that a variety of interventions may be needed to enhance self-care.
- Help clients to understand that enhanced self-care is an achievable goal.
- Empower clients.
- Teach clients about the decision-making process and self-care activities needed to manage their illness state and promote well-being.
- Continuously stress that all self-care activities must be regularly evaluated to ensure that enhanced levels of self-care can be maintained.

S

Bathing Self-Care Deficit

Domain 4 Activity/rest Class 5 Self-care

Suzanne C. Ashworth, MSN, APRN, CCRN, CCNS

NANDA-I

Definition

Inability to independently complete cleansing activities.

Defining Characteristics

Difficulty accessing bathroom; difficulty accessing water; difficulty drying body; difficulty gathering bathing supplies; difficulty regulating bath water; difficulty washing body

Related Factors

Anxiety; decreased motivation; environmental constraints; impaired physical mobility; neurobehavioral manifestations; pain; weakness

At-Risk Population

Older adults

Associated Conditions

Impaired ability to perceive body part; impaired ability to perceive spatial relationships; musculoskeletal diseases; neuromuscular diseases

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Self-Care: Activities of Daily Living (ADLs); Self-Care: Bathing; Self-Care: Hygiene

Example NOC Outcome with Indicators

Self-Care: ADLs as evidenced by the following indicators: Bathing/Hygiene. (Rate outcome and indicators of **Self-Care: ADLs:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of body odor and maintain intact skin
- State satisfaction with ability to use adaptive devices to bathe
- Maintain independency with bathing and hygiene
- Use methods to bathe safely and effectively with minimal difficulty
- Bathe with assistance of caregiver as needed and report satisfaction and dignity maintained during bathing experience
- Bathe with assistance of caregiver as needed without exhibiting defensive (aggressive) behaviors

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Self-Care Assistance: Bathing/Hygiene

Example NIC Activities—Self-Care Assistance: Bathing/Hygiene

Determine amount and type of assistance needed; Consider the culture of the client when promoting self-care activities; Provide assistance until client is fully able to assume self-care

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Nursing Interventions and *Rationales*

- Ask clients about their bathing preferences, which can increase client privacy and satisfaction. **EBN:** *A qualitative study analyzed client perceptions and experiences regarding bathing methods* (n = *16). Daily washing was a necessity to maintain skin integrity and overall feelings of "wellness." Showering was the preferred method to maintain hygiene (Veje et al, 2018).*
- ✱ Adjust room temperature above 20°C (68°F) and avoid hot water bathing, especially during cold seasons. **EB:** *Older clients may not verbalize a dependable sense of temperature. Low bathroom temperature and higher water temperature may lead to serious physiological changes and accidents (Ono et al, 2017).*
- ✱ Bathe critically ill clients or clients outside of critical care who have a central venous access device with a nonrinse chlorhexidine-impregnated wipe or chlorhexidine solution with rinsing. **EB:** *Bathing with chlorhexidine gluconate reduces the risk of hospital-acquired bloodstream infections (Musuuza et al, 2019).*
- ✱ Avoid using a bath basin for bathing to avoid client exposure to multidrug-resistant pathogens from contaminated bath basins or hospital water supply. **EB:** *In a 44-month study by Marchaim et al (2012), hospital bath basins* (n = *1103) were found 62.2% of the time to be contaminated with hospital-acquired pathogens.* **EB:** *An outbreak of* Pseudomonas aeruginosa *infections in a neonatal intensive care unit was attributed to contaminated water supply after 67% of environmental samples from client rooms grew* P. aeruginosa *(Bicking-Kinsey et al, 2017).*
- ✱ If a bath basin is used, use chlorhexidine gluconate solution for client bathing. **EBN:** *Powers et al (2012) found in a study* (n = *90) that when clients are bathed with chlorhexidine gluconate the bacterial growth in the bath basin is significantly reduced.*
- ✱ Consider using a prepackaged bath for immobile clients who cannot shower. **EBN:** *A prospective randomized study compared soap and water with disposable packaged bathing wipes. Disposable bathing wipes caused less alterations in client skin integrity (Martin et al, 2017).* EB: *A systematic review of 33 studies found moderate- to high-quality evidence that washing without water is not inferior to traditional bed bathing techniques and should be considered for immobile clients (Groven et al, 2017).*
- Avoid using high pressure during wiping. Monitor the client's skin and ask for feedback regarding sensation. **EBN:** *A quasi-experimental study examined differences in wiping pressure by nurses during bathing. Subjective data suggested that clients experienced some degree of pain during bathing (Konya et al, 2020).*
- Consider bathing for terminally ill cancer clients who have pain and anxiety to promote comfort. **EB:** *The thermal effect of bathing has been found to act as an analgesic and promotes physiological and psychological relaxation (Fujimoto et al, 2017).*
- Consider using music intervention in clients who have pain during bathing. **EB:** *A pilot study done in critically ill, mechanically ventilated clients found that music used during bathing significantly decreased pain intensity during bathing (Jacq et al, 2018).*
- Use person-centered bathing approach: plan for client's comfort and bathing preferences, show respect in communications by listening, critically think to solve issues that arise, and use a gentle approach. **CEB:** *Focusing on the client rather than the task of bathing results in greater comfort and fewer aggressive behaviors, which are likely defensive behaviors that result from feeling threatened or anxious and increase with shower (especially) and tub bathing (Hoeffer et al, 2006).*
- ▲ Provide pain relief measures, such as ice packs, heat, and analgesics for sore joints, 45 minutes before bathing; move extremities slowly and carefully; and inform the client before movements associated with pain occur (walking; transferring to a new location; moving joints; and washing genitals, face, and between toes and under arms). Have the client wash painful areas; recognize indicators of pain and apologize for any pain caused. **EB:** *Pain may lead to ADL deficits such as bathing and showering (Pieber et al, 2015).*
- ▲ Use a comfortable padded shower chair with foot support or adapt a chair: pad it with towels/washcloths, cover the cold back with dry towels, and cover the arms with foam pipe insulation. **CEB:** *Unpadded shower chairs with large openings and no foot support contribute to pain by allowing clients to sink into the opening with their feet unsupported (Rader et al, 2006).*
- Ensure that bathing assistance preserves client dignity through use of privacy with a traffic-free bathing area and posted privacy signs, timeliness of personal care, and encourage client participation and involvement in the delivery of care. **EBN:** *Clients' perceptions of being bathed are often described as being embarrassing due to being undressed in front of someone or even the opposite sex. Bed bathing has been reported to be less positive when compared to showering. Respect for privacy may lessen embarrassment and minimize client dissatisfaction (Lopes et al, 2013).*
- For cognitively impaired clients, avoid upsetting factors associated with bathing: instead of using the terms *bath, shower,* or *wash,* use comforting words, such as *warm, relaxing,* or *massage.* Start at the client's

feet and bathe upward; bathe the face last after washing hands and using a clean cloth. Use a beautician/barber or wash hair at another time to avoid water dripping in the face. **CEB:** *Some words are associated with unpleasant bathing experiences, whereas others convey a pleasant bathing experience. Starting with the face or hair is distressing, because water drips on the face and the head becomes cold and wet (Rader et al, 2006).*

- Use towel bathing to bathe client in bed, a bath blanket, and warm towels to keep the client covered the entire time. Warm and moisten towels/washcloths and place in plastic bags to keep them warm. Use the towels to massage large areas (front, back) and one washcloth for facial areas and another one for genital areas. No rinsing or drying is needed, as is commonly thought for bathing. **CEB:** *Towel bathing is a gentle experience with less discomfort that significantly reduces aggression as well as bathing time and soap residue after showering without accumulation of pathogenic bacteria (Hoeffer et al, 2006).*
- For shower bathing use person-centered techniques, keep client covered with towels and cleanse under the towels, use no-rinse products, use favorite bathing items, and use a handheld shower with adjustable spray. **CEB:** *Covering the client is an easy means to maintain dignity, reduce embarrassment, and keep the client warm and unexposed without increasing bathing time (Rader et al, 2006).*
- Provide nighttime bathing or showering or a warm foot bath 1 to 2 hours before bedtime for at least 10 minutes to improve sleep. **EB:** *A systematic review and meta-analysis of 13 studies determined that bathing before bedtime improved sleep and shortened sleep onset latency (Haghayegh et al, 2019).*

▲ Request referral of client who has had a stroke to rehabilitation services. **EB:** *In a systematic review of 45 studies, Mehrholz et al (2018) found that electromechanical and robot-assisted arm training devices used in rehabilitation may assist in improving arm function after stroke, which is important for ADLs such as bathing.*

Geriatric

▲ Advocate for the use of the Bathing Without a Battle educational program for clients with dementia. **EB:** *In a randomized crossover diffusion study, the Bathing Without a Battle educational program that trains caregivers in methods for improving the bathing experience of clients with dementia in nursing homes was found to be effective in reducing the rate of aggressive and agitated behaviors (Gozalo et al, 2014).*

- Arrange the bathing environment to promote sensory comfort. Reduce noise of voices and water. Do not allow traffic into bathing room. Add fabric to absorb sound (three to four times the width of the opening for sound-absorbing folds). Play soft music. **CEB:** *Noise discomfort can result from high-echo tiled walls, loud voices, and running water. Traffic can compromise privacy. Absorb negative sounds, and add positive sounds through music (Ray & Fitzsimmons, 2014).* **EBN:** *In an observational study* (n = 53) *by Joosse (2012), sound was a predictor of agitation for those with dementia.*
- Design the bathing environment for comfort and safety. Use grab bars with nonslip grip and bathmats. Ensure that flooring is not slippery. **EB:** *Bathroom assistive devices are used to improve safety during bathing transfer. King and Novak (2017) evaluated the effectiveness of common aids. The vertical grab bar and bath mat resulted in safe bathing transfers.*
- Use music during shower for clients with dementia. **EB:** *Music may reduce agitation and improve mood to increase job satisfaction (Ray & Fitzsimmons, 2014).*
- Train caregivers bathing clients with dementia to avoid behaviors that can trigger assault: confrontational communication, invalidation of the resident's feelings, failure to prepare a resident for a task, initiating shower spray or touch during bathing without verbal prompts beforehand, washing the hair and face, speaking disrespectfully to the client, and hurrying the pace of the bath. **CEB:** *During bathing, assaults (defensive behavior) by nursing home residents with dementia are frequently triggered by caregiver actions that startle, frighten, hurt, or upset the resident. This might happen when caregivers spray water on a resident without warning or when they touch a resident's feet, axilla, or perineum, which is possibly caused by the startle reflex (Somboontanont et al, 2004).*
- Focus on the abilities of the client with dementia to obtain client's participation in bathing. **CEB:** *The use of an abilities-focused approach increases the ability of people with dementia to participate in their care (Sidani, Streiner, & Leclerc, 2012).*

Multicultural

- Ask the client for input on bathing habits and cultural bathing preferences. **CEB:** *Bathing is a personal experience with variability in attitudes, preferences, and adaptations to disability to be considered when developing interventions for bathing (Ahluwalia et al, 2010).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Home Care

- An individualized home-based caregiver training program can improve caregiver skills and competence with managing behavior issues with dementia clients during bathing. **EB:** *A study found that family caregivers who received a home-based training intervention were better prepared and competent to manage dementia behavior issues (Huang et al, 2013).*
- Provide home occupational therapy targeting self-bathing and environmental modifications for clients with bathing disabilities. **EB:** *Rehabilitation that targets improving self-care deficits with bathing improve quality of life for individuals with bathing disabilities (Zingmark et al, 2016).*
- Turn down temperature of water heater and recommend use of a water temperature-sensing shower valve to prevent scalding. **EB:** *Bathing at excessive water temperature can lead to shock and scalding, especially in elderly and infants. For elderly clients, water temperature of 38°C to 40°C is recommended (Wei et al, 2020).*
- Remove physical barriers in the home to maximize the client's ability to function independently and safely while bathing. **EB:** *A qualitative study within the randomized control trial (BATH-OUT) analyzed experiences of individuals who had received housing modifications to promote independence during bathing. Older adults with disabilities presented feeling safe, clean, and independent and had improved quality of life during bathing. This led to a greater sense of freedom due to improved functioning (Whitehead & Golding-Day, 2019).*

Client/Family Teaching and Discharge Planning

Provide client/family education regarding chlorhexidine bathing for the reduction of common hospital-acquired infections. **EB:** *Refusal for chlorhexidine gluconate (CHG) bathing in one study ranged from 3% to 39%. Clients expressed a low knowledge of the benefits of chlorhexidine for preventing hospital-acquired infections, and only 35% of clients reporting receiving CHG education (Caya et al, 2019).*

Dressing Self-Care Deficit

Domain 4 Activity/Rest Class 5 Self-Care

Suzanne C. Ashworth, MSN, APRN, CCRN, CCNS

NANDA-I

Definition

Inability to independently put on or remove clothing.

Defining Characteristics

Difficulty choosing clothing; difficulty fastening clothing; difficulty gathering clothing; difficulty maintaining appearance; difficulty picking up clothing; difficulty putting clothing on lower body; difficulty putting clothing on upper body; difficulty putting on various items of clothing; difficulty removing clothing item; difficulty using assistive device; difficulty using zipper

Related Factors

Anxiety; decreased motivation; discomfort; environmental constraints; fatigue; neurobehavioral manifestations; pain; weakness

Associated Conditions

Musculoskeletal impairment; neuromuscular diseases

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Self-Care: Activities of Daily Living (ADLs), Dressing, Hygiene

Example NOC Outcome with Indicators

Self-Care: Dressing as evidenced by the following indicators: Gets clothing from drawer and closet/Puts clothing on upper body and lower body. (Rate outcome and indicators of **Self-Care: Dressing:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Client Outcomes

Client Will (Specify Time Frame)

- Dress and groom self to optimal potential
- Use assistive technology to dress and groom
- Explain and use methods to enhance strengths during dressing and grooming
- Dress and groom with assistance of caregiver as needed

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Self-Care Assistance: Dressing/Grooming

Example NIC Activities—Self-Care Assistance: Dressing/Grooming

Be available for assistance in dressing, as necessary; Reinforce efforts to dress self; Maintain privacy while the client is dressing

Nursing Interventions and *Rationales*

▲ Assess independence in dressing and bathing skills after rehabilitation to determine the need for follow-up care. **EB:** *It was found that dressing and bathing independence at rehabilitation discharge were predictors of independence at 5 years after stroke* (De Wit et al, 2014).

▲ Assess the motor impairment and balance of all clients after stroke. **EB:** *A study of 60 stroke clients demonstrated that balance reduced the ability to perform dressing activities due to the fear of falling* (*Fujita et al, 2016*).

▲ Routinely assess functional impairment and report functional changes to the health care provider for hospitalized clients with advanced cancer. **EB:** *A prospective study of hospitalized cancer clients found a correlation with functional impairment and inability to perform activities of daily living (ADLs), and the study found that cancer clients had significant increase in physical and psychological symptoms and worse clinical outcomes compared to those clients without functional impairment (Lage et al, 2020).*

▲ Refer clients with rehabilitation needs to physical and occupational therapy for functional rehabilitation with ADLs. **EB:** *A prospective study of 230 stroke clients found improved ADL function with a multiprofessional rehabilitation (Langhammer et al, 2017).*

● For clients with spinal cord injury, encourage their self-efficacy and involve them in decision-making. **EBN:** *A systematic review of 6 studies* (n = *84) showed that rehabilitation is influenced by resilience, which can be enhanced with encouragement by nurses (Kornhaber et al, 2018).*

● Use adaptive dressing and grooming equipment as needed (e.g., button hooks, dressing stick, elastic shoelaces, long-handled shoehorn, reacher, sock application devices, Velcro clothing and shoes, zipper pull, long-handled brushes, soap-on-a-rope, suction holders). Use of adaptive clothing and devices for dressing and grooming can improve self-care ability and promote independence.

● Provide client analgesics before dressing as needed, sufficient time for dressing, and assist as needed. Analgesics, adequate time, and assistance if tiring can promote independence in dressing.

▲ For clients who are wheelchair dependent, consider the use of functional adaptive clothing. **EB:** *Functional clothing for wheelchairs was newly designed and evaluated for improving ADLs. Dressing competence was improved by 24.6% and toileting was improved by 52.9%* (*Wang et al, 2014*).

Geriatric

▲ Gather information on the client's personal clothing style and allow the client freedom to choose from a few selected outfits. **EB:** *Dementia clients are more able to maintain independence when provided choices (Prizer & Zimmerman, 2018).*

▲ When dressing dementia clients, give short verbal instructions, provide encouragement, and provide positive reinforcement. Use gentle physical prompting when needed, never debate, and never argue. **EB:** *When providing simple verbal instructions and maintaining dignity, dementia clients are more able to dress themselves independently (Prizer & Zimmerman, 2018).*

▲ Provide training to nursing home direct care staff regarding how to assist dementia clients with dressing that maintains dignity and respect of choice. **EBN:** *A mixed-method study that provided online training to*

Certified Nursing Assistants (CNAs) in 10 nursing homes found that the CNAs gained additional knowledge and understanding for providing person-centered care to dementia clients (Dobbs et al, 2018).

Multicultural

- Consider use of assistive technology versus personal care assistance for Native Americans. **EB:** *Older American Indians use more assistive technology for assistance with ADLs than the general same-age population and view the technology as allowing them to engage in activities (Reisinger & Ripat, 2014).*
- Consider cultural differences in clothing choices for Latino/Hispanic clients and respect dressing norms. **EB:** *Providing care for family elders is an important part of Latino/Hispanic culture. Easy-to-apply clothing, such as sweatpants, may not be deemed appropriate depending on the ethnicity (Mahoney, Coon, & Lozano, 2016).*

Home Care

- Ensure the client is dressing in a safe area. The bathroom may increase risk for falls during dressing. **EB:** *A systematic review of the literature for supporting ADLs of dementia clients found good evidence that the environment for dressing dementia clients should be safe and comfortable (Prizer & Zimmerman, 2018).*
- Consider home occupational therapy for elderly frail clients living at home. **EB:** *A systematic review and meta-analysis of home occupational therapy intervention found strong evidence that occupational therapy has a moderate improvement in ADL function (De Coninck et al, 2017).*

Client/Family Teaching and Discharge Planning

- ✱ Include caregiver's perceptions of client rehabilitation needs after stroke. **EB:** *A meta-analysis of 66 studies of stroke survivors' needs as perceived by their caregivers found three areas of perceived needs that may improve outcomes by including caregivers in the rehabilitation planning (Krishnan et al, 2017).*
- Provide family caregiver training for assisting the client with dressing. **EB:** *A study was conducted on 36 family caregivers of dementia clients. Family training provided knowledge to assist caregivers with providing ADLs (DiZazzo-Miller et al, 2017).*

Feeding Self-Care Deficit

Domain 4 Activity/rest Class 5 Self-care

Suzanne C. Ashworth, MSN, APRN, CCRN, CCNS

NANDA-I

Definition

Inability to eat independently.

Defining Characteristics

Difficulty bringing food to mouth; difficulty chewing food; difficulty getting food onto utensils; difficulty handling utensils; difficulty manipulating food in mouth; difficulty opening containers; difficulty picking up cup; difficulty preparing food; difficulty self-feeding a complete meal; difficulty self-feeding in an acceptable manner; difficulty swallowing food; difficulty swallowing sufficient amount of food; difficulty using assistive device

Related Factors

Anxiety; decreased motivation; discomfort; environmental constraints; fatigue; neurobehavioral manifestations; pain; weakness

Associated Conditions

Musculoskeletal impairment; neuromuscular diseases

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Self-Care: Activities of Daily Living (ADLs), Eating

Example NOC Outcome with Indicators

Self-Care: Eating as evidenced by the following indicators: Opens containers/Uses utensils/Completes a meal. (Rate the outcome and indicators of **Self-Care: Eating:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Feed self safely and effectively
- State satisfaction with ability to use adaptive devices for feeding
- Use assistance with feeding when necessary (caregiver)
- Maintain adequate nutritional intake

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Self-Care Assistance: Feeding

Example NIC Activities—Self-Care Assistance: Feeding

Provide adaptive devices to facilitate client's feeding self (e.g., long handles, handle with large circumference, or small strap-on utensils), as needed; Provide frequent cueing and close supervision as appropriate

Nursing Interventions and *Rationales*

▲ Screen for oropharyngeal dysphagia and malnutrition in elderly and high-risk hospitalized clients. **EB:** *A study conducted by Amaro Andrade et al (2018) aimed to determine the frequency of dysphagia risk and*

associated malnutrition in 909 hospitalized clients. Dysphagia prevalence was found in 10.5% and malnutrition in 13.2%. Advanced age was an associated risk factor for dysphagia.

- ▲ The Eating Assessment Tool-10 (EAT-10) may be used to screen for dysphagia. **EB:** *A cross-sectional study conducted in older community members in Japan* (n = *202) found a correlation for the presence of dysphagia when compared with the 100 mL water swallow test* (*Nishida et al, 2020*).
- ▲ For critical care clients who receive prolonged endotracheal intubation (>48 hours), assess swallowing using a valid tool to avoid aspiration related to dysphagia. **EBN:** *A prospective study conducted in four medical-surgical intensive care units* (n = *66) tested the use of the Post Extubation Dysphagia Screening tool (PEDS). The tool was found to have a sensitivity of 81% and specificity of 69% and was determined to be reliable for assessing swallowing ability after prolonged endotracheal intubation (Johnson et al, 2018).*
- ▲ A formalized screening for dysphagia should be done in all stroke clients before any oral intake using the 3-ounce water swallow test by a trained clinician. **EB:** *A systematic review and meta-analysis* (n = *770) found the 3-ounce water swallow test accurate and recommended for aspiration screening in poststroke clients (Chen et al, 2016b).*
- ▲ The Edinburgh Feeding Evaluation in Dementia can be used to determine the presence of behaviors that lead to feeding or eating problems in late-stage dementia clients. **EBN:** *The Edinburgh Feeding Evaluation in Dementia (EdFED) has been widely used in dementia clients. A recent study summarized the validity of assessment tools for dementia clients. The study determined that the EdFED continues to demonstrate high validity and inter-rater reliability (Spencer et al, 2020).*
- ▲ Assess for fatigue, sedating medications, and frailty before meals. Supervision and eating assistance may be required to avoid aspiration. **EB:** *In a review conducted by Cichero (2018), age >65, fatigue, hand weakness, and sedating medications were found to impair swallowing and cough reflexes.*
- ▲ Individualize the feeding process to promote interdependence, especially for younger adults who need feeding assistance. **EB:** *A qualitative study explored client attitudes toward feeding assistance. Younger adults had more negative feelings regarding being fed due to the loss of autonomy* (*Shune, 2020*).
- ▲ Consider consultation with a speech and language pathologist for clients with dysphagia for diet modifications and swallowing exercise therapy. **EB:** *In a study of 9 healthy older adults with dysphagia, clients had a significant improvement in swallowing ability from baseline using a high-intensity rehabilitation protocol (Balou et al, 2019).*
- ▲ Assess the ability to self-feed and communicate which clients require feeding assistance to decrease missed meals and allow for adequate nutrition. **EBN:** *A pilot study redesigned meal trays to include a method to communicate when assistance is needed. This resulted in an improvement of client nutritional status (Teeling et al, 2019).*
- ▲ Conduct repeat structured observations of clients at mealtime after a stroke to detect clients with eating difficulties to prevent possible social and functional consequences. **EB:** *A qualitative study of stroke survivors explored experiences with managing eating. Difficulties with sensory and motor function had an impact on social well-being. Clients described eating activities as being important for overall well-being and eating was a way to self-monitor recovery (Jones & Nasr, 2018).*
- ▲ Prioritize assisted feeding as important in a caregiver's assignment to allow adequate time for the client to eat. **EBN:** *A prospective study conducted by Chen et al (2016a) performed a before and after analysis of dementia clients' eating after implementing a Feeding Intervention Model. During the study, nurses who assisted clients allowed adequate time for clients to eat at a slow to moderate speed, ensuring consummation of the clients' meal. After implementation of the feeding intervention, clients had a significant improvement in nutritional status.*
- ▲ Consider using adaptive eating devices for clients with an upper limb motor impairment to assist with eating independently. **EB:** *An experimental study found significant improvements in eating and increased clients' satisfaction with introduction of an adaptive eating device (Cavalcanti et al, 2020).*
- ▲ Ensure oral care is provided to all clients using an American Dental Association–approved toothbrush and toothpaste after meals and at bedtime. Increase oral care frequency for clients who are on nothing-by-mouth (NPO) status. **EBN:** *Oral hygiene interventions have been shown to decrease hospital-acquired pneumonia, length of stay, and client mortality (Warren et al, 2019).*

Geriatric

- ▲ Assess for absent teeth and ill-fitting dentures in older clients before feeding. **EB:** *Tooth loss contributes to swallowing difficulties that can increase risk of aspiration in the older client. Adequate dentition is essential for effective chewing and to prevent choking* (*Cichero, 2018*).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- ▲ Establish a routine during mealtime and create a controlled stimulated environment with adequate lighting that simulates a home-like dining experience. **EBN:** *Promoting and maintaining eating independency is possible in nursing home residents by creating a controlled stimulated environment. Modifications to routines may trigger agitation that can affect nutritional intake (Palese et al, 2018).*
- ▲ Supervise the feeding of those with moderate dependency and provide physical assistance when needed. **CEBN:** *A feeding intervention study conducted in a nursing home with dementia clients* (n = *30) placed emphasis on clients' autonomous eating while monitoring compliance with swallowing and chewing. The study demonstrated statistically significant improvement in food intake and independent eating compliance* (*Chen et al, 2016a*).
- ▲ When eating assistance is needed, (1) position clients in an upright position; (2) do not provide too much food at one time (approximately $^3/_4$ spoonful); and (3) offer food slowly, allowing the food to be chewed completely. For visually impaired clients, press the food to the client's lips and provide encouragement. **EBN:** *A prospective study of nursing home residents with dementia and dysphagia implemented a feeding intervention and found overall improvements in eating and dysphagia (Chen et al, 2016a).*
- ▲ Consider implementing Montessori interventions for dementia clients who have eating problems, such as playing music for sensory stimulation and employing hand-eye coordination, scooping, pouring, and squeezing activities. **EB:** *A systematic review of Montessori activities in dementia clients found strong evidence that eating difficulties may be improved when using Montessori interventions (Sheppard et al, 2016).*
- ▲ Limit activities and avoid noise and interruptions during mealtimes. **EB:** *A mixed-method systematic review found that interruptions can have a negative impact during mealtime (Edwards, Carrier, & Hopkinson, 2017).*
- ▲ Use high-calorie oral nutritional supplements for clients with advanced dementia who cannot meet their nutrition requirements by food alone. **EB:** *According to the European Society for Clinical Nutrition and Metabolism (ESPEN) guidelines on nutrition for dementia clients, older clients with dementia are at an increased risk for malnutrition. There is high evidence that the use of oral nutritional supplements improves nutritional status (Volkert et al, 2015).*
- ▲ Provide nutritional supplement drinks in a glass to older adults with cognitive impairment. **EBN:** *Allen, Methven, and Gosney (2014) conducted a nonblind randomized control trial that identified that the best method to provide nutritional supplement drinks to older adults with cognitive impairment is in a glass/beaker rather than using a straw in the container.*
- ✱ Provide verbal cues and encouragement during mealtimes. **EBN:** *A review conducted by Liu et al (2015) found good evidence that offering verbal cues and positive reinforcement leads to improved food intake.*
- ▲ Avoid changes or modifications to mealtime routines. **EB:** *Any modification or change in routine can result in agitation for nursing home residents, which can lead to decreased food intake for the individual and other residents* (*Palese et al, 2018*).
- ▲ Encourage family members to assist clients during mealtime for those who need eating assistance. **EBN:** *Family assistance was associated with a higher consumption of protein and energy intake for clients in a long-term care setting* (*Wu et al, 2020*).
- ▲ Play familiar soothing music during meals for clients with dementia. **EB:** *A systematic review by Bunn et al (2016) found evidence that music can increase food intake for dementia clients.*
- ▲ Provide feeding training and education programs for caregivers. **EBN:** *A systematic review of the literature about improving eating difficulties in older adults with dementia found good evidence that training and education programs for caregivers lead to decreased feeding difficulties* (*Liu et al, 2015*).

Multicultural

- ▲ For those with impaired hand function who use chopsticks, suggest adapted chopsticks. **CEB:** *In a pilot equipment study, adapted chopsticks, which can be inexpensive and easily constructed, for those with lower cervical spinal cord injury and residual gross grasp were found to convert gross grasp into 2-point pinch* (*Chang et al, 2006*).
- ▲ Use the simplified Chinese Edinburgh Feeding Evaluation in Dementia scale to measure feeding problems in people with dementia from Mainland China and other Chinese cultural groups. **EBN:** *Identifying client behaviors during feeding allows development of effective interventions for feeding (Liu, Watson, & Lou, 2014).*
- ▲ The culturally adaptive Spanish version of the Edinburgh Feeding Evaluation in Dementia Scale is valid for measuring feeding difficulties in Spanish-speaking dementia clients. **EBN:** *A cross-sectional study was*

done to determine validity of the Spanish version of the Edinburgh Feeding Assessment. The adapted version was found to be reliable (Saucedo Figueredo et al, 2018).

Home Care

▲ For elderly home care clients with chronic diseases, assess nutritional status and chewing/swallowing ability. **EB:** *A cross-sectional study examined the nutritional status of elderly home care clients with disease burden in Germany. Chewing problems were found in 52% of the study population. More than one-third were found to have a moderate to poor appetite and a lower body mass index (Pohlhausen et al, 2016).*

▲ Provide multiprofessional nutritional support for home care clients by involving physical therapy, occupational therapy, and dietitians. **EB:** *Beck et al (2016) assessed the effect of a nutritional support team for undernourished elderly clients in a nursing home and in home care (n = 389). Improvements in quality of life, muscle strength, and oral care were found in the intervention group.*

Client/Family Teaching and Discharge Planning

▲ Educate family caregivers who are involved in the feeding of a family member by providing demonstration and hands-on training by a qualified trainer. **EBN:** *Caregivers of older adults with dementia identified the need for structured training and support. Insufficient education and lack of information were found to lead to caregiver emotional distress (Lee et al, 2019).*

▲ Educate family members that neither insertion of a feeding tube nor timing of its insertion affects client survival for those with advanced dementia who have eating problems. **EB:** *A longitudinal study of 169 clients compared hand feeding with nasogastric feeding (NGF) of bedridden dementia clients. NGF was not associated with a lower risk of pneumonia. Hospitalization and mortality were not decreased with use of NGF. Hand feeding can be considered an alternative to NGF (Chou, Tsou, & Hwang, 2020).*

Toileting Self-Care Deficit

Domain 4 Activity/rest Class 5 Self-care

Suzanne C. Ashworth, MSN, APRN, CCRN, CCNS

NANDA-I

Definition

Inability to independently perform tasks associated with bowel and bladder elimination.

Defining Characteristics

Difficulty completing toilet hygiene; difficulty flushing toilet; difficulty manipulating clothing for toileting; difficulty reaching toilet; difficulty rising from toilet; difficulty sitting on toilet

Related Factors

Anxiety; decreased motivation; environmental constraints; fatigue; impaired physical mobility; impaired transfer ability; neurobehavioral manifestation; pain; weakness

Associated Conditions

Musculoskeletal impairment; neuromuscular diseases

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Self-Care: Activities of Daily Living (ADLs), Toileting

Example NOC Outcome with Indicators

Self-Care: Toileting as evidenced by the following indicators: Responds to full bladder and urge to have a bowel movement in a timely manner/Gets to toilet between urge and passage of urine/Between urge and evacuation of stool. (Rate the outcome and indicators of **Self-Care: Toileting:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of incontinence and impaction with no urine or stool on skin
- State satisfaction with ability to use adaptive devices for toileting
- Explain and demonstrate use of methods to be safe and independent in toileting

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Environmental Management; Self-Care Assistance: Toileting

Example NIC Activities—Self-Care Assistance: Toileting

Assist client to toilet/commode/bedpan/fracture pan/urinal at specified intervals; Institute a toileting schedule, as appropriate

Nursing Interventions and *Rationales*

∗ Assess clients for fall risk using established and valid fall risk assessment tools and implement fall prevention interventions for those at risk for falling. **EBN:** *A retrospective study of 409 fall incidents within a hospital setting found that 34% of all falls were related to toileting and 44% of falls occurred at night; in 80% of nighttime falls, clients mobilized without calling for assistance as recommended (Rose et al, 2020).*

∗ Implement purposeful hourly or 2-hourly rounding that targets toileting needs of the client. **EBN:** *A quality improvement project conducted on a medical-surgical unit implemented a purposeful rounding protocol that address the four Ps (pain, position, potty, possessions) to decrease the number of client falls. The project led to a 41% increase in toileting and a 50% decrease in client falls (Daniels, 2016).*

● Perform a bladder scan for postvoid residual in neurological clients who are at high risk for neurogenic bladder and urinary retention. **EBN:** *A study conducted on poststroke clients found 53% of clients to have postvoid residuals >100 mL (Smith & Schneider, 2020).*

∗ Use disposable underpads versus reusable washable underpads for hospitalized adult clients with urine or fecal incontinence. **EBN:** *A study conducted in four medical-surgical units (n = 462) found that disposable pads reduced the rate of hospital-acquired pressure injuries (Francis et al, 2017).*

● In the acute care setting, use absorbent pads left open under the client for fecal and urine incontinence. **EB:** *Incontinence absorbent pads that are occlusive around the client create a warm environment and increase the risk for incontinent-associated dermatitis (Thayer, Rozenboom, & Baranoski, 2016).*

● Consider use of external urinary collection devices and avoid use of an indwelling urinary catheter for the purpose of incontinence. **EBN:** *Introduction of a female external urinary collection device reduced rates of catheter-associated urinary tract infection in a community hospital setting (Eckert et al, 2020).*

● Perform intermittent straight catheterization for clients who are unable to empty their bladder and have urinary retention. **EB:** *A retrospective study conducted in a trauma population demonstrated statistically significant improvements in rate of urinary tract infections after implementation of an intermittent straight catheterization protocol (Kelley et al, 2017).*

● Ensure a timely planned evacuation of bowel for spinal cord injury clients by implementing a low-fiber diet and digital stimulation. **EB:** *Spinal cord injury clients have increased morbidity due to symptoms of neurogenic bowel. Understanding physiology and working collaboratively with the client can improve quality of life (Stoffel et al, 2018).*

● Assess bowel symptoms and self-management strategies of clients who have had sphincter-saving surgery. Develop client-specific interventions to continue to support and meet client needs. **EBN:** *In a quantitative descriptive study of self-care strategies used by clients who had sphincter-saving surgery and bowel symptoms (n = 143), the strategy of proximity and knowing the location of a toilet at all times was used most by those with more bowel symptoms (Landers et al, 2014).*

● Consider use of a female urinal for female cancer clients who are receiving palliative care. **EBN:** *A qualitative study using a female urinal prototype was found to be easier to use compared to a bedpan, was more comfortable, and provided more dignity (Farrington et al, 2016).*

▲ Before use of a bedpan, discuss its use with clients. **EBN:** *A study conducted on women in labor with epidural analgesic, nurse education, and training regarding bedpan use increased nurse comfort and client ability to use a bedpan, decreasing the need for urinary catheters (McLain, 2019).*

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

* ✱ Promote use of assistive toileting equipment when needed for toileting transfer assistance. **EB:** *A study of 193 older people living at home found a greater sense of independence and improved quality of life when using bathroom assistive products (De-Rosende-Celeiro et al, 2019).*
* ✱ Avoid prolonged time sitting on a toilet, commode, or bedpan to reduce pressure-related skin injury risk. Use padded toilet cushions if needed. **EB:** *Lustig et al (2018) confirmed that prolonged time on a toilet seat leads to potential pressure injury. This risk was reduced with specialized cushions.*
* ✱ Consider use of toilet alarm systems for clients who are at risk for falling and not cognitively impaired. **EBN:** *The use of a toilet alarm was studied in two community-based hospitals; clients rated higher privacy, greater toileting independence, and less fear of falling (Jones et al, 2021).*
* ● Close toilet lid before flushing toilet and teach client to do so. **EB:** *A study conducted in hospital bathrooms that measured potential infectious aerosols after toilet flushing during client care found a significant increase of bioaerosol after flushing, which can lead to environmental contamination (Knowlton et al, 2018).*

Geriatric

* ● Assess residents without dementia for risk factors associated with toileting disability (such as rating health as fair or poor; living in a residence with four or less residents or that is for-profit; incontinence; physical, visual, or hearing impairment; and need for ADL or transferring assistance to guide prevention interventions). **EBN:** *In a cross-sectional analysis of adults 65 years or older without dementia in residential care facilities (n = 2395), 15% were found to have toileting disability that was associated with rating health as fair or poor; living in a residence with four or fewer residents or that is for-profit; incontinence; physical, visual, or hearing impairment; and need for ADL or transferring assistance (Talley et al, 2014).*
* ● Promote a toileting pattern using timed voiding and verbal prompts to develop habits and promote continence in dementia clients. **EB:** *Clients with memory impairment may forget how to ask for help with toileting or how to use the toilet. Developing a toileting schedule may help maintain continence (Payne, 2020).*
* ● Assess the client's functional ability to manipulate clothing for toileting, and if necessary, modify clothing with Velcro fasteners, elastic waists, drop-front underwear, or slacks. **EB:** *For clients with impaired dexterity or weakness, wearing shirts or pants with Velcro attachments can be easier to remove and promote independence during toileting (Mlinac & Feng, 2016).*
* ● Consider an exercise training of routine walking and pelvic floor exercises for frail incontinent women. **EBN:** *A randomized control trial of 42 women with urinary incontinence found improvement of symptoms after a 12-week therapy program that combined lifestyle, behavioral, and physical therapy (Talley et al, 2017).*

Multicultural

* ● Remove barriers to toileting, support client's cultural beliefs, and protect dignity during continence care. **EB:** *A concept analysis literature search defined the key attributes of dignity for continence care in a long-term care setting as privacy, respect, autonomy, empathy, trust, and communication (Ostaszkiewicz et al, 2020).*

Home Care

* ▲ Instruct client/family member or caregiver to develop a bladder diary to obtain a better understanding of incontinent patterns. **EB:** *Bladder diaries should be used for a minimum of 3 days for the initial assessment of incontinence or overactive bladder (National Institute for Health and Care Excellence [NICE], 2019).*
* ▲ Involve the client's caregiver in developing a written plan for managing incontinence in dementia clients. **EB:** *Providing optimal support of caregivers through use of planning can help avoid long-term conditions associated due to stress (Robinson, 2018).*
* ▲ Consider consultation with occupational therapy to evaluate home bathroom design, to evaluate assistive device needs, and to provide training for proper body mechanics for home caregivers. **EB:** *Improving safety and avoiding musculoskeletal injuries of caregivers is necessary. Caregivers often identify toileting assistance as a difficult activity (King et al, 2019).*
* ● Consider the use of technology-assisted toilets with perineal washing ability. **EB:** *A pilot study of stroke rehabilitation clients found effective cleaning and improved psychosocial outcomes (Yachin et al, 2017).*

S

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

Client/Family Teaching and Discharge Planning

- Instruct clients with mixed (stress and urge) urinary incontinence to perform pelvic floor exercises for at least 3 months and increase walking to build muscle strength. **EBN:** *A 12-week study of behavioral incontinence treatments found 50% improvement in urine leakage and toileting abilities (Talley et al, 2017).*
- Instruct female clients not to use sanitary pads for urinary incontinence. *Sanitary pads are not manufactured for absorbing urine and do not protect the skin (Payne, 2020).*
- Explain to family and caregivers of clients with dementia that toilet self-care activities decrease when self-awareness is lost. **EB:** *An observational study of toileting self-care in older adults with dementia revealed that toilet activities are affected and decline when self-awareness is lost (composed of theory of mind, self-evaluation, and self-consciousness) (Uchimoto et al, 2013).*

✱ Educate male clients who perform self-straight catheterization on use of the coude tip catheter to avoid difficulties with insertion. **EBN:** *With proper training and education, use of the Tiemann (coude) tip catheter can benefit clients by preventing failed catheterization (Rew, Lake, & Brownlee-Moore, 2018).*

Readiness for Enhanced Self-Concept

Domain 6 Self-perception Class 1 Self-concept

Marina Martinez-Kratz, RN, MS, CNE

NANDA-I

Definition

A pattern of perceptions or ideas about the self, which can be strengthened.

Defining Characteristics

Expresses desire to enhance acceptance of limitations; expresses desire to enhance acceptance of strengths; expresses desire to enhance body image satisfaction; expresses desire to enhance confidence in abilities; expresses desire to enhance congruence between actions and words; expresses desire to enhance role performance; expresses desire to enhance satisfaction with personal identity; expresses desire to enhance satisfaction with sense of worth; expresses desire to enhance self-esteem

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Self-Esteem; Personal Well-Being; Psychosocial Adjustment Life Change

Example NOC Outcome with Indicators

Self-Esteem as evidenced by the following indicators: Verbalizations of self-acceptance/Open communication/Confidence level/Description of pride in self. (Rate the outcome and indicators of **Self-Esteem:** 1 = never positive, 2 = rarely positive, 3 = sometimes positive, 4 = often positive, 5 = consistently positive [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State willingness to enhance self-concept
- State satisfaction with thoughts about self, sense of worthiness, role performance, body image, and personal identity
- Demonstrate actions that are congruent with expressed feelings and thoughts
- State confidence in abilities
- Accept strengths and limitations

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Self-Esteem Enhancement

Example NIC Activities—Self-Esteem Enhancement

Encourage client to identify strengths; Assist client in setting realistic goals to achieve higher self-esteem

Nursing Interventions and *Rationales*

- Encourage client to express feelings through songwriting. **EB:** *Study findings suggested that people who find songwriting has strong meaning for them might be more likely to start accepting their emotions and as a result experience decreases in anxiety and depression* (*Baker et al, 2016*).
- Refer to nutritional and exercise programs to support weight loss. **EB:** *Study findings suggested that weight-loss treatments emphasize changes in self-perception (Annesi & Porter, 2015).*
- Offer client complementary and alternative medicine (CAM) interventions such as acupressure, aromatherapy, compress, and massage. **EBN:** *A study reviewed the development of a complex nursing intervention including CAM for breast and gynecological cancer clients during chemotherapy to improve quality of life (Klafke et al, 2016).*
- Support homeless individuals to identify and endorse a positive self-concept. **EB:** *A study found that assumption of positive identity meanings, even a stigmatized identity such as being a homeless person, may provide support for a more general sense of self-esteem (Parker et al, 2016).*
- Support unemployed individuals to cope with identity threats and support individual identity growth. **EB:** *Research shows that to cope with self-definition threats, mature-aged workers protect and restructure their self-definitions with alternative goals of either remaining in paid employment or opting out from it (Kira & Klehe, 2016).*
- Support establishing community-based partnerships to address health needs. **EBN:** *To prevent suicide and substance abuse, a community-based participatory research approach was used to obtain community input, which led to the development of a strengths-based intervention incorporating the Gathering of Native Americans curriculum (Holliday et al, 2018).*
- For clients with a history of trauma, offer a mindfulness-based intervention of hatha yoga. **EB:** *A qualitative study explored the experiences of women with posttraumatic stress disorder (PTSD) who participated in a 10-week Trauma Sensitive Yoga (TSY) class. It was found that they specifically perceived changes in symptoms and feelings of gratitude and compassion, relatedness, acceptance, centeredness, and empowerment (West et al, 2017).*

Pediatric

- Facilitate healthy relationships with teachers, coaches, and other supportive adults in the adolescents' lives. **EB:** *Research found that the presence of supportive teachers and coaches in an adolescent's social network is associated with healthier self-concept and decreased substance use* (*Dudovitz et al, 2017*).
- Provide parents with information designed to promote body satisfaction, healthy eating, and weight management in early childhood. **EB:** *Research evaluated Confident Body, Confident Child (CBCC), which is an intervention for parents of 2- to 6-year-old children, and found significant increases in parents' intentions to use positive behaviors and knowledge of child body image and healthy eating patterns* (*Hart et al, 2016*).
- Promote the adoption of a recovery identity through online interactions and support groups for individuals with eating disorders. **EB:** *A study found that an eating disorder identity is seen as problematic and most interventions are targeted at changing an individual's self-concept. The study suggested that interventions could instead focus on identity resources to support a transition to a recovery identity (McNamara & Parsons, 2016).*
- Provide activities to bolster physical self-concept. **EB:** *A meta-analytic review found that physical activity interventions increased positive self-concept in adolescents (Spruit et al, 2016).*
- ▲ Provide overweight adolescents access to group-based weight control interventions. **EB:** *A 12-week group-based exergaming intervention was associated with positive effects on overweight and obese adolescent girls' television viewing, self-efficacy, and intrinsic motivation* (*Staiano et al, 2017*).
- Provide an alternative school-based program for pregnant and parenting adolescents. **EB:** *Despite Title IX legislation mandating equal educational opportunities for pregnant and parenting teens, only 50% of adolescent parents graduate high school. A study found themes of struggle, support, hope, perseverance, and transformation in a cohort of young mothers' descriptions of finishing high school* (*Watson & Vogel, 2017*).

Geriatric

- Encourage clients to consider online support programs when they are in a caregiving situation. **EBN:** *Research found that participation in a Web-based family support network provided a venue to share experiences, to be informed, and to gain insights into care issues. Participation reinforced the caregiver's sense of competence, helped them meet caregiving demands, and allowed them to identify the positive aspects of their situation* (*Andersson et al, 2017*).

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based; ✱ = QSEN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Encourage activity and a strength, mobility, balance, and endurance training program. **EB:** *Older participants in a fitness training trial demonstrated beneficial effects on muscular strength, functionality, and confidence* (*Schreier et al, 2016*).
- Support meaning and purpose in the lives of older adults through a focus on everyday well-being and facilitation of personally treasured activities. **EBN:** *An exploratory study found four key experiences that promote meaning and purpose in life: (1) physical and mental well-being, (2) belonging and recognition, (3) personally treasured activities, and (4) spiritual closeness and connectedness* (*Drageset et al, 2017*).
- Use an approach that reduces the emphasis put on ageist self-concept attributions when working with older clients. **EB:** *Ageism includes cognitive, behavioral, and emotional manifestations. Ageism tends to reinforce social inequalities because it is more pronounced toward older women, poor people, or those with dementia* (*Ayalon & Tesch-Römer, 2017*).

Multicultural

- Refer to the care plans Disturbed **Body Image,** Readiness for Enhanced **Coping,** Chronic Low **Self-Esteem,** and Readiness for Enhanced **Spiritual** Well-Being.

Home Care

- Previously discussed interventions may be used in the home care setting.

Chronic Low Self-Esteem

Domain 6 Self-perception Class 2 Self-esteem

Marina Martinez-Kratz, MS, RN, CNE

NANDA-I

Definition

Long-standing negative perception of self-worth, self-acceptance, self-respect, competence, and attitude toward self.

Defining Characteristics

Dependent on others' opinions; depressive symptoms; excessive guilt; excessive seeking of reassurance; expresses loneliness; hopelessness; insomnia; loneliness; nonassertive behavior; overly conforming behaviors; reduced eye contact; rejects positive feedback; reports repeated failures; rumination; self-negating verbalizations; shame; suicidal ideation; underestimates ability to deal with situation

Related Factors

Decreased mindful acceptance; difficulty managing finances; disturbed body image; fatigue; fear of rejection; impaired religiosity; inadequate affection received; inadequate attachment behavior; inadequate family cohesiveness; inadequate group membership; inadequate respect from others; inadequate sense of belonging; inadequate social support; ineffective communication skills; insufficient approval from others; low self efficacy; maladaptive grieving; negative resignation; repeated negative reinforcement; spiritual incongruence; stigmatization; stressors; values incongruent with cultural norms

At-Risk Population

Economically disadvantaged individuals; individuals experiencing repeated failure; individuals exposed to traumatic situation; individuals with difficult developmental transition; individuals with history of being abandoned; individuals with history of being abused; individuals with history of being neglected; individuals with history of loss

Associated Conditions

Depression; functional impairment; mental disorders; physical illness

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Self-Esteem

Example NOC Outcome with Indicators

Demonstrates improved **Self-Esteem** as evidenced by the following indicators: Verbalizations of acceptance of self and limitations/Open communication. (Rate the outcome and indicators of **Self-Esteem:** 1 = never positive, 2 = rarely positive, 3 = sometimes positive, 4 = often positive, 5 = consistently positive [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate improved ability to interact with others (e.g., maintains eye contact, engages in conversation, expresses thoughts/feelings)
- Verbalize increased self-acceptance through positive self-statements about self
- Identify personal strengths, accomplishments, and values
- Identify and work on small, achievable goals
- Improve independent decision-making and problem-solving skills

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Self-Esteem Enhancement

Example NIC Activities—Self-Esteem Enhancement

Encourage client to identify strengths; Assist in setting realistic goals to achieve higher self-esteem

Nursing Interventions and *Rationales*

- Assess existing strengths and coping abilities, and provide opportunities for their expression and recognition. **EB:** *Study results found that cancer clients had lower self-esteem, and upper-level cognitive functions and problem-focused coping were worse compared with healthy controls (Inci et al, 2020).*
- Assess the client's self-esteem using valid and established tools such as the Rosenberg Self-Esteem Scale. **CEB:** *The use of valid and established measures of self-esteem will facilitate the identification of appropriate nursing interventions that strengthen self-esteem (Rosenberg, 1965).*
- Assess the client for addictive use of social media. **EB:** *Results from a study demonstrated that lower age, being a woman, not being in a relationship, being a student, lower education, lower income, lower self-esteem, and narcissism were associated with higher scores on the Bergen Social Media Addiction Scale (BSMAS) (Andreasson et al, 2017).*
- Reinforce the personal strengths and positive self-perceptions that a client identifies. **EB:** *A study found that self-esteem mediates the relationship between hope and life satisfaction (Du et al, 2015).*
- Encourage self-affirmations by reflecting on values and strengths, in response to daily threats. **EB:** *A study found that engaging in spontaneous self-affirmation was related to greater happiness, hopefulness, optimism, subjective health, personal health efficacy, and less anger and sadness (Emanuel et al, 2018).*
- Identify client's negative self-assessments. **EB:** *Body image was found to have significant effects on both self-esteem and depression (You et al, 2017).*
- Assess individuals with low self-esteem for nonsuicidal self-injury (NSSI). **EB:** *A systemic review indicated a significant negative relationship between self-esteem and NSSI (Forrester et al, 2017).*
- Assess individuals with low self-esteem for symptoms of depression. **EB:** *Self-esteem is related to depressive symptoms and interpersonal problems. Improvement of self-esteem during psychotherapy correlates with improvements of symptoms and interpersonal problems (Dinger et al, 2017).*
- Encourage realistic and achievable goal setting and resources and identify impediments to achievement. **EB:** *A combined decision support and goal-setting intervention improved diet quality, diabetes-related self-efficacy, and empowerment and reduced diabetes-related distress and depressive symptoms (Swoboda et al, 2017).*
- Assist client in challenging negative perceptions of self and performance. **EB:** *A study found that more often than not, self-critical thoughts were viewed as facts and would rarely be seen as distorted or biased (Kolubinski et al, 2016).*
- Encourage the client's usual religious or spiritual practices. **EB:** *Research supports a positive association between religious involvement and self-esteem (Schieman et al, 2017).*
- Promote maintaining a level of functioning in the community and a sense of community feeling. **EB:** *Research found that the community feeling is positively connected with self-esteem and psychological well-being (Kałużna-Wielobób, 2017).*

Pediatric

- Assess children/adolescents with chronic illness for evidence of reduced self-esteem and make needed referrals. **EB:** *A review of literature found that effective management of chronic skin conditions has been shown to increase pediatric clients' self-esteem (Vivar & Kruse, 2017).*
- Encourage parents to use active listening to foster respectful relationships with children and adolescents. **EB:** *A study found that self-esteem had a mediating effect on parenting practices and satisfaction with the life of the adolescent (Pérez-Fuentes et al, 2019).*
- Monitor young adolescents during the transition to middle school for changes in self-concept. **EB:** *A study of adolescents found that middle school transition was associated with a lower self-concept (Onetti, Fernández-García, & Castillo-Rodríguez, 2019).*

- Encourage mothers of premature infants to use skin-to-skin care for at least 30 minutes/day. **EBN:** *A study found that skin-to-skin care showed significantly positive effects on stabilizing infant physiological functions such as respiration rate, increasing maternal–infant attachment, and reducing maternal stress (Cho et al, 2016).*
- Implement interventions that promote and maintain positive peer relations for adolescent clients. **EB:** *A large German study found positive associations between academic achievement, perceived peer acceptance, and self-esteem (Tetzner, Becker, Maaz, 2017).*
- Encourage attendance at social support groups. **EB:** *A study found that lesbian, gay, bisexual, transgender, and queer (LGBTQ) youth who attended a Hatch group-level intervention that consisted of unstructured social time, consciousness-raising (education), and a youth-led peer support group had higher levels of self-esteem (Wilkerson et al, 2017).*
- Encourage parents to praise children in ways that are not overly positive or inflated. **EB:** *A study found that parents' inflated praise predicted lower self-esteem in children (Brummelman et al, 2017).*
- Provide parents with information designed to promote body satisfaction, healthy eating, and weight management in early childhood. **EB:** *Research evaluated Confident Body, Confident Child (CBCC), which is an intervention for parents of 2- to 6-year-old children, and found significant increases in parents' intentions to use positive behaviors and knowledge of child body image and healthy eating patterns (Hart et al, 2016).*
- Assess children/adolescents that express a body image of self-perceived underweight, self-perceived overweight, and/or frustration with appearance for evidence of bullying. **EB:** *Research indicated that self-perceived underweight, self-perceived overweight, and frustration with appearance were positively associated with being bullied (Lin et al, 2018).*

▲ Provide bully prevention programs and include information on cyberbullying. **EB:** *A moderate and statistically significant relationship exists between low self-esteem and experiences with cyberbullying (Lin et al, 2018).*

Geriatric

- Support client in identifying and adapting to functional changes. **EBN:** *A study outlined the importance of enquiring about feelings of uselessness, which is linked to both psychological and physical health status, especially in older people who need help in daily activities (Curzio et al, 2017).*
- Implement reminiscence therapy. **EBN:** *Research suggests that a reminiscence program could increase self-esteem of hospitalized elders with chronic disease (Trerin, Naka, & Nukaew, 2017).*
- Encourage older adult clients to participate in flexibility, toning, and balance exercise. **EB:** *Older participants in a fitness training trial demonstrated beneficial effects on muscular strength, functionality, and confidence (Schreier et al, 2016).*
- Encourage regular physical activity with prerecorded workouts. **EB:** *Research found that a DVD-delivered exercise intervention for older adults was associated with improved and maintained levels of self-esteem (Awick et al, 2017).*
- Encourage participation in intergenerational social activities. **EB:** *Older adults reported that their participation in the "Time After Time" intergenerational program enhanced their confidence, self-esteem, and social skills; contributed to their emotional and overall health and well-being; and enabled them to learn about others and feel connected to their community (Teater, 2016).*
- Encourage activities in which a client can volunteer to support/help others. **EB:** *Research indicates that participation in volunteering mitigates the negative effects of older adults' low self-esteem on their sense of belonging and life satisfaction (Russell et al, 2019).*
- Encourage home and community gardening activities. **EB:** *Research found that older adult participation in gardening activities enhanced self-esteem (Scott, Masser, & Pachana, 2020).*

Multicultural

- Assess for the influence of cultural beliefs, norms, and values on the client's sense of self-esteem. **EB:** *A study of Latino youth suggested that specific cultural orientations were associated with increased global self-worth and increased levels of acculturation risk factors were associated with decreased global self-worth (Kapke et al, 2017).*
- Assess individuals with low self-esteem for symptoms of depression. **EB:** *Research found that low self-esteem and high depressive symptoms are more closely associated among blacks than whites (Assari, 2017).*
- Validate the client's feelings regarding ethnic or racial identity. **EB:** *A study found high ethnic identity to be protective against perceived stress (Espinosa et al, 2018).*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Home Care

- Assess a client's immediate support system/family for relationship patterns and content of communication. **EB:** *A study supported the beneficial effects of perceived family support on mental and physical health after surgery (Cardoso-Moreno & Tomás-Aragones, 2017).*

▲ Refer to continuous support and help from medical social services to assist the family in care of the client and support the caregiver's well-being. **EB:** *A study found that caregiving stress showed a significant positive correlation with depression and with economic and psychological stress, and it showed a significant negative correlation with self-esteem (Kim, 2017).*

▲ If a client is involved in counseling or self-help groups, monitor and encourage attendance. Help the client identify the value of group participation after each group encounter. Discussion about group participation clarifies and reinforces group feedback and support.

Client/Family Teaching and Discharge Planning

- Encourage clients to consider online support programs when they are in a caregiving situation. **EBN:** *Research found that participation in a Web-based family support network provided a venue to share experiences, to be informed, and to gain insights into care issues. Participation reinforced caregivers' sense of competence, helped them meet caregiving demands, and allowed them to identify the positive aspects of their situation (Andersson et al, 2017).*

▲ Refer to community agencies for psychotherapeutic counseling. **EB:** *Self-esteem is related to depressive symptoms and interpersonal problems. Improvement of self-esteem during psychotherapy correlates with improvements of symptoms and interpersonal problems (Dinger et al, 2017).*
