All professionals should have a copy of Photoshop on their computer in case you need it and don't want to install it. On the other hand, a competent photographer who needs to work with imagery should familiarize herself with GIMP. It's a free, open source cross-platform open-source image manipulation program. If you need to edit imagery in GIMP, you can. For more on GIMP, check out the online tutorial at `www.gimp.org` or buy a copy of the GIMP User Manual. However, don't expect to get any guidance on Adobe Photoshop from this book. Creating a New Project Photoshop saves a new document — that is, a blank canvas, the precursor to your images — with a name and a default setting. It's usually a good idea to have a name unique to this project to avoid confusion later. You can create new projects from any image that you want to manipulate. However, the programs I discuss in this chapter — GIMP, Affinity Photo, and Photoshop — are really designed to work with full-color images. After you create your new project, you should save it to a folder or disk. Saving an image is simple: Choose File⇒Save and then select the location for the new file. For example, you can save a new project in your `C:\` folder, but for simplicity, I save my new projects in the My Pictures folder. After you save the new file, Photoshop makes it available to you. To open it, choose Photoshop⇒Applications⇒Photoshop (or press Alt+N on your keyboard). From there, you can double-click on a saved file or open it from the New menu. Creating a new document with GIMP You use GIMP in much the same way you use Photoshop for raster images. The following steps show you how to create a new image. As with Photoshop, you see the 'old school' interface shown in Figure 4-3: 1. In GIMP, choose File⇒New. The New dialog box appears, as shown in Figure 4-3. 2. Name your new document. For example, call it background.jpg.

Q: Data grid won't show data I'm trying to create a Data Grid that will display data from an ArrayList. The method in the controller invokes the getData method (in the DAO) which returns the data and populates the ArrayList. The problem is that the Data Grid never displays the data, even when the getData method is printing to the console successfully. The data is there, the ArrayList is updated, the list item in the Data Grid View never updates. I've also tried the solution offered in this question Datagrid is not updating, using DataGridTemplateColumn and DataGridRow public class AndroidActivity1 : AndroidActivity { protected override void OnCreate(Bundle savedInstanceState) { base.OnCreate(savedInstanceState); // Set our view from the "main" layout resource setContentView(Resource.Layout.test); // Get our button from the layout resource, // and attach an event to it var button = FindViewById(Resource.Id.myButton); button.Click += button_Click; } void button_Click(object sender, System.EventArgs e) { var data = new Data(); var dao = new DAO(); dao.getData(data); ArrayList arraylist = new ArrayList(); arraylist.Add(data); dataGridView1.ItemsSource = arraylist; Console.WriteLine(arraylist); } } I expect the Data Grid View to update when I click the button. A: Based on your comment, this should solve your problem. public class AndroidActivity1 : AndroidActivity { protected override void OnCreate(Bundle savedInstanceState) {

Q: Select products from one specific store I have a form, which adds new products to the database and the system creates a store_id and a category_id for the product. The store_id and category_id are only numbers. The form I have added is selecting products from store_id, however I also want products from the category_id. So in a way I want to exclude the products from category_id if the products are from the store_id. Example From store_id 1, I want to select products with categories_id 5 and 6. From store_id 2, I want to select products with categories_id 3, 4 and 7. How can I do this? A: The short answer to your question is you can't, but not for any obvious reason. What you need is a "one-to-many relationship" between products and store and categories. This is called a "one-to-many relationship". Unfortunately in some cases MySQL may have a "one-to-many" relationship by default, but not in the case you're using it. The reason I'm mentioning this is that by the time you've come to these comments you'll have a lot of experience with one-to-one relationships and I want to be certain you have an understanding of them. Storing one-to-many relationships is possible because MySQL works using columns. The columns which store the one-to-many relationship are called junction tables. The first table is the one-to-one and has a primary key in common. The other table is the many and has a foreign key which references the primary key of the first table. If you're going to go any further, you should also look into what an extra column is doing in the junction table, in case it's acting as a "flag". The reason for this is that you can use this to distinguish between "one-to-many" and "one-to-one" relationships between tables. For example, a photo album might have a "parent album" relationship with that album having many photos. But there's no actual one-to-many relationship in the database, the "parent album" is just a note to say, "this photo album was part of a photo album before and you're viewing it now". As a final note, I'd recommend staying away from using a word like
