Q: Performing Outlier Detection I have some data that looks like the following: Each of the columns are some measurements of some data. What is the best way to remove the outliers in the data? I was thinking to use a standard deviation threshold, that is if the standard deviation of any of the column is greater than twice the mean of the column, then that means that the column is an outlier. But I feel like this would not be a very robust method and for example, I was thinking if it is a truly outlier that would make sense, but if the only difference in the mean is that for one of the columns I got 1 instead of 0.5, then the standard deviation will be almost the same and that will get in as a false positive. A: There's no standard test for outliers. The standard way to deal with data like this is to run outlier detection on each of your columns independently, and to let your data speak for itself. The fact that you have a very skewed distribution means that you should generally look for outliers in only one or a few of the columns at once, at least for computation reasons. You would usually eliminate outliers on the basis of visual inspection and/or hypothesis testing. For example: in the extreme case of a very sharply peaked bell-curve, you might pick on the basis of the maximum deviation from the mean. Similarly, you might pick on the basis of your data's standard deviation, or standard error. The other way to do it would be to calculate the Mahalanobis distance (see here, or here), and decide whether the data were less likely to be outliers in that case than in your data. You could also use multiple columns in a hypothesis test, and pick on the basis of the p-value. You would usually start with a test on each of the columns in order, and combine the results if there's a lot of overlap. Hypothesis testing is a trade-off between separation power (ideally, you want tests that find outliers that are generally distinct, rather than searches for "everything that is not normally distributed") and Type I error (to be expected if there really is an outlier, you want to be careful not to "call normal behavior normal behavior" by picking it as a point of reference). Here, the type I error of a test can be calculated easily on the basis of the hypotheses
