Scattered about on the sand were chips and fragments of white quartz. Two imperfect arrowpoints made of this material were obtained. A portion of the stem and tip of one of these, a small roughly chipped point, are missing. The other is finely chipped but is probably unfinished. A small notch appears on one side of the blade near the base. This point is 1¾ inches in length.

Two small triangular points and a stemmed point were found by others on this ridge. One of the former, made of white chert has serrated edges, the other is made of gray chert. The stemmed point is made of white chert, as may be seen at its tip, a portion of which is broken away. Its surfaces are weathered to a tan color. This point is of a very common and widely distributed Wisconsin form. It was probably originally about 3½ inches in length.

By the direction of these same parties we proceeded from here to the property of Jacob Ullman (SE. ¼, NW. ¼, Sec. 29, Maple Valley Twp., Oconto Co.,) where it was reported that a number of arrowpoints and other implements had been found. Here was found a sandy ridge near the Peshtigo brook, a tributary of the Oconto, which offered considerable evidence of its former use as an Indian camp or village site. The ridge was in the shape of a crescent or semi-circle, being about one half mile long, from one to five rods wide, and at an elevation of about fifty feet above the brook. The materials employed in the manufacture of implements on this site were quartz and chert. At least four varieties of the latter were employed,— a glossy, whitish chert, probably not native to this region; a dark reddish chert; a whitish chert tinted or blotched with salmon color, and a shiny dark grayish chert of good quality. A single small leaf-shaped blank of grayish quartzite, a small chert scraper and a portion of the blade of an iron trade hoe were found.

The potsherds collected here are of a rather coarse and heavy character some of them being about one half inch in thickness. All are tempered with crushed stone. The two
