CHAPTER 24: GLOSSARY .................................................... 300
CHAPTER 1: INTRODUCTION TO
ZERTO VIRTUAL REPLICATION

Disaster recovery is the process of preparing for recovery or continuation of IT processing tasks that support critical business processes in the event of a threat to the IT infrastructure. Zerto's Long Term Retention is the additional process of enabling recovery of IT processing tasks after an extended period. This section describes Zerto Virtual Replication general concepts to enable replication and recovery in a virtual environment.

The following topics are described in this section:
- “What is Zerto Virtual Replication?”, below
- “Zerto Virtual Replication Architecture”, on page 9
- “How Zerto Virtual Replication Recovery Works”, on page 10
- “Zerto Analytics - Overview”, on page 10
- “Benefits of Using Zerto Virtual Replication”, on page 15

What is Zerto Virtual Replication?

Zerto Virtual Replication provides a business continuity (BC) and disaster recovery (DR) solution in a virtual environment, providing near real-time replication, with write-order fidelity, with minimal impact on product workloads. Fully automated orchestration delivers failover, failback, and reverse protection in one click. Non-disruptive disaster recovery testing gives you confidence that your DR solution will work predictably and consistently. Consistency groups ensure all virtual machines that comprise an application are protected in the exact same manner no matter where they are in the environment.

Zerto Virtual Replication provides a business continuity (BC) and disaster recovery (DR) solution in a virtual environment, providing near real-time replication, with write-order fidelity, with minimal impact on product workloads. Fully automated orchestration delivers failover, failback, and reverse protection in one click. Non-disruptive disaster recovery testing gives you confidence that your DR solution will work predictably and consistently. Consistency groups ensure all virtual machines that comprise an application are protected in the exact same manner no matter where they are in the environment.

With support for different hypervisors such as vSphere or Hyper-V, and public cloud sites such as Azure, workloads can be protected, migrated, and recovered, either within the same hypervisor environment or across hypervisor environments.

Zerto Virtual Replication is installed in both the protected and the recovery sites. The disaster recovery across these sites is managed by a browser-based user interface. Managing Zerto Virtual Replication is also possible programmatically, either via a set of RESTful APIs or PowerShell cmdlets.

Recovery that does rely on native replication functionality, such as recovery available with Microsoft Active Directory or SQL Server, can also be replicated using Zerto Virtual Replication, and whether the native replication functionality is used or not is determined by site considerations, such as increased complexity of having multiple points of control and possible additional costs incurred when using vendor native replication.

You configure replication by first pairing the site with the virtual machines to be protected, with a recovery site. You then define what virtual machines you want replicated in consistency groups, where the virtual machines in a group comprise the application and data you want to protect. You can group different virtual machines together or keep them separate. By creating different replication groups, you can customize the replication requirements for each group to better optimize the recovery plan.

Disaster recovery is based on the premise that you will want to recover with a minimum RPO. However, to enable full recovery in cases such as virus attacks, Zerto Virtual Replication provides the ability to recover to a point in time up to 30 days prior to the disaster. When recovery earlier than 30 days is required, Zerto Virtual Replication provides an extended recovery, using a Long Term Retention process mechanism that enables you to recover to a recovery site based on daily, weekly or monthly retention sets, going as far back as a year. The majority of the processing for both disaster recovery and extended recovery is done at the recovery site, minimizing the impact on the production site.
Zerto Virtual Replication Architecture

Zerto helps customers accelerate IT transformation by eliminating the risk and complexity of modernization and cloud adoption. By replacing multiple legacy solutions with a single IT Resilience Platform™, Zerto is changing the way disaster recovery, retention and cloud are managed. This is done by providing enterprise-class disaster recovery and business continuity software for virtualized infrastructure and cloud environments.

In on-premise environments, Zerto Virtual Replication is installed with virtual machines to be protected and recovered.

In public cloud environments, Zerto Cloud Appliance (ZCA) is installed in the public cloud site that is to be used for recovery.

The installation includes the following:

- **Zerto Virtual Manager** (ZVM): A Windows service that manages everything required for the replication between the protection and recovery sites, except for the actual replication of data. The ZVM interacts with the hypervisor management user interface, such as vCenter Server or Microsoft SCVMM, to get the inventory of VMs, disks, networks, hosts, etc. and then the Zerto User Interface manages this protection. The ZVM also monitors changes in the hypervisor environment and responds accordingly. For example, a VMware vMotion operation, or Microsoft Live Migration of a protected VM from one host to another is intercepted by the ZVM and the Zerto User Interface is updated accordingly.
  - For the maximum number of virtual machines, either being protected or recovered to that site, see Zerto Scale and Benchmarking Guidelines.

- **Virtual Replication Appliance* (VRA):** A virtual machine installed on each hypervisor hosting virtual machines to be protected or recovered, to manage the replication of data from protected virtual machines to the recovery site.
  - For the maximum number of volumes, either being protected or recovered to that site, see Zerto Scale and Benchmarking Guidelines.

  Note: *In vSphere installations, OVF to enable installing Virtual Replication Appliances.

- **Virtual Backup Appliance** (VBA): A Windows service that manages File Level Recovery operations within Zerto Virtual Replication.

- **Zerto User Interface:** Recovery using Zerto Virtual Replication is managed in a browser or, in VMware vSphere Web Client or Client console.

When Zerto Virtual Replication is installed to work with an on-premise hypervisor it also comprises the following component:

- **Data Streaming Service** (DSS): Installed on the VRA machine, and runs in the same process as the VRA. It is responsible for all the retention data path operations.

The following diagram shows how the main Zerto Virtual Replication components are deployed across hypervisor-based enterprise sites to provide disaster recovery across these sites.

Note: For the architecture diagrams when one of the sites is a cloud service provider, see Zerto Cloud Manager Administration Guide.
When you plan to recover the enterprise site to a public cloud, Zerto Virtual Replication is installed in the cloud environment. Zerto Virtual Replication comprises the same components but the VRA runs as a service, so that the ZVM, VRA, and VBA all run as services on a single virtual machine instance in the public cloud.

How Zerto Virtual Replication Recovery Works

Installing Zerto Virtual Replication installs the Zerto Virtual Manager, which sits in the hypervisor layer on the enterprise site. You manage the Zerto Virtual Manager, one on each of the protected and recovery sites, using the Zerto User Interface.

Zerto also provides a set of RESTful APIs and PowerShell cmdlets to enable incorporating some of the disaster recovery functionality within scripts or programs.

In the protected site you define the virtual machines that you want to replicate, either individually or together, as a virtual protection group (VPG). The virtual machines that you include in the VPG can come from one or more hypervisor hosts. In this way, you can protect applications that run on multiple virtual machines and disks as a single unit – a VPG. An example of an application that runs on multiple virtual machines includes software that requires a web server and database, both of which run on virtual machines different than the virtual machine where the application software runs.

A virtual machine can be included in several VPGs so that you can recover it to several sites, depending on the needs of the organization. For example the same workload can be protected to a local or a remote location as well as to the cloud. Using several recovery sites also enables migrating disaster recovery datacenters from one location to another.

Note: CD and DVD drives cannot be protected.

Every write is copied by Zerto Virtual Replication and sent, asynchronously, to the recovery site, while the write continues to be processed on the protected site. For greater efficiency and performance, the write can be compressed before being sent to the recovery site with throttling techniques being used to prioritize network traffic.

On the recovery site the write is written to a journal managed by a Virtual Replication Appliance (VRA). Each protected virtual machine has its own journal. Every few seconds, a checkpoint is also written to each journal. These checkpoints ensure write order fidelity and crash-consistency to each checkpoint. During recovery you pick one of these crash-consistent checkpoints and recover to this point. Additionally, checkpoints can be manually added by the administrator, with a description of the checkpoint. For example, when an event is going to take place that might result in the need to perform a recovery, you can pinpoint when this event occurs as a checkpoint written to each journal.

The VRA manages the journals for every virtual machine that will be recovered to the hypervisor hosting that VRA. It also manages images of the protected volumes for these virtual machines. During a failover, you can specify that you want to recover the virtual machines in the VPG using the last checkpoint or you can specify an earlier checkpoint, in which case the recovery of the mirror images under the VRA are synchronized to this checkpoint. Thus, you can recover the environment to the point before any corruption and ignore later writes in the journal that were corrupted, regardless of the cause of the corruption, such as a crash in the protected site or a virus attack.

To improve the RTO during recovery, the user is able to start working even before the virtual machine volumes on the recovery site have been fully synchronized. Every request is analyzed and the response returned either from the virtual machine directly or from the journal if the information in the journal is more up-to-date. This continues until the recovery site virtual environment is fully synchronized, up until the last checkpoint or an earlier checkpoint, when the integrity of the protected site was assured.

When recovery to a point is required that is further in the past than the time saved in the journal, you can restore from files created during the Retention process. Retention is an extension of disaster recovery, with the virtual machine files, such as the configuration and virtual disk files, saved to a repository for up to one year. These files are then used to restore the virtual machines to the point of the stored retention sets at the recovery site.
Zerto Analytics allows you to track and monitor the health of your entire protected environment from browsers and mobile devices.

Using Zerto Analytics, you can see aggregated information from the Zerto Virtual Managers, and view the status of your environment. All your alerts, tasks, events and information on Virtual Protection Groups (VPGs) can be viewed together. This allows you to monitor your Disaster Recovery and Business Continuity status from any location that has internet connectivity. No VPN is required.

Zerto Analytics is developed with an API first approach, therefore, everything that is presented in the GUI, is also available with APIs. The APIs are delivered with Swagger open source that help you develop and test REST integration using standardized examples. This allows to easily populate custom portals with Zerto Analytic content.

“Accessing the Zerto Analytics Portal”, on page 11
“Accessing Zerto Mobile”, on page 11
“Accessing Zerto Analytics APIs”, on page 11
“Using the Zerto Analytics Portal”, on page 11
“End-User Analytics for Service Providers”, on page 13
“SaaS Analytics Product Feature Matrix”, on page 14

Before Getting Started with Zerto Analytics
Verify the following:
■ At least 1 ZVM running Zerto Virtual Replication version 5.0 or higher.
■ Enable Zerto SaaS features check box is selected. This is accessed in the ZVM application in Settings > About.
■ Internet access.
■ A myZerto account using your corporate email address.

Accessing the Zerto Analytics Portal
Zerto Analytics is accessed from one of the following locations:
■ From a URL: https://analytics.zerto.com
■ From myZerto: www.zerto.com/myzerto. Sign in using your credentials and select the Analytics tab.

Accessing Zerto Mobile
The Zerto Mobile app is available for both iOS or Android operating systems.
Sign in using your myZerto credentials.

Accessing Zerto Analytics APIs
Zerto Analytics API documentation is accessed from:
■ https://docs.api.zerto.com/

Using the Zerto Analytics Portal
When accessing Zerto Analytics, the Dashboard tab opens by default. This tab displays a summary of the entire protected environment, including the average RPO and VPG health, site details and topology, active alerts, running tasks and events.
TIP:

Use the What's New 📝WHAT'S NEW and Help 🔄 widgets in Zerto Analytics to learn more about each of the features available in Zerto Analytics.

TIPS:

- Use the sites topology to identify sites without remote protection, to identify network issues and to identify cloud issues.
- To handle any issues in the ZVM site, in the Dashboard tab > SITES area, click the icon Open ZVM in a new tab. This routes you to the specific ZVM site.

In the same Sites area, click the Menu button to navigate to the VPGs, Alerts or Tasks for the specified site.

In addition to the Dashboard, there are three additional views that provide details on the overall health of your environment. See the following sections:

1. Monitoring Alerts, Events and Tasks
2. Troubleshooting VPGs
3. Reviewing Reports

Monitoring Alerts, Events and Tasks

From the Monitoring tab review the active alerts, alerts history, running events and tasks.

To see active alerts, events or tasks from a specific ZVM, use the filter in the top left of the screen. Events are displayed for the last 24 hours by default. Use the date selector to filter the Events List by date.

To view a history of alerts, select the Events tab and Alert History in the sub menu. Inactive alerts are displayed for the selected time range.

TIP:

Click the Alert ID and Event ID to open the help and view the full details for that specific alert or event.
**Troubleshooting VPGs**

From the **VPGs** tab, review the list of VPGs with Errors and Warnings. In the VPGs status area, click either VPGs with Warnings or VPGs with Errors to filter the VPGs list.

To review the status of a VPG, click in the column of the VPG you want to review to open the **VPG Details** page. From here you can view the details of the virtual machines associated with the VPG as well.

If you want to view the details of another VPG, select the VPG from the VPGs drop-down list.

---

**TIP:**

To further investigate about a selected VPG, click the **VPG History** button, and select to view either the **RPO, Journal or Network** Reports page. (See **Reviewing Reports** for more details about Reports).

---

**Reviewing Reports**

The SaaS Analytics reports provide real-time and historical data analysis. ECE and CSP licenses can view up to 90 days of report history. Use the date controller to filter your reports. Statistics are displayed according to the selected time frame.

---

**TIP:**

Zoom in to view more granular data by selecting and dragging your mouse over the selected time frame.

---

From the **Reports** tab, review the RPO, Journal and Network performance history on the VPGs.

Use the **Network** reports for reviewing the network history for any VPG or Site. You can also view the network summary for a selected time frame, the network performance history and IOPs history.

Use the **RPO** reports for viewing a summary to see if RPO SLAs are being met, the RPO history and the RPO breach table for viewing when the specific time breach occurred and the duration of the SLA breach.

Use the **Journal** reports for understanding if resilience is at risk due to journal storage capacity and plan for storage growth.

---

**End-User Analytics for Service Providers**

Service providers can filter their customers in Zerto Analytics using the ZORG filter located at the top of the screen.

Using the ZORG filter, CSPs can see historical data and status for any individual customer.

Additionally, using the Zerto Analytics **APIs**, CSPs can create custom reports and automate reporting delivery of real-time content to their customers. The APIs can also be used to provide content for customer portals.
### SaaS Analytics Product Feature Matrix

The following table lists the available features and from which ZVM version it's supported:

<table>

Benefits of Using Zerto Virtual Replication

Datacenter optimization and virtualization technologies have matured and are now commonly used in IT infrastructure. As more applications are deployed in a virtualized infrastructure, there is a growing need for recovery mechanisms that support mission critical application deployments while providing complete BC and DR.

Traditional replication and disaster recovery solutions were not conceived to deal with the demands created by the virtualization paradigm. For example, most replication solutions are not managed in the hypervisor layer, considering the virtual machines and disks, but at the physical disk level. Hence they are not truly virtualization aware.

The lack of virtualization awareness creates a huge operational and administrative burden. It also results in operational inflexibility. Zerto Virtual Replication has been designed to resolve these issues by being fully virtualization aware.

See the following topics:

- Fully Virtual – Sits in the Hypervisor or Cloud
- Hardware Agnostic
- Hypervisor Agnostic
- Focus is on the Application, Not the Physical Storage
- Compatibility Across Virtual Environments – Cross-Hypervisor Platform and Version Agnostic
- Fully Scalable
- Efficient Asynchronous Replication
- One-Click Failover and Control of the Recovery Process
- One-Click Migration
- File and Folder Recovery
- Long Term Retention
- Policy-based
- Minimal RPO
- WAN Optimization Between Protected and Recovery Sites
- WAN Resilience on Both the Protected and Recovery Sites
- DR Management Anywhere

Fully Virtual – Sits in the Hypervisor or Cloud

Zerto Virtual Replication software sits in the hypervisor level. Protection groups are configured with virtual machines and virtual disks, without the need to consider the physical disks.

Hardware Agnostic

Because Zerto Virtual Replication software manages recovery of virtual machines and virtual disks only, it does not matter what hardware is used in either the protected or recovery sites; it can be from the same vendor or different vendors. With Zerto Virtual Replication the logical storage is separated from the physical storage so that the vendor and actual type of storage hardware do not need to be considered.

Zerto Virtual Replication provides a workload mobility and protection layer providing seamless connectivity, portability, protection, orchestration, and application encapsulation of workloads across clouds without vendor lock-in. High scale, mission critical applications, and data are encapsulated, as well as features, specifications, and configurations, and can be seamlessly migrated across different servers, storage, hypervisors, and clouds without any disruption to business services.

With Zerto Virtual Replication, IT managers can choose the right infrastructure for the right use case for the right price. One application can leverage several different environments for disaster recovery, bursting, production, retention, testing, and development. With Zerto Virtual Replication there is no vendor lock-in to a cloud, technology, or vendor. Any choice, any cloud, any technology, any price, any service level is available in minutes for any workload.

Hypervisor Agnostic

Zerto Virtual Replication runs both in VMware vCenter Server and Microsoft SCVMM. It is compatible with VMware hypervisor management features, such as vMotion and Microsoft hypervisor management features, such as Live Migration.
Focus is on the Application, Not the Physical Storage

By considering the physical disk level and not the virtual disk level, traditional replication is not truly application aware. Even virtual replication recovers block writes at the SCSI level and not at the application level. Zerto Virtual Replication is truly application focused, replicating the writes from the application in a consistent manner.

Compatibility Across Virtual Environments – Cross-Hypervisor Platform and Version Agnostic

Zerto Virtual Replication enables replication across multiple hypervisor managers, such as VMware vCenter Server and Microsoft SCVMM, and to public clouds such as Amazon Web Services (AWS) or Microsoft Azure. You can protect virtual machines in one hypervisor platform and recover to a different hypervisor platform. This feature can also be used to migrate virtual machines to a different hypervisor platform.

Also, virtual machines running in one version a hypervisor can be recovered in a different version of the same type of hypervisor, as long as Zerto Virtual Replication supports the hypervisor versions, virtual machines can be protected across versions.

Fully Scalable

Zerto Virtual Replication enables defining software-only Virtual Replication Appliances (VRAs) on each hypervisor host to manage the replication of virtual machines on that host. Increasing the number of hypervisor hosts is handled by defining a new VRA on each new host. There is no need to install additional software to the hypervisor management tool, such as VMware vCenter Server or Microsoft SCVMM, to handle additional hosts or virtual machines and no need to consider additional hardware acquisitions.

Efficient Asynchronous Replication

Writes are captured by the Zerto Virtual Replication software in the hypervisor level, before they are written to the physical disk at the protected site. These writes are sent to the recovery site asynchronously, thus avoiding long distance replication latency for the production applications.

Also, because these writes are captured and sent to the recovery site, it is only the delta changes and not the whole file or disk that is sent to the recovery site, reducing the amount of network traffic, which reduces WAN requirements and significantly improves the ability to meet both RPO and RTO targets.

One-Click Failover and Control of the Recovery Process

When recovery is required, the administrator clicks on a button in the Zerto User Interface to initiate failover. This means that controlling the start of a recovery remains in the hands of the administrator, who can decide when to initiate the recovery and, by selecting a checkpoint, to what point-in-time to recover to.

One-Click Migration

Application migrations can be resource intensive projects that take weeks of planning, execution, and downtime. With Zerto Virtual Replication migrations are greatly simplified and can be completed without extended outages or maintenance windows and across different types of hardware and even different hypervisors, such as VMware ESXi or Microsoft Hyper-V. Migrations across different versions within a type of hypervisor, such as from a VMware vCenter environment to a vCloud environment or even cross hypervisor migration, such as migration from a vCenter environment to a Hyper-V environment is as easy as a migration from one site to another using the same hypervisor infrastructure.

File and Folder Recovery

You can recover specific files and folders from the recovery site for virtual machines that are being protected by Zerto Virtual Replication and running Windows or Linux operating systems. You can recover the files and folders from a specific point-in-time.

You can choose to recover one or several files or folders from the recovery site.
Long Term Retention

Zerto Virtual Replication provides a Retention option that enables saving the protected virtual machines for up to one year in a state where they can be easily deployed. Because retention uses the same mechanism used for disaster recovery, there is no performance impact on the production site, since the processing is performed on the recovery site. The data copied for retention are fixed points saved daily, weekly or monthly.

**Note:** Zerto recommends weekly retention sets.

Policy-based

In the protected site you define the virtual machines that you want to recover, either individually or as groups, as a virtual protection group (VPG). The virtual machines that you include in the VPG can come from one or more hypervisor hosts. In this way, you can protect applications that run on multiple virtual machines and disks as a single unit, in a single VPG.

Minimal RPO

Zerto Virtual Replication utilizes continuous data protection, sending a record of every write in the virtual protection group to the recovery site. The transfer of this information is done over an optimized WAN asynchronously. If recovery is required, all the data that was transferred to the recovery site is available resulting in recovery within the requested RPO.

WAN Optimization Between Protected and Recovery Sites

Using compression to minimize bandwidth and other techniques such as throttling to prioritize network traffic to reduce the impact on day-to-day operations, you can make sure that the communication between the protected and recovery sites is fully optimized.

Zerto Virtual Replication also uses signature matching to reduce the amount of data sent across the WAN. During synchronization of the protected site and recovery site for every virtual machine in a VPG, Zerto Virtual Replication maintains a map of disk sectors so that if there is a need to resynchronize sites, the map signatures can be used to ensure that only data where changes occurred are passed over the WAN.

WAN Resilience on Both the Protected and Recovery Sites

Zerto Virtual Replication is highly resilient to WAN interruptions. In order to reduce storage overhead used for replication purposes, on WAN failure or when the load over the WAN is too great for the WAN to handle, Zerto Virtual Replication starts to maintain a smart bitmap in memory, in which it tracks and records the storage areas that changed. Since the bitmap is kept in memory, Zerto Virtual Replication does not require any LUN or volume per VPG at the protected side. The bitmap is small and scales dynamically, but does not contain any actual IO data, just references to the areas of the protected disk that have changed. The bitmap is stored locally on the VRA within the available resources. Once the WAN connection resumes or the load returns to normal traffic, Zerto Virtual Replication uses this bitmap to check whether there were updates to the protected disks and if there were updates to the disks, these updates are sent to the recovery site.

DR Management Anywhere

With Zerto Virtual Replication everything is managed from a standalone browser-base user interface, enabling disaster recovery management from anywhere using any device.
CHAPTER 2: ACCESSING THE ZERTO USER INTERFACE

You manage the protection and replication of virtual machines in Microsoft System Center Virtual Machine Manager (SCVMM), between the protected and recovery sites, using the Zerto User Interface. On first access to the user interface, you might have to add a security certificate to set up secure communication. Zerto also provides a set of RESTful APIs and PowerShell cmdlets to enable incorporating some of the disaster recovery functionality within scripts or programs.

You manage the protection and replication of virtual machines between the protected and recovery sites using Zerto Virtual Manager Web Client.

**Note:** Microsoft Windows Explorer 9 is not supported and version 10 does not work well with the user interface. Zerto recommends using Chrome, Firefox, or later versions of Internet Explorer.

**Note:** You must exclude both the Zerto Virtual Replication folder and %ProgramData%\Zerto\Data\zvm_db.mdf from antivirus scanning. Failure to do so may lead to the Zerto Virtual Replication folder being incorrectly identified as a threat and in some circumstances corrupt the Zerto Virtual Replication folder.

The following topics are described in this chapter:

- “Using the Zerto Virtual Manager Web Client”, below
- “Adding a Security Certificate for the Zerto User Interface”, on page 18
- “Working With the Zerto User Interface”, on page 20

### Using the Zerto Virtual Manager Web Client

1. In a browser, enter the following URL:
   ```
   https://zvm_IP:9669
   ```
   where zvm_IP is the IP address of the Zerto Virtual Manager for the site you want to manage.

2. Login using the user name and password for the machine where you installed Zerto Virtual Replication.
   - **Username:** The user name for the user for the machine where the Zerto Virtual Manager is installed. If the user is part of a domain, you must also specify the domain, with the following format:
     ```
     domain\username
     ```
   - **Password:** A valid password for the given user name.

### Adding a Security Certificate for the Zerto User Interface

Communication between the Zerto Virtual Manager and the user interface uses HTTPS. On the first login to the Zerto User Interface, you must install a security certificate in order to be able to continue working without each login requiring acceptance of the security.

**To install a security certificate for the Zerto User Interface:**

On first access to the Zerto User Interface, if you haven’t installed the security certificate, a security alert is issued.

Note the following:

- To run this procedure run Microsoft Internet Explorer as administrator. The procedure is similar for Google Chrome and for Mozilla Firefox.
- Access the Zerto User Interface using the IP and not the name of the machine where Zerto Virtual Replication is installed.

1. Click **View Certificate**.
   - The Certificate dialog is displayed.
2. Click **Install Certificate**.
The Certificate Import wizard dialog is displayed.

3. Follow the wizard: Place all the certificates in the **Trusted Root Certification Authorities store**: Select the **Place all certificates in the following store** option and browse to select the **Trusted Root Certification Authorities store**.

![Certificate Import Wizard](image1)

4. Continue to the end of the wizard. Click **Yes** when the Security Warning is displayed.

![Security Warning](image2)

5. Click **OK** that the installation was successful.
6. Click **OK** when prompted and then **Yes** in the **Security Alert** dialog to continue.
Working With the Zerto User Interface

After logging on to the Zerto User Interface for the first time, the dashboard is displayed. The dashboard provides summary information about the status of the site, as shown in the following diagram:

Use the tabs to access the specific information you want:

- **DASHBOARD**: General information about the site, including the status of the VPGs being protected or recovered to the site.
- **VPGs**: All the VPGs from both the local and remote sites and provides summary details of each VPG.
- **VMs**: All the protected virtual machines from both the local and remote sites and provides summary details of each virtual machine.
- **SITES**: Details of the paired sites. This tab lists all the paired sites to the local site and provides summary details of each paired site.
- **SETUP**: Details about VRAs, storage and repositories.
- **RETENTION STATUS**: Details of the retention repository jobs either by VPG or virtual machine. This tab lists all the defined retention sets and their statuses.
- **MONITORING**: Details about the alerts, events and tasks for the site.
- **REPORTS**: General reports.

Zerto User Interface - Subtabs

You can see and manage details for a specific VPG and VRA from different perspective, from the SETUP, RETENTION STATUS and MONITORING tabs. For example, under SETUP, from the subtabs, you can manage VRAs, Storage/Datastores and Repositories.
Zerto User Interface - Views

Lists can be displayed with different views. For each view you can filter the information in columns via the filter icon next to each column title. Clicking the column title enables sorting the column in ascending to descending order.

You can customize the default views or add a new view by clicking the view configuration button.

Customize a default view by selecting Show/Hide Columns and then checking the columns you want displayed. Create a new view by selecting Create View.
There are a number of configuration tasks that you should do as part of the initial site configuration.

The following configuration topics are described in this chapter:

■ “Enabling Replication to the Same Site”, below
■ “WAN Sizing”, on page 23

### Enabling Replication to the Same Site

When a single SCVMM is used, for example with remote branch offices, when replicating from one datacenter to another datacenter, both managed by the same SCVMM, you must enable replication to the same SCVMM and pairing is not required. In this case, replication to the same SCVMM must be set in the Site Settings dialog.

**To enable replication to the same SCVMM:**

1. In the Zerto User Interface, click SETTING ( ) in the top right of the header and select Site Settings. The Site Settings dialog is displayed.

2. Click Policies.
3. Select the **Enable Replication to Self** checkbox.
4. Click **APPLY** or **SAVE**.

The Zerto Virtual Manager, when used to protect to itself, can manage the protection of up to 5000 virtual machines.

---

**WAN Sizing**

When preparing your deployment, you need to verify that the connectivity between the two sites has bandwidth capacity that can handle the data to be replicated between the sites.

For minimum bandwidth requirements, see **Zerto Scale and Benchmarking Guidelines**.

Zerto Virtual Replication employs sophisticated compression algorithms to reduce the bandwidth required between the sites. While compression can be very effective in reducing the bandwidth requirements, its efficiency is dependent on data characteristics.

**Note:** Zerto Virtual Replication can also work with third-party WAN optimization and acceleration technologies, such as those supplied by Riverbed Technologies and Silver Peak.

Estimating the bandwidth requirements between the protected and recovery sites involves the following:

1. “Collecting Data Characteristics for VMs”, on page 23.

**Note:** When the recovery site is Amazon Web Services (AWS), you estimate the required bandwidth for the protected machines as described below.

---

**Collecting Data Characteristics for VMs**

You can collect data characteristics for the virtual machines in a VPG in one of the following ways:

- By using operating system performance monitors, such as the Windows Performance Monitor utility or the `iostat` command for Linux operating systems.
- By using Windows PowerShell in Windows Server 2012 to collect network utilization (and other information). When using metering ACLs, you can measure the total network traffic sent and received by a virtual machine. To collect performance characteristics for the virtual machines in a VPG, using PowerShell, do the following:
  - Turn on resource metering for the relevant virtual machines, if it is not already enabled.
  - Adjust the collection frequency, if necessary.
  - Collect the relevant statistics.
Turning on Resource Metering

By default, resource metering is not enabled. To turn on resource metering for one virtual machine, enter the following PowerShell command:

```powershell
Get-VM <VM-name> | Enable-VMResourceMetering
```

To turn on monitoring for all virtual machines on a server at one time, enter the following PowerShell command:

```powershell
Get-VM | Enable-VMResourceMetering
```

Once you enable resource metering, Hyper-V begins to collect data. You can reset metering at any time, which discards the data that has been collected up to that point.

If resource metering is enabled but no NetworkAdapterAcls are configured, Hyper-V configures them to measure total network traffic. To measure network traffic through an IP range, configure the NetworkAdapterAcls for the IP range before running Enable-VMResourceMetering.

Adjusting the Collection Frequency

By default, the collection frequency is once every hour. You can change the collection frequency, but understand that data collection can impact performance. To change the collection frequency, enter the following command:

```powershell
Set-VMHost -ComputerName <host-server-name> -ResourceMeteringSaveInterval <HH:MM:SS>
```

The collection frequency is always set at the host server level. You cannot adjust the collection frequency per virtual machine. For example, if you enter 01:30:00, resource consumption will be collected every hour and a half.

Collecting and Viewing the Relevant Statistics

To view resource usage for one virtual machine, enter the following command:

```powershell
Get-VM <VM-name> | Measure-VM
```

Resource metering data can be displayed for all of the virtual machines that are running on a host. To see data for all of the virtual machines on a host, enter the following command:

```powershell
Get_VM | Measure-VM
```

You can configure PowerShell to display only certain statistics. To do this, you must know the object names that PowerShell assigns to each statistic. You can see the object names by entering the following command:

```powershell
Get-VM | Measure-VM | Select-Object *
```

For example, when working with Zerto Virtual Replication, you are interested in network traffic. To list the network traffic for each virtual machine, enter the following command:

```powershell
Get-VM | Measure-VM | Select-Object VMName, NetworkMeteredTrafficReport
```

You can use VM Network Adapter ACLs to measure network activity to and from a specific network. For example, to meter network traffic for a special subnet or IP address:

```powershell
Add-VMNetworkAdapterAcl -VMName <VM-name> -Action Meter -RemoteIPAddress 10.10.0.0/16 -Direction Outbound
```

Turning off Resource Metering

To disable the collection of performance statistics, enter the following PowerShell command:

```powershell
Disable-VMResourceMetering -VMName <VM-name>
```
Calculating the Estimated Bandwidth Requirement

Use the average write rate for the virtual machines in a VPG in the Zerto WAN Sizing Estimator to estimate the minimum bandwidth required.

For each VM you also must decide whether compression will be enabled for the VM, based on the data characteristics.

Use one of the following procedures:

- Estimating sizing using the Zerto WAN Sizing Estimator
- Estimating sizing without using the Zerto WAN Sizing Estimator

Estimating sizing using the Zerto WAN Sizing Estimator

To estimate sizing using the Zerto WAN Sizing Estimator:

1. Open the Zerto WAN Sizing Estimator.
2. Enter the following information in the VM data sheet:
   - The VM name.
   - The Write KB/s data, based on the statistics gathered in the previous task. Use a period for the decimal mark.
   - Define whether compression is enabled for this VM: Select Yes or No.
   - The application data characteristics: Select Compressed or Compressible.
     The Zerto WAN Sizing Estimator colors the cell red if you decide to employ compression on compressible data and orange if you decide to avoid compression for compressible data.
3. The Zerto WAN Sizing Estimator estimates the total bandwidth needed for your deployment, using a minimum value of 5 Mb/sec.
   The estimation is displayed on the top of each page of the Zerto WAN Sizing Estimator.

To estimate the WAN sizing required without using the Zerto WAN Sizing Estimator, using the following procedure.

Estimating sizing without using the Zerto WAN Sizing Estimator

To estimate sizing without using the Zerto WAN Sizing Estimator:

1. For each virtual machine in the VPG multiply the KB/sec (which is based on the statistics gathered) by 8, and divide the result by 1024 to provide an answer in Mb/sec.
   - If compression is enabled for the VM and the data is compressible, divide this result by 2.
2. Sum the results of 1.

\[
\text{WAN Mb/sec} = \text{SUM(KB/sec \times (8/1024/(1 or 2 if compressible data that will be compressed)))}
\]

The result is an estimate of the required Mb/sec for the WAN.

Note: If the result is less than 5 Mb/sec, see Zerto Scale and Benchmarking Guidelines for minimum bandwidth requirements.
Virtual machines are protected in virtual protection groups. A virtual protection group (VPG) is a group of virtual machines that you group together for recovery purposes. For example, the virtual machines that comprise an application like Microsoft Exchange, where one virtual machine is used for the software, one for the database, and a third for the Web Server require that all three virtual machines be replicated to maintain data integrity.

Any virtual machine whose operating system is supported in both the protected site and recovery site can be protected in a VPG.

Once a virtual machine is protected, all changes made on the machine are replicated in the remote site. The replicated virtual machines in the remote site can be recovered to any point in time defined for the VPG or if a period further in the past is required, a retention set can be restored.

When a VPG is created, a replica of each virtual machine disk in the VPG is created under a VRA on the recovery site. These replica virtual disks must be populated with the data in the protected virtual machines, which is done by synchronizing the protected virtual machines with the recovery site replicas. This synchronization between the protected site and remote site takes time, depending on the size of the virtual machines.

After the initial synchronization completes, only the writes to disk from the virtual machines in the protected site are sent to the remote site. These writes are stored by the VRA in the remote site in journals for a specified period, after which they are promoted to the replica virtual disks managed by the VRA.

The number of VPGs that can be defined on a site is limited only by the number of virtual machines that can be protected.

For the maximum number of virtual machines, either being protected or recovered to a site, see Zerto Scale and Benchmarking Guidelines

Note: If the total number of protected virtual machines on the paired sites is 5000, then any additional machines are not protected.

Any virtual machine that is supported by the hypervisor can be protected. When recovering to a different hypervisor, the protected virtual machines must also be supported by the recovery hypervisors.

The following topics are described in this chapter:

- “Configuring Virtual Protection Groups”, below
- “The Role of the Journal During Protection”, on page 27
- “What Happens After the VPG is Defined”, on page 29

Configuring Virtual Protection Groups

Use the following guidelines:

- You protect one or more virtual machines in a VPG.
- The VPG must include at least one virtual machine.
- After creating a VPG, you can add or remove virtual machines as required.
- You can only protect a virtual machine in a VPG when the virtual machine has no more than 60 disks.

The 60 disks can be a combination of IDE and SCSI disks, where each virtual machine can have up to 2 IDE controllers each with a maximum of 4 IDE disks and up to 4 SCSI controllers each with a maximum of 15 disks, so that the total of IDE and SCSI disks does not exceed 60 disks.

When the recovery site is VMware vSphere, any IDE disks are converted to SCSI disks. When the recovery site is Amazon Web Services (AWS), you can only protect virtual machines in the protected site that are supported by AWS in the recovery site and the maximum number of supported disks is 12 for virtual machines running a Windows operating system and 1 for virtual machines running a Linux operating system.

You can protect a virtual machine in several VPGs. A virtual machine can be in a maximum of three VPGs. VPGs that contain the same virtual machine cannot be recovered to the same site.
Note: Protecting virtual machines in several VPGs is enabled only if both the protected site and the recovery site, as well as the VRAs installed on these sites, are of version 5.0 and higher.

The virtual machines can be defined under a single hypervisor host or under multiple hosts. The recovery can also be to a single host or multiple hosts. The virtual machines are recovered with the same configuration as the protected machines. For example, if a virtual machine in the protected site is configured so that space is allocated on demand and this machine is protected in a VPG, then during recovery the machine is defined in the recovery site with the same space allocation configuration. You protect virtual machines by creating the VPG on the site hosting these virtual machines. After the VPG is created, you can add or remove virtual machines from the VPG by editing the VPG in the Zerto User Interface running on either the protected or recovery site.

Note: To create a VPG you must have a recovery site available with a host with a VRA installed. The recovery site can either be a remote site, paired with the protected site, or the protected site itself, where both protection and recovery are to the same Zerto Virtual Manager site.

The VPG definition consists of the following:

General: A name to identify the VPG and the priority to assign to the VPG.

Virtual machines: The list of virtual machines being protected as well as the boot order and boot delay to apply to the virtual protection groups during recovery.

Replication Settings: VPG replication settings, such as the recovery site, host and storage and the VPG SLA. SLA information includes the default journal history settings and how often tests should be performed on the VPG. The defaults are applied to every virtual machine in the VPG but can be overridden per virtual machine, as required.

Cloud service providers can group the VPG SLA properties together in a service profile. When a service profile is used, the VPG SLA settings cannot be modified unless a Custom service profile is available.

Storage Settings: By default the storage used for the virtual machine definition is also used for the virtual machine data. This storage can be overridden per virtual machine, as required.

Recovery Settings: Recovery details include the networks to use for recovered virtual machines and scripts that should be run either at the start or end of a recovery operation.

NIC Settings: Specify the network details to use for the recovered virtual machines after a live or test failover or migration.

Retention Policy Settings: Specify the VPG’s retention properties, including the repository where the retention sets are saved.

The Role of the Journal During Protection

After defining a VPG, the protected virtual machine disks are synced with the recovery site. After initial synchronization, every write to a protected virtual machine is copied by Zerto Virtual Replication to the recovery site. The write continues to be processed normally on the protected site and the copy is sent asynchronously to the recovery site and written to a journal managed by a Virtual Replication Appliance (VRA). Each protected virtual machine has its own journal.

In addition to the writes, every few seconds all journals are updated with a checkpoint time-stamp. Checkpoints are used to ensure write order fidelity and crash-consistency. A recovery can be done to the last checkpoint or to a user-selected, crash-consistent, checkpoint. This enables recovering the virtual machines, either to the last crash-consistent point-in-time or, for example, when the virtual machine is attacked by a virus, to a point-in-time before the virus attack.

Data and checkpoints are written to the journal until the specified journal history size is reached, which is the optimum situation. At this point, as new writes and checkpoints are written to a journal, the older writes are written to the virtual machine recovery virtual disks. When specifying a checkpoint to recover to, the checkpoint must still be in the journal. For example, if the value specified is 24 hours then recovery can be specified to any checkpoint up to 24 hours. After the time specified, the mirror virtual disk volumes maintained by the VRA are updated.

During recovery, the virtual machines at the recovery site are created and the recovery disks for each virtual machine, managed by the VRA, are attached to the recovered virtual machines. Information in the journal is promoted to the virtual machines to bring them up to the date and time of the selected checkpoint. To improve the RTO during recovery, the virtual machine can be used even before the journal data has been fully promoted. Every request is analyzed and the response is returned from the virtual machine directly or, if the information in the journal is more up-to-date, it comes from the journal. This continues until the recovery site’s virtual environment is fully restored to the selected checkpoint.
Each protected virtual machine has its own dedicated journal, consisting of one or more volumes. A dedicated journal enables journal data to be maintained, even when changing the host for the recovery. The default storage used for a journal is the storage used for recovery of each virtual machine. Thus for example, if protected virtual machines in a VPG are configured with different recovery storage, the journal data is by default stored for each virtual machine on that virtual machine recovery storage.

The journals for the protected virtual machines are defined as part of the VPG definition and by default are defined to reside on the same storage as the virtual machine. This can be overridden at the virtual machine and VPG levels as follows.

<table>

</tbody>
</table>

**Journal Sizing**

The journal space is always allocated on demand. The provisioned journal size initially allocated for a journal is 16GB. The provisioned journal size is the current size of all the journal volumes.

If the journal grows to approximately 80% of the provisioned journal size or less than 6GB remains free, a new volume is added to increase the journal size. Each new journal volume added is bigger than the previous volume. The journal size can increase up until a specified hard limit. If the size of the journal is reduced in the VPG definition after new volumes have been added, these volumes are not reduced and continue to be used if required. In this case, the journal size can be bigger than the set size and the reduced journal size definition is not applied, except to ensure that no new volumes are created if the new journal size is reached or exceeded.

The provisioned journal size reported in the Resources report can fluctuate considerably when new volumes are added or removed.

When the amount of the journal used is approximately 50% of the provisioned journal size, the biggest unused journal volume from the added volumes is marked for removal. This volume is then removed after the time equivalent to three times the amount specified for the journal history, or twenty-four hours, whichever is more if it is still not used.

Reclaiming space

The size of the datastore where the journal resides must have at least 30GB free, or have 15% free space, relative to the total datastore space, whichever number of GBs is smaller.

If the available storage of the journal datastore falls below 30GB or 15% of the total datastore size:

- The datastore itself is considered full.
- An error alert is issued and all writes to the journal volumes that datastore storage are blocked.
- Replication is halted, but history is not lost.
- The RPO begins to steadily increase until additional datastore space is made available.

Examples:

- For a large (2TB) datastore: 15% free space remaining = 307GB.
  
  The ZVM would not consider the datastore full if 307GB of free space were remaining. 30GB free space remaining would trigger an alert, as it is the smaller figure.
For a small (100GB) datastore: 15% free space remaining = 15GB.

The ZVM would not consider the datastore full if 30GB of free space were remaining. 15GB free space remaining would trigger an alert, as it is the smaller figure.

For a volume does not change the provisioned journal size, which is the current size of all the journal volumes.

When a virtual machine journal comes close to a specified hard limit, Zerto Virtual Replication starts to move data to the target disks. Once this begins, the maintained history begins to decrease. If the journal history falls below 75% of the value specified for the journal history, a warning alert is issued in the GUI. If the history falls below one hour, an error is issued. However, if the amount of history defined is only one hour, an error is issued if it is less than 45 minutes.

The size of the datastore where the journal resides must have at least 30GB free, or have 15% free space, relative to the total datastore space, whichever number of GBs is smaller.

If the available storage of the journal datastore falls below 30GB or 15% of the total datastore size:

- The datastore itself is considered full.
- An error alert is issued and all writes to the journal volumes that datastore storage are blocked.
- Replication is halted, but history is not lost.
- The RPO begins to steadily increase until additional datastore space is made available.

Examples:

- For a large (2TB) datastore: 15% free space remaining = 307GB.
  The ZVM would not consider the datastore full if 307GB of free space were remaining. 30GB free space remaining would trigger an alert, as it is the smaller figure.
- For a small (100GB) datastore: 15% free space remaining = 15GB.
  The ZVM would not consider the datastore full if 30GB of free space were remaining. 15GB free space remaining would trigger an alert, as it is the smaller figure.

Testing Considerations When Determining Journal Size

When a VPG is tested, either during a failover test or before committing a Move or Failover operation, a scratch volume is created for each virtual machine being tested. The scratch volume created uses the same size limit defined for the virtual machine journal.

The size limit of the scratch volume determines the length of time that you can test for. Larger limits enable longer testing times if the constant rate of change is constant. If a small hard limit size is set for this amount of history, for example 2–3 hours, the scratch volume created for testing will also be small, thus limiting the time available for testing.

What Happens After the VPG is Defined

After defining a VPG, the VPG is created. For the creation to be successful, the storage used for the recovery must have either 30GB free space or 15% of the size free. This requirement ensures that during protection the VRA, which manages the virtual machine journal and data, cannot completely fill the storage, which would result in the VRA freezing and stopping to protect all virtual machines using that VRA.

The VRA in the remote site is updated with information about the VPG and then the data on the protected virtual machines are synchronized with the replication virtual machines managed by the VRA on the recovery site. This process can take some time, depending on the size of the VMs and the bandwidth between the sites.

During this synchronization, you cannot perform any replication task, such as adding a checkpoint.

For synchronization to work, the protected virtual machines must be powered on. The VRA requires an active IO stack to access the virtual machine data to be synchronized across the sites. If the virtual machine is not powered on, there is no IO stack to use to access the protected data to replicate to the target recovery disks and an alert is issued.

Once synchronized, the VRA on the recovery site includes a complete copy of every virtual machine in the VPG. After synchronization the virtual machines in the VPG are fully protected, meeting their SLA, and the delta changes to these virtual machines are sent to the recovery site.
For details of the screen, see “Monitoring a Single VPG”, on page 114.

**Recovery**

After initializing the VPG, all writes to the protected virtual machines are sent by the VRA on the relevant host for each virtual machine on the protected site to the VRA on the recovery site specified as the recovery host for the virtual machine. The information is saved in the journal for the virtual machine with a timestamp, ensuring write-fidelity. Every few seconds the Zerto Virtual Manager writes a checkpoint to every journal on the recovery site for every virtual machine in the VPG, ensuring crash-consistency.

The data remains in the journal for the time defined by the journal history configuration, after which it is moved to the relevant mirror disks for each virtual machine. Both the journal and the mirror disks are managed by the VRA.

When recovering, either a failover or move, or testing failover or cloning protected virtual machines in the recovery site, you specify the checkpoint at which you want the recovered virtual machines to be recovered. The mirror disks and journal are used to recover the virtual machines to this point-in-time.

**File and Folder Recovery**

After initializing the VPG, instead of recovering a virtual machine, you can recover specific files and folders in the protected virtual machines from a checkpoint.
Zerto Virtual Replication enables protecting virtual machines, for both disaster recovery or for extended, longer term recovery from a retention repository, by protecting the relevant virtual machines in virtual protection groups. A virtual protection group (VPG) is a group comprised of virtual machines that are grouped together for recovery purposes. For example, the virtual machines that comprise an application like Microsoft Exchange, where one virtual machine is used for the software, one for the database, and a third for the Web Server require that all three virtual machines be replicated to maintain data integrity.

Once a VPG has been created, each virtual machine in the VPG can be replicated on the recovery site under the VRA on the host specified in the VPG definition as the host for the recovery of the virtual machine.

In addition to disaster recovery and recovery from retention, Zerto Virtual Replication enables recovery of individual files or folders from a certain point of time.

The following are described in this section:

■ “What is Zerto’s Disaster Recovery Operation?”, below
■ “What is Zerto’s File or Folder Level Restore?”, on page 32
■ “What is Zerto’s Long Term Retention and Restore VPG?”, on page 32

What is Zerto’s Disaster Recovery Operation?

Disaster recovery using Zerto Virtual Replication enables recovering from a disaster to any point between the moment just before the disaster and a specified amount of time in the past up to 30 days. The recovery is done in real time at the recovery site with a minimal RTO.

A recovery operation is one of the following:

■ A failover.
■ A planned move of the protected virtual machines from the protected site to the recovery site.
■ A clone of the protected virtual machine to the recovery site.

What is Zerto’s Disaster Recovery Operation in On-Premise Environments?

Virtual machines are protected in VPGs. Once a VPG is created, Zerto Virtual Replication creates a copy under the management of a Virtual Replication Appliance, VRA, on the recovery site, of the protected virtual machine files, such as the configuration and data files. A VRA is installed on every host where the machines are to be recovered.

When a recovery operation is performed, the VRA creates the virtual machines defined in the VPG and attaches the virtual disks to these machines. It then promotes the data from the journal to the virtual machine disks.

Every write to the protected virtual machine in a VPG is copied by the VRA on the same host as the protected machine and passed to the VRA on the host in the recovery site. The VRA on the host in the recovery site was specified in the VPG definition as the host for the recovery of the virtual machine. These writes first are saved in a journal for a specified period, and then moved to replica virtual disks managed by the VRA, which mirror the protected virtual machine disks.

The following link references the appropriate procedure to protect virtual machines:

<table>
<thead>
<tr>
<th>Recovery from: Hyper-V</th>
<th>Protecting Virtual Machines from Hyper-V</th>
</tr>
</thead>
</table>

After initializing the VPG, all writes to the protected virtual machines are sent by the VRA on the relevant host for each virtual machine on the protected site to the VRA on the recovery site specified as the recovery host for the virtual machine. The information is saved in the journal for the virtual machine with a timestamp, ensuring write-fidelity. Every few seconds the Zerto Virtual Manager causes a checkpoint to be written to every journal on the recovery site for every virtual machine in the VPG, ensuring crash-consistency.

The data remains in the journal until the time specified for the journal when it is moved to the relevant mirror disks, also managed by the VRA for the virtual machine. In this way, you can recover the virtual machines using the mirror disks and then promoting the data from the journal to include the final few hours of data for each virtual machine. For more details about the journal, see “The Role of the Journal During Protection”, on page 27.
Overview of Recovery Flows

The following references the operations to recover virtual machines which are protected in a VPG:

- “Overview of Disaster Recovery Operations”, on page 182
- “Managing Failover Live”, on page 206
- “Migrating a VPG to the Recovery Site”, on page 197
- “Cloning a VPG to the Recovery Site”, on page 215

What is Zerto's Test Failover Operation in On-Premise Environments?

When testing that the recovery works as planned, the VRA creates the virtual machines defined in the VPG and uses scratch disks to simulate the virtual machine disks for the duration of the test. This enables the ongoing protection of the virtual machines and the possibility of a failover if required during the test.

The following references the procedure to recover virtual machines:

- “Overview of Disaster Recovery Operations”, on page 182
- “Testing Recovery”, on page 186

What is Zerto's File or Folder Level Restore?

You can recover specific files and folders from the recovery site for virtual machines that are being protected by Zerto Virtual Replication and running Windows operating systems. You can recover the files and folders from a specific point-in-time.

To recover files and folders, see “Recovering Files and Folders”, on page 219.

What is Zerto's Long Term Retention and Restore VPG?

NOTE:

You cannot restore a retention set in Azure, or in AWS.
For Azure environments, use Windows Azure Backup to restore VPGs.

If you need to extend the recovery ability to more than the 30 days that are available with disaster recovery, Zerto Virtual Replication provides Long Term Retention that enables saving the protected VPGs for up to one year in a state where they can easily be deployed.

During the retention process, data from the recovery VPGs is saved in a repository as repository sets that can extend as far back as a year. These repository sets are fixed points saved either daily, weekly or monthly.

When a Retention process starts, the DSS communicates with the VRA on the recovery site to create the retention sets of the VPGs, and saves these sets in the repository.

To set up Long Term Retention to protect VPGs, see “Using Zerto's Long Term Retention”, on page 236. Configuring Long Term Retention is part of defining a VPG.

After initializing the VPG, Zerto Virtual Replication periodically checks that the time to run a Retention process has not passed. At the scheduled Retention process time, the Retention Process is run and the retention set is stored in the specified repository.

Retention sets are kept for the retention period specified in the VPG's Retention Policy. Over time the number of stored retention sets are reduced to save space.

To restore VPGs, see “Using Zerto’s Long Term Retention”, on page 236.
When the protected site is SCVMM, protection can be set up to cope with the following situations:

- A disaster, enabling recovery to a point in time in the 30 days prior to the disaster.
- The need to retain files saved either daily or weekly for a period of up to one year. The same wizard is used to set up both disaster recovery and the retention policy.

Use any of the following procedures depending on the site to which you need to recover:

<table>

Requirements for Hyper-V Environments

Before protecting your virtual machines, review Zerto Virtual Replication - Prerequisites & Requirements for Microsoft Hyper-V Environments

Considerations

- Virtual machines with pass-through disks and shared disks cannot be protected.
- A Hyper-V host with a pass-through disk is ignored by the Zerto Virtual Manager.
- Any virtual machine that is supported by the hypervisor can be protected. When recovering to a different hypervisor, the protected virtual machines must also be supported by the recovery hypervisor.
Replication From a Protected Site Hyper-V Server to a Recovery Site Hyper-V

You can protect virtual machines to Hyper-V. The procedure is the same whether you intend to protect one virtual machine or multiple virtual machines.

To create a virtual protection group (VPG) to recover in Hyper-V:

1. In the Zerto User Interface, select ACTIONS > CREATE VPG.
   The GENERAL step of the Create VPG wizard is displayed.

2. Specify the name of the VPG and the priority of the VPG.
   - **VPG Name**: The VPG name must be unique. The name cannot be more than 80 characters.
   - **Priority**: Determine the priority for transferring data from the protected site to the recovery site when there is limited bandwidth and more than one VPG is defined on the protected site.
     - **High Priority**: When there are updates to virtual machines protected in VPGs with different priorities, updates from the VPG with the highest priority are passed over the WAN first.
     - **Medium Priority**: Medium priority VPGs will only be able to use whatever bandwidth is left after the high priority VPGs have used it.
     - **Low Priority**: Low priority VPGs will use whatever bandwidth is left after the medium priority VPGs have use it.
   Updates to the protected virtual machines are always sent across the WAN before synchronization data, such as during a bitmap or delta sync.
   During synchronization, data from the VPG with the highest priority is passed over the WAN before data from medium and low priority VPGs.

3. Click NEXT.
4. Select the VMs that will be part of this VPG and click the arrow pointing right to include these VMs in the VPG.
   - When using the Search field, you can use the wildcards; * or ?

Virtual machines that are not yet protected are displayed in the list. A VPG can include virtual machines that are not yet protected and virtual machines that are already protected.

5. You can view protected virtual machines in the Advanced (One-to-Many) section, by clicking Select VMs. The Select VMs dialog is displayed.

![Select VMs](image)

**Note:** Virtual machines can be protected in a maximum of three VPGs. These VPGs cannot be recovered to the same site. Virtual machines protected in the maximum number of VPGs are not displayed in the Select VMs dialog.

Protecting virtual machines in several VPGs is enabled only if both the protected site and the recovery site, as well as the VRAs installed on these sites, are of version 5.0 and higher.

6. To define the boot order of the virtual machines in the VPG, click **DEFINE BOOT ORDER**, otherwise go to the next step.

When virtual machines in a VPG are started in the recovery site, by default these machines are not started up in a particular order. If you want specific virtual machines to start before other machines, you can specify a boot order. The virtual machines are defined in groups and the boot order applies to the groups and not to individual virtual machines in the groups. You can specify a delay between groups during startup.
Note: Up to five (5) virtual machines may boot on a host simultaneously. Following the boot, a 300 second (default) delay occurs until the next boot batch.

Initially, virtual machines in the VPG are displayed together under the Default group. If you want specific machines to start before other virtual machines, define new groups with one or more virtual machines in each group.

7. Click **ADD GROUP** to add a new group. Then, do the following:
   a) To change the name of a group, click the Pencil icon next to the group.
   b) To delete a group, click the delete icon on the right side. You cannot delete the Default group nor a group that contains a virtual machine.
   c) Drag virtual machines to move them from one group to another.
   d) Drag groups to change the order the groups are started, or, optionally, in **Boot Delay**, specify a time delay between starting up the virtual machines in the group and starting up the virtual machines in the next group. 

   **For Example:** Assume three groups, Default, Server, and Client, defined in this order. The boot delay defined for the Default group is 10, for the Server group is 100, and for the Client group 0. The virtual machines in the Default group are started together and after 10 seconds the virtual machines in the Server group are started. After 100 seconds the virtual machines in the Client group are started.
   e) Click **OK** to save the boot order.

8. Click **NEXT**.

   The REPLICATION step is displayed.

Note: If the protected site is paired with only one recovery site, the recovery step is displayed with the **Recovery Site** field automatically filled in and defaults set for the SLA and Advanced settings, as shown below.

9. Specify the recovery site.
   - **Recovery Site:** The site to which you want to recover the virtual machines. After specifying the recovery site, the host and storage on the site to use for the replication can be specified.
Note: You cannot select a recovery site if any of the virtual machines you selected are already in VPGs that recover to that site.

- **Host:** The default cluster or host, in the recovery site that handles the replicated data.
- **Storage:** The default storage volume to use for the recovered virtual machine files and for their data volumes. Every storage for the recovery host is included in the drop-down list. If a cluster is selected for the host, only storage accessible by every host in the cluster are displayed.

10. Optionally, change the SLA settings, which apply to every virtual machine in the group.

- **Journal History:** The time that all write commands are saved in the journal. The longer the information is saved in the journal, the more space is required for each journal in the VPG. Select the number of **hours** from 1 to 24 or the number of **days** from 2 to 30.

11. For advanced journal settings, click **ADVANCED**.

The Advanced Journal Settings dialog is displayed.

<table>
<thead>
<tr>
<th>SETTING &amp; DESCRIPTION</th>
<th>SELECT...</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Journal History</strong></td>
<td></td>
</tr>
</tbody>
</table>
| The time that all write commands are saved in the journal. The longer the information is saved in the journal, the more space is required for each journal in the VPG. | Number of **hours** from 1 to 24  
Number of **days** from 2 to 30 |
### Default Journal Storage (Hyper-V), or Default Journal Datastore (vSphere)

The storage/datastore used for the journal data for each virtual machine in the VPG.

**Note:** This field is not relevant when replicating to a vCD recovery site.

### Journal Size Hard Limit

The maximum size that the journal can grow, either as a percentage or a fixed amount. The journal is always thin-provisioned.

**Note:** The Journal Size Hard Limit applies independently both to the Journal History and also to the Scratch Journal Volume.

*For Example:* If the Journal Size Hard Limit is configured to a maximum size of 160 GB limit, then during Failover Test, both the Journal History and the Scratch Journal Volume together can take up to 320 GB. Each one with a maximum size of 160 GB limit.

### Journal Size Warning Threshold

The size of the journal that triggers a warning that the journal is nearing its hard limit.

---

12. **Target RPO Alert:** The maximum desired time between each automatic checkpoint write to the journal before an alert is issued.

13. **Test Reminder:** The amount of time in months recommended between each test, where you test the integrity of the VPG. A warning is issued if a test is not performed within this time frame.
14. **Enable WAN Traffic Compression**: Whether or not data is compressed before being transferred to the recovery site. Compressing the data is more efficient, but results in a small performance degradation.

   **Note:** WAN Traffic Compression is enabled by default when replicating to vCD.
   - Enable WAN traffic compression if network considerations are more critical than CPU usage considerations.
   - When WAN compression is enabled, the compressed data is written in compressed format to the recovery site journal. Even if WAN compression is selected, Zerto Virtual Replication decreases the level of compression if it takes too many resources. The VRA automatically adjusts the compression level according to CPU usage, including totally disabling it if needed. Zerto recommends enabling WAN compression.
   - Zerto Virtual Replication can also work with third-party WAN optimization and acceleration technologies, such as those supplied by Riverbed Technologies and Silver Peak.
   - When third-party WAN optimization is implemented, Zerto recommends disabling VPG WAN compression.

15. To change the replication settings per virtual machine, click **VM SETTINGS**.

   The Advanced VM Replication Settings dialog is displayed.

   ![Advanced VM Replication Settings](image)

   In this dialog, you can edit the values of one or more of the virtual machines in the VPG.

16. To edit information in **one field**, click the field and update the information.

17. To edit information for **several virtual machines** at the same time, select the virtual machines and click **EDIT SELECTED**.

   The Edit VM dialog is displayed.

   ![Edit VM](image)

18. Define as follows:

19. Click **OK**.

20. In the Advanced VM Replication Settings dialog, click **OK**.

21. Click **NEXT**.

   The STORAGE step is displayed.

   By default the storage used for the virtual machine definition is also used for the virtual machine data.

   For each virtual machine in the VPG, Zerto Virtual Replication displays its storage-related information.

---

<table>
<thead>
<tr>
<th>SETTING &amp; DESCRIPTION</th>
<th>SELECT...</th>
</tr>
</thead>
</table>
| **Journal Size Warning Threshold** | **Unlimited**: The size of the journal is unlimited and it can grow to the size of the recovery storage/datastore. If Unlimited is selected, Size and Percentage options are **not** displayed.  
**Size** *(GB)*: The size in GB that will generate a warning.  
**Percentage***: The percentage of the virtual machine volume size that will generate a warning.  
*The values of Size and Percentage must be less than the configured Journal Size Hard Limit so that the warning will be generated when needed.  
In addition to the warning threshold, Zerto Virtual Replication will issue a message when the free space available for the journal is almost full. |

| **Journal Storage (Hyper-V), or Journal Datastore (vSphere) (not relevant when replicating to vCD)** | **vSphere** To change the default, specify a host and then select one of the datastores accessible by this host to be used as the journal datastore. When you select specific journal datastore, the journals for each virtual machine in the VPG are stored in this datastore, regardless of where the recovery datastores are for each virtual machine. In this case, all the protected virtual machines must be recovered to hosts that can access the specified journal datastore.  
**Hyper-V** To change the default, specify a host and then select the storage location accessible by this host to be used as the journal storage. When you select specific journal storage, the journals for each virtual machine in the VPG are stored in this storage, regardless of where the recovery storage is for each virtual machine. In this case, all the protected virtual machines must be recovered to hosts that can access the specified journal storage. |

---

*Note: The values of Size and Percentage must be less than the configured Journal Size Hard Limit so that the warning will be generated when needed.*
Note: Steps that do not require input are marked with a check mark. You can jump directly to a step that has been marked with a check mark to edit the values for that step. Every step must be marked with a check mark before you can click DONE to create the VPG.

- **Temp Data**: If the virtual machine to be replicated includes a temp data disk as part of its configuration, mark the recovery disk for this disk as a temp data disk. In this case, data is **not** replicated to the temp data disk after initial synchronization.

22. To edit storage information for one of the virtual machines' volume location, first select the virtual machine, then click **EDIT SELECTED**. The Edit Volumes window is displayed.

- In Hyper-V environments, the following window appears.

- In vSphere environments, the following window appears.

<tr>
<td><strong>Volume Source</strong></td>
<td></td>
</tr>
<tr>
<td>(Hyper-V) Select a <strong>Volume Source</strong> for recovery from one of the drop-down options:</td>
<td><strong>Volume Source &gt; Storage:</strong> A new volume is used for replicated data. From the <strong>Storage</strong> drop-down list, specify the storage to use to create disks for the replicated data. The storage specified for the replication must have at least the same amount of space as the protected volume and then an additional amount for the journal. The amount of additional space needed for the journal can be fixed by specifying a maximum size for the journal, or can be calculated as the average change rate for the virtual machines in the VPG, multiplied by the length of time specified for the journal history.</td>
</tr>
<tr>
<td>■ Storage</td>
<td></td>
</tr>
<tr>
<td>■ Preseeded volume</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Volume Source &gt; Preseeded volume:</strong> Whether to copy the protected data to a virtual disk in the recovery site. Zerto <strong>recommends</strong> using this option particularly for large disks so that the initial synchronization will be faster since a <strong>Delta Sync</strong> can be used to synchronize any changes written to the recovery site after the creation of the preseeded disk. When <strong>not</strong> using a preseeded disk, the initial synchronization phase must copy the whole disk over the WAN. When using a preseeded virtual disk, you select the storage and exact location, folder, and name of the preseeded disk. Zerto Virtual Replication takes ownership of the preseeded disk, moving it from its source folder to the folder used by the VRA. Only disks with the same size as the protected disk can be selected when browsing for a preseeded disk. The storage where the preseeded disk is placed is also used as the recovery storage for the replicated data.</td>
</tr>
</tbody>
</table>
(vSphere) Select a **Volume Source** for recovery from one of the drop-down options:
- **Datastore**
- **RDM**
- **Preseeded volume**

**Volume Source > Datastore:** A new volume is used for replicated data.

- Specify the **Datastore** to use to create disks for the replicated data.
- If the **source disk is thin provisioned**, the default for the recovery volume is also thin provisioned.
- The datastore specified for replication must have at least the same amount of space as the **protected volume** and an additional amount for the **journal**.
- The amount of additional space needed for the journal can be fixed by specifying a maximum size for the journal, or can be calculated as the average change rate for the virtual machines in the VPG, multiplied by the length of time specified for the journal history.
- Zerto Virtual Replication supports the SCSI protocol. Only disks that support this protocol can be specified.

Then, define the following:
- **Datastore:** The Datastore where the preseeded disk is located. Only disks with the same size as the protected disk can be selected when browsing for a preseeded disk.

**Volume Source > RDM:** The VMware RDM (Raw Device Mapping) which will be used for the replication.

By default, **RDM is recovered as thin-provisioned VMDK** in the datastore specified in the **VM Recovery Datastore/Storage** field in the Edit VM dialog, and not to RDM.

Only a raw disk with the **same size as the protected disk** can be selected from the list of available raw disks. Other raw disks with different sizes are not available for selection.

The RDM is always stored in the recovery datastore, used for the virtual machine.

The following **limitations** apply to protecting RDM disks:
- RDM disks with an even number of blocks can replicate to RDM disks of the same size with an even number of blocks and to VMDKs.
- RDM disks with an odd number of blocks can only replicate to RDM disks of the same size with an odd number of blocks and not to VMDKs.
- You cannot define an RDM disk to be protected to a cloud service provider via a Zerto Cloud Connector nor if the virtual machine uses a BusLogic SCSI controller, nor when protecting or recovering virtual machines in an environment running vCenter Server 5.x with ESX/ESXi version 4.1 hosts.
Protecting Virtual Machines from Hyper-V

■ (vSphere) **Volume Source** continued

**Volume Source > Preseeded volume:** Select this when you want to copy the protected data to a virtual disk in the recovery site.

Consider the following, then proceed to define the Datastore and the Path:

- **Zerto recommends** using this option particularly for **large disks** so that the initial synchronization is **faster** since a Delta Sync can be used to synchronize any changes written to the recovery site after the creation of the preseeded disk.
- If a preseeded disk is **not** selected, the initial synchronization phase must copy the **whole disk** over the WAN.
- If you use a preseeded virtual disk, you select the datastore and exact location, folder, and name of the preseeded disk, which cannot be an IDE disk. Zerto Virtual Replication takes ownership of the preseeded disk, moving it from its source folder to the folder used by the VRA.
- The datastore where the preseeded disk is placed is also used as the recovery datastore for the replicated data.
- If the preseeded disk is **greater than 1TB on NFS storage**, the VPG creation might fail. This is a known VMware problem when the NFS client does not wait for sufficient time for the NFS storage array to initialize the virtual disk after the RPC parameter of the NFS client times out. The timeout default value is 10 seconds. See VMware documentation, http://kb.vmware.com/selfservice/microsites/search.do?language=en_US&cmd=displayKC&externalid=1027919, which describes the configuration option to tune the RPC timeout parameter by using the command: `esxcfg-advcfg -s <Timeout>/NFS/SetAttrRPCTimeout`
- If the protected disks are **non-default geometry**, configure the VPG using preseeded volumes.
- If the protected disk is an **RDM disk**, it can be used to preseed to a recovery VMDK disk. Zerto Virtual Replication makes sure that the VMDK disk size is a correct match for the RDM disk.
- If the VPG is being defined for a Zerto Organization, ZORG, the location of the preseeded disk must be defined in the Zerto Cloud Manager. See Zerto Cloud Manager Administration Guide.

Then, define the following:

- **Datastore:** The Datastore where the preseeded disk is located. Only disks with the same size as the protected disk can be selected when browsing for a preseeded disk.
- **Path:** The full path to the preseeded disk.

### Temp Data disk

If the virtual machine to be replicated includes a temp data disk as part of its configuration.

Specify a mirror disk for replication that is marked as a temp data disk. In this case, data is not replicated to the temp data disk after initial synchronization.
23. Click **OK**.
24. Click **NEXT**.

The RECOVERY step is displayed. Recovery details include the networks to use for failover, move, and for testing failover, and whether scripts should run as part of the recovery operation.

25. Select the default recovery settings. These are applied to every virtual machine in the VPG.
   - **Failover/Move Network**: The network to use during a failover or move operation in which the recovered virtual machines will run.
   - **Failover Test Network**: The network to use when testing the failover of virtual machines in the recovery site. Zerto recommends using a fenced-out network so as not to impact the production network at this site.

26. Enter the name of the script to run in the Command to run text box. You can then enter details about the script.
   - **Pre-recovery Script**: The information about a script that should run at the beginning of the recovery process.
   - **Post-recovery Script**: The information about a script that should run at the end of the recovery process.

For both types of scripts, enter the following information:

<table>
<thead>
<tr>
<th>TEXT BOX</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command to run</td>
<td>The full path of the script. The script must be located on the same machine as the Zerto Virtual Manager for the recovery site.</td>
</tr>
<tr>
<td>Params</td>
<td>The parameters to pass to the script. Separate parameters with a space.</td>
</tr>
<tr>
<td>Timeout</td>
<td>The time-out, in seconds, for the script to run. If the script runs before executing a failover, move, or test failover, and the script fails or the timeout value is reached, an alert is generated and the failover, move, or test failover is not performed. If the script runs after executing a failover, move, or test failover, and the timeout value is reached, an alert is generated. The default time-out value is specified in Site Settings &gt; Performance and Throttling tab.</td>
</tr>
</tbody>
</table>

**NOTE:**

Pre and post recovery scripts run in parallel. Therefore, ensure that the pre and post recovery scripts are not using common resources.
27. Click **NEXT**.

The NICs step is displayed. In this step, you can specify the NIC details to use for the recovered virtual machines after a failover, a test failover, or migration.

28. To edit information in one field, click the field and update the information.

29. To edit information for several virtual machines at the same time, select the virtual machines and click **EDIT SELECTED**.

30. Otherwise, go to step 34.

The Edit VNIC dialog is displayed.

31. Specify the network details to use for the recovered virtual machines after a failover or move operation, in the Failover/Move column, and for the recovered virtual machines when testing replication, in the Test column.

In each column, **specify** the following:

- **Network**: The network to use for this virtual machine.
- **Create New MAC Address**: Whether the Media Access Control address (MAC address) used on the protected site should be replicated on the recovery site. The default is to use the same MAC address on both sites. Note that if you check this option, to create a new MAC address, and the current IP address is not specified, the protected virtual machine static IP address might not be used for the recovered virtual machine.
- **Change vNIC IP Configuration**: Whether or not to keep the default virtual NIC (vNIC) IP configuration. Configuration is possible only when the guest operating system is defined in the hypervisor manager and Integration Services are
32. To change the vNIC IP configuration, select Yes in the Failover/Move or Test column. If you select to use a statically-assigned IP address, set the IP address, subnet mask, and default gateway. Optionally, change the preferred and alternate DNS server IP addresses and the DNS suffix. If you leave the DNS server and suffix entries empty, or select to use DHCP, the IP address and DNS server configurations are assigned automatically, to match the protected virtual machine. You can change the DNS suffix.

If the virtual machine has multiple NICs but is configured to only have a single default gateway, fill in a 0 for each octet in the Default gateway field for the NICs with no default gateway.

Note: During a failover, move, or test failover, if the recovered virtual machine is assigned a different IP address than the original IP address, after the virtual machine has started it is injected with the correct IP address. If the same network is used for both production and test failovers, Zerto recommends changing the IP address for the virtual machines started for the test, so that there is no IP address clash between the test machines and the production machines.

■ Copy to failover test: Select this to copy the settings in the Failover/Move column to the Test column.
■ Copy to failover/move: Select this to copy the settings in the Test column to the Failover/Move column.

33. Click OK.
34. Click NEXT.

The RETENTION POLICY step is displayed. Retention properties govern the VPG retention, including the repository where the retention sets are saved. VPG retention extends the ability to recover virtual machines in a VPG going back one year.

35. By default, Long Term Retention is OFF. To keep this value, go to step 39.
36. Otherwise, toggle OFF to ON and enter the following information:
   ■ Enter the Target Repository name. This is the name of the repository where the repository sets are written. Repositories are configured via the SETUP tab as described in Creating a New Repository for Retention.
   ■ Select the Retention Period from the drop-down list. The time you select is the length of time to keep repository sets. This is up to a maximum of one year. For details of how this affects the number of retention sets saved, see Storing Repository Sets.

37. Run Job Every: The recurrence and time to start the retention process.
38. Retries: Select Automatic retry after failure to automatically rerun the retention process, if the job fails.
   ■ If you select this option, you must also define Number of attempts, and the Wait time between retries.
39. Click NEXT.
The SUMMARY step is displayed. It shows the VPG configuration that you defined in previous tabs.

40. Click **DONE**. The VPG is created.

For details of what happens after saving the VPG, see “What Happens After the VPG is Defined”, on page 29.
Replication From a Protected Site Hyper-V Server to the Same Site

The same site can be used as both the protected and recovery sites. Even if the site is not paired with another site, VPGs can be created.

Before you continue, see the following topic: "When to Replicate to the Same Site", on page 50

When to Replicate to the Same Site

The following scenarios show when replicating to the same site can be beneficial. The list is not inclusive.

- Where the same SCVMM manages different datacenters in different geographical locations. The main datacenter can be used as the recovery site. This scenario describes situations where there are remote offices or branch offices (ROBOs).
- In an organization that does not have a recovery site but wants to protect its virtual machines that use one storage by creating recovery on a second storage. This protects against a disaster happening to the primary storage.
- Between hosts in different clusters.
- Protection against viruses, even in a single cluster: A different host within the cluster can serve as the recovery host for a host with an internal problem with a virtual machine, such as a virus.

To create a virtual protection group (VPG) to recover to the same site:

1. Select Site Settings. In the Site Settings dialog, select Policies.

![Site Settings dialog](image)

2. In the Replication section, select the option Enable replication to self.
3. Click SAVE or APPLY.

To define a VPG to recover to the protection site:

- In the Zerto User Interface, select ACTIONS > CREATE VPG.
  The GENERAL step of the Create VPG wizard is displayed.
  The procedure is the same as when protecting virtual machines, described in “Replication From a Protected Site Hyper-V Server to a Recovery Site Hyper-V”, on page 34.
Replication From a Protected Site Hyper-V Server to a Recovery Site VMware vCenter Server

You can protect virtual machines to a recovery site VMware vCenter Server. The procedure is the same whether you intend to protect one virtual machine or multiple virtual machines.

When creating a VPG from Hyper-V to a VMware vCenter Server, all recovery operations bring up the recovered machines on VMware vCenter Server hosts.

Zerto Virtual Replication uses SCSI for vCenter Server virtual machine disks. Any Hyper-V virtual machines with IDE disks will be recovered with SCSI disks.

When protecting virtual machines from Hyper-V to vCenter Server, the operating systems of the protected machines must be supported by vCenter Server. Refer to VMware documentation for the list of supported operating systems.

The following conversions are done to a protected virtual machine when it is recovered in vCenter Server:

- Virtual machines are recovered in vCenter Server with the highest hardware version supported by the vCenter Server host version under which the virtual machine is recovered.
- A Generation 1 virtual machine is recovered in vCenter Server with BIOS with the highest supported hardware version.
- A Generation 2 virtual machine is recovered in vCenter Server with EUFI. The host in vCenter must support hardware version 8 or higher. Also the following restrictions apply for Generation 2 virtual machines:
  - The secure boot option for the machine in Hyper-V must be disabled.
  - The boot disk must be less than 2TB if the recovery host version is lower than ESXi 5.5.
- All IDE disks are converted to SCSI disks. The boot disk is ported to a disk on a SCSI controller with location 0:0.
- Recovered virtual machines use the VMware Virtual E1000 network adapter.

To create a virtual protection group (VPG) to recover in VMware vCenter:

1. In the Zerto User Interface, select ACTIONS > CREATE VPG.
   The GENERAL step of the Create VPG wizard is displayed.

2. Specify the name of the VPG and the priority of the VPG.
   - **VPG Name**: The VPG name must be unique. The name cannot be more than 80 characters.
   - **Priority**: Determine the priority for transferring data from the protected site to the recovery site when there is limited bandwidth and more than one VPG is defined on the protected site.
     - **High Priority**: When there are updates to virtual machines protected in VPGs with different priorities, updates from the VPG with the highest priority are passed over the WAN first.
     - **Medium Priority**: Medium priority VPGs will only be able to use whatever bandwidth is left after the high priority VPGs have used it.
     - **Low Priority**: Low priority VPGs will use whatever bandwidth is left after the medium priority VPGs have used it.
Updates to the protected virtual machines are always sent across the WAN before synchronization data, such as during a bitmap or delta sync.
During synchronization, data from the VPG with the highest priority is passed over the WAN before data from medium and low priority VPGs.

3. Click NEXT.
The VMs step is displayed.

4. Select the VMs that will be part of this VPG and click the arrow pointing right to include these VMs in the VPG.
   - When using the Search field, you can use the wildcards; * or ?
   Virtual machines that are not yet protected are displayed in the list. A VPG can include virtual machines that are not yet protected and virtual machines that are already protected.

5. You can view protected virtual machines in the Advanced (One-to-Many) section, by clicking Select VMs.
The Select VMs dialog is displayed.

[Image of Select VMs dialog]

**Note:** Virtual machines can be protected in a maximum of three VPGs. These VPGs cannot be recovered to the same site. Virtual machines protected in the maximum number of VPGs are not displayed in the Select VMs dialog.
Protecting virtual machines in several VPGs is enabled only if both the protected site and the recovery site, as well as the VRAs installed on these sites, are of version 5.0 and higher.

6. To define the boot order of the virtual machines in the VPG, click DEFINE BOOT ORDER, otherwise go to the next step.
When virtual machines in a VPG are started in the recovery site, by default these machines are not started up in a particular order. If you want specific virtual machines to start before other machines, you can specify a boot order. The virtual machines are defined in groups and the boot order applies to the groups and not to individual virtual machines in the groups. You can specify a delay between groups during startup.

**Note:** Up to five (5) virtual machines may boot on a host simultaneously. Following the boot, a 300 second (default) delay occurs until the next boot batch.

Initially, virtual machines in the VPG are displayed together under the Default group. If you want specific machines to start before other virtual machines, define new groups with one or more virtual machines in each group.

7. Click **ADD GROUP** to add a new group. Then, do the following:
   a) To change the name of a group, click the Pencil icon next to the group.
   b) To delete a group, click the delete icon on the right side. You cannot delete the Default group nor a group that contains a virtual machine.
   c) Drag virtual machines to move them from one group to another.
   d) Drag groups to change the order the groups are started, or, optionally, in **Boot Delay**, specify a time delay between starting up the virtual machines in the group and starting up the virtual machines in the next group.  
   **For Example:** Assume three groups, Default, Server, and Client, defined in this order. The boot delay defined for the Default group is 10, for the Server group is 100, and for the Client group 0. The virtual machines in the Default group are started together and after 10 seconds the virtual machines in the Server group are started. After 100 seconds the virtual machines in the Client group are started.
   e) Click **OK** to save the boot order.

8. Click **NEXT**.
   The REPLICATION step is displayed.
Note: If the protected site is paired with only one recovery site, the recovery step is displayed with the Recovery Site field automatically filled in and defaults set for the SLA and Advanced settings, as shown below.

9. Specify the recovery site and default values to use for the replication to this site.
   ■ **Recovery Site:** The site to which you want to recover the virtual machines. After specifying the recovery site, other fields are displayed including the host and datastore to use for replication.

![Create VPG](image)

10. **ZORG:** If the site is defined in Zerto Cloud Manager, select the name used by the cloud service provider (CSP) to identify you as a Zerto Organization (ZORG). For details about Zerto Cloud Manager, see Zerto Cloud Manager Administration Guide.

11. **Host:** The default cluster, resource pool or host in the recovery site that handles the replicated data. If the site is defined in Zerto Cloud Manager, only a resource pool can be specified and the resource pool must also have been specified as a resource in Zerto Cloud Manager.
   
   **Note:** If Zerto Cloud Manager is used, vSphere Standard edition cannot be used.
   
   For details about Zerto Cloud Manager, refer to Zerto Cloud Manager Administration Guide.
   
   When a resource pool is specified, Zerto Virtual Replication checks that the resource pool capacity is enough for any virtual machines specified in the VPG.
   
   All resource pool checks are made at the level of the VPG and do not take into account multiple VPGs using the same resource pool. If the resource pool CPU resources are specified as unlimited, the actual limit is inherited from the parent but if this inherited value is too small, failover, move, and failover test operations can fail, even without a warning alert being issued by Zerto Virtual Manager.
   
   **Note:** If a resource pool is specified and DRS is disabled for the site later on, all the resource pools are removed by VMware and recovery will be to any one of the hosts in the recovery site with a VRA installed on it.

   **Datastore:** The default datastore to use for recovered virtual machine files and for their data volumes. Every datastore for the selected recovery host is included in the drop-down list. If a cluster or resource pool is selected for the host, only datastores that are accessible by every host in the cluster or resource pool are displayed.

12. In the **SLA** area, you define the Service Level Agreement for which this VPG is associated.
   
   ■ When Zerto Cloud Manager is used, select the **Service Profile** to use.
   
   The Service Profile determines the VPG SLA settings for the group. This applies predefined settings for the Journal History, Target RPO Alert and the Test Reminder. These settings apply to every virtual machine in the group.
   
   ■ When a **Custom** service profile is available, the VPG SLA settings are editable, and the **Advanced** button becomes available. When you change these settings, they apply to every virtual machine in the group.

13. Click **ADVANCED**. The Advanced Journal Settings dialog is displayed.
14. Set the following fields:

<table>
<thead>
<tr>
<th>SETTING &amp; DESCRIPTION</th>
<th>SELECT...</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Journal History</strong></td>
<td>- Number of <strong>hours</strong> from <strong>1</strong> to <strong>24</strong></td>
</tr>
<tr>
<td></td>
<td>- Number of <strong>days</strong> from <strong>2</strong> to <strong>30</strong></td>
</tr>
<tr>
<td><strong>Default Journal Storage (Hyper-V), or Default Journal Datastore (vSphere)</strong></td>
<td>- Select the storage/datastore accessible to the host.</td>
</tr>
<tr>
<td>The storage/datastore used for the journal data for each virtual machine in the VPG.</td>
<td>When you select a specific journal storage/datastore, the journals for each virtual machine in the VPG are stored in this storage/datastore, regardless of where the recovery storage/datastore is for each virtual machine. All protected virtual machines are recovered to the hosts that can access the specified journal storage/datastore.</td>
</tr>
<tr>
<td><strong>Journal Size Hard Limit</strong></td>
<td>- <strong>Unlimited</strong>: The size of the journal is unlimited and it can grow to the size of the recovery storage/datastore. If Unlimited is selected, Size and Percentage options are <strong>not</strong> displayed.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Size (GB)</strong>: The maximum journal size in GB. The <strong>minimum</strong> journal size, set by Zerto Virtual Replication, is <strong>8GB</strong> for Hyper-V and vSphere environments, and <strong>10GB</strong> for Microsoft Azure environments.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Percentage</strong>: The percentage of the virtual machine volume size to which the journal can grow. This value can be configured to more than 100% of the protected VM’s volume size.</td>
</tr>
<tr>
<td><strong>Note</strong>: This field is <strong>not</strong> relevant when replicating to a vCD recovery site.</td>
<td></td>
</tr>
<tr>
<td><strong>Note</strong>: The Journal Size Hard Limit applies independently both to the Journal History and also to the Scratch Journal Volume.</td>
<td></td>
</tr>
<tr>
<td><strong>For Example</strong>: If the Journal Size Hard Limit is configured to a maximum size of 160 GB limit, then during Failover Test, both the Journal History and the Scratch Journal Volume together can take up to 320 GB. Each one with a maximum size of 160 GB limit.</td>
<td></td>
</tr>
<tr>
<td>The journal is always <strong>thin-provisioned</strong>.</td>
<td></td>
</tr>
</tbody>
</table>

The longer the information is saved in the journal, the more space is required for each journal in the VPG.
15. **Target RPO Alert**: The maximum desired time between each automatic checkpoint write to the journal before an alert is issued.

16. **Test Reminder**: The amount of time in months recommended between each test, where you test the integrity of the VPG. A warning is issued if a test is not performed within this time frame.

17. Click **OK**.

18. **Enable WAN Traffic Compression**: Whether or not data is compressed before being transferred to the recovery site.

   Compressing the data is more efficient, but results in a small performance degradation.

   **Note**: WAN Traffic Compression is enabled by default when replicating to vCD.

   - Enable WAN traffic compression if network considerations are more critical than CPU usage considerations.
   - When WAN compression is enabled, the compressed data is written in compressed format to the recovery site journal. Even if WAN compression is selected, Zerto Virtual Replication decreases the level of compression if it takes too many resources. The VRA automatically adjusts the compression level according to CPU usage, including totally disabling it if needed. Zerto recommends enabling WAN compression.
   - Zerto Virtual Replication can also work with third-party WAN optimization and acceleration technologies, such as those supplied by Riverbed Technologies and Silver Peak.
   - When third-party WAN optimization is implemented, Zerto recommends disabling VPG WAN compression.

19. To change the replication settings per virtual machine, click **VM SETTINGS**.
The Advanced VM Replication Settings dialog is displayed.

In this dialog, you can edit the values of one or more of the virtual machines in the VPG.

20. To edit information in one field, click the field and update the information.

21. To edit information for several virtual machines at the same time, select the virtual machines and click **EDIT SELECTED**. The Edit VM dialog is displayed.

<table>
<thead>
<tr>
<th>SETTING &amp; DESCRIPTION</th>

<tr>
<td></td>
<td>- This value can be configured to more than 100% of the protected VM’s volume size.</td>
</tr>
</tbody>
</table>

Unlimited: The size of the journal is unlimited and it can grow to the size of the recovery storage/datastore. If Unlimited is selected, Size and Percentage options are not displayed.
22. Click OK.

23. In the Advanced VM Replication Settings dialog, click OK.

24. Click NEXT.

The STORAGE step is displayed.

By default the storage used for the virtual machine definition is also used for the virtual machine data.

For each virtual machine in the VPG, Zerto Virtual Replication displays its storage-related information.
Note: Steps that do not require input are marked with a check mark. You can jump directly to a step that has been marked with a check mark to edit the values for that step. Every step must be marked with a check mark before you can click DONE to create the VPG.

You can define Thin provisioning and Temp Data in this window, or you can alternatively define them when you separately select and edit each VMs volume.

IMPORTANT:

Changing the VPG recovery volume from thin-provisioned to thick-provisioned or vice versa, results in volume initial synchronization.

See the following considerations regarding Thin provisioning:

- Unless the user explicitly requests Thin provisioning, provisioning type is the same type as provisioning in the source VM.
- If the source disk is Thin provisioned, the default for the recovery volume is also Thin provisioned.
- If the user uses preseed disks, Zerto maintains the provisioning types of the disks, so they can have other provisioning types.

<table>
<thead>
<tr>
<th>PRESEED</th>
<th>PROVISIONING IN THE RECOVERY VM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not selected</td>
<td>User can select Thin provisioning</td>
</tr>
<tr>
<td>Selected</td>
<td>User cannot select Thin provisioning</td>
</tr>
<tr>
<td></td>
<td>Provisioning is the same as defined in source VMs</td>
</tr>
</tbody>
</table>

25. To define whether the recovery volumes are thin-provisioned or not, select the Thin checkbox.

26. If the virtual machine to be replicated includes a temp data disk as part of its configuration, select the Temp Data checkbox to mark the recovery disk for this disk as a temp data disk. In this case, data is not replicated to the temp data disk after initial synchronization.

</thead>
<tbody>
<tr>
<td>Journal Size Warning Threshold</td>
<td>Unlimited: The size of the journal is unlimited and it can grow to the size of the recovery storage/datastore. If Unlimited is selected, Size and Percentage options are not displayed. Size* (GB): The size in GB that will generate a warning. Percentage*: The percentage of the virtual machine volume size that will generate a warning. *The values of Size and Percentage must be less than the configured Journal Size Hard Limit so that the warning will be generated when needed. In addition to the warning threshold, Zerto Virtual Replication will issue a message when the free space available for the journal is almost full.</td>
</tr>
</tbody>
</table>

Journal Storage (Hyper-V), or Journal Datastore (vSphere) (not relevant when replicating to vCD)

The storage/datastore used for the journal data for each virtual machine in the VPG.

<table>
<thead>
<tr>
<th>SETTING &amp; DESCRIPTION</th>
<th>SELECT...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Journal Storage (Hyper-V), or Journal Datastore (vSphere) (not relevant when replicating to vCD)</td>
<td>(vSphere) To change the default, specify a host and then select one of the datastores accessible by this host to be used as the journal datastore. When you select specific journal datastore, the journals for each virtual machine in the VPG are stored in this datastore, regardless of where the recovery datastores are for each virtual machine. In this case, all the protected virtual machines must be recovered to hosts that can access the specified journal datastore. (Hyper-V) To change the default, specify a host and then select the storage location accessible by this host to be used as the journal storage. When you select specific journal storage, the journals for each virtual machine in the VPG are stored in this storage, regardless of where the recovery storage is for each virtual machine. In this case, all the protected virtual machines must be recovered to hosts that can access the specified journal storage.</td>
</tr>
</tbody>
</table>

27. Click **OK**.
28. Click **NEXT**.

The RECOVERY step is displayed. Recovery details include the networks to use for failover, move, and for testing failover, and whether scripts should run as part of the recovery operation.
29. Select the default recovery settings.
   - **Failover/Move Network**: The network to use during a failover or move operation in which the recovered virtual machines will run.
   - **Failover Test Network**: The network to use when testing the failover of virtual machines in the recovery site. Zerto recommends using a fenced-out network so as not to impact the production network at this site.

30. **Recovery Folder**: The folder to which the virtual machines are recovered.
   
   **Note**: If the recovery site is a cloud service provider site, it is not possible to select a recovery folder.

31. To specify a recovery folder for each virtual machine in the VPG, click **VM SETTINGS**. The Advanced VM Recovery Settings window is displayed.

   In this window, you can edit the values of one or more of the virtual machines in the VPG.

32. To edit information in **one field**, click the field and update the information.

33. To edit information for **several virtual machines** at the same time, select the virtual machines and click **EDIT SELECTED**.
The Edit VM window is displayed.

- **Recovery Folder:** The folder to which the virtual machine is recovered.

34. Click **SAVE**.

35. In the Advanced VM Recovery Settings window, click **OK**.

36. Enter the name of the script to run in the Command to run text box. You can then enter details about the script.
   - **Pre-recovery Script:** The information about a script that should run at the beginning of the recovery process.
   - **Post-recovery Script:** The information about a script that should run at the end of the recovery process.

For both types of scripts, enter the following information:

<table>
<thead>
<tr>
<th>TEXT BOX</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command to run</td>
<td>The full path of the script. The script must be located on the same machine as the Zerto Virtual Manager for the recovery site.</td>
</tr>
<tr>
<td>Params</td>
<td>The parameters to pass to the script. Separate parameters with a space.</td>
</tr>
<tr>
<td>Timeout</td>
<td>The time-out, in seconds, for the script to run. However, if the script runs before executing a failover, move, or test failover, and the script fails or the timeout value is reached, an alert is generated and the failover, move, or test failover is not performed. If the script runs after executing a failover, move, or test failover, and the timeout value is reached, an alert is generated. The default time-out value is specified in <strong>Site Settings &gt; Performance and Throttling</strong> tab.</td>
</tr>
</tbody>
</table>

**NOTE:**

Pre and post recovery scripts run in parallel. Therefore, ensure that the pre and post recovery scripts are not using common resources.

37.

38. Click **NEXT**.
The NICs step is displayed. In this step, you can specify the NIC details to use for the recovered virtual machines after a failover, a test failover, or migration.

39. To edit information in one field, click the field and update the information.
40. To edit information for several virtual machines at the same time, select the virtual machines and click **EDIT SELECTED**.
41. Otherwise, go to step 44.

The Edit VNIC dialog is displayed.

42. Specify the network details to use for the recovered virtual machines after a failover or move operation, in the Failover/Move column, and for the recovered virtual machines when testing replication, in the Test column.

   In each column, specify the following:
   - **Network**: The network to use for this virtual machine.
   - **Create New MAC Address**: Whether the Media Access Control address (MAC address) used on the protected site should be replicated on the recovery site. The default is to use the same MAC address on both sites. Note that if you check this option, to create a new MAC address, and the current IP address is not specified, the protected virtual machine static IP address might not be used for the recovered virtual machine.
   - **Change vNIC IP Configuration**: Whether or not to keep the default virtual NIC (vNIC) IP configuration. Configuration is possible only when the guest operating system is defined in the hypervisor manager and Integration Services or VMWare
Tools are detected. The vNIC IP address is only changed after recovery for virtual machines with VMware Tools and Microsoft Integration Services running.

Refer to the Zerto Virtual Replication Interoperability Matrix for the list of operating systems for which Zerto supports Re-IPing.

To change the vNIC IP configuration, select Yes in the Failover/Move or Test column. If you select to use a statically-assigned IP address, set the IP address, subnet mask, and default gateway. Optionally, change the preferred and alternate DNS server IP addresses and the DNS suffix. If you leave the DNS server and suffix entries empty, or select to use DHCP, the IP address and DNS server configurations are assigned automatically, to match the protected virtual machine. You can change the DNS suffix.

If the virtual machine has multiple NICs but is configured to only have a single default gateway, fill in a 0 for each octet in the Default gateway field for the NICs with no default gateway.

During a failover, move, or test failover, if the recovered virtual machine is assigned a different IP than the original IP, then after the virtual machine has started, it is automatically rebooted so that it starts up with the correct IP. If the same network is used for both production and test failovers, Zerto recommends changing the IP address for the virtual machines started for the test, so that there is no IP clash between the test machines and the production machines.

- **Copy to failover test**: Select this to copy the settings in the Failover/Move column to the Test column.
- **Copy to failover/move**: Select this to copy the settings in the Test column to the Failover/Move column.

43. Click **OK**.
44. Click **NEXT**.

The RETENTION POLICY step is displayed. Retention properties govern the VPG retention, including the repository where the retention sets are saved. VPG retention extends the ability to recover virtual machines in a VPG going back one year.

45. By default, Long Term Retention is **OFF**. To keep this value, go to step 27.
46. Otherwise, toggle **OFF** to **ON** and enter the following information:
   - Enter the **Target Repository** name. This is the name of the repository where the repository sets are written. Repositories are configured via the SETUP tab as described in Creating a New Repository for Retention.
   - Select the **Retention Period** from the drop-down list. The time you select is the length of time to keep repository sets. This is up to a maximum of one year. For details of how this affects the number of retention sets saved, see Storing Repository Sets.
47. **Run Job Every**: The recurrence and time to start the retention process.
48. **Retries**: Select Automatic retry after failure to automatically rerun the retention process, if the job fails.
   - If you select this option, you must also define **Number of attempts**, and the **Wait time between retries**.
49. Click **NEXT**.
The SUMMARY step is displayed. It shows the VPG configuration that you defined in previous tabs.

50. Click **DONE**. The VPG is created.

For details of what happens after saving the VPG, see “What Happens After the VPG is Defined”, on page 29.
Replication From a Protected Site Hyper-V Server to a Recovery Site VMware vCloud Director

You can protect virtual machines to a recovery site VMware vCloud Director (vCD). The procedure is the same whether you intend to protect one virtual machine or multiple virtual machines.

When creating a VPG from Hyper-V to a VMware vCD, all recovery operations bring up the recovered machines as vCD vApps.

Zerto Virtual Replication uses SCSI for recovered virtual machine disks. Any Hyper-V virtual machines with IDE disks will be recovered with SCSI disks.

When protecting virtual machines from Hyper-V to vCD, the operating systems of the protected machines must be supported by vCD. Refer to VMware documentation for the list of supported operating systems.

The following conversions are done to a protected virtual machine when it is recovered in vCD:

- Virtual machines are recovered in vCenter Server with the highest hardware version supported by the vCenter Server host version under which the virtual machine is recovered.
- A Generation 1 virtual machine is recovered in vCenter Server with BIOS with the highest supported hardware version.
- A Generation 2 virtual machine is recovered in vCenter Server with EUFI. The host in vCenter must support hardware version 8 or higher. Also the following restrictions apply for Generation 2 virtual machines:
  - The secure boot option for the machine in Hyper-V must be disabled.
  - The boot disk must be less than 2TB if the recovery host version is lower than ESXi 5.5.
- All IDE disks are converted to SCSI disks. The boot disk is ported to a disk on a SCSI controller with location 0:0.
- Recovered virtual machines use the VMware Virtual E1000 network adapter.

To create a virtual protection group (VPG) to recover in vCD:

1. In the Zerto User Interface, select ACTIONS > CREATE VPG.

   The GENERAL step of the Create VPG wizard is displayed.

2. Specify the name of the VPG and the priority of the VPG.

   - **VPG Name**: The VPG name must be unique. The name cannot be more than 80 characters.
   - **Priority**: Determine the priority for transferring data from the protected site to the recovery site when there is limited bandwidth and more than one VPG is defined on the protected site.
     - **High Priority**: When there are updates to virtual machines protected in VPGs with different priorities, updates from the VPG with the highest priority are passed over the WAN first.
     - **Medium Priority**: Medium priority VPGs will only be able to use whatever bandwidth is left after the high priority VPGs have used it.
     - **Low Priority**: Low priority VPGs will use whatever bandwidth is left after the medium priority VPGs have use it.
Updates to the protected virtual machines are always sent across the WAN before synchronization data, such as during a bitmap or delta sync. During synchronization, data from the VPG with the highest priority is passed over the WAN before data from medium and low priority VPGs.

3. Click **NEXT**. The VMs step is displayed.

4. Select the VMs that will be part of this VPG and click the arrow pointing right to include these VMs in the VPG.
   - When using the **Search** field, you can use the wildcards; * or ?
   Virtual machines that are not yet protected are displayed in the list. A VPG can include virtual machines that are not yet protected and virtual machines that are already protected.

5. You can view protected virtual machines in the **Advanced (One-to-Many)** section, by clicking **Select VMs**.
   The Select VMs dialog is displayed.

### Note:
Virtual machines can be protected in a maximum of three VPGs. These VPGs cannot be recovered to the same site. Virtual machines protected in the maximum number of VPGs are not displayed in the Select VMs dialog. Protecting virtual machines in several VPGs is enabled only if both the protected site and the recovery site, as well as the VRAs installed on these sites, are of version 5.0 and higher.

### Note:
A boot order for virtual machines recovered in a vCloud Director vApp is defined in the vCloud Director console.

6. Click **NEXT**.
7. Choose the Recovery vCD Site, and select **vCD** from the drop-down list.

   The REPLICATION step is re-displayed, displaying additional fields relevant for vCD.

   Define as follows:

8. **ZORG**: If the site is defined in **Zerto Cloud Manager**, select the name used by the cloud service provider (CSP) to identify you as a Zerto Organization (ZORG). For details about Zerto Cloud Manager, see **Zerto Cloud Manager Administration Guide**.

9. Specify the **Recovery Org vDC** to use in the recovery site.

   **Note**: You cannot select a recovery site if any of the virtual machines you selected are already in VPGs that recover to that site.

   **Note**: At least one VRA needs to be installed on a host within a resource pool being used by a Recovery Org vDC.

10. In the **SLA** area, you define the Service Level Agreement for which this VPG is associated.

    - When **Zerto Cloud Manager** is used, select the **Service Profile** to use.
      
      The Service Profile determines the VPG SLA settings for the group. This applies predefined settings for the Journal History, Target RPO Alert and the Test Reminder. These settings apply to **every** virtual machine in the group.

    - When a **Custom** service profile is available, the VPG SLA settings are editable, and the **Advanced** button becomes available. When you change these settings, they apply to **every** virtual machine in the group.

11. Click **ADVANCED**. The Advanced Journal Settings dialog is displayed.
## SETTING & DESCRIPTION

### Journal History

The time that all write commands are saved in the journal. The longer the information is saved in the journal, the more space is required for each journal in the VPG.

- **SELECT...**
  - Number of **hours** from 1 to 24
  - Number of **days** from 2 to 30

### Default Journal Storage (Hyper-V), or Default Journal Datastore (vSphere)

The storage/datastore used for the journal data for each virtual machine in the VPG.

**Note:** This field is **not** relevant when replicating to a vCD recovery site.

- **SELECT...**
  - Select the storage/datastore accessible to the host.
  - When you select a specific journal storage/datastore, the journals for each virtual machine in the VPG are stored in this storage/datastore, regardless of where the recovery storage/datastore is for each virtual machine. All protected virtual machines are recovered to the hosts that can access the specified journal storage/datastore.

### Journal Size Hard Limit

The maximum size that the journal can grow, either as a percentage or a fixed amount.

The journal is always **thin-provisioned**.

**Note:** The Journal Size Hard Limit applies independently **both** to the Journal History and also to the Scratch Journal Volume.

*For Example:* If the Journal Size Hard Limit is configured to a maximum size of 160 GB limit, then during Failover Test, both the Journal History and the Scratch Journal Volume together can take up to 320 GB. Each one with a maximum size of 160 GB limit.

- **SELECT...**
  - **Unlimited:** The size of the journal is unlimited and it can grow to the size of the recovery storage/datastore.
  - If Unlimited is selected, Size and Percentage options are **not** displayed.
  - **Size (GB):** The maximum journal size in GB.
    - The **minimum** journal size, set by Zerto Virtual Replication, is 8GB for Hyper-V and vSphere environments, and 10GB for Microsoft Azure environments.
  - **Percentage:** The percentage of the virtual machine volume size to which the journal can grow.
    - This value can be configured to more than 100% of the protected VM's volume size.
12. **Target RPO Alert:** The maximum desired time between each automatic checkpoint write to the journal before an alert is issued.

13. **Test Reminder:** The amount of time in months recommended between each test, where you test the integrity of the VPG. A warning is issued if a test is not performed within this time frame.

14. **Enable WAN Traffic Compression:** Whether or not data is compressed before being transferred to the recovery site. Compressing the data is more efficient, but results in a small performance degradation.

   **Note:** WAN Traffic Compression is enabled by default when replicating to vCD.

   - Enable WAN traffic compression if network considerations are more critical than CPU usage considerations.
   - When WAN compression is enabled, the compressed data is written in compressed format to the recovery site journal. Even if WAN compression is selected, Zerto Virtual Replication decreases the level of compression if it takes too many resources. The VRA automatically adjusts the compression level according to CPU usage, including totally disabling it if needed. Zerto recommends enabling WAN compression.
   - Zerto Virtual Replication can also work with third-party WAN optimization and acceleration technologies, such as those supplied by Riverbed Technologies and Silver Peak.
   - When third-party WAN optimization is implemented, Zerto recommends disabling VPG WAN compression.

15. To change the replication settings per virtual machine, click **VM SETTINGS**.
The Advanced VM Replication Settings window is displayed.
In this window, you can edit the values of one or more of the virtual machines in the VPG.

16. To edit information for a **single VM**, click the field **Storage Policy**, or **Journal Storage Policy**, and update the information.
   - **Storage Policy**: The Storage Policy in which the **VM configuration files** will reside. For considerations, see step 18.
   - **Journal Storage Policy**: The Storage Policy in which the **VM Journal files** will reside. For considerations, see step 18.

17. To edit information for **several** virtual machines at the same time, select the virtual machines and click **EDIT SELECTED**.
    The Edit VM window is displayed.

18. When selecting **Storage Policy**, consider the following:
   - Zerto will select a datastore from the selected Storage Policy in which to place these files, unless the datastore is excluded in the Configure Provider vDCs Dialog.
   - Zerto will try to determine a default Storage Policy according to:
     - A Storage Policy with the same name as the protected Storage Policy.
     - The default Orgvdc Storage Policy.
   - If Zerto did not manage to determine a default Storage Policy, this field appears empty.
   - When you **click to edit**, a list of Storage Policies appear. These Storage Policies:
     - Were defined in VMware vCloud Director and are configured in the Orgvdc.
     - Have at least one Datastore that was not excluded as a Recovery Volume in the Configure Provider vDCs Dialog.
     - To review site-specific configurations, see Configure Provider vDCs Dialog.

19. When selecting **Journal Storage Policy**, consider the following:
   - Zerto will select a datastore from the selected Storage Policy in which to place the Journal files, unless the datastore is excluded in the Configure Provider vDCs Dialog.
   - The default Journal Storage Policy is the same as the default VM Storage Policy.
   - If Zerto did not manage to determine a default Journal Storage Policy, this field appears empty.
   - When you **click to edit**, the option **Auto Select** appears, and a list of Storage Policies.
   - The list of Storage Policies associated with the Journal:
     - Were defined in VMware vCloud Director and are configured in the Orgvdc.
20. Define the remaining fields as follows:

<table>
<thead>
<tr>
<th>SETTING &amp; DESCRIPTION</th>
<th>SELECT…</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Recovery Host</strong> (not relevant when replicating to vCD)</td>
<td>(Hyper-V) The cluster or host that will host the recovered virtual machine. When a resource pool is specified, Zerto Virtual Replication checks that the resource pool capacity is enough for all the virtual machines specified in the VPG. If a resource pool is specified and DRS is disabled for the site later on, all the resource pools are removed by VMware and recovery is to any one of the hosts in the recovery site with a VRA installed on it. All resource pool checks are made at the level of the VPG and do not take into account multiple VPGs using the same resource pool. If the resource pool CPU resources are defined as unlimited, the actual limit is inherited from the parent but if this inherited value is too small, failover, move, and failover test operations can fail, even without a warning alert being issued by Zerto Virtual Manager.</td>
</tr>
<tr>
<td><strong>(vSphere)</strong> The cluster, resource pool, or host that will host the recovered virtual machine.</td>
<td>(vSphere) When a cluster or resource pool is selected for the host, only datastores that are accessible by every ESX/ESXi host in the cluster or resource pool are displayed. This is also the datastore where RDM backing files for recovery volumes are located.</td>
</tr>
<tr>
<td><strong>VM Recovery Datastore</strong> (vSphere) (not relevant when replicating to vCD)</td>
<td>The datastore where the VMware metadata files for the virtual machine are stored, such as the VMX file. If a cluster or resource pool is selected for the host, only datastores that are accessible by every ESX/ESXi host in the cluster or resource pool are displayed. This is also the datastore where RDM backing files for recovery volumes are located.</td>
</tr>
<tr>
<td><strong>Recovery Storage</strong> (Hyper-V)</td>
<td>The location where the metadata files for the virtual machine are stored, such as the VHDX file. If a cluster is selected for the host, only storage that are accessible by every host in the cluster are displayed.</td>
</tr>
<tr>
<td><strong>Journal Size Hard Limit</strong></td>
<td>The maximum size that the journal can grow, either as a percentage or a fixed amount. Unlimited: The size of the journal is unlimited and it can grow to the size of the recovery storage/datastore. If Unlimited is selected, Size and Percentage options are not displayed. Size (GB): The maximum journal size in GB. The minimum journal size, set by Zerto Virtual Replication, is 8GB for Hyper-V and vSphere environments, and 10GB for Microsoft Azure environments. Percentage: The percentage of the virtual machine volume size to which the journal can grow. This value can be configured to more than 100% of the protected VM’s volume size.</td>
</tr>
<tr>
<td></td>
<td>■ The journal is always thin-provisioned. ■ The Journal Size Hard Limit applies independently both to the Journal History and also to the Scratch Journal Volume. For Example: If the Journal Size Hard Limit is configured to a maximum size of 160 GB limit, then during Failover Test, both the Journal History and the Scratch Journal Volume together can take up to 320 GB. Each one with a maximum size of 160 GB limit.</td>
</tr>
</tbody>
</table>
In the Advanced VM Replication Settings window, click **OK**.

Click **NEXT**.

The STORAGE step is displayed.

By default the storage used for the virtual machine definition is also used for the virtual machine data.

For each virtual machine in the VPG, Zerto Virtual Replication displays its storage-related information.
Note: Steps that do not require input are marked with a check mark. You can jump directly to a step that has been marked with a check mark to edit the values for that step. Every step must be marked with a check mark before you can click DONE to create the VPG.

You can define Thin provisioning and Temp Data in this window, or you can alternatively define them when you separately select and edit each VMs volume.

IMPORTANT:

Changing the VPG recovery volume from thin-provisioned to thick-provisioned or vice versa, results in volume initial synchronization.

See the following considerations regarding Thin provisioning:

- Unless the user explicitly requests Thin provisioning, provisioning type is the same type as provisioning in the source VM.
- If the source disk is Thin provisioned, the default for the recovery volume is also Thin provisioned.
- If the user uses preseed disks, Zerto maintains the provisioning types of the disks, so they can have other provisioning types.

<table>
<thead>
<tr>
<th>PRESEED</th>
<th>PROVISIONING IN THE RECOVERY VM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not selected</td>
<td>User can select Thin provisioning</td>
</tr>
<tr>
<td>Selected</td>
<td>User cannot select Thin provisioning</td>
</tr>
<tr>
<td></td>
<td>Provisioning is the same as defined in source VMs</td>
</tr>
</tbody>
</table>

23. To define whether the recovery volumes are thin-provisioned or not, select the Thin checkbox.

24. If the virtual machine to be replicated includes a temp data disk as part of its configuration, select the Temp Data checkbox to mark the recovery disk for this disk as a temp data disk. In this case, data is not replicated to the temp data disk after initial synchronization.

25. To edit storage information for one of the virtual machines volumes, select the volume/s and click EDIT SELECTED. When protecting to vCenter, the following Edit Volumes window is displayed. Continue with 26.

When protecting to vCD environments, the following Edit Volumes window is displayed. Continue with 28.
26. **Volume Source**: The source on the recovery site for the replicated data: **Datastore, RDM or Preseeded volume**.

- **Volume Source > Datastore**.

  **Datastore**: A new volume is used for replicated data. Specify the datastore to use to create disks for the replicated data. If the source disk is thin provisioned, the default for the recovery volume is that it is also thin provisioned. The datastore specified for replication must have at least the same amount of space as the protected volume and an additional amount for the journal. The amount of additional space needed for the journal can be fixed by specifying a maximum size for the journal, or can be calculated as the average change rate for the virtual machines in the VPG, multiplied by the length of time specified for the journal history.

  You can use the vSphere Client console Performance tab for each virtual machine to help estimate the change rate. For more details, see the section **Collecting Data Characteristics for VMs**.

- **Volume Source > RDM**.

  **Raw Disk**: The VMware RDM (Raw Device Mapping) to use for the replication.

  - By default, RDM is recovered as **thin-provisioned** VMDK in the datastore specified in the **VM Recovery Datastore** field in the Edit VM dialog, and **not to RDM**.
  
  - You cannot define an RDM disk if the virtual machine uses a BusLogic SCSI controller, nor when protecting or recovering virtual machines in an environment running vCenter Server 5.x with ESX/ESXi version 4.1 hosts.
  
  - Only a raw disk with the same size as the protected disk can be selected from the list of available raw disks. Other raw disks with different sizes are not available for selection.
  
  - The RDM is always stored in the recovery datastore used for the virtual machine.
  
  - The following **limitations** apply to protecting RDM disks:
    
    - RDM disks with an even number of blocks can replicate to RDM disks of the same size with an even number of blocks and to VMDKs.
    
    - RDM disks with an odd number of blocks can only replicate to RDM disks of the same size with an odd number of blocks and not to VMDKs.

- **Volume Source > Preseeded volume**.
Whether to copy the protected data to a virtual disk in the recovery site. Zerto recommends using this option particularly for large disks so that the initial synchronization will be faster since a Delta Sync can be used to synchronize any changes written to the recovery site after the creation of the preseeded disk.

- When not using a preseeded disk, the initial synchronization phase must copy the whole disk over the WAN.
- When using a preseeded virtual disk, you select the datastore and exact location, folder, and name of the preseeded disk, which cannot be an IDE disk.
- Zerto Virtual Replication takes ownership of the preseeded disk, moving it from its source folder to the folder used by the VRA.
- Only disks with the same size as the protected disk can be selected when browsing for a preseeded disk.
- The datastore where the preseeded disk is placed is also used as the recovery datastore for the replicated data.
- If the preseeded disk is greater than 1TB on NFS storage, the VPG creation might fail. This is a known VMware problem when the NFS client does not wait for sufficient time for the NFS storage array to initialize the virtual disk after the RPC parameter of the NFS client times out. The timeout default value is 10 seconds. See the VMware documentation, http://kb.vmware.com/selfservice/microsites/search.do?language=en_US&cmd=displayKC&externalId=1027919, which describes the configuration option to tune the RPC timeout parameter using the command:
  esxcfg-advcfg -s <Timeout> /NFS/SetAttrRPCTimeout

Note the following conditions:

- If the protected disks are non-default geometry, configure the VPG using preseeded volumes.
- If the protected disk is an RDM disk, it can be used to preseed to a recovery VMDK disk. Zerto Virtual Replication makes sure that the VMDK disk size is a correct match for the RDM disk.
- If the VPG is being defined for a Zerto Organization, ZORG, the location of the preseeded disk must be defined in the Zerto Cloud Manager. For details, see Zerto Cloud Manager Administration Guide.

**Datastore:** The datastore where the preseeded disk is located.

**Path:** The full path to the preseeded disk.

27. Continue with 30.

28. Specify the **Volume Source** for recovery from one of the options.

- **vCD managed storage policy:** Zerto will select a datastore, from the list of available datastores, in the selected Storage Policy in which to place the Volume, unless the datastore is excluded in the Configure Provider vDCs Dialog.
  - If there are several valid datastores, the datastore with the most available space is selected.
  - Zerto recalculates the datastore available space for each volume sequentially, taking into consideration previously allocated volumes.

- **Preseeded volume:** A virtual disk (the VMDK flat file and descriptor) in the recovery site that has been prepared with a copy of the protected data. Zerto recommends using this option particularly for large disks so that the initial synchronization is much faster since a Delta Sync is used to synchronize any changes written to the recovery site after the creation of the preseeded disk. When not using a preseeded disk the initial synchronization phase has to copy the whole disk over the WAN. Browse to the preseed folder configured for the customer and the disk name, of the preseeded disk. In order to use a preseeded VMDK, do the following:
  - Create a folder in vCD to use for the preseeded disks in the datastore you want to use for the customer.
  - Specify this datastore as a provider datastore for preseeded disks in the Configure Provider vDCs window, from the Advanced Settings window, as described in Zerto Cloud Manager Administration Guide.
  - In the Zerto Cloud Manager specify the Preseed Folder Name for the ZORG, in the Manage ZORG tab. Zerto Virtual Replication searches for the preseeded folder in the available datastores in the Org vDCs specified in the vCD Cloud Resources for the ZORG in the Zerto Cloud Manager and takes ownership of the preseeded disk, moving it from its source folder to the folder used by the VRA. Note that if the virtual machine has more than one preseeded disk, these disks must reside on the same datastore. If the preseeded disk is greater than 1TB on NFS storage, the VPG creation might fail. This is a known VMware problem when the NFS client does not wait for sufficient time for the NFS
storage array to initialize the virtual disk after the RPC parameter of the NFS client times out. The timeout default value is 10 seconds.

Refer to the VMware documentation, http://kb.vmware.com/selfservice/microsites/search.do?language=en_US&cmd=displayKC&externalId=1027919, which describes the configuration option to tune the RPC timeout parameter using the esxcfg-advcfg -s <Timeout> /NFS/SetAttrRPCTimeout command.

If the VPG is being defined for a Zerto Organization, ZORG, the location of the preseeded disk must be defined in the Zerto Cloud Manager. For details, refer to Zerto Cloud Manager Administration Guide.

Zerto Virtual Replication supports the SCSI protocol. Only disks that support this protocol can be specified. Virtual machine RDMs in a vCenter Server are replicated as VMDKs in a vCD environment.

29. Specify the **Storage Policy** for recovery from one of the options. When selecting the **Storage Policy**, consider the following:

- Storage Policy per volume is supported only in vCD supported versions, and when the selected Orgvdc is not configured for fast provisioning.
- Zerto will select a datastore from the selected Storage Policy in which to place these files, unless the datastore is excluded in the Configure Provider vDCs Dialog.
- The Storage Policies which appear in the drop-down list:
  - Include the **Use VM Default** option (default), which will apply the VM’s storage policy to this volume. This is also the Storage Policy default value.
  - Were defined in VMware vCloud Director and are configured in the Orgvdc.
  - Have at least one Datastore that was not excluded as a Recovery Volume in the Configure Provider vDCs Dialog.

To review site-specific configurations, see Configure Provider vDCs Dialog.

30. If the virtual machine to be replicated includes a Temp Data disk as part of its configuration, select **Temp Data disk** to mark the recovery disk for this disk as a temp data disk. In this case, data is not replicated to the temp data disk after initial synchronization.

31. You can specify whether the recovery volume is **thin-provisioned** or not, unless the Org vDC only supports thin-provisioned volumes.

32. Click **OK**.

33. Click **NEXT**.

The **RECOVERY** step is displayed. Recovery details include the scripts that should be run either at the start or end of a recovery operation.

34. Select the default recovery settings.

- **vCD Guest Customization**: When selected, VMware Guest OS Customization is enabled for the virtual machine in vCloud Director. Enabling guest customization means that the computer name and network settings configured for this virtual machine are applied to its Guest OS when the virtual machine is powered on. vCD Guest Customization must be selected to enable re-IPing the recovered virtual machines.

- **vApp Network Mapping**: The networks to use for failover and move operations, for failover test operations, and for test failover operations after a failover or move when reverse protection is configured. The list of current Org
Networks is displayed and you can specify what network to use in each of the situations. \textit{<Isolated>} means that the network is an internal only vApp network.

35. Enter the name of the script to run in the Command to run text box. You can then enter details about the script.

- **Pre-recovery Script:** The information about a script that should run at the beginning of the recovery process.
- **Post-recovery Script:** The information about a script that should run at the end of the recovery process.

For both types of scripts, enter the following information:

<table>
<thead>
<tr>
<th>TEXT BOX</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command to run</td>
<td>The full path of the script. The script must be located on the same machine as the Zerto Virtual Manager for the recovery site.</td>
</tr>
<tr>
<td>Params</td>
<td>The parameters to pass to the script. Separate parameters with a space.</td>
</tr>
<tr>
<td>Timeout</td>
<td>The time-out, in seconds, for the script to run.</td>
</tr>
<tr>
<td></td>
<td>- If the script runs before executing a failover, move, or test failover, and the script fails or the timeout value is reached, an alert is generated and the failover, move, or test failover is not performed.</td>
</tr>
<tr>
<td></td>
<td>- If the script runs after executing a failover, move, or test failover, and the timeout value is reached, an alert is generated.</td>
</tr>
<tr>
<td></td>
<td>- The default time-out value is specified in \textit{Site Settings &gt; Performance and Throttling} tab.</td>
</tr>
</tbody>
</table>

**NOTE:**

Pre and post recovery scripts run in parallel. Therefore, ensure that the pre and post recovery scripts are not using common resources.

36. Click **NEXT**.

The NICs step is displayed. In this step, you can specify the NIC details to use for the recovered virtual machines after a failover, a test failover, or migration.

37. To edit information in **one field**, click the field and update the information.

38. To edit information for **several virtual machines** at the same time, select the virtual machines and click **EDIT SELECTED**.

39. Otherwise, go to step 42.
The Edit VNIC dialog is displayed.

40. Specify the network details to use for the recovered virtual machines after a failover or move operation, in the Failover/Move column, and for the recovered virtual machines when testing replication, in the Test column.

In each column, specify the following:

- **Network**: The network to use for this virtual machine.
- **New MAC Address**: Whether the Media Access Control address (MAC address) used on the protected site should be replicated on the recovery site. The default is to use the same MAC address on both sites.
- **vNIC IP Mode**: Which IP mode to use. Specify the IP address if you choose static IP pool.
  
  See the Zerto Virtual Replication Interoperability Matrix for the list of operating systems for which Zerto supports RePIng.
  
  During a failover, move, or test failover, if the recovered virtual machine is assigned a different IP than the original IP, then after the virtual machine has started, it is automatically rebooted so that it starts up with the correct IP. If the same network is used for both production and test failovers, Zerto recommends changing the IP address for the virtual machines started for the test, so that there is no IP clash between the test machines and the production machines.

- **Copy to failover test**: Select this to copy the settings in the Failover/Move column to the Test column.
- **Copy to failover/move**: Select this to copy the settings in the Test column to the Failover/Move column.

41. Click **OK**.

42. Click **NEXT**.

The RETENTION POLICY step is displayed. Retention properties govern the VPG retention, including the repository where the retention sets are saved. VPG retention extends the ability to recover virtual machines in a VPG going back one year.

43. By default, Long Term Retention is **OFF**. To keep this value, go to step 47.

44. Otherwise, toggle **OFF** to **ON** and enter the following information:

   - Enter the **Target Repository** name. This is the name of the repository where the repository sets are written.
Repositories are configured via the SETUP tab as described in Creating a New Repository for Retention.
- Select the Retention Period from the drop-down list. The time you select is the length of time to keep repository sets. This is up to a maximum of one year. For details of how this affects the number of retention sets saved, see Storing Repository Sets.

45. Run Job Every: The recurrence and time to start the retention process.
46. Retries: Select Automatic retry after failure to automatically rerun the retention process, if the job fails.
   - If you select this option, you must also define Number of attempts, and the Wait time between retries.
47. Click NEXT.
   The SUMMARY step is displayed. It shows the VPG configuration that you defined in previous steps.
48. Click DONE. The VPG is created.

For details of what happens after saving the VPG, see “What Happens After the VPG is Defined”, on page 29.

The virtual machines in the VPG are protected as a vCD vApp in the recovery site.
Replication From a Protected Site Hyper-V Server to a Recovery Site AWS

You can protect a Hyper-V site to Amazon Web Services (AWS).

When creating a VPG from Hyper-V to AWS the data is stored in S3 and all replicated data from protected virtual machines to AWS is encrypted in S3. All recovery operations bring up the recovered machines in EC2 in AWS.

Before replicating from a protected Hyper-V site to a recovery AWS site, review the following guidelines for AWS environments, and considerations when protecting to AWS: Zerto Virtual Replication - Prerequisites & Requirements for Amazon Web Services (AWS)

See also: “Import Methods for AWS”, on page 83

After reviewing the guidelines and considerations, proceed with “Creating a Virtual Protection Group to Recover in AWS”, on page 86.

Import Methods for AWS

During recovery operations, Zerto uses a combination of the following APIs and methods to convert the Amazon S3 objects into recovery disks in EC2 as EBS disks:

- **AWS Import:**
  - **Import-instance**: for the boot volume
  - **Import-volume**: for data volumes

For more information see the relevant AWS documentation:
- API_ImportInstance
- API_ImportVolume

**Note:** The ImportImage API is not used by Zerto.

- **Zerto Import - zImport**, an import method that does not have the same limitations as the AWS APIs. It creates an AWS EC2 instance per protected VM volume, called zimporter, to convert the S3 objects and write them to a zImport local disk. When all the data has been imported and its disk have been attached to the recovered instance, the zImport instance is terminated.

**Notes:**
- zimporter is based on an official AWS Linux AMI (Amazon Machine Image), into which a script is injected to perform the import. The script is located online and downloaded to the zimporter, and thus the zimporter requires internet access in order to access and download the script. The zimporter instance is therefore created with a public IP.
- The only network in the customer environment that is certain to have internet access is the network that the ZCA is connected to.
- To ensure that the zimporter instance cannot be accessed from the outside world, a security group is created. During a recovery operation the zimporter instance is connected to this security group. All inbound traffic is blocked and only outbound traffic to access the script online is allowed. The security group is deleted at the end of the recovery operation.
- The default zimporter instance type is c5.4xlarge and the AWS EC2 default maximum instance quota is 10. If during the creation of zimport instances the maximum EC2 instance quota is reached, the creation of the next and subsequent zimport instances will be queued, increasing the RTO. If during recovery operations, the ZVM identifies a VPG with the potential to exceed the EC2 instance quota, the user will receive an alert with advice to contact AWS support to increase the service limits in order to improve RTO.
- Each zimporter VM is responsible for the import process of a single volume. Therefore, it is recommended to contact AWS and increase the maximum instance quota of the c5.4xlarge instance type to the maximum number of volumes you are planning to failover to AWS at once.
- GPT formatted disks are supported for data volumes only, when using either of the zimport methods.
- When using either of the zimport methods, each volume is created with EBS disk of type io1 with maximum 1000 EBS Provision IOPS allocated. EBS disk type can be changed post recovery without downtime, see the relevant AWS documentation. The minimum disk size for io1 is 4GB.
- The default Max EBS Provision IOPS quota in a region across all io1 disks is 40000 EBS Provision IOPS, meaning that with 1000 EBS Provision IOPS per volume, the maximum possible number of volumes is 40. If the Max EBS Provision
IOPS quota is reached, the failover process will switch to using slower gp2 disks. An event will notify the user of this, and recommend that the user contact AWS support to increase the Max EBS Provision IOPS quota.

- Depending on the desired RTO during recovery operations, or when testing failover, the user can select an import method per VPG or per virtual machine from the following options:
  - “Zerto Import for Data Volumes”, on page 84
  - “Zerto Import for All Volumes”, on page 84
  - “AWS Import”, on page 85

Zerto Import for Data Volumes

This method is the default setting and has a faster RTO than AWS Import. This method uses a combination of the AWS import-instance API for the boot volume, and the zImport method for data volumes.

- Each machine that you intend to protect must have at least 250MB free space. This is because AWS adds files to the recovered machines during failover, move, test failover, and clone operations.
- Protected boot volumes are recovered in EC2 as EBS disks with magnetic disk type. Virtual machines with disks that are less than 1GB are recovered with disks of 1GB. Temporary disks may be created based on the selected instance size.
- Temporary disks may be created based on the selected instance size.
- The maximum protected data volume size is 16TB, while the boot volume can be up to 1TB.
- The AWS ImportInstance API only supports single volume VMs. The boot volume of the protected virtual machine should not be attached to any other volume to successfully boot. For more information, see http://docs.aws.amazon.com/AWSEC2/latest/APIReference/API_ImportInstance.html

Zerto Import for All Volumes

This method uses the zImport method for all volumes and ensures the fastest RTO.

This method creates an AWS EC2 instance per protected VM volume, called zImporter, to convert the S3 objects and write them to a zimport local disk. When all the data has been imported and its disk have been attached to the recovered instance, the zImport instance is terminated.

- Temporary disks may be created based on the selected instance size.
- The maximum protected data volume size is 16TB, while the boot volume can be up to 2047GiB.

Note: Some VMs use the MBR partitioning scheme, which only supports up to 2047 GiB boot volumes. If your instance does not boot with a boot volume that is 2TB or larger, the VM you are using may be limited to a 2047 GiB boot volume size. Non-boot volumes do not have this limitation. See AWS Documentation for more information: http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/EBSVolumeTypes.html

When using Zerto Import for All Volumes import method, if the protected virtual machine using this import method is running Windows 2012, Windows 2012R2 or Windows 2016, the following drivers must be installed on the protected virtual machine before starting recovery operations:

- Windows ENA (Elastic Network Adapter) Drivers

When recovering to C5/M5 instances using Zerto Import for All Volumes import method, only Windows 2012R2 and Windows 2016 are supported. The following drivers must be installed on the protected virtual machine before starting recovery operations when recovering to C5/M5 instances:

- Windows ENA (Elastic Network Adapter) Drivers
- NVMe driver

Note: If these drivers are installed on a VM running Windows 2012R2, the other AWS import methods will fail. To overcome this, you must uninstall the drivers before using the other AWS import methods.

The following steps must be performed to ensure that the virtual machine will be able to run on the recovery site:

1. Download and Install Windows ENA Drivers:

   **NOTE:**

   If you are recovering to C5/M5 instances, skip this step and go to step 2.
If you are running Windows 2012 or Windows 2016 on any of the following AWS instance types:

- C3
- C4
- D2
- I2
- R3
- M4 (excluding M4.16xlarge)

  a) Go to http://docs.aws.amazon.com/AWSEC2/latest/WindowsGuide/sriov-networking.html#enable-enhanced-networking
  b) Follow the instructions at the site for downloading and installing the Windows ENA Drivers.

2. When using **C5/M5 instance types only**, the following drivers need to be installed:
   a) Download ENA (Enhanced Network Adapter) from this link.
   b) Extract and execute "InstallEna.ps1"
   c) Download the NVMe driver from this link.
   d) Extract and execute "Dpinst.exe"

---

**NOTES:**

C5/M5 instance types are supported with the Zerto Import for All Volumes import method only.

---

**IMPORTANT:**

When using this import method for Windows machines, **ZertoTools** for AWS needs to be run on the **protected** Windows virtual machine in VMware **before VPG creation**. For more information, see [ZertoTools for AWS](http://<link>)

---

**AWS Import**

This method uses a combination of the **AWS import-instance** and **import-volume** APIs for the boot and data volumes respectively. This was the only method supported until version 5.5.

- **Each machine that you intend to protect** must have at least **250MB free space**. This is because AWS adds files to the recovered machines during failover, move, test failover, and clone operations.

- **Protected boot volumes** are recovered in EC2 as EBS disks with magnetic disk type. Virtual machines with disks that are less than 1GB are recovered with disks of 1GB. Additional volumes might be created in the recovered instance, dependent on the instance type used for the recovery. These volumes can be ignored.

- **Protected volumes** are recovered in EC2 as EBS disks with magnetic disk type. Virtual machines with disks that are less than 1GB are recovered with disks of 1GB. Additional volumes might be created in the recovered instance, dependent on the instance type used for the recovery. These volumes can be ignored. Temporary disks may be created based on the selected instance size.

- The **maximum** protected **data volume** and **boot disk** size is **1TB**.

The AWS ImportInstance API only supports single volume VMs. The boot volume of the protected virtual machine should not be attached to any other volume to successfully boot. For more information, see [http://docs.aws.amazon.com/AWSEC2/latest/APIReference/API_ImportInstance.html](http://docs.aws.amazon.com/AWSEC2/latest/APIReference/API_ImportInstance.html)
Creating a Virtual Protection Group to Recover in AWS

Use the following procedure to create a VPG in a protected Hyper-V site to recover to an AWS site.

To create a virtual protection group (VPG) to recover in AWS:
1. In the Zerto User Interface, select ACTIONS > CREATE VPG.
   The GENERAL step of the Create VPG wizard is displayed.

2. Specify the name of the VPG and the priority of the VPG.
   - **VPG Name**: The VPG name must be unique. The name cannot be more than 80 characters.
   - **Priority**: Determine the priority for transferring data from the protected site to the recovery site when there is limited bandwidth and more than one VPG is defined on the protected site.
     - **High Priority**: When there are updates to virtual machines protected in VPGs with different priorities, updates from the VPG with the highest priority are passed over the WAN first.
     - **Medium Priority**: Medium priority VPGs will only be able to use whatever bandwidth is left after the high priority VPGs have used it.
     - **Low Priority**: Low priority VPGs will use whatever bandwidth is left after the medium priority VPGs have use it. Updates to the protected virtual machines are always sent across the WAN before synchronization data, such as during a bitmap or delta sync. During synchronization, data from the VPG with the highest priority is passed over the WAN before data from medium and low priority VPGs.

3. Click **NEXT**.
4. Select the VMs that will be part of this VPG and click the arrow pointing right to include these VMs in the VPG.
   - When using the Search field, you can use the wildcards; * or ?
   Virtual machines that are not yet protected are displayed in the list. A VPG can include virtual machines that are not yet protected and virtual machines that are already protected.
5. You can view protected virtual machines in the Advanced (One-to-Many) section, by clicking Select VMs.
   The Select VMs dialog is displayed.

   ![Select VMs dialog](image)

   Note: Virtual machines can be protected in a maximum of three VPGs. These VPGs cannot be recovered to the same site. Virtual machines protected in the maximum number of VPGs are not displayed in the Select VMs dialog.

   Protecting virtual machines in several VPGs is enabled only if both the protected site and the recovery site, as well as the VRAs installed on these sites, are of version 5.0 and higher.
6. To define the boot order of the virtual machines in the VPG, click DEFINE BOOT ORDER, otherwise go to the next step.
   When virtual machines in a VPG are started in the recovery site, by default these machines are not started up in a particular order. If you want specific virtual machines to start before other machines, you can specify a boot order. The virtual machines are defined in groups and the boot order applies to the groups and not to individual virtual machines in the groups. You can specify a delay between groups during startup.
Note: Up to five (5) virtual machines may boot on a host simultaneously. Following the boot, a 300 second (default) delay occurs until the next boot batch.

Initially, virtual machines in the VPG are displayed together under the Default group. If you want specific machines to start before other virtual machines, define new groups with one or more virtual machines in each group.

7. Click **ADD GROUP** to add a new group. Then, do the following:
   a) To change the name of a group, click the Pencil icon next to the group.
   b) To delete a group, click the delete icon on the right side. You cannot delete the Default group nor a group that contains a virtual machine.
   c) Drag virtual machines to move them from one group to another.
   d) Drag groups to change the order the groups are started, or, optionally, in **Boot Delay**, specify a time delay between starting up the virtual machines in the group and starting up the virtual machines in the next group.
   For Example: Assume three groups, Default, Server, and Client, defined in this order. The boot delay defined for the Default group is 10, for the Server group is 100, and for the Client group 0. The virtual machines in the Default group are started together and after 10 seconds the virtual machines in the Server group are started. After 100 seconds the virtual machines in the Client group are started.
   e) Click **OK** to save the boot order.

When configuring boot order settings, define the boot disk to be first in the boot sequence in order to avoid boot failure.

8. Click **NEXT**.

The **REPLICATION** step is displayed.

Note: If the protected site is paired with only one recovery site, the recovery step is displayed with the **Recovery Site** field automatically filled in and defaults set, as shown below.
9. Specify the **Recovery Site**. This is the site to which you want to recover the virtual machines. After specifying the recovery site, other fields are displayed.

![Recovery Site Configuration](image)

**Note:** Steps that do not require input are marked with a check mark. You can jump directly to a step that has been marked with a check mark to edit the values for that step. Every step must be marked with a check mark before you can click **DONE** to create the VPG.

10. Optionally, change the default **SLA** values:
   - **Journal History:** The time that all write commands are saved in the journal. The longer the information is saved in the journal, the more space is required for each journal in the VPG. Select the number of **hours** from 1 to 24 or the number of **days** from 2 to 30.
   - **Target RPO Alert:** The maximum desired time between each automatic checkpoint write to the journal before an alert is issued.
   - **Test Reminder:** The amount of time in months recommended between each test, where you test the integrity of the VPG. A warning is issued if a test is not performed within this time frame.

11. Click **NEXT**.

   The **STORAGE** step is displayed.

   By default, the storage used for the virtual machine definition is also used for the virtual machine data. For each virtual machine in the VPG, Zerto Virtual Replication displays its storage-related information.

![Storage Configuration](image)

14. Specify whether the protected volume is a temp data disk.
**Temp Data:** If the virtual machine to be replicated includes a temp data disk as part of its configuration, mark the recovery disk for this disk as a temp data disk. In this case, data is not replicated to the temp data disk after initial synchronization.

15. Click **NEXT**.

The **RECOVERY** step is displayed. Recovery details include the import method, networks, security group, instance family, and instance type to use for failover, move, and testing failover, and whether scripts should run as part of the recovery process.

**Note:** Steps that do not require input are marked with a check mark. You can jump directly to a step that has been marked with a check mark to edit the values for that step. Every step must be marked with a check mark before you can click **DONE** to create the VPG.

16. Select recovery settings for failover/move and failover testing.

**Import Method**

The Import Method drop-down list allows you to select an import method.

- **Zerto Import for data volumes:** Uses the zImport method for **data volumes** only. This is the **default** setting and usually has a faster RTO than AWS Import.
- **Zerto Import for all volumes:** This is usually the fastest import method and uses a zImport VM for **all volumes**.
- **AWS Import:** This was the only import method supported until version 5.5.
- **VPC Network:** The virtual network dedicated to your AWS account. A security group and subnet must be assigned to this VPC.
- **Subnet:** The subnet for the VPC network.

Depending on the import method selected, the list of subnets available for selection is shown.

- **Zerto Import - zImport:** The subnet drop-down list shows the options available when either the Zerto Import for data volumes or the Zerto Import for all volumes is selected. Only the subnets that are supported by the zImport method are selectable. Other Subnets are grayed out and are not selectable.
Zerto Virtual Manager Administration Guide for the Microsoft Hyper-V Environment - Version 6.5
Protecting Virtual Machines from Hyper-V

Note: The zImport virtual machine must have access to the internet in order to access the S3 Bucket and the AMI in EC2. The only network in the customer environment that is certain to have internet access is the network that the ZCA is connected to. If the import method is not AWS Import, then the user can select only subnets that are part of the same Availability Zone as the one in which the ZCA resides. Other Subnets are disabled.

- **AWS Import:** The Subnet drop-down list shows options available when AWS Import method is selected. All subnets are listed. A tool tip alert is displayed when the user hovers over a subnet that is not supported.

Note: If a subnet is chosen in a network that is not in the same Availability Zone as the one in which the ZCA resides, options that utilize the zImport method will not be made available for selection.

- **Security Group:** The AWS security to be associated with the virtual machines in this VPG.
- **Instance Family:** The instance family from which to select the type. AWS instance families are optimized for different types of applications. Choose the instance family appropriate for the application being protected in the VPG.
- **Instance Type:** The instance type, within the instance family, to assign to recovered instances. Different types within an instance family vary, for example in vCPU, RAM, and local storage size. Choose the instance type appropriate for the application being protected in the VPG. The price per instance is related to the instance configuration.

**NOTE:**

**C5/M5** instance types are supported with the Zerto Import for All Volumes import method only.

- For additional settings, click **ADVANCED VM SETTINGS**.
The Advanced VM Settings window is displayed, which shows the recovery network settings for \texttt{FAILOVER/MOVE} for virtual machines in the VPG. You can see the recovery network settings for failover tests by clicking \texttt{TEST}.

17. To edit information in one field, click the field and update the information.

18. To edit information for several virtual machines at the same time, select the virtual machines and click \texttt{EDIT SELECTED}. The Edit VM Settings dialog is displayed.

19. Update the values for Import Method, VPC network, subnet, security group, instance family, instance type, and private IP as necessary.

\textbf{Note:} Only private IPs specified for Windows machines are assigned during a recovery operation. For Linux machines, the IP is assigned from the specified subnet range.

Clearing the values in the \texttt{Private IP} field results in an IP being automatically assigned from the subnet range during a recovery operation.

See the Zerto Virtual Replication Interoperability Matrix for the list of operating systems for which Zerto supports Re-IpIn.

20. Click \texttt{OK} twice to return to the main page of the \texttt{RECOVERY} step.

21. Enter the name of the script to run in the Command to run text box. You can then enter details about the script.
   - \texttt{Pre-recovery Script:} The information about a script that should run at the beginning of the recovery process.
   - \texttt{Post-recovery Script:} The information about a script that should run at the end of the recovery process.
For both types of scripts, enter the following information:

<table>
<thead>
<tr>
<th>TEXT BOX</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command to run</td>
<td>The full path of the script. The script must be located on the same machine as the Zerto Virtual Manager for the recovery site.</td>
</tr>
<tr>
<td>Params</td>
<td>The parameters to pass to the script. Separate parameters with a space.</td>
</tr>
<tr>
<td>Timeout</td>
<td>The time-out, in seconds, for the script to run.</td>
</tr>
<tr>
<td></td>
<td>■ If the script runs before executing a failover, move, or test failover, and the script fails or the timeout value is reached, an alert is generated and the failover, move, or test failover is not performed.</td>
</tr>
<tr>
<td></td>
<td>■ If the script runs after executing a failover, move, or test failover, and the timeout value is reached, an alert is generated.</td>
</tr>
<tr>
<td></td>
<td>■ The default time-out value is specified in Site Settings &gt; Performance and Throttling tab.</td>
</tr>
</tbody>
</table>

**NOTE:**

Pre and post recovery scripts run in parallel. Therefore, ensure that the pre and post recovery scripts are not using common resources.

22. Click NEXT.

The RETENTION POLICY step is displayed. Retention properties govern the VPG retention, including the repository where the retention sets are saved. VPG retention extends the ability to recover virtual machines in a VPG going back one year.

23. By default, Long Term Retention is OFF. To keep this value, go to step 27.

24. Otherwise, toggle OFF to ON and enter the following information:

■ Enter the **Target Repository** name. This is the name of the repository where the repository sets are written. Repositories are configured via the SETUP tab as described in Creating a New Repository for Retention.

■ Select the **Retention Period** from the drop-down list. The time you select is the length of time to keep repository sets. This is up to a maximum of one year. For details of how this affects the number of retention sets saved, see Storing Repository Sets.

25. **Run Job Every:** The recurrence and time to start the retention process.

26. **Retries:** Select **Automatic retry after failure** to automatically rerun the retention process, if the job fails.

■ If you select this option, you must also define **Number of attempts**, and the **Wait time between retries**.

**Note:** You cannot restore a retention set in AWS.

27. Click NEXT.
The SUMMARY step is displayed. It shows the VPG configuration that you defined in the previous steps.

28. Click **DONE**. The VPG is created.

For details of what happens after creating the VPG, see “What Happens After the VPG is Defined”, on page 29.
Replication From a Protected Site Hyper-V Server to a Recovery Site Microsoft Azure

You can protect virtual machines to Microsoft Azure. The procedure is the same whether you intend to protect one virtual machine or multiple virtual machines.

When creating a VPG from Hyper-V to Azure the data is stored in a storage account and all replicated data from protected virtual machines to Azure is encrypted in the storage account. All recovery operations bring up the recovered machines in resource groups in Azure.

See also:
- “Requirements for Microsoft Azure Environments”, on page 95
- “VPGs Recovering to Azure Standard Storage and Premium Managed Disks”, on page 97
- “Converting Premium Virtual Machines for Protection”, on page 98
- “Protecting From Hyper-V - To a Microsoft Azure Recovery Site”, on page 100

Requirements for Microsoft Azure Environments

- Azure ZCA can be installed only on Windows Server 2012 R2 and higher. Only virtual machines that are supported by Azure can be protected by Zerto Virtual Replication. All Windows operating systems are supported.
  - Note: Microsoft does not support operating systems that are past the End of Support date, without a Custom Support Agreement (CSA). For more information about Microsoft operating systems support for Microsoft Azure, refer to https://support.microsoft.com/en-us/kb/2721672.
- To replicate between Azure and your site, you must have a virtual machine in Azure with a Zerto Cloud Appliance installed on it. This ZCA must be paired with your site.
- Only general-purpose v1 (GPv1) accounts are supported.
- It is recommended to use a separate storage account for each ZCA.
- For Linux distribution, refer to Azure documentation:
- Ultra SSD storage is not supported.

Requirements for Replication From Azure

- For Virtual Machines to be protected from Azure, the VM volumes must reside in the Standard storage account defined during ZCA installation.
  - A Standard storage account is created or selected upon ZCA installation.
  - Type: Standard storage
  - Recovery and journal volumes reside on this Zerto Storage Account.
  - Only general-purpose v1 (GPv1) accounts are supported.
  - Azure VMs with all disks on this Zerto Storage Account can be protected by Zerto.
  - Blob Storage is not supported.
  - VMs which are not deployed via the Azure Resource Manager cannot be protected from Azure.

Requirements for Replication To Azure

- Protected volumes are recovered in Azure as VHD disks in a page blob. Virtual machines with disks that are less than 1GB are recovered with disks of 1GB.
  - Note: For some instance sizes, the Azure virtual machine is created with a Local SSD disk which is a temporary disk. This disk is in addition to the disks associated with each protected virtual machine.
- The following limitations apply when protecting to Azure
  - Virtual machines with UEFI Firmware cannot be protected.
  - You cannot protect machines that have a disk larger than 4 TB.
  - The protected virtual machines needs to have at least one NIC.
 Reserve at least **2 CPUs** and **4GB RAM** for the machine using a subnet accessible by other Zerto Virtual Replication sites.

- The supported number of data disks and NICS per virtual machine is dependent on the selected instance size. For example, instance size D3_v2 allows up to eight data disks per virtual machine.

**Requirements for Replication within Azure**

- Azure ZCA on both Azure sites need to be version 6.0 and higher.
- The following limitations apply when protecting within Azure:
  - Self replication is not supported.

**Additional Azure Considerations**

For additional considerations, see [Azure subscription and service limits, quotas and constraints](https://docs.microsoft.com/en-us/azure/azure-subscription-service-limits).

For example from the link, see the following default values:

- There can be multiple Zerto Cloud Appliances per Azure subscription and region.
- 20 cores per subscription
- 200 Storage accounts per subscription
- 20 VMs per region per subscription
- 20 VMs per series (Dv2, F, etc.) cores per subscription per Region

Additionally, see the following example for **maximum** values:

- A Standard storage account has a maximum total request rate of 20,000 IOPS. The total IOPS across all of your virtual machine disks in a Standard storage account should not exceed this limit.

<table>
<thead>
<tr>
<th>VM TIER</th>
<th>BASIC TIER VM</th>
<th>STANDARD TIER VM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disk size</td>
<td>4 TB</td>
<td>4 TB</td>
</tr>
<tr>
<td>Max 8 KB IOPS per persistent disk</td>
<td>300</td>
<td>500</td>
</tr>
<tr>
<td>Max number of disks performing max IOPS</td>
<td>66</td>
<td>50</td>
</tr>
</tbody>
</table>

See also “Azure Limitations Which Affect Installation and Recoverability”, on page 96.

**Azure Limitations Which Affect Installation and Recoverability**

Below are the default Azure limitations which affect installation and recovery.

**Default Azure limitations which Affect Installation**

- **Storage Limitations:**
  - Number of storage accounts: **200 per subscription** (note: max is 250)

**Default Azure Limitations which Affect Recovery**

<table>
<thead>
<tr>
<th>Virtual Machines Limitations</th>
<th>VMs per subscription per region: 20 (max: 10K)</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM total cores per subscription per region:</td>
<td>20</td>
</tr>
<tr>
<td>Instance sizes:</td>
<td>Limited per region. Many of them are 20 cores per region per subscription</td>
</tr>
<tr>
<td>Resource groups per subscription:</td>
<td>800</td>
</tr>
</tbody>
</table>
VPGs Recovering to Azure Standard Storage and Premium Managed Disks

Azure recovery of the VPG can be configured to Premium Managed or Standard Storage.

- **Recovering VMs to the Standard Storage Account:**
  A VPG that all its virtual machines are recovered to the Standard storage account, as defined during the ZCA installation, can be Reverse Protected. For more information about Reverse Protection, see the Reverse Protection for a Moved VPG section.

- **Recovering VMs to Premium Managed Disks:**
  A VPG that all its virtual machines are recovered to Premium Managed disks goes into Recovered state. To protect a virtual machine with Premium Managed disks, see the Converting Premium Virtual Machines for Protection section.

- **Recovering VMs to Both Standard Storage and Premium Managed Disks:**
  In the case where a VPG has virtual machines recovering to both Standard storage and Premium Managed disks, the recovered VPG goes into a Needs Configuration state. In this scenario, you can remove the virtual machines that are recovered to Premium Managed disks in order to protect the virtual machines recovered to Standard storage.

To remove virtual machines recovered to Premium Managed disks:

a) Open the **Edit VPG** window > **VMs** tab.

b) Remove the VMs that are in Premium Managed disks. (These VMs appear as grayed out.)

c) Click **Edit Save**; the VPG is updated.
Converting Premium Virtual Machines for Protection

The **Premium to Standard Conversion** tool enables replicating and failing over Premium VMs in Azure. The tool clones the Premium Managed VMs and creates the same VM with Standard Storage disks, which the ZCA will then be able to protect.

The Premium to Standard Conversion tool is installed on the Azure ZCA machine as part of the ZVM installation.

The tool requires the user to enter input parameters which are then parsed and validated. Once the input parameters are validated, the application starts running. The conversion process then begins for each of the Premium VMs received in the input parameters.

**GLOSSARY:**

**Premium VM:** A Premium VM is when the original VM has all its disks on **Premium Managed storage**.

**Note:** We do not support conversion of VMs with disks on Premium Storage account.

**Standard VM:** A Standard VM is a copy made of the Premium VM, where the disks are copied from Premium Managed storage to the **ZCA's Standard Storage account**.

**IMPORTANT:**

Note that running the Premium to Standard Conversion tool will cause your Premium VM to be powered off.

**To convert Premium VMs for protection:**

1. From the Azure ZCA machine, locate the **Premium to Standard Conversion tool** folder from under the main ZVM installer folder.
2. Download and extract the Convert Premium VM tool files.
3. Copy the name of the tool (exe. file).
4. Open the **Command Prompt** window and paste the name of the tool (exe. file) to the command.
5. There are two ways to insert parameters; either as flag arguments or as a path to a .json file that contains the input parameters.

   The following parameters need to be entered:
   - **User Name & Password:** These are the same credentials used in the ZCA installation.
   - **Region Id:** The region in which the VM to be converted resides.
   - **Subscription Id:** The subscription in which the VM to be converted resides.
   - **VM Identifiers:** The list of VMs that need to be converted. If more than one VM needs to be converted, the VM identifiers should be separated with commas. The VM identifier should be copied from the Premium VM properties (**Properties tab > Resource ID**.)
   - **Storage Account Name:** The storage account as defined for the ZCA.
   - **Container Name:** The name of the container in the Standard Storage Account where the new volumes will be stored.

**NOTE:**

You can view argument examples within the Command Prompt window by entering the help argument (e.g. ‘-h’).
6. The information is parsed and the log files are printed and saved to the Premium to Standard Conversion tool folder. The conversion process is performed for each VM sequentially. The following occurs:
   ■ The Premium VM is turned off (if necessary).
   ■ The VM’s volumes are copied into the Standard Storage account as defined in the Storage Account Name parameter. The copy is done sequentially.
   ■ The Premium VM NICs are detached and receives a NIC with a single IP, regardless of its original NIC/IP configuration.
   ■ A new VM is created in the Standard Storage account, with the identical NICs as defined in the original VM.
   ■ The name of the new VM is “<original_name>-Standard” with the new standard volumes attached to it.

7. Create a VPG with the new Standard Storage VMs to start protecting them. See Protecting From a Microsoft Azure Site - To a Microsoft Azure Recovery Site.
NOTE:

Upon failing over the Standard VM, only one IP address is assigned to the recovered VM. Any additional network configurations should be entered manually.

Undo Process

If there is a failure in one of the phases during the conversion process, the system will automatically rollback to the previous state.

If at least one volume cannot be copied, all volumes that have already been copied to the Standard VM are deleted. The Premium VM is then powered on again (only if the VM was powered on in its original state).

In some cases the system won’t succeed to automatically rollback, for example, if the tool’s application crashes. You can open the log entries to see which undo operations are left to execute. In this case, you need to manually rollback to the previous state, as required at each stage, depending where the failure occurred.

To manually rollback:
1. Detach the NICs from the Standard VM and attach it to the powered down Premium VM.
2. Delete the new primary NIC that was created for the Premium VM.
3. Remove disks from the Standard Storage account.
4. Power on the Premium VM (if necessary).

Protecting From Hyper-V - To a Microsoft Azure Recovery Site

Use the following procedure to replicate from a protected site Hyper-V to a recovery site Microsoft Azure.

To create a virtual protection group (VPG) to recover in Microsoft Azure:

Note: Steps that do not require input are marked with a check mark. You can jump directly to a step that has been marked with a check mark to edit the values for that step. Every step must be marked with a check mark before you can click DONE to create the VPG.

1. In the Zerto User Interface, select ACTIONS > CREATE VPG.

The GENERAL step of the Create VPG wizard is displayed.
2. Specify the name of the VPG and the priority of the VPG.
   ■ **VPG Name:** The VPG name must be unique. The name cannot be more than 80 characters.
   ■ **Priority:** Determine the priority for transferring data from the protected site to the recovery site when there is limited bandwidth and more than one VPG is defined on the protected site.
     ■ **High Priority:** When there are updates to virtual machines protected in VPGs with different priorities, updates from the VPG with the highest priority are passed over the WAN first.
     ■ **Medium Priority:** Medium priority VPGs will only be able to use whatever bandwidth is left after the high priority VPGs have used it.
     ■ **Low Priority:** Low priority VPGs will use whatever bandwidth is left after the medium priority VPGs have use it.
     Updates to the protected virtual machines are always sent across the WAN before synchronization data, such as during a bitmap or delta sync.
     During synchronization, data from the VPG with the highest priority is passed over the WAN before data from medium and low priority VPGs.

3. Click **NEXT**.
   The VMs step is displayed.

4. Select the VMs that will be part of this VPG and click the arrow pointing right to include these VMs in the VPG.
   ■ When using the **Search** field, you can use the wildcards; * or ?
   Virtual machines that are not yet protected are displayed in the list. A VPG can include virtual machines that are not yet protected and virtual machines that are already protected.

5. You can view protected virtual machines in the **Advanced (One-to-Many)** section, by clicking **Select VMs**.
   The Select VMs dialog is displayed.
Note: Virtual machines can be protected in a maximum of three VPGs. These VPGs cannot be recovered to the same site. Virtual machines protected in the maximum number of VPGs are not displayed in the Select VMs dialog.
Protecting virtual machines in several VPGs is enabled only if both the protected site and the recovery site, as well as the VRAs installed on these sites, are of version 5.0 and higher.

6. Click NEXT.
The REPLICATION step is displayed.

Note: If the protected site is paired with only one recovery site, the recovery step is displayed with the Recovery Site field automatically filled in and defaults set, as shown below.

7. Specify the Recovery Site. This is the site to which you want to recover the virtual machines. After specifying the recovery site, other fields are displayed.
8. Optionally, change the default SLA values:
   - **Journal History**: The time that all write commands are saved in the journal. The longer the information is saved in the journal, the more space is required for each journal in the VPG. Select the number of hours from 1 to 24 or the number of days from 2 to 30.

9. **Target RPO Alert**: The maximum desired time between each automatic checkpoint write to the journal before an alert is issued.

10. **Test Reminder**: The amount of time in months recommended between each test, where you test the integrity of the VPG. A warning is issued if a test is not performed within this time frame.

11. Click **NEXT**. The STORAGE step is displayed.

By default the storage used for the virtual machine definition is also used for the virtual machine data. For each virtual machine in the VPG, Zerto Virtual Replication displays its storage-related information.

12. Specify whether the protected volume is a temp data disk.
   - **Temp Data**: If the virtual machine to be replicated includes a temp data disk as part of its configuration, mark the recovery disk for this disk as a temp data disk. In this case, data is not replicated to the temp data disk after initial synchronization.
14. Select recovery settings for failover/move and failover testing.
   - **VNet:** The virtual network dedicated to your Azure subscription.
   - **Subnet:** The subnet or the VNet network.
   - **Network Security Group:** The Azure network security to be associated with the virtual machines in this VPG. You can associate one network security group with the virtual machines. The NIC will be associated with the network security group defined at the virtual machine level.
   - **Recovery Disk Type:** Select the Azure recovery storage type to which the entire VPG will be recovered to; Premium Managed or Standard Storage. The Virtual Machine Series and Virtual Machine Size fields are updated with the relevant options based on the selected Recovery Disk Type.
     
     **Note:** To protect Premium Managed disks, see Converting Premium Virtual Machines for Protection.
   - **Virtual Machine Series:** The virtual machine series from which to select the size. Azure virtual machine series are optimized for different types of applications. The default is set to DSv2. You can choose the virtual machine series appropriate for the application being protected in the VPG.
   - **Virtual Machine Size:** The virtual machine size, within the virtual machine series, to assign to recovered virtual machines. Different sizes within a virtual machine series vary, for example in a number of cores, RAM, and local storage size. The default is set to Standard_DS1_v2. You can choose the virtual machine size appropriate for the application being protected in the VPG. The price per virtual machine is related to the virtual machine configuration.

15. For additional settings, click **ADVANCED VM SETTINGS**.
The Advanced VM Settings dialog is displayed, which shows the recovery network settings for failover and move for virtual machines in the VPG. You can see the recovery network settings for failover tests by clicking TEST.

16. To edit information in one field, click the field and update the information.
17. To edit information for several virtual machines at the same time, select the virtual machines and click EDIT SELECTED. The Edit VM Settings dialog is displayed.

18. Update the values for VNet, subnet, security group, instance family, instance size, and private IP as necessary.
   **Note:** Only private IPs specified for Windows machines are assigned during a recovery operation. For Linux machines, the IP is assigned from the specified subnet range.
   Clearing the values in the Private IP field results in an IP being automatically assigned from the subnet range during a recovery operation.
   See the Zerto Virtual Replication Interoperability Matrix for the list of operating systems for which Zerto supports Re-IPing.
19. Click OK twice to return to the main page of the RECOVERY step.
20. Enter the name of the script to run in the Command to run text box. You can then enter details about the script.
   - **Pre-recovery Script:** The information about a script that should run at the beginning of the recovery process.
   - **Post-recovery Script:** The information about a script that should run at the end of the recovery process.
   For both types of scripts, enter the following information:

<table>
<thead>
<tr>
<th>TEXT BOX</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command to run</td>
<td>The full path of the script. The script must be located on the same machine as the Zerto Virtual Manager for the recovery site.</td>
</tr>
</tbody>
</table>
21. Click **NEXT**.

The RETENTION POLICY step is displayed. Retention properties govern the VPG retention, including the repository where the retention sets are saved. VPG retention extends the ability to recover virtual machines in a VPG going back one year.

22. By default, Long Term Retention is **OFF**. To keep this value, go to step 27.

23. Otherwise, toggle OFF to **ON** and enter the following information:
   - Enter the **Target Repository** name. This is the name of the repository where the repository sets are written. Repositories are configured via the SETUP tab as described in Creating a New Repository for Retention.
   - Select the **Retention Period** from the drop-down list. The time you select is the length of time to keep repository sets. This is up to a maximum of one year. For details of how this affects the number of retention sets saved, see Storing Repository Sets.

24. **Run Job Every**: The recurrence and time to start the retention process.

25. **Retries**: Select **Automatic retry after failure** to automatically rerun the retention process, if the job fails.
   - If you select this option, you must also define **Number of attempts**, and the **Wait time between retries**.
   - **Note**: You cannot restore a retention set in Azure.

26. Click **NEXT**.
The SUMMARY step is displayed. It shows the VPG configuration that you defined in the previous steps.

27. Click **DONE**. The VPG is created.

For details of what happens after creating the VPG, see “What Happens After the VPG is Defined”, on page 29.
You can monitor information about all the VPGs either protected at the local site or recovered to the local site in the VPGs tab. You can also drill-down to monitor information about a specific VPG displayed in the VPGs tab or about the virtual machines being protected by VPGs. You can also view summary details of the protected and recovery sites in either the protected or recovery site as well as monitor the status of each virtual protection group and any of the virtual machines being protected in either site.

The following general monitoring options are described in this section:

- “The DASHBOARD Tab”, below
- “Monitoring VPGs – The VPGs Tab”, on page 110
- “Monitoring a Single VPG”, on page 114
- “Monitoring Tasks”, on page 117
- “Monitoring Protected Virtual Machines – The VMs Tab”, on page 119

The following site monitoring option is described in this section:

- “Monitoring Peer Sites - The SITES Tab”, on page 120

The following VRA monitoring option is described in this section:

- “Monitoring Virtual Replication Appliances”, on page 122

The following storage monitoring option is described in this section:

- “Monitoring Storage - The SETUP Tab – The STORAGE Tab”, on page 127

The following performance counters are described in this section:

- “Zerto Performance Counters”, on page 129

For details about Zerto Virtual Manager alerts and events, refer to Zerto Virtual Replication Guide to Alarms, Alerts and Events.

For details about monitoring Zerto Virtual Manager Long Term Retention repositories, see “Monitoring Your Long Term Retention Status”, on page 243.
The DASHBOARD Tab

The DASHBOARD provides an overview of the sites and VPGs being protected at the site or recovered to the site.

The following information is displayed:

VPG HEALTH

The VPGs being recovered with the health of each VPG, represented by a colored block, where the color represents the following:

- **Green**: The VPG is being replicated, including syncing the VPG between the sites.
- **Orange**: The VPG is being replicated but there are problems, such as an RPO value larger than the target RPO value specified for the VPG.
- **Red**: The VPG is not being replicated, for example because communication with the site is down.

Positioning the mouse over a block displays the VPG name as a tooltip. Clicking the block opens the details tab for the VPG.

STATUS

The status of the site, including the following:
- The number of VPGs and virtual machines being protected or recovered.
- The amount of storage being protected.
- The average RPO.
- The percentage compression of data passed between the site and peer sites.
Performance Graphs

The current site performance, which includes the following information:

**IOPS (I/O per Second)**: The total amount of I/O write operations generated by the protected virtual machines on the viewed site. (The IOPS graph is displayed for VPGs replicating from on-premise sites).

**Throughput (MB per second)**: The total amount of uncompressed data written by the virtual machines protected to the recovery sites.

During synchronization processes (such as bitmap sync, initial sync and delta sync) this value will also consist of the uncompressed data read from the protected disks.

**WAN Traffic (MB per second)**: The total amount of compressed data transferred between the viewed site and all its recovery sites.

A listing of the currently active alerts and running tasks, and the events run during the last few hours.

User input, for example, stopping a failover test or committing or rolling back a Move or Failover operation, can be initiated from the relevant task displayed in the RUNNING TASKS section.

**ACTIVE ALERTS, RUNNING TASKS, and EVENTS**

A listing of the currently active alerts and running tasks, and the events run during the last few hours.

User input, for example, stopping a failover test or committing or rolling back a Move or Failover operation, can be initiated from the relevant task displayed in the RUNNING TASKS section.

**Monitoring VPGs – The VPGs Tab**

View details of all VPGs in the VPGs tab. This tab lists all the VPGs from both the local and remote sites and provides summary details of each VPG.
You can create a query using the view buttons ( ) to display VPG information in a list or as a grid. In both list and grid views you can filter the VPGs that will be displayed according to their status by checking the checkboxes alongside the VPG status icons ( ). The query can be customized by adding and removing filters.

The QUER Y option allows you to save or run a personal query, or set the VPG tab back to its default view.

See also:
- “List View - GENERAL”, on page 111
- “List View - PERFORMANCE”, on page 111
- “List View - Retention”, on page 112
- “Additional Fields and Options”, on page 112
- “Grid View”, on page 113

**List View - GENERAL**

The following information is displayed in the GENERAL view:

- **Alert status indicator**: The color indicates the status of the VPG. Hovering over the alert displays a popup of all active alerts with descriptions:
  - **Green**: The VPG is being replicated, including syncing the VPG between the sites.
  - **Orange**: The VPG is being replicated but there are problems, such as an RPO value larger than the Target RPO Alert value specified for the VPG.
  - **Red**: The VPG is not being replicated, for example, because communication with the remote site is down.

  Move the cursor over the Alert status indicator to display details of the alert.

- **VPG Name (#VMs)**: The name of the VPG. The name is a link: Click the VPG name to drill-down to more specific details about the VPG that are displayed in a dynamic tab. The number of VMs protected in the VPG is displayed in parentheses.

- **Direction**: The direction of the replication, from this site to the remote site or from the remote site to this site.

- **Peer Site**: The name of the site with which this site is paired: the site where the VPG is protected or will be recovered to.

- **Priority**: The priority of the VPG.

- **Protection Status**: The current status of the VPG, such as Meeting SLA. Where appropriate, the percentage of the operation completed, such as syncing, is displayed.

- **State**: The current substatus of the VPG, such as Delta syncing. Where appropriate, the percentage of the operation completed, such as syncing, is displayed.

- **Actual RPO**: The time since the last checkpoint was written to the journal. This should be less than the Target RPO Alert value specified for the VPG.

- **Operation**: The operation, such as Move, that is currently being performed.

**List View - PERFORMANCE**

The following information is displayed in the PERFORMANCE view:

- **IO**: The IO per second between all the applications running on the virtual machines in the VPG and the VRA that sends a copy to the remote site for replication.
Throughput: The MB per second for all the applications running on the virtual machines being protected. There can be a high IO rate with lots of small writes resulting in a small throughput as well as a small IO with a large throughput. Thus, both the IOPS and Throughput values together provide a more accurate indication of performance.

Network: The amount of WAN traffic.

Provisioned Storage (not shown by default): The provisioned storage for all the virtual machines in the VPG. This value is the sum of the values that are used in the vSphere Client console per virtual machine in the Virtual Machines tab for the root vCenter Server node. Each value is the sum of both the hard disk and memory. Thus, a virtual machine with 1GB hard disk and 4GB memory will show 5GB provisioned storage.

Used Storage: The storage used by all of the virtual machines in the VPG. This value is the sum of the values that are used in the vSphere Client console per virtual machine in the Virtual Machines tab for the root vCenter Server node.

List View - Retention

The following information is displayed in the RETENTION STATUS view:

- **Alert status indicator**: The color indicates the status of the VPG. Hovering over the alert displays a popup of all active alerts with descriptions:
  - **Green**: The VPG is being replicated, including syncing the VPG between the sites.
  - **Orange**: The VPG is being replicated but there are problems, such as an RPO value larger than the Target RPO Alert value specified for the VPG.
  - **Red**: The VPG is not being replicated, for example, because communication with the remote site is down.

Move the cursor over the Alert status indicator to display details of the alert.

- **VPG Name (#VMs)**: The name of the VPG. The name is a link: Click the VPG name to drill-down to more specific details about the VPG that are displayed in a dynamic tab.
- **Retention Policy**: Whether the VPG is protected against a disaster only with the ability to recover to a point in time up to 30 days before the disaster, or protection is extended to include retention sets of the virtual machines, going back for a maximum of one year.
- **Retention Policy Status**: The status of the retention set.
- **Repository Name**: The name of the repository where the jobs are stored.
- **Restore Point Range**: The restore points for the retention job out of the total retention jobs run for the VPG.
- **Retention Policy Scheduling**: The schedule for the retention process.

Additional Fields and Options

In the GENERAL, PERFORMANCE, and RETENTION views you can:

- Show/Hide Columns, Create View and Reset Columns using the settings ( ) menu.
- Sort the list by a column by clicking in the column title.
- Filter information in the columns by clicking the filter button ( ) that is displayed when the mouse cursor is moved into the column title. Active filters are displayed with a yellow background.
Grid View

In the grid view each VPG is displayed as a card.

The default view is of all the VPG cards, un-grouped and sorted by VPG name.

The cards displayed can be filtered by clicking the filter button( ). The default filters are Direction and Protection Status. You can click the ADD button to open the filters drop-down, and select additional filters. Active filters are displayed with a yellow background.

Each card contains the following:
- **Alert status indicator:** The color indicates the status of the VPG. Hovering over the alert displays a popup of all active alerts with descriptions:
  - **Green:** The VPG is being replicated, including syncing the VPG between the sites.
  - **Orange:** The VPG is being replicated but there are problems, such as an RPO value larger than the Target RPO Alert value specified for the VPG.
  - **Red:** The VPG is not being replicated, for example, because communication with the remote site is down.

Move the cursor over the **Alert status indicator** to display details of the alert.

- **VPG Name (#VMs):** The name of the VPG. The name is a link: Click the VPG name to drill-down to more specific details about the VPG that are displayed in a dynamic tab. The number of VMs protected in the VPG is displayed in parentheses.
- **Direction:** The direction of the replication, from this site to the remote site or from the remote site to this site.
- **Peer Site:** The name of the site with which this site is paired: the site where the VPG is protected or will be recovered to.
- **State:** The current substatus of the VPG, such as **Delta syncing.** Where appropriate, the percentage of the operation completed, such as syncing, is displayed.
- **Actual RPO:** The time since the last checkpoint was written to the journal. This should be less than the **Target RPO Alert** value specified for the VPG.
- **Operation:** The operation, such as Move, that is currently being performed.

**Saving Details of Virtual Protection Groups to File**

You can save details of every VPG displayed in the VPGs tab to a CSV file, which can be opened using programs such as Microsoft Excel.

In the VPGs tab, click **EXPORT** and specify where to save the VPG details.
Monitoring a Single VPG

You can monitor the status of a specific VPG by clicking the VPG name in the VPGs tab or clicking the VPG name in the VMs tab. The VPG details are displayed in a dynamic tab.

General Tab
The tab on the left side shows the status of the VPG. The following information is displayed in this tab:

Performance Graphs
The current VPG performance, which includes the following information:

**RPO**: The current Recovery Point Objective (RPO) of the Virtual Protection Group (VPG).

**IOPS (I/O per second)**: The total amount of I/O write operations generated by the protected virtual machines comprising the Virtual Protection Group (VPG).

**Throughput (MB per Second)**: The total amount of uncompressed data written by the protected virtual machines comprising the Virtual Protection Group (VPG).

During synchronization processes (such as bitmap sync, initial sync and delta sync) this value will also consist of the uncompressed data read from the protected disks.

**WAN Traffic (MB per second)**: The total amount of compressed data transferred between the protected and recovery sites of the Virtual Protection Group (VPG).

**JOURNAL HISTORY**
The journal history shows:
- The SLA defined for the VPG.
- The amount of time currently covered by information in the journal.
- The earliest—oldest—checkpoint currently in the journal that can be used for a recovery operation.

Long Term Retention
If Long Term Retention is enabled, the following details are displayed:
Monitoring a Single VPG

- **Retention Policy**: Whether the VPG is protected against a disaster only with the ability to recover to a point in time up to 30 days before the disaster, or protection is extended to include retention sets of the virtual machines, going back for a maximum of one year.
- **Retention Status**: The status of the retention set.
- **Repository**: The name of the repository where the retention sets are stored.
- **Restore Point Range**: The restore points for the retention sets out of the total retention sets run for the VPG.
- **Scheduling**: The retention schedule.

**ACTIVE ALERTS, RUNNING TASKS, and EVENTS**

A listing of the currently active alerts and running tasks, and the events run during the last few hours.

User input, for example, stopping a failover test or committing or rolling back a Move or Failover operation, can be initiated from the relevant task displayed in the RUNNING TASKS section.

A listing of the currently active alerts and running tasks, and the events run during the last few hours.

User input, for example, stopping a failover test or committing or rolling back a Move or Failover operation, can be initiated from the relevant task displayed in the RUNNING TASKS section.

**PROTECTED VMs Tab**

The **PROTECTED VMs** tab shows details about the protected virtual machines:

- **Name**: The name of the virtual machine.
- **Group**: The boot order group to which the virtual machine belongs.
- **Protection Host**: The protected virtual machine host.
- **Storage Protected**: The name of the protected storage.
- **Provisioned**: The protected virtual machine provisioned storage.
- **Used**: The amount of data used on the recovery site for this virtual machine.
- **Recovery Data Size**: The total size of the data on the recovery site.
- **Failover Network**: The failover network used when recovering this virtual machine.
- **Test Network**: The test network used when testing the recovery of this virtual machine.
The following details are displayed with a vSphere recovery site:

- **Recovery Host**: The host to use for recovery.
- **VM Recovery Datastore**: The name of the recovery datastore.
- **Folder**: The folder where the virtual machine is recovered to.

The following details are displayed with a Hyper-V recovery site:

- **Recovery Host**: The host to use for recovery.
- **VM Recovery Storage**: The name of the recovery storage.

The following details are displayed with an AWS recovery site:

- **Failover/Move VPC**: The virtual network dedicated to your AWS account during a failover or move operation. A security group and subnet must be assigned to this VPC.
- **Failover/Move Subnet**: The subnet mask for the VPC network during a failover or move operation.
- **Failover/Move Security Groups**: The AWS security to be associated with the virtual machines in this VPG during a failover or move operation.
- **Test VPC**: The virtual network dedicated to your AWS account during a failover test operation. A security group and subnet must be assigned to this VPC.
- **Test Subnet**: The subnet mask for the VPC network during a failover test operation.
- **Test Security Groups**: The AWS security to be associated with the virtual machines in this VPG during a failover test operation.
- **Folder**: The folder where the virtual machine is recovered to.

**SITES Tab**

The SITES tab shows the topology of the VPG, including both the protected and recovery sites.
Monitoring Zerto Virtual Replication

SETTINGS Tab

The SETTINGS tab shows details about the VPG settings, divided into general, replication, recovery, and retention categories.

Monitoring Tasks

Recent tasks can also be reviewed for a site by clicking the TASKS area in the status bar at the bottom of the user interface.

The following information is displayed for each task:

**Status**: The task status.

**Name**: The name of the task.

**Description**: A description of the task.

**Action**: The ability to perform an action directly. For example, stop a failover test, or commit or rollback a move or failover operation.
The full details of the tasks can be monitored in the TASKS subtab under the MONITORING tab.

The following information is displayed for each task:

**Task status indicator:** The color indicates the status of the task. The following statuses exist for each task:
- **Green:** The task was completed successfully.
- **Red:** The task failed.

**Task:** The task name.

**Status:** The task status.

**Related Entities:** The sites which were effected by the task.

**User:** The user who initiated the task.

**Started:** The date and time the task started.

**Completed:** The date and time the task completed.

**Notes:** Notes added at the completion of a failover test.
Monitoring Protected Virtual Machines - The VMs Tab

View details of the protected VMs in the VMs tab. This tab lists all the protected virtual machines from both the local and remote sites and provides summary details of each virtual machine.

![VM List](image)

You can filter information in columns via the filter icon next to each column title. You can also sort the list by each column.

**GENERAL View**

The following information is displayed in the GENERAL view:

- **Alert status indicator**: The color indicates the status of the VPG:
  - **Green**: The VPG is being replicated, including syncing the VPG between the sites.
  - **Orange**: The VPG is being replicated but there are problems, such as an RPO value larger than the Target RPO Alert value specified for the VPG.
  - **Red**: The VPG is not being replicated, for example, because communication with the remote site is down.
- **VM Name**: The name of the virtual machine. The name is a link.
- **VPG Name**: The name of the VPG. The name is a link: Click the VPG name to drill-down to more specific details about the VPG that are displayed in a dynamic tab.
- **Direction**: The direction of the replication, from this site to the remote site or from the remote site to this site.
- **Peer Site**: The name of the site with which this site is paired: the site where the VPG is protected or will be recovered to.
- **Priority**: The priority of the VPG.
- **Protection Status**: The current status of the virtual machine, such as Meeting SLA. Where appropriate, the percentage of the operation completed, such as syncing, is displayed.
- **State**: The current substatus of the VPG, such as Delta syncing. Where appropriate, the percentage of the operation completed, such as syncing, is displayed.
- **Actual RPO**: The time since the last checkpoint was written to the journal. This should be less than the Target RPO Alert value specified for the VPG.
- **Operation**: The operation, such as Move, that is currently being performed.

**PERFORMANCE View**

The following information is displayed in the PERFORMANCE view:

- **IO**: The IO per second between all the applications running on the virtual machine and the VRA that sends a copy to the remote site for replication.
- **Throughput**: The MB per second for all the applications running on the virtual machines being protected. There can be a high IO rate with lots of small writes resulting in a small throughput as well as a small IO with a large throughput. Thus, both the IOPS and Throughput values together provide a more accurate indication of performance.
- **Network**: The amount of WAN traffic.
Monitoring Peer Sites - The SITES Tab

Provisioned Storage: The provisioned storage for the virtual machine in the recovery site.

Used Storage: The storage used by the virtual machine in the recovery site.

Retention View

The following information is displayed in the RETENTION STATUS view:

- **Alert status indicator**: The color indicates the status of the VPG. Hovering over the alert displays a popup of all active alerts with descriptions:
  - **Green**: The VPG is being replicated, including syncing the VPG between the sites.
  - **Orange**: The VPG is being replicated but there are problems, such as an RPO value larger than the Target RPO Alert value specified for the VPG.
  - **Red**: The VPG is not being replicated, for example, because communication with the remote site is down.

Move the cursor over the Alert status indicator to display details of the alert.

- **VPG Name (#VMs)**: The name of the VPG. The name is a link: Click the VPG name to drill-down to more specific details about the VPG that are displayed in a dynamic tab.
- **Retention Policy**: Whether the VPG is protected against a disaster only with the ability to recover to a point in time up to 30 days before the disaster, or protection is extended to include retention sets of the virtual machines, going back for a maximum of one year.
- **Retention Policy Status**: The status of the retention set.
- **Repository Name**: The name of the repository where the jobs are stored.
- **Restore Point Range**: The restore points for the retention job out of the total retention jobs run for the VPG.
- **Retention Policy Scheduling**: The schedule for the retention process.

Additional Fields

There are additional fields that you can display that are listed when you select Show/Hide Columns from the dropdown list shown by clicking the configuration icon (○):

- **Protected Site**: The name of the protected site.
- **Recovery Site**: The name of the recovery site.
- **ZORG**: A name given to an organization by a cloud service provider. For details refer to Zerto Cloud Manager Administration Guide.
- **Last Test**: The time and date of the last retention process performed by Zerto Virtual Manager.

**Monitoring Peer Sites - The SITES Tab**

View details of the paired sites in the SITES tab. This tab lists all the sites paired to the local site and provides summary details of each paired site.
You can filter information in columns via the filter icon next to each column title. You can also sort the list by each column.

**GENERAL View**

The following information is displayed in the GENERAL view:

**Alert status indicator:** The color indicates the alert status of the site:
- **Green:** The Zerto Virtual Manager for the site is running without problems.
- **Orange:** The Zerto Virtual Manager for the site has a problem that does not stop the protection of virtual machines, such as an RPO value larger than the Target RPO Alert value for a VPG.
- **Red:** The Zerto Virtual Manager for the site is not running correctly, for example, because communication with the site is down.

**Site Name:** The name specified for the paired site during installation or in the Site Settings dialog.

**Location:** The location specified for the paired site during installation or in the Site Settings dialog.

**Site IP:** The IP of the peer site.

**Network:** The amount of WAN traffic.

**IOPS:** The IO per second between all the applications running on the virtual machine in the VPG and the VRA that sends a copy to the remote site for replication.

**Incoming Throughput:** The MBs for all the applications running on the virtual machine being protected. There can be a high IO rate with lots of small writes resulting in a small throughput as well as a small IO with a large throughput. Thus, both the IO and Incoming Throughput values together provide a more accurate indication of performance.

**Provisioned Storage (GB):** The maximum storage that can be protected.

**# VPGs:** The total number of VPGs being protected by the site and replicated to the site.

**# VMs:** The total number of virtual machines being protected by the site and replicated to the site.

**Additional Fields**

There are additional fields that you can display that are listed when you select Show/Hide Columns from the dropdown list shown by clicking the configuration icon ( • •):

**Used Storage (GB):** The name of the protected site.

**ZORG Name:** A name given to the organization by a cloud service provider. For details refer to Zerto Cloud Manager Administration Guide.

**Version:** The Zerto Virtual Replication version installed at this site.
Monitoring Virtual Replication Appliances

You can monitor information about all the VRAs for the local site in the VRAs tab. You can also drill-down to monitor information about a specific VRA displayed in the VRAs tab:

- “Monitoring VRAs – The SETUP Tab – VRAs Tab”, below.
- “Monitoring a Single VRA”, on page 123.

Monitoring VRAs – The SETUP Tab – VRAs Tab

View details of the VRAs in the VRAs subtab, under the SETUP tab. All the hosts in the SCVMM are listed, and details of VRAs for each host, when installed, are also shown.

You can filter information in columns via the filter icon next to each column title. You can also sort the list by each column.

GENERAL View

In this view, the number of installed VRAs is displayed in the VRAs tab. The following information is displayed in this view:

Cluster: The cluster name, if relevant.

Host Address: The host IP address for the VRA. If the host is part of a cluster, the cluster name is displayed with the hosts under the cluster.

Host Version: The host version.

Alert Status: The alerts status of the VRA virtual machine.

VRA Name: The name of the VRA virtual machine.

VRA Status: The VRA status. For example, Installed, Ghost VRA.

VRA Version: Either Latest if the version installed is the most current version or Outdated if it can be upgraded. A tooltip displays the actual version.

VRA Address: The IP address of the VRA virtual machine.

# VPGs: The number of VPGs with a virtual machine for which the VRA either manages the protection or the recovery of the data.

# VMs: The number of virtual machines for which the VRA either manages the protection or the recovery of the data.

SETTINGS View

The following information is displayed in the SETTINGS view:

VRA Group: The group of VRAs to which this VRA belongs. When VRAs use different networks, they can be grouped by network.
Monitoring Zerto Virtual Replication Appliances

VRA RAM: The amount of memory allocated to the VRA to buffer data before it is sent to the recovery site or at the recovery site before it is written to the journal.

Storage: The storage used by the VRA.

Storage Cluster: The storage cluster used by the VRA.

WORKLOAD PROTECTION View

The following information is displayed in the WORKLOAD PROTECTION view:

- # VPGs: The number of VPGs with a virtual machine for which the VRA is used either for protection or recovery.
- # VMs: The number of virtual machines for which the VRA is used either for protection or recovery.
- # of Protected VPGs: The number of VPGs with a virtual machine for which the VRA manages the protection of their data.
- # of Protected VMs: The number of virtual machines for which the VRA manages the protection of their data.
- # of Protected Volumes: The number of volumes for which the VRA manages the protection of their data.
- # of Recovery VPGs: The number of VPGs with a virtual machine for which the VRA manages the recovery of the data.
- # of Recovery VMs: The number of virtual machines for which the VRA manages the recovery of the data.
- # of Recovery Volumes: The number of volumes for which the VRA manages the recovery of the data.

Additional Fields

There are additional fields that you can display that are listed when you select Show/Hide Columns from the dropdown list shown by clicking the configuration icon (▲):  

Cluster: The cluster with the host used by the VRA.

VC Network: The network used by the VRA.

# Volumes: The number of volumes for which the VRA manages the protection or recovery of data.

Monitoring a Single VRA

You monitor the status of a single VRA by clicking the VRA name in the VRAs tab. The VRA details are displayed in a dynamic tab.
You can filter information in columns via the filter icon next to each column title. You can also sort the list by each column.

### Installed Tab

The tab on the left side shows the status of the VRA. The following information is displayed when this tab is selected:

#### Performance Graphs

- **CPU Usage**: The percentage of CPU usage by the VRA.
- **Local Memory**: The percentage of the VRA memory used by protected volumes managed by the VRA. If the memory consumption is high you can consider vMotioning some of the virtual machines to a different host.
- **Remote Memory**: The percentage of the VRA memory used by recovery volumes managed by the VRA. If the memory consumption is high you can consider changing the target host for some of the virtual machines to a different host.

### ACTIVE ALERTS, RUNNING TASKS, and EVENTS

A listing of the currently active alerts, running tasks, and events run over the last few hours.

### VPGs Tab

Information about the VPGs with virtual machines that are on the host with the VRA is displayed in the VPGs tab.

#### GENERAL View

The following information is displayed in the **GENERAL view**:

- **Alert status indicator**: The color indicates the status of the VPG:
  - **Green**: The VPG is being replicated, including syncing the VPG between the sites.
  - **Orange**: The VPG is being replicated but there are problems, such as an RPO value larger than the Target RPO Alert value specified for the VPG.
  - **Red**: The VPG is not being replicated, for example, because communication with the remote site is down.

- **Direction**: The direction of the replication, from this site to the remote site or from the remote site to this site.
- **Protected Site**: The name of the protected site.
- **Recovery Site**: The name of the recovery site.
Name: The name of the VPG.

Protection Status: The current status of the VPG, such as Meeting SLA. Where appropriate, the percentage of the operation completed, such as syncing, is displayed.

State: The current substatus of the VPG, such as Delta syncing. Where appropriate, the percentage of the operation completed, such as syncing, is displayed.

PERFORMANCE View

The following information is displayed in the PERFORMANCE view:

# VMs on VRA/#VMs in VPG: The number of virtual machines on the VRA and the number of virtual machines in the VPG.

Provisioned: The provisioned storage for all the virtual machines in the VPG. Each value is the sum of both the hard disk and memory. Thus, a virtual machine with 1GB hard disk and 4GB memory will show 5GB provisioned storage.

Used: The storage used by all virtual machines in the VPG.

IOPS: The IO per second between all the applications running on the virtual machines in the VPG and the VRA that sends a copy to the remote site for replication.

Throughput: The MB per second for all the applications running on the virtual machines being protected. There can be a high IO rate with lots of small writes resulting in a small throughput as well as a small IO with a large throughput. Thus, both the IOPS and Throughput values together provide a more accurate indication of performance.

Retention View

The following information is displayed in the RETENTION STATUS view:

- **Alert status indicator**: The color indicates the status of the VPG. Hovering over the alert displays a popup of all active alerts with descriptions:
  - **Green**: The VPG is being replicated, including syncing the VPG between the sites.
  - **Orange**: The VPG is being replicated but there are problems, such as an RPO value larger than the Target RPO Alert value specified for the VPG.
  - **Red**: The VPG is not being replicated, for example, because communication with the remote site is down.

  Move the cursor over the Alert status indicator to display details of the alert.

- **VPG Name (#VMs)**: The name of the VPG. The name is a link: Click the VPG name to drill-down to more specific details about the VPG that are displayed in a dynamic tab.

- **Retention Policy**: Whether the VPG is protected against a disaster only with the ability to recover to a point in time up to 30 days before the disaster, or protection is extended to include retention sets of the virtual machines, going back for a maximum of one year.

- **Retention Policy Status**: The status of the retention set.

- **Repository Name**: The name of the repository where the jobs are stored.

- **Restore Point Range**: The restore points for the retention job out of the total retention jobs run for the VPG.

- **Retention Policy Scheduling**: The schedule for the retention process.

Additional Fields

There is an additional field that you can display. This field is listed when you select Show/Hide Columns from the dropdown list shown by clicking the configuration icon (○):

**ZORG**: A name given to an organization by a cloud service provider. For details refer to Zerto Cloud Manager Administration Guide.
VMs Tab

Information about the virtual machines that are on the host with the VRA is displayed in the VMs tab.

**GENERAL View**

The following information is displayed in the **GENERAL** view:

**Alert status indicator:** The color indicates the status of the VPG:
- **Green:** The VPG is being replicated, including syncing the VPG between the sites.
- **Orange:** The VPG is being replicated but there are problems, such as an RPO value larger than the Target RPO Alert value specified for the VPG.
- **Red:** The VPG is not being replicated, for example, because communication with the remote site is down.

**Direction:** The direction of the replication, from this site to the remote site or from the remote site to this site.

**Protected Site:** The name of the protected site.

**Recovery Site:** The name of the recovery site.

**VM Name:** The name of the virtual machine.

**VPG Name:** The name of the VPG with which this virtual machine is associated.

**Protection Status:** The current status of the virtual machine, such as Meeting SLA. Where appropriate, the percentage of the operation completed, such as syncing, is displayed.

**State:** The current substatus of the virtual machine, such as Delta syncing. Where appropriate, the percentage of the operation completed, such as syncing, is displayed.

**PERFORMANCE View**

The following information is displayed in the **PERFORMANCE** view:

**Provisioned on Host:** The provisioned storage for the virtual machine on the host.

**Used on Host:** The storage used by the virtual machine in the VPG.

**IO:** The IO per second between all the applications running on the virtual machines in the VPG and the VRA that sends a copy to the remote site for replication.
Monitoring Virtual Replication Appliances

**Throughput:** The MB per second for all the applications running on the virtual machine. There can be a high IO rate with lots of small writes resulting in a small throughput as well as a small IO with a large throughput. Thus, both the **IOPS** and **Throughput** values together provide a more accurate indication of performance.

**Additional Fields**

There is an additional field that you can display. This field is listed when you select **Show/Hide Columns** from the dropdown list shown by clicking the configuration icon (:):

**ZORG:** A name given to an organization by a cloud service provider. For details refer to **Zerto Cloud Manager Administration Guide**.

**SETTINGS Tab**

Information about the VRA is displayed in the SETTINGS tab. This includes its version, the host on which it is located, its definition, the networks it uses, and its replication and recovery settings.

---

**Monitoring Storage – The SETUP Tab – The STORAGE Tab**

View details of the storage used by Zerto Virtual Replication in the STORAGE subtab, under the SETUP tab. This tab lists all the storage used by Zerto Virtual Replication with an option to show all the storage per cluster or for the hosts, whether used by Zerto Virtual Replication or not.

You can filter information in columns via the filter icon next to each column title. You can also sort the list by each column.
GENERAL View

In this view, the number of available storage is displayed in the STORAGE subtab. The following information is displayed in the GENERAL view:

**Storage:** The name of the datastore or cluster.

**Alert status indicator:** The color indicates the alert status of the storage:
- **Green:** The storage is functioning as required.
- **Orange:** The storage is functioning, but there are problems, such as not enough free space.
- **Red:** There is a problem with the storage.

**Status:** The status of the storage:

**Device:** The storage device identifier.

**Cluster:** The cluster that the storage is associated with.

**Total Usage (GB):** The amount of GB used in relation to the total amount available.

**DR Usage (GB):** The amount of GB used by Zerto Virtual Replication in relation to the total amount available.

**# VRAs:** The number of VRAs using the storage.

WORKLOAD PROTECTION View

The following information is displayed in the WORKLOAD PROTECTION view:

**Storage:** The name of the storage or cluster.

**Alert status indicator:** The color indicates the alert status of the storage:
- **Green:** The storage is functioning as required.
- **Orange:** The storage is functioning, but there are problems, such as not enough free space.
- **Red:** There is a problem with the storage.

**Total Usage (GB):** The amount of space, in GB, used in relation to the total amount available.

**Recovery Size:** The amount space used for recovery.

**Journal Size:** The amount of space used by the journals.

**# Protected VMs:** The number of protected virtual machines using the storage.
# Incoming VMs: The number of virtual machines are specified to be recovered using the storage.

Additional Fields

There are no additional fields that you can display. However, you can display all the fields shown in these views when you select Show/Hide Columns from the dropdown list shown by clicking the configuration icon (  ).

Zerto Performance Counters

During installation of Zerto Virtual Replication, Zerto-related performance counters are added to the Windows Performance Monitor on the machine where the Zerto Virtual Manager runs.

Uninstalling Zerto Virtual Replication, uninstalls the Zerto-related performance counters. Upgrading Zerto Virtual Replication updates any changes to the Zerto-related performance counters.

The Zerto-related performance counters are collected on the protected site only. These counters are described as follows.

<table>
<thead>
<tr>
<th>Category</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zerto Checkpoints</td>
<td>Checkpoint failures in last 10 minutes</td>
<td>Number of checkpoints that failed to be inserted in last 10 minutes.</td>
</tr>
<tr>
<td></td>
<td>Checkpoint insertions in last 10 minutes</td>
<td>Number of checkpoints inserted in last 10 minutes.</td>
</tr>
<tr>
<td></td>
<td>Time to insert last checkpoint</td>
<td>Time in milliseconds needed to insert the last checkpoint; normal is less than 5 seconds.</td>
</tr>
<tr>
<td>Zerto Connectivity</td>
<td># of connected VRAs</td>
<td>Number of VRAs connected to the local Zerto Virtual Manager.</td>
</tr>
<tr>
<td></td>
<td># of peer Zerto Virtual Managers (ZVMs)</td>
<td>Number of Zerto Virtual Managers connected to the local Zerto Virtual Manager.</td>
</tr>

## Zerto Performance Counters

### Zerto Visual Query
- **Time to execute a VQ build loop**: Time in milliseconds needed to execute a single VQ build loop. This should be less than 25 milliseconds.
- **Time to retrieve hypervisor information (reflection)**: Time in milliseconds to execute a remote query on peer Zerto Virtual Managers to retrieve hypervisor information from remote sites.
- **Time to retrieve local VM list**: Time in milliseconds needed to retrieve the list of virtual machines from the local hypervisor.
- **Time to retrieve local VPG data**: Time in milliseconds needed to retrieve VPG data from the local Zerto Virtual Manager.
- **Time to retrieve VPG list**: Time in milliseconds to execute a remote query on peer Zerto Virtual Managers to build a list of VPGs on remote sites.

### Zerto VRA Counters
- **# of VRAs not updated**: Should be zero or close to zero.
- **# of VRAs updated**: Should be near or equal to the number of active VRAs.
- **Average time of 5 most time-consuming VRA updates**: Should be close to the median VRA update time.
- **Median VRA update time**: Median time in milliseconds of last 100 VRA updates.
CHAPTER 8: MANAGING VPGS

After defining virtual protection groups (VPGs) the virtual machines specified as part of each VPG are protected. There are a number of ongoing management tasks that you can perform on a VPG, such as specifying a checkpoint to enable recovery to that specific point or you can modify the configurations of existing VPGs.

The following VPG management options are described in this chapter:

- “Editing a VPG”, below
- “Adding Virtual Machines to a VPG - Overview”, on page 133
- “Removing Virtual Machines from a VPG”, on page 138
- “Removing Protected Virtual Machines from the Hypervisor Inventory”, on page 138
- “Modifying Protected Virtual Machine Volumes”, on page 139
- “Pausing the Protection of a VPG”, on page 139
- “Forcing the Synchronization of a VPG”, on page 140
- “Handling a VPG with in an Error State”, on page 140
- “Deleting a VPG”, on page 141
- “Ensuring Application Consistency – Checkpoints”, on page 141
- “Running Scripts Before or After Recovering a VPG”, on page 144
- “Exporting and Importing VPG Definitions”, on page 147
- “VPG Statuses and Synchronization Triggers”, on page 149

Monitoring VPGs and the VMs that are protected is described in “Monitoring Zerto Virtual Replication”, on page 108.

Note:
To set up Long Term Retention to protect VPGs, or to manually run a Retention process (unscheduled retention process) on the VPG, and to restore the VPG see “Using Zerto's Long Term Retention”, on page 236. Configuring Long Term Retention is part of defining a VPG.

Editing a VPG

You can edit a VPG definition, including adding virtual machines to the VPG, as described in “Adding Virtual Machines to a VPG - Overview”, on page 133, deleting virtual machines from the VPG, or changing the information about how virtual machines are recovered, such as adding or removing volumes from the virtual machine.

Note: You cannot edit the VPG while a retention process is running.

After modifying the VPG, the definition is updated.

While the VPG definition is being updated, you cannot perform any operations on the VPG, such as adding a checkpoint, editing the VPG properties, or failing the VPG.

After the definition is updated, the VPG is synchronized with the recovery site.

To modify a VPG:

1. In the VPGs tab in the Zerto User Interface, select the VPG to be edited and click MORE > Edit VPG. You can also select the VPG, display the VPG details, and click EDIT VPG.

   The Edit VPG wizard is displayed, enabling editing the VPG, including adding and removing virtual machines from the VPG.

   Note: If the VPG was previously viewed, and the tab for this VPG is still displayed, you can access the details by selecting the tab.

2. Make any required changes to the VPG definition, as described in “Protecting Virtual Machines from Hyper-V”, on page 33. You can jump directly to a step to make a change in that step, for example, the REPLICATION step or the RECOVERY step, by clicking the step. Steps that have been completed are marked with a check.
Adding Virtual Machines to a VPG - Overview

You can add virtual machines that are not already included in a VPG, to an existing VPG. A virtual machine can be protected in a maximum of three existing VPGs, provided that the VPGs are recovered to different sites.

- Protecting virtual machines in several VPGs is enabled only if both the protected site and the recovery site, as well as the VRAs installed on these sites, are of version 5.0 and higher.
- You cannot add a virtual machine in an existing VPG, while a retention process is running.
- Only virtual machines with a maximum of 60 disks can be protected.
  - 60 disks can be a combination of IDE and SCSI disks, where:
    - Each virtual machine can have up to 2 IDE controllers.
    - Each IDE controller can have a maximum of 4 IDE disks, and up to 4 SCSI controllers.
    - The IDE disks and SCSI controllers can each have a maximum of 15 disks, so that the total of IDE and SCSI disks does not exceed 60 disks.
    - When the recovery site is VMware vSphere, any IDE disks are converted to SCSI disks.

For AWS or Azure recovery sites, see the following topic, then continue with “How to Add Virtual Machines to an Existing VPG”, on page 136.

“Adding Virtual Machines to a VPG - When the Recovery Site is AWS”, on page 134

“Adding Virtual Machines to a VPG - When the Recovery Site is Azure”, on page 134
Adding Virtual Machines to a VPG - When the Recovery Site is AWS

- Only virtual machines that are supported by AWS can be protected by Zerto Virtual Replication. Refer to AWS documentation for the supported operating systems.
- A VPC must exist, and a security group and subnet must be assigned to it and to all other VPCs you want to use for recovered virtual machines.
- The following limitations apply when protecting to AWS:
  - For Linux, AWS supports virtual machines with up to **40 volumes**, including the boot volume.
  - For Windows, AWS supports virtual machines with up to **26 volumes**, including the boot volume.
  - Note that C5/M5 instances have 28 available devices and each volume/NIC utilizes one device. Windows supports up to 26 volumes. For more information, see Elastic Network Interfaces.
  - GBT formatted disks are supported for data volumes only.
  - The following table describes the limitations per Import Method:

<table>
<thead>
<tr>
<th>OS</th>
<th>AWS Import</th>
<th>zImport for Data Volumes</th>
<th>zImport for all volumes</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Boot Volume</td>
<td>Boot Volume</td>
<td>Boot Volumes</td>
</tr>
<tr>
<td>Linux</td>
<td>1 TB</td>
<td>1 TB</td>
<td>16 TB</td>
</tr>
<tr>
<td>Windows</td>
<td>1 TB</td>
<td>1 TB</td>
<td>16 TB</td>
</tr>
</tbody>
</table>

* Some VMs use the MBR partitioning scheme, which only supports up to 2047 GiB boot volumes. If your instance does not boot with a boot volume that is 2 TB or larger, the VM you are using may be limited to a 2047 GiB boot volume. See the relevant AWS documentation for more information: [http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/EBSVolume-Types.html](http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/EBSVolume-Types.html)

- For the AWS Import and zImport for Data Volumes import methods, the AWS ImportInstance API only supports single volume VMs. The boot volume of the protected virtual machine should not be attached to any other volume to successfully boot. For more information, see [http://docs.aws.amazon.com/AWSEC2/latest/APIReference/API_ImportInstance.html](http://docs.aws.amazon.com/AWSEC2/latest/APIReference/API_ImportInstance.html)

It is strongly recommended to perform a Failover Test to ensure that the recovered instance is successfully running on AWS.

Adding Virtual Machines to a VPG - When the Recovery Site is Azure

- Azure ZCA can be installed only on Windows Server 2012 R2 and higher. Only virtual machines that are supported by Azure can be protected by Zerto Virtual Replication. All Windows operating systems are supported.
  - **Note:** Microsoft does not support operating systems that are past the **End of Support date**, without a **Custom Support Agreement (CSA)**. For more information about Microsoft operating systems support for Microsoft Azure, refer to [https://support.microsoft.com/en-us/kb/2721672](https://support.microsoft.com/en-us/kb/2721672).
- To replicate between Azure and your site, you must have a virtual machine in Azure with a Zerto Cloud Appliance installed on it. This ZCA must be paired with your site.
- Only general-purpose v1 (GPv1) accounts are supported.
- It is recommended to use a separate storage account for each ZCA.
- For Linux distribution, refer to Azure documentation:
  - Ultra SSD storage is not supported.

Requirements for Replication From Azure

- For Virtual Machines to be protected from Azure, the VM volumes must reside in the Standard storage account defined during ZCA installation.
  - A Standard storage account is created or selected upon ZCA installation.
Managing VPGs

- Type: Standard storage
- Recovery and journal volumes reside on this Zerto Storage Account.
- Only general-purpose v1 (GPv1) accounts are supported.
- Azure VMs with all disks on this Zerto Storage Account can be protected by Zerto.
- Blob Storage is not supported.
- VMs which are not deployed via the Azure Resource Manager cannot be protected from Azure.

Requirements for Replication To Azure

- **Protected volumes** are recovered in Azure as VHD disks in a page blob. Virtual machines with disks that are less than 1GB are recovered with disks of 1GB.
  
  **Note:** For some instance sizes, the Azure virtual machine is created with a Local SSD disk which is a temporary disk. This disk is in addition to the disks associated with each protected virtual machine.

- The following limitations apply when protecting to Azure
  - Virtual machines with **UEFI Firmware** cannot be protected.
  - You cannot protect machines that have a disk larger than **4 TB**.
  - The protected virtual machines needs to have at least one NIC.
  - Reserve at least **2 CPUs** and **4GB RAM** for the machine using a subnet accessible by other Zerto Virtual Replication sites.
  - The supported number of data disks and NICS per virtual machine is dependent on the selected instance size. For example, instance size D3_v2 allows up to eight data disks per virtual machine.

Requirements for Replication within Azure

- Azure ZCA on both Azure sites need to be version 6.0 and higher.
- The following limitations apply when protecting within Azure:
  - Self replication is not supported.

Additional Azure Considerations

For additional considerations, see **Azure subscription and service limits, quotas and constraints**: https://docs.microsoft.com/en-us/azure/azure-subscription-service-limits.

For example from the link, see the following default values:

- There can be multiple Zerto Cloud Appliances per Azure subscription and region.
- 20 cores per subscription
- 200 Storage accounts per subscription
- 20 VMs per region per subscription
- 20 VMs per series (Dv2, F, etc.) cores per subscription per Region

Additionally, see the following example for **maximum** values:

- A Standard storage account has a maximum total request rate of 20,000 IOPS. The total IOPS across all of your virtual machine disks in a Standard storage account should not exceed this limit.

<table>
<thead>
<tr>
<th>VM TIER</th>
<th>BASIC TIER VM</th>
<th>STANDARD TIER VM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disk size</td>
<td>4 TB</td>
<td>4 TB</td>
</tr>
<tr>
<td>Max 8 KB IOPS per persistent disk</td>
<td>300</td>
<td>500</td>
</tr>
<tr>
<td>Max number of disks performing max IOPS</td>
<td>66</td>
<td>50</td>
</tr>
</tbody>
</table>

See also “Azure Limitations Which Affect Installation and Recoverability”, on page 135.

Azure Limitations Which Affect Installation and Recoverability

Below are the default Azure limitations which affect installation and recovery.
Default Azure limitations which Affect Installation

- **Storage Limitations:**
  - Number of storage accounts: **200 per subscription** (note: max is 250)

### How to Add Virtual Machines to an Existing VPG

Use the following procedure to add a virtual machine to an existing VPG.

**To add a virtual machine to a VPG:**

1. In the VPGs tab in the Zerto User Interface, select the VPG and click **MORE > Edit VPG**. You can also select the VPG to display the VPG details and click **EDIT VPG**.

   The Edit VPG wizard is displayed, enabling you to edit the VPG, including adding and removing virtual machines from the VPG.
2. In the VMs step, select the virtual machines to add and click the arrow pointing right to include these machines in the VPG. A VPG can include virtual machines that are not yet protected and virtual machines that are already protected.

   - You can view protected virtual machines by clicking Select VMs in the Advanced (Multi Target) section.

   Virtual machines protected in the maximum number of VPGs are not displayed in the Select VMs dialog.

   **Note:** Protecting virtual machines in several VPGs is enabled only if both the protected site and the recovery site, as well as the VRAs installed on these sites, are of version 5.0 and higher.

3. To define the boot order of the VPGs, click DEFINE BOOT ORDER.

4. Configure the settings for the new virtual machines in the same way that you configured the other virtual machines in the VPG, when you created the VPG.

5. Click DONE.

The virtual machines are added to the VPG. This process may take a few minutes. While the VPG definition is being updated, you cannot perform any operation on the VPG, such as adding a checkpoint, editing its properties, or recovering it.

After the VPG definition has been updated, the protected and recovery sites are then synchronized. During the synchronization period, the Protection Status displayed in the VPGs tab of the Zerto User Interface is: Meeting SLA n/m VMs where n is the number of virtual machines that were originally in the VPG, and m is the total number of virtual machines in the VPG, including the virtual machines that are currently being synced. While the virtual machines that were added are being synced, the VPG can be failed over but the failover only includes the original virtual machines in the VPG.

For example, in the following screen shot, two virtual machines were added to the VPG, Operations, that originally contained 2 other virtual machines.

![Virtual Machines Added to VPG](image)

When the sync process for a virtual machine is complete, Zerto Virtual Manager tags the first checkpoint that includes a new virtual machine with: VM ‘XXX’ is fully synced where XXX is the name of the virtual machine that was synced.

When you perform a recovery operation using one of these checkpoints, or any later checkpoint, all the virtual machines that have completed syncing will be recovered.
Managing VPGs

Removing Virtual Machines from a VPG

If a user removes a virtual machine (VM) from a VPG, the checkpoints of the VPG are retained.

**Note:** Once a VM is removed, it is no longer possible to recover it.

Removing Protected Virtual Machines from the Hypervisor Inventory

From time to time, a virtual machine (VM) or a host is removed from the hypervisor inventory for various purposes, such as maintenance. If the removed VMs are protected in VPGs, the VPGs enter a pause state and the replication is paused. The removed VM is grayed out in the VMs tab in the site.

When a VPG is in a state of pause, the recovery of all the VMs, including the removed, grayed out VMs, is possible.
Modifying Protected Virtual Machine Volumes

Adding or deleting volumes for a virtual machine protected in a VPG, are automatically reflected in the volumes used for the mirror virtual machine, managed by the VRA in the recovery site.

Deleting a volume in any virtual machine protected in a VPG, causes the journal to be reset as all the checkpoints in the journal are removed.

Adding a volume in any virtual machine protected in a VPG, causes a new checkpoint to be added, to mark the action.

When adding a volume to the virtual machine the total number of disks cannot exceed 60 disks, which can be a combination of IDE and SCSI disks, where:

- Each virtual machine can have up to 2 IDE controllers.
- Each IDE controller can have a maximum of 4 IDE disks, and up to 4 SCSI controllers.
- The IDE disks and SCSI controllers can each have a maximum of 15 disks, so that the total of IDE and SCSI disks does not exceed 60 disks.

When the recovery site is VMware vSphere, any IDE disks are converted to SCSI disks.

Changing the defined size of a journal of a virtual machine in a VPG is automatically reflected in the VRA in the recovery site.

When protecting to AWS, if you add a volume to the virtual machine the total number of disks cannot exceed 12, including the boot disk.

Changing the Recovery Storage for a Protected Virtual Machine

To change the recovery storage for a virtual machine volume, the new storage must have 45GB or 25% of the storage size for the change to be performed.

Pausing the Protection of a VPG

During periods when the WAN bandwidth is utilized to its maximum, you can pause the protection of a VPG, to free up some of this bandwidth. After pausing the protection, the VPG can still be recovered to the last checkpoint written to the journal before the pause operation.

Note:
- Zerto recommends adding a checkpoint to the VPG immediately before pausing protection, if you might want to recover the VPG to the latest point in time before the pause.
- You cannot pause a VPG while a retention process is running.

To pause the protection of VPGs:
1. In the Zerto User Interface, click the VPGs or VMs tab and select one or more VPGs to pause protection.
2. Click MORE > PAUSE.
   A warning is displayed. If you click PROCEED in this warning, the VPG protection is paused.
   
   Note: If the VPG was previously viewed, and the tab for this VPG is still displayed, you can access the details by selecting the tab.
   
   The VPG protection is paused until you click Resume VPGs.
To resume the protection of VPGs:
1. In the Zerto User Interface, click the VPGs or VMs tab and select one or more VPGs to resume protection.
2. Click MORE > Resume.
   After resuming protection, a Bitmap Sync will most probably be performed to synchronize the protection and recovery sites.

Forcing the Synchronization of a VPG

If the protected virtual machines are updated such that they are no longer synchronized with their mirror machines in the recovery site, you can force the resynchronization of the machines. An example of when the machines can be out-of-sync is when there is a rollback of a virtual machine to a snapshot. In this case, the recovery virtual machine will include changes that have been rolled back in the protected machine, so that they are no longer synchronized.

You can force the synchronization of the machines in a VPG to remedy this type of situation.

Note: You cannot force the synchronization of a VPG while a retention is running.

To forcibly synchronize a VPG:
1. In the Zerto User Interface, select the VPGs or VMs tab and click the VPG to display the VPG details.
2. Click MORE > Force Sync.
   Note: If the VPG was previously viewed, and the tab for this VPG is still displayed, you can access the details by selecting the tab.

The VPG starts to synchronize with the recovery site. As the journal fills up during the synchronization, older checkpoints are deleted from the journal to make room for the new data and the data prior to these checkpoints are promoted to the virtual machine virtual disks. Thus, during the synchronization, you can recover the virtual machine to any checkpoint still in the journal, but as time progresses the list of checkpoints available can lessen. If the journal is not big enough to complete the synchronization without leaving at least ten minutes worth of checkpoints, the synchronization pauses for the time specified in the Replication Pause Time value for the VPG, to enable intervention to ensure recovery to a checkpoint remains available. The intervention can be, for example, increasing the size of the journal, or cloning the journal as described in “Deleting a VPG”, on page 141.

Handling a VPG with in an Error State

When a volume connected to a virtual machine in a VPG is deleted, the VPG and all the virtual machines in that VPG enter an error state and an alert is issued.

When a VPG is in an error state, recovery operations cannot be performed.

Edit the VPG definition to resolve the error in one of the following ways.

- Remove the virtual machine that was connected to the deleted volume from the VPG:
  - In the VPGs tab in the Zerto User Interface, select the VPG to be edited and click MORE > Edit VPG.
  - In the Edit VPG wizard, go to the VMs step.
  - Select the virtual machine to be removed and click the arrow pointing left.

- Replace the volume that was deleted:
  - In the VPGs tab in the Zerto User Interface, select the VPG to be edited and click MORE > Edit VPG.
  - In the Edit VPG wizard, go to the STORAGE step and click the empty Recovery Volume Location field or select that row and click EDIT SELECTED.
  - In the Edit Volumes dialog that is displayed, choose the volume source: Storage or Preseeded volume, specify other volume options and click OK.

Notes:
Deleting a VPG

You can delete a VPG and either keep the target disks to use later for preseeding if you want to reprotect any of the virtual machines in the deleted VPG or delete these disks. Any offsite retention sets stored for the VPG are not deleted and the virtual machines that were retained can be restored.

Note: You cannot delete a VPG while a retention process is running.

To delete a VPG:
1. In the Zerto User Interface, click the VPGs or VMs tab and select one or more VPGs to delete.
2. Click MORE > Delete. 
   The Delete VPG window opens.
3. Select Keep the recovery disks at the peer site if you might reprotect the virtual machines. Checking this option means that the target replica disks for the virtual machines are saved so that they can be used as preseeded disks if the virtual machines are re-protected.
4. Click APPLY to delete the VPG.
   The VPG configuration is deleted. The VRA on the recovery site that handles the replication for the VPG is updated including keeping or removing the replicated data for the deleted VPG, dependent on the Keep the recovery disks at the peer site setting during the deletion.
   The locations of the saved target disks are specified in the description of the event for the virtual machines being removed, event EV0040, displayed in MONITORING > EVENTS.

Deleting a VPG When the Status is Deleting

If, for some reason, the VPG cannot be deleted, the VPG status changes to Deleting and the substatus is VPG waiting to be removed. Attempting to delete the VPG a second time causes the following to be displayed:
- **Retry**: Retry deleting the VPG.
- **Force Delete**: Forcibly delete the VPG.
- **Cancel**: Cancel the delete operation.

Ensuring Application Consistency – Checkpoints

Checkpoints are recorded automatically every few seconds in the journal. These checkpoints ensure crash-consistency, and are written to the virtual machines journals by the Zerto Virtual Manager.

Each checkpoint has the same timestamp which is set by the Zerto Virtual Manager.

During recovery you pick a checkpoint in the journal and recover to this point. The crash-consistent checkpoints guarantee write order fidelity.
For Example:

If write A on a virtual machine in the VPG occurred before write B on a virtual machine in the VPG, then when a checkpoint is written, the journal will contain:

- Neither of the writes
- Both writes, and if they overlap the B data takes precedence
- Only A – indicating the checkpoint occurred between A and B

The coordination is done by the Zerto Virtual Manager.

You can also use a script to place the application in a quiesced mode, such as Oracle Hot Backup mode, and execute the Zerto Virtual Replication PowerShell cmdlet `Set-Checkpoint`, then release the quiesced mode. For more information about Zerto Virtual Replication PowerShell cmdlets, see Zerto Virtual Replication Cmdlets.

Note:

- To write application-consistent checkpoints, there is a performance impact on the virtual machine running the application as a result of the application-consistent mechanism used. This is because the guest operating system and any integrated applications will be quiesced.

  This impact on performance may be negligible and does not always happen since not all applications require these checkpoints in order to achieve successful application recovery. Also, Zerto Virtual Replication only requires the guest and application to quiesce for a brief moment, just long enough to add a checkpoint.

As previously mentioned, checkpoints are recorded every few seconds in the journal. After a while, the number of checkpoints available from which to choose a recovery point can be in excess of thousands per VPG.

When this threshold is reached, in order to enable efficient management and use of the checkpoints, the number of checkpoints is diluted with respect to time, as follows:

- Within the latest 2 hours: All of the checkpoints are available for recovery.
- Between 2 and ~4.5 hours: There are about two to three checkpoints every 15 minutes.
- From 4.5 hours and over: 1 checkpoint is kept every 15 minutes.

  Note: Checkpoints which are either added manually, or marked as part of a Failover test are not diluted.

This section describes the different options available to ensure application consistency:

- “Adding a Checkpoint to Identify a Key Point”, below.

Adding a Checkpoint to Identify a Key Point

In addition to the automatically generated checkpoints, you can add checkpoints manually to ensure application consistency and to identify events that might influence recovery, such as a planned switch-over to a secondary generator. You can recover the machines in a VPG to any checkpoint in the journal, to one added automatically or to one added manually. Thus, recovery is done to a point-in-time when the data integrity of the protected virtual machines is ensured.

Note:

- Adding a checkpoint manually does not guarantee transaction consistency.
- Changes to a VPG that result in re-synchronization of the VPG results in all checkpoints being removed. Adding checkpoints to the journal is resumed after synchronization completes. A forced synchronization of the VPG only removes checkpoints if the journal fills up during the synchronization.
To add a checkpoint to a VPG:

1. In the Zerto User Interface select **ACTIONS > ADD CHECKPOINT**.
   The Add Checkpoint dialog is displayed.

   ![Add Checkpoint Dialog]

   A list of VPGs is displayed with the requested VPG selected. You can select more VPGs to add the same checkpoint to, for example, when something is happening at your site that affects multiple VPGs.

   **Note:** Crash-consistency is per VPG and not across VPGs, even if a checkpoint was added to multiple VPGs.

2. Enter a name for the checkpoint.

3. Click **SAVE**.

When testing a failover, as described in “Testing Recovery”, on page 186, or actually performing a failover, as described in “Managing Failover Live”, on page 206, you can choose the checkpoint as the point to recover to.
Running Scripts Before or After Recovering a VPG

Before and after executing a failover, move, or test failover, you can run executable scripts, such as Windows .bat files or PowerShell scripts. A pre-recovery script is always run at the beginning of the recovery operation. A post-recovery script is run after all the virtual machines are powered on at the recovery site.

The scripts must be saved to the machine where the remote Zerto Virtual Manager (ZVM) is installed.

Both pre-recovery and post-recovery scripts are run by the ZVM service on the ZVM machine. The account running the ZVM service is the account that will run the scripts when they are executed.

Note: Zerto recommends duplicating scripts on the Zerto Virtual Managers for both the protected and recovery sites, so that if reverse replication is required, the scripts are available. The location of the script for reverse replication, on the machine where the Zerto Virtual Manager that manages the protected site is installed, must be to the same path as in the remote Zerto Virtual Manager machine. For example, if the scripts are saved to C:\ZertScripts on the remote Zerto Virtual Manager machine, they must be saved to C:\ZertScripts on the local Zerto Virtual Manager machine.

The scripts can include environment variables that can be included as part of the script itself, or passed to the script as parameters. When the script is passed an environment variable as a parameter, the variable is evaluated before executing the script. The following environment variables are available:

- `%ZertoVPGName%`: The name of the VPG. If the name includes a space, enclose the variable in double quotes ("`). For example, the VPG MyVPG uses the format `%ZertoVPGName%` but the VPG My VPG uses the format "%ZertoVPGName%".

- `%ZertoOperation%`: The operation being run: FailoverBeforeCommit, FailoverRollback, Test, MoveBeforeCommit, MoveRollback. Use the result returned for this variable to limit when the script runs, dependent on the operation. The scripts are run after all the virtual machines are powered on at the recovery site and the variable is set to FailoverBeforeCommit or MoveBeforeCommit. Use FailoverRollback or MoveRollback when rolling back the Failover or Move operation, to undo whatever changes a previous script has done (such as updating the DNS records).

- `%ZertoVCenterIP%`: The IP address of the hypervisor manager, VMware vCenter Server or Microsoft SCVMM, where the VPG is recovered.

- `%ZertoVCenterPort%`: The port used by the Zerto Virtual Manager to communicate with the hypervisor manager, VMware vCenter Server or Microsoft SCVMM.

- `%ZertoHypervisorManagerIP%`: The IP address of the hypervisor manager, VMware vCenter Server or Microsoft SCVMM, where the VPG is recovered.

- `%ZertoHypervisorManagerPort%`: The port used by the Zerto Virtual Manager to communicate with the hypervisor manager, VMware vCenter Server or Microsoft SCVMM.

- `%ZertoForce%`: A Boolean value, Yes/No, that dictates whether to abort the recovery operation if the script fails. For example, whether to rollback a Move operation when the script fails and returns a non-zero value.

For example, if a specific VPG should not be migrated, the pre-recovery script can determine whether to continue based on the values of the `%ZertoOperation%` and `%ZertoVPGName%`. 
When specifying scripts in the definition of a VPG, enter values for the Pre-recovery Script and Post-recovery Script:

- **Command to run**: The full path of the script to run. The script must be located on the same machine as the Zerto Virtual Manager for the recovery site.
- **Params**: The values of any parameters to pass to the script. Separate parameters with a space.
- **Timeout (sec)**: The time-out in seconds for the script to run. If the script runs before executing a failover, move, or test failover and the script fails or a timeout value is reached, an alert is generated and the failover, move, or test failover is not performed. If the script runs after executing a failover, move, or test failover and the timeout value is reached, an alert is generated. The default timeout value is specified in the Site Configuration Advanced Settings dialog.

- “Example Scripts”, on page 147

### Creating a Script

There are many ways to create scripts to run before or after recovering a VPG. The following procedure uses a Windows PowerShell file (.ps1) or a batch (.bat) file.

**To create a script:**
1. Create a file on the machine where the Zerto Virtual Manager that manages the recovery is installed.
2. Enter the script that you want to run in the file.
3. Save the file as a Windows PowerShell file (.ps1) or batch (.bat) file.
When writing a PowerShell script, you can include the environment variables in the script. For example, the following code snippet shows the use of the %ZertoOperation% and %ZertoVPGName% environment variables:

```powershell
$Operation = $env:ZertoOperation
$VPG = $env:ZertoVPGName
$time = Get-Date

if ($Operation -eq "Test") {
    "$time VPG: $VPG was tested." >> "C:\ZertoScripts\VPG_DR.txt"
}

if ($Operation -eq "FailoverBeforeCommit") {
    "$time Failover before commit was performed. VPG: $VPG" >> "C:\ZertoScripts\VPG_DR.txt"
}

if ($Operation -eq "MoveBeforeCommit"){
    "$time Move before commit was performed. VPG: $VPG" >> "C:\ZertoScripts\VPG_DR.txt"
}
```

Pre-recovery scripts must be saved on the protected site Zerto Virtual Manager machine. Post-recovery scripts must be saved on the recovery site Zerto Virtual Manager machine.

**Note:** Zerto recommends having both pre- and post-recovery scripts, available on both the protected and recovery Zerto Virtual Manager machines, so that they will work from the protected site and after reverse protection from the recovery site.

### 4. Update Command to run and Params fields for all the VPG definitions that you want to run the script.

Passing parameters is implemented differently for the two script types. For information about passing command line parameters, refer to the relevant PowerShell or batch file documentation.

#### Using a BAT File

Windows Batch (.bat) is an executable file that does not require anything in order to run. Update Command to run and Params fields for all the VPG definitions that you want to run the script.

**Command to run** - `<script_including_path>`

```bat
C:\ZertoScripts\PostScript.bat
```

Use quotes (”) around the path if it includes spaces. The bat file is an executable file and is therefore included in the Command to run field.

**Params** - `<Zerto_Params>`, for example:

```powershell
%ZertoOperation% %ZertoVPGName%
```

#### Using a PowerShell Script

Windows PowerShell scripts require Windows PowerShell (.exe) to execute. To specify a PowerShell script, update Command to run and Params fields for all the VPG definitions that you want to run the script.

**Command to run** - `powershell.exe`

**Params** - `<script_including_path> <Zerto_Params>`, for example:

```powershell
C:\ZertoScripts\PostScript.ps1 %ZertoOperation% %ZertoVPGName%
```

Use quotes (”) around the path if it includes spaces.

**Note:** You might have to set the remote signed execution policy. For example, using the following:

```powershell
##PowerCLI requires remote signed execution policy - if this is not enabled,
##it may be enabled here by uncommenting the line below.

##Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Force
```

**Note:** Zerto recommends testing both PowerShell and batch scripts by running them from the command line, to ensure that they run correctly.
Example Scripts

**IMPORTANT:** The scripts are provided by example only and are not supported under any Zerto support program or service.

The following script is an example of how to track failover tests.

The following script, `c:\ZertoScripts\TestedVPGs.bat`, writes the VPG name and date to the `ListOfTestedVPGs.txt` file every time a failover test is run:

```
SET isodt=%date:~10,4%-%date:~7,2%-%date:~4,2% %time:~0,2%-%time:~3,2%-%time:~6,2%
IF %1==Test ECHO %2 %isodt% >> c:\ZertoScripts\Results\TestedVPGs.txt
```

Where `%1` is the first parameter in the list of parameters, `%ZertoOperation%`, and `%2` is the second parameter in the list of parameters, `%ZertoVPGName%.`

**Note:** If the file `TestedVPGs.txt` does not exist it is created, as long as the folder, `c:\ZertoScripts\Results`, exists.

Exporting and Importing VPG Definitions

You can save VPG definitions to an external file and import these definitions back to Zerto Virtual Replication, for example, exporting the settings before uninstalling a version of Zerto Virtual Replication and importing the settings after reinstalling Zerto Virtual Replication.

**Note:** Zerto Virtual Replication regularly exports settings to the `Zerto_Installation_Folder\Zerto Virtual Replication\ExportedSettings` folder. You can use one of these exported files instead of creating a new export file. The default location of `Zerto_Installation_Folder` is `C:\Program Files\Zerto`.

**To export VPG settings:**

1. Open the Zerto Diagnostics application. For example, via Start > Programs > Zerto Virtual Replication > Zerto Diagnostics. The Zerto Virtual Replication Diagnostics menu dialog is displayed.

2. Select the Export Protection Group Settings option and click **Next**.
3. Select the destination for the file to contain exported settings and specify the Zerto Virtual Manager IP address and port where the VPGs are protecting virtual machines.

4. Click **Next**.
   The list of exported VPGs is displayed.

5. Click **Done**.

**Note:** If you are uninstalling Zerto Virtual Replication, the VPGs are deleted. To prevent having to perform a full synchronization when the VPG definitions are imported, Zerto recommends deleting the VPGs in the Zerto User Interface, keeping their target disks.

**To import VPG settings:**

1. Click **Start > Programs > Zerto Virtual Replication > Zerto Diagnostics**.
   The Zerto Virtual Replication Diagnostics menu dialog is displayed.
2. Select the Import Protection Group Settings option.
3. Click **Next**.

   ![Zerto Diagnostics Collection](image)

4. Select the file previously exported and enter the Zerto Virtual Manager IP address and port specified when exporting the VPGs.

5. Click **Next**.
   The list of exported VPGs is displayed.
6. Select the VPGs to import. Only VPGs with names that are not already defined can be imported. VPGs in the import files with the same name as an existing VPG are disabled.

7. Click Next.
   The list of imported VPGs is displayed. If the VPG could not be imported, the reason for the failure is specified.
   **Note:** If a host was removed from and then re-added to the environment it is advisable to wait approximately 5 minutes from when the host was re-added before performing the import of the VPGs.

8. Click Done.

**VPG Statuses and Synchronization Triggers**

During normal operations the VPG status can change. For example, a change can be made to the VPG definition, or an operation such as move or failover is performed on the VPG, or an external event impacts the system such as the WAN going down. When the status changes, resulting in the VPG being synchronized, for example with a Delta Sync, the estimated time to complete the synchronization is displayed under the VPG status, and if relevant, the synchronization trigger, such as Network Congestion.

<table>
<thead>
<tr>
<th>SUBSTATUS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Backing Up</td>
<td>Retention process is running.</td>
</tr>
</tbody>
</table>
| Bitmap Syncing  | A change tracking mechanism of the protected machines during a disconnected state or when a VRA buffer is full. In these situations, Zerto Virtual Replication starts to maintain a smart bitmap in memory, in which it tracks and records the storage areas that changed. Since the bitmap is kept in memory, Zerto Virtual Replication does not require any LUN or volume per VPG at the protected side.  
  
  **Note:** The VRA buffer is set via the Amount of VRA RAM value, specified when the VRA is installed

  The bitmap is small and scales dynamically, containing references to the areas of the protected disk that have changed but not the actual I/O. The bitmap is stored locally on the VRA within the available resources. For example, when a VRA goes down and is then rebooted.

  When required, Zerto Virtual Replication starts to maintain a smart bitmap in memory, to track and record storage areas that change. When the issue that caused the bitmap sync is resolved, the bitmap is used to check updates to the protected disks and send any updates to the recovery site. A bitmap sync occurs when any of the following conditions occur:

  - Synchronization after WAN failure or when the load over the WAN is too great for the WAN to handle, in which case the VPGs with the lower priorities will be the first to enter a bitmap sync.
  - When there is storage congestion at the recovery site, for example when the VRA at the recovery site cannot handle all the writes received from the protected site in a timely fashion.
  - When the VRA at the recovery site goes down and is then rebooted, for example during a Zerto Virtual Replication upgrade.

  During the synchronization, new checkpoints are not added to the journal but recovery operations are still possible, assuming there are valid checkpoints in the journal. If a disaster occurs requiring a failover during a bitmap synchronization, the VPG status changes to **Recovery Possible** and you can recover to the last checkpoint written to the journal.

  For synchronization to work, the protected virtual machines must be powered on so that the VRA has an active IO stack, which is only available when the virtual machine is powered on.

  **Note:** If the synchronization takes longer than the configured history, all the checkpoints in the journal can be lost, preventing a failover from being performed. For the resolution of this situation, see “To configure disaster recovery policies:”, on page 175.

  **Note:** Synchronization after a recovery starts after the promotion of data from the journal to the virtual machine disks ends. Thus, synchronization of virtual machines can start at different times, depending on when the promotion to the virtual machine ends. All synchronizations are done in parallel, whether a delta sync or initial sync, etc.

Delta Syncing

The Delta Sync uses a checksum comparison to minimize the use of network resources. A Delta Sync is used when the protected virtual machine disks and the recovery disks should already be synchronized, except for a possible few changes to the protected disks, for example:

- When a virtual machine was added to the VPG and the target recovery disk is defined as a preseeded disk.
- After a source VRA upgrade: Depending on the nature of the upgrade, a VRA upgrade on the protected side may trigger either a Delta Sync or a Bitmap Sync. See the version release notes to determine if a sync will be triggered with a source VRA upgrade.
- For reverse protection after a move or failover.
- A Force Sync operation was manually initiated on the VPG.
- A host protecting virtual machines was restarted and the protected virtual machines on the host had not been Live Migrated to other hosts in the cluster or a protected virtual machine was Live Migrated to another host without a VRA, and then Live Migrated back to the original host.

For synchronization to work, the protected virtual machines must be powered on so that the VRA has an active IO stack, which is only available when the virtual machine is powered on.

During the synchronization, new checkpoints are not added to the journal but recovery operations are still possible, assuming there are valid checkpoints in the journal. If a disaster occurs requiring a failover during a delta synchronization, you can recover to the last checkpoint written to the journal.

It is not possible to perform a move during a delta sync.

Note: Synchronization after a recovery starts after the promotion of data from the journal to the virtual machine disks ends. Thus, synchronization of virtual machines can start at different times, depending on when the promotion to the virtual machine ends. All synchronizations are done in parallel, whether a delta sync or initial sync, etc.

Delta syncing a volume

Synchronization when only delta changes for a volume needs synchronizing, for example, when a volume is added to a protected virtual machine in a VPG, and a preseeded disk is used.

For synchronization to work, the protected virtual machines must be powered on so that the VRA has an active IO stack, which is only available when the virtual machine is powered on.

During the synchronization, new checkpoints are not added to the journal but recovery operations are still possible, assuming there are valid checkpoints in the journal. If a disaster occurs requiring a failover during a delta volume synchronization, you can recover to the last checkpoint written to the journal.

It is not possible to perform a move during a delta sync.

Note: Synchronization after a recovery starts after the promotion of data from the journal to the virtual machine disks ends. Thus, synchronization of virtual machines can start at different times, depending on when the promotion to the virtual machine ends. All synchronizations are done in parallel, whether a delta sync or initial sync, etc.

Error

Problem situation, for example, when a ZVM is disconnected from a VRA used to protect virtual machines. The VPG cannot be recovered until the problem is resolved,

Failing over - Before commit

Preparing and checking the VPG virtual machines in the recovery site.
### SUBSTATUS | DESCRIPTION
--- | ---
### Full Syncing | Full synchronization to ensure that the protected disks and recovery disks are the same after some change to the system. This type of sync is the same as an Initial Sync but occurs after protection started. In general, this type of sync should not happen.  
  
  For synchronization to work, the protected virtual machines must be powered on so that the VRA has an active IO stack, which is only available when the virtual machine is powered on. 
  
  During the synchronization, new checkpoints are not added to the journal. Also, recovery operations are not possible.  
  
  **Note:** Synchronization after a recovery starts after the promotion of data from the journal to the virtual machine disks ends. Thus, synchronization of virtual machines can start at different times, depending on when the promotion to the virtual machine ends. All synchronizations are done in parallel, whether a delta sync or initial sync, etc.

### Initial Sync | Synchronization performed after creating the VPG to ensure that the protected disks and recovery disks are the same. Recovery operations cannot occur until after the initial synchronization has completed.  
  
  For synchronization to work, the protected virtual machines must be powered on so that the VRA has an active IO stack, which is only available when the virtual machine is powered on. 
  
  Adding a virtual machine to a VPG is similar to creating a new VPG, a volume initial sync is performed for the new virtual machine. For more information, see Volume Initial Sync.  
  
  **Note:** Synchronization after a recovery starts after the promotion of data from the journal to the virtual machine disks ends. Thus, synchronization of virtual machines can start at different times, depending on when the promotion to the virtual machine ends. All synchronizations are done in parallel, whether a delta sync or initial sync, etc.

### Journal storage error | There was an I/O error to the journal. For example, if the journal was full and the size was increased. Once the problem is resolved a synchronization is required.

### Moving - Before commit | Preparing and checking the VPG virtual machines in the recovery site.

### Needs Configuration | One or more configuration settings are missing, for example, when reverse protection is not specified or a virtual machine is added to a vApp.

### Promoting | Updating recovered virtual machines in the VPG with data from the journal.

### Recovery is possible | Communication with the Zerto Virtual Manager at the protected site is down so continuing protection is halted, but recovery on the remote site is available (compare with Site disconnection).

### Recovery storage error | There was an I/O error to the recovery storage. For example, the storage is almost full or the virtual machines are turned off and the recovery disks are inaccessible.

### Recovery storage profile error | The storage profile in the recovery site specified to be used by the VPG cannot be found.

### Rolling back | Rolling back to an initial status, for example, after canceling a cloning operation on the VPG.

### Rolling back Failover | Rolling back a Failover operation before committing it.

### Rolling back Move | Rolling back a Move operation before committing it.

### Site disconnection | Communication with the Zerto Virtual Manager at the remote, recovery, site is down so continuing protection is halted (compare with Recovery is possible).

### Site disconnection. No checkpoints | Communication with the Zerto Virtual Manager at the remote, recovery, site is down and there are no checkpoints to use to recover the VPG at the recovery site.

### Syncing | Status while type of synchronization is being evaluated.

### User paused protection | Protection is paused to enable solving a Journal disk space problem, for example, by increasing the disk size or cloning the VPG.
### VPG Synchronization Triggers

The following synchronization triggers can be applied:

<table>
<thead>
<tr>
<th>TRIGGER</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Force Sync</td>
<td>The user requested to synchronize the VPG, as described in “Forcing the Synchronization of a VPG”, on page 140.</td>
</tr>
<tr>
<td>Network Congestion</td>
<td>The network bandwidth is not wide enough to handle all the data, causing some of the data to be backed up.</td>
</tr>
<tr>
<td>Protected Storage Error</td>
<td>An I/O error occurred to a protected virtual machine, after the data was sent to the recovery side.</td>
</tr>
<tr>
<td>Protected VRA Congestion</td>
<td>The host where the VRA is installed is highly loaded: many updates are made to the protected machines at the same time, causing a time lapse before the updates are passed to the recovery site.</td>
</tr>
</tbody>
</table>

### VPG Statuses and Synchronization Triggers

The following synchronization triggers can be applied:

<table>
<thead>
<tr>
<th>SUBSTATUS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM not protected</td>
<td>A virtual machine in the VPG is no longer being protected. For example, when the virtual machine was moved to another host without a VRA.</td>
</tr>
<tr>
<td>Volume Full Syncing</td>
<td>Synchronization when a full synchronization is required on a single volume.</td>
</tr>
<tr>
<td></td>

<td>A network error, such as the network being down for a period, requires a synchronization of the VPG between the two sites, for example a bitmap sync.</td>
</tr>
<tr>
<td>VPG Configuration Changed</td>
<td>The configuration of the VPG changed resulting in a synchronization being required. For example, the size of the journal was changed.</td>
</tr>
</tbody>
</table>
A VRA is a Zerto Virtual Replication virtual machine that manages the replication of virtual machines across sites. A VRA must be installed on every hypervisor that hosts virtual machines that require protecting in the protected site and on every hypervisor that will host the replicated virtual machines in the recovery site. The VRA compresses the data that is passed across the WAN from the protected site to the recovery site. The VRA automatically adjusts the compression level according to CPU usage, including totally disabling it if needed.

The VRA is a custom, very thin, Linux-based virtual machine with a small footprint, disk – memory and CPU – and increased security since there are a minimum number of services installed.

Zerto recommends installing a VRA on every host so that if protected virtual machines are moved from one host in the cluster to another host in the cluster there is always a VRA to protect the moved virtual machines.

A VRA can manage a maximum of 1500 volumes, whether these are volumes being protected or recovered.

Note: VRAs and shadow VRAs are configured and managed by the Zerto Virtual Manager. You cannot take snapshots of VRAs as snapshots cause operational problems for the VRAs.

The priority assigned to a VPG dictates the bandwidth used. The Zerto Virtual Manager distributes bandwidth among the VRAs based on this priority and the VPGs with higher priorities are handled before writes from VPGs with lower priorities.

There are a number of tasks that you might need to perform on VRAs, including installing a new VRA on a host added to the hypervisor management tool or uninstalling VRAs and moving the data maintained by a VRA to another VRA when a host requires maintenance.

During normal operation, a VRA might require more disks than a single virtual machine can support. If this situation arises, the VRA creates new shadow VRA virtual machines, used by the VRA to maintain additional disks (a diskbox). A shadow VRA does not have an operating system and therefore does not have an IP address, or use Integration Services. A shadow VRA is created pro-actively at the recovery site. Similar to a VRA, a shadow VRA must be left to Zerto Virtual Replication to manage, and must not be modified or removed for any reason.

The following VRA management options are described in this chapter:

- “Installing a VRA”, below
- “Upgrading VRAs”, on page 159
- “Editing VRA Settings”, on page 160
- “Changing a Recovery VRA”, on page 162
- “Uninstalling VRAs”, on page 162
- “Handling a VRA in an Error State (Ghost VRA)”, on page 163
- “Managing Protection When Moving a Host to a Different Cluster”, on page 163

Monitoring VRAs is described in “Monitoring Virtual Replication Appliances”, on page 122.

### Installing a VRA

It is recommended to install a VRA on every host in every site so that if protected virtual machines are moved from one host in the cluster to another host in the cluster there is always a VRA to protect the moved virtual machines.

### VRA Installation Requirements

To install a VRA you require the following on the host:

- **15GB** storage space
- At least **1GB** of reserved memory.
- *(vSphere only)* The ESX/ESXi version must be in accordance with supported ESX/ESXi versions in the Interoperability Matrix, and Ports 22 and 443 must be enabled on the host during the installation.
- **Port 8100** must be enabled on SCVMM.
Installing a VRA

Before You Begin:

You must know the following information to install a VRA:

- (vSphere only) If the ESXi version is 5.5 or higher and the VRA should connect to the host with user credentials, or if the ESXi version is lower than 5.5 (4.x or 5.x), the password to access the host root account.
  
  **Note:** For ESXi versions 5.5 or higher, by default the VRA connects to the host with a vSphere Installation Bundle, VIB. Therefore, it is not necessary to enter the password used to access the host root account.

- The storage the VRA will use, and the local network used by the host.

- The network settings to access the peer site; either the default gateway or the IP address, subnet mask, and gateway.
  
  **Note:** When the gateway is not required, you can specify 0.0.0.0 as the gateway, for example when performing self replication.

- If a static IP is used, instead of DHCP, which is the Zerto recommendation, you need to know the IP address, subnet mask, and default gateway to be used by the VRA.
  
  **Note:** In a non-production environment it is often convenient to use DHCP to allocate an IP to the VRA. In a production environment this is not recommended. For example, if the DHCP server changes the IP allocation on a reboot, the VRA does not handle the change.

- If the peer site VRAs are not on the default gateway, you must set up routing to enable the VRAs on this site to communicate with the peer site VRAs before defining the VRAs.
  
  - Setting up routing after defining VRAs only applies to VRAs installed after the routing is set.
  
  - Any existing VRA is not affected and access to these VRAs continues via the default gateway.
  
  - If the default gateway stops being used, you must reinstall the VRAs that were installed before setting up paired site routing.

- (vSphere only) For the duration of the installation of the VRA, the Zerto Virtual Manager enables SSH in the vCenter Server.

- (vSphere only) You must know the following information to install a VRA:
  
  - The password to access the host root account, for ESXi 4.x and 5.x.
  
  - The datastore the VRA will use and the local network used by the host.
  
  - The network settings to access the peer site; either the default gateway or the IP address, subnet mask, and gateway.
  
  - If a static IP is used, instead of DHCP, which is the Zerto recommendation, you need to know the IP address, subnet mask, and default gateway to be used by the VRA.

  **Note:** In a non-production environment it is often convenient to use DHCP to allocate an IP to the VRA. In a production environment this is not recommended. For example, if the DHCP server changes the IP allocation on a reboot, the VRA does not handle the change.

You must also know the following information to install a VRA:

- The storage the VRA will use and the local network used by the host.

- The network settings to access the peer site; either the default gateway or the IP address, subnet mask, and gateway.

- If a static IP is used, which is the Zerto recommendation\(^1\), instead of DHCP, the IP address, subnet mask and default gateway to be used by the VRA.

If the peer site VRAs are not on the default gateway, you must set up routing to enable the VRAs on this site to communicate with the peer site VRAs before defining the VRAs. Setting up routing after defining VRAs only applies to VRAs installed after the routing is set. Any existing VRA is not affected and access to these VRAs continues via the default gateway. If the default gateway stops being used, you must reinstall the VRAs that were installed before setting up paired site routing.

**To set up routing:**

1. In the SETUP > VRAs tab, select **MORE > Paired Site Routing**.

   The Configure Paired Site Routing dialog is displayed.

---

1. In a non-production environment it is often convenient to use DHCP to allocate an IP to the VRA. In a production environment this is not recommended. For example, if the DHCP server changes the IP allocation on a reboot, the VRA does not handle the change.
2. Click **Enable Paired Site Routing**.
3. Specify the following, and then click **SAVE**:
   - **Address**: The IP address of the next hop at the local site, the router or gateway address, that is used to access the peer site network.
   - **Subnet Mask**: The subnet mask for the peer site network.
   - **Gateway**: The gateway for the peer site network.

   These access details are used to access all VRAs installed on the peer site after the information is saved.

To install a Zerto Virtual Replication Appliance (VRA) on a host:
1. In the Zerto User Interface, click **SETUP > VRAs**.
2. Select a host which requires a VRA and click **NEW VRA**.
   The Configure and Install VRA dialog is displayed.

   - If you selected a cluster or multiple hosts, the VRA is installed on the first host in the displayed list.
3. Specify the following **Host Details**:
   - **Host**: The host under which the VRA is installed. The drop-down displays the hosts which do not have a VRA installed, with the selected host displayed by default.
   - **Host Root Password**: For future use.
   - **Storage**: The storage that contains the OS disks of the VRA VM. You can install more than one VRA on the same storage.

   - **Network**: The network used to access the VRA.
   - **VRA RAM**: The amount of memory to allocate to the VRA. The amount determines the maximum buffer size for the VRA for buffering IOs written by the protected virtual machines, before the writes are sent over the network to the recovery VRA. The recovery VRA also buffers the incoming IOs until they are written to the journal. If a buffer becomes full, a Bitmap Sync is performed after space is freed up in the buffer. For details, refer to Zerto Scale and Benchmarking Guidelines.
   - **VRA Group** – Choose the **VRA Group** from the dropdown list. If you want to create a new VRA group, type in the name of the new group and click **CREATE**. You can then choose the new group from the dropdown list.
You group VRAs together when VRAs use different networks so they can be grouped by network, for example when the protected and recovery sites are managed by the same SCVMM and you want to replicate from the branch site to the main site. Within a group the priority assigned to a VPG dictates the bandwidth used and is applicable within a group and not between groups. Thus, a VPG with a high priority is allocated bandwidth before VPGs with lower priorities. VPGs that are on VRAs with different VRA groups, for example, VPG1 on VRA1 in group1 and VPG2 on VRA2 in group2, do not affect each other, as the priority is relevant only within each group.

- Specify the following VRA Network Details:
  - **Configuration:** Either have the IP address allocated via a static IP address or a DHCP server. If you select the *Static* option, which is the recommended option, enter the following:
    - **Address:** The IP address for the VRA.
    - **Subnet Mask:** The subnet mask for the network. The default value is *255.255.255.0*.
    - **Default Gateway:** The default gateway for the network.

4. Click **INSTALL**.
   
The VRA installation starts and the status is displayed in the TASKS popup dialog in the status bar and under **MONITORING > TASKS**.

   The VRA displayed name, and DNS name, is Z-VRA-hostname. If a virtual machine with this name exists, for example when a previous VRA was not deleted, the VRA name has a number appended to it.

### Upgrading VRAs

This section is applicable if **Auto-Upgrade Virtual Replication Appliances** was not selected when upgrading Zerto Virtual Replication, or if a manual VRA upgrade is required.

- If a newer version of the installed VRAs exists, you can continue to use the current VRAs with the new version of Zerto Virtual Replication, or you can upgrade these VRAs from within the Zerto User Interface.
- VRAs installed with the previous version of Zerto Virtual Replication can work with VRAs installed with the current version of Zerto Virtual Replication in any combination (all from one version or a mix of VRA versions) as long as the VRAs are only one version lower than the version of Zerto Virtual Replication installed on the site.
- Zerto **recommends** that you **always upgrade the VRAs** on your site to the latest version.
- Not all new installations of Zerto Virtual Replication require upgrading VRAs. If your VRA is outdated relative to your current version of Zerto Virtual Replication and an upgrade is available, the VRA version will be reported in the column as outdated. In addition, an alert is issued on the site using the old VRA and on any site that is paired with it.

**Note:** You can move the mouse over the **Outdated** value to display the VRA version as a tooltip.

### Considerations when upgrading VRAs

- VRAs managing protected virtual machines: Either **live migrate the protected virtual machines and storage** managed by the VRA to another host with a VRA, or **upgrade the VRA** without migrating the virtual machines and a **delta sync** will be performed following the upgrade.
- Upgrading a VRA that manages the recovery of virtual machines results in a bitmap sync being performed after the upgrade. Note that the time to upgrade a VRA is short so the bitmap sync should also be quick.

### To upgrade VRAs:

1. For a VRA protecting virtual machines, if **live migrating** the protected virtual machines:
   a) Remove affinity rules for protected virtual machines on the host with the VRA to be upgraded.
   b) Migrate these protected machines from the host to another host with a VRA.

2. In the Zerto User Interface, click **SETUP > VRAs**, select the VRAs to upgrade, and then click **MORE > Upgrade**.
   
The Upgrade VRAs dialog is displayed, listing the selected VRAs and whether an upgrade is available.
3. Review the list for the VRAs that you want to upgrade. Deselect any VRAs that you decide not to upgrade.
4. Click **Upgrade Selected VRAs**.
5. The upgrade progress is displayed in the **VRAs** tab.
   - After the upgrade, a **delta sync** is performed at the protected site, and a bitmap sync is performed at the recovered site.

**Note:** The VRA name does not change, even if the naming convention in the latest version is different.

**Note:** You do not need to upgrade Integration Services on a VRA.

---

**Editing VRA Settings**

If you need to change the host password, VRA Group or network settings for a VRA, for example when the gateway to the VRA is changed, you can do this by editing the VRA.

**To edit the VRA:**

1. In the Zerto User Interface, click **SETUP > VRAs**, select the VRAs to edit, and click **MORE > Edit**.
   - The Edit VRA dialog is displayed.

2. Edit the host root password if the password for the host has changed. To display the password in plain text, click in the checkbox next to the field.
3. Edit the group if required.
VRA Group: You can change the free text to change the group that a VRA belongs. If you create a group and then change the name when editing the VRA so that there is no VRA in the site that belongs to the originally specified group, the group is automatically deleted from the system.

To create a new group, enter the new group name over the text New group and click CREATE.

4. Edit the VRA network settings as follows:
   - Configuration: Either have the IP address allocated via a static IP address or a DHCP server. If the VRA was originally installed with a static IP, you cannot change this to DHCP. If the VRA was originally installed to use a DHCP server, you can change this to use a static IP. Zerto always recommends using a static IP.
   - Address: The static IP address for the VRA to communicate with the Zerto Virtual Manager.
   - Subnet Mask: The subnet mask for the network. The default value is 255.255.255.0.
   - Default Gateway: The default mask for the network.

5. Click SAVE.

The following folder is created as part of the VRA installation and must not be removed:

C:\zerto-temp-<storage_name> – VRA installation files. <storage_name> signifies the target host. When a VRA is installed using the local storage (C:\), there is only one folder with this name. When a VRA is installed on remote storage, a second folders with the same name is also created where the VRA is installed.
Managing VRAs

Changing a Recovery VRA

When a VPG is defined, the recovery host to use for each virtual machine in the VPG is specified. If required, you can change the recovery host for a protected virtual machine.

Note: The storage used by the original VRA and the changed VRA must be accessible by both the original target host and by the changed target host.

To change a host VRA:
1. In the Zerto User Interface, select the VRA to change in the VRAs subtab under the SETUP tab.
2. Click MORE > Change VM Recovery VRA.
   The Change VM Recovery VRA dialog is displayed, listing all the virtual machines that require a change to the recovery host.
3. Review the list and select the virtual machines to change the target host to another specified target host.
4. Select the target host for these virtual machines in the Select the replacement host drop-down list. You can move some virtual machines to one replacement target host and by repeating the operation, move other virtual machines to a different target host.
   Validation is performed to make sure the selected target host can be used, for example the storage used by both the VRAs are accessible from both hosts.
   Any implications of the change, such as whether synchronization might be required after the change is also displayed.
5. Click SAVE.
   - During this procedure you cannot edit the affected VPGs nor attempt a failover, move, failover test or clone operation.
   - At the end of the procedure a Bitmap Sync might be required to resynchronize the protected machines with the recovery VRAs.

Uninstalling VRAs

VRAs are uninstalled via the Zerto User Interface and not via SCVMM. You cannot uninstall a VRA which is used to protect or recover virtual machines.

For a VRA protecting virtual machines – Before uninstalling the VRA, remove affinity rules for protected virtual machines on the host and live migrate these protected virtual machines to another host in the cluster with a VRA installed.

For a VRA recovering virtual machines – Before uninstalling the VRA, change the host for all virtual machines in VPGs recovering to this VRA to another host as described in “Changing a Recovery VRA”, on page 162. A bitmap sync occurs to synchronize the VPGs with the new host.

Note: If the VRA has crashed, or was accidentally deleted, it must be forcibly uninstalled, as described in “Handling a VRA in an Error State (Ghost VRA)”, on page 163.

For a VRA in a cluster, you can remove it and then install a new VRA. However, to ensure that virtual machines in the cluster are not moved to the host without a VRA from the time the VRA is removed to the time a new VRA is installed, it is recommended to perform the following procedure.

Changing a Recovery VRA
Managing VRAs

To uninstall a VRA with virtual machines being recovered to it:
1. When the VRA to be removed is in a cluster, make sure that virtual machines in the cluster are not moved to the host without a VRA from the time the VRA is removed to the time a new VRA is installed.
2. Remove affinity rules for protected virtual machines on the host and live migrate any protected virtual machines to another host with a VRA installed.
3. Change the host for all virtual machines in VPGs recovering to this VRA to another host as described in “Changing a Recovery VRA”, on page 162.
4. Wait for any synchronization to complete.
5. Either select the VRAs to uninstall in the VRAs tab or for a single VRA display the VRA details by clicking the VRA Name link in the VRAs tab, and click Actions > Uninstall.
6. Once the VRAs are completely removed, install a new VRA on the host.

After the VRA is uninstalled, connectivity from that VRA to any Zerto Cloud Connector is lost. After a VRA is reinstalled on the host, the ports that were used for the connection to the Zerto Cloud Connector are not reused and new ports must be opened in the firewall for the cloud site. For details about Zerto Cloud Connectors, refer to Zerto Cloud Manager Administration Guide.

Handling a VRA in an Error State (Ghost VRA)

When an event occurs that causes a VRA to enter an error state, for example the host machine crashes or the VRA or a shadow VRA is accidentally deleted, if the VRA has shared storage disks that are accessible by other hosts in the site, you can copy these disks to another VRA in the site.

To recover VRA disks from a ghost VRA:
1. Remove the VPGs, keeping the recovery disks when removing to use as preseeded disks.
2. Uninstall the VRA.
3. Reinstall the VRA, as described in “Installing a VRA”, on page 156.
4. Recreate the VPGs using the preseeded disks.

Managing Protection When Moving a Host to a Different Cluster

When a host machine has to be moved to another cluster:

- **For a host machine on the protected site:** Remove affinity rules for protected virtual machines on the host that is going to be moved and live migrate these machines to any other host in the cluster with a VRA installed. Shut down the VRA before moving the host.
- **For a host machine on the recovery site:** Shut down the VRA. After shutting down the VRA VPGs with virtual machines being recovered to the VRA will enter an error state. Move the host to the new cluster and power on the VRA. The VPGs in an error state will enter a bitmap sync and then resume a Meeting SLA status.

**Note:** Any VPGs that were defined with a recovery resource pool in the original cluster must be edited to change the default and virtual machine specific target host settings for the new cluster, even when the new cluster has a resource pool that is displayed in the VPG definitions.
CHAPTER 10: MANAGING A ZERTO VIRTUAL MANAGER

The Zerto Virtual Manager runs as a Windows service and connects to Zerto Virtual Replication components, such as VRAs, as well as hypervisor management tools, such as VMware vCenter Server and Microsoft SCVMM.

For the maximum number of virtual machines, either being protected or recovered to the Zerto Virtual Manager, see Zerto Scale and Benchmarking Guidelines.

The following topics are described in this section:

- “Checking Connectivity Between Zerto Virtual Replication Components”, below
- “Reconfiguring the Zerto Virtual Manager Setup”, on page 165
- “Reconfiguring the Microsoft SQL Server Database Used by the Zerto Virtual Manager”, on page 167
- “Replacing the SSL Certificate”, on page 168
- “Pairing to Another Site and Unpairing Sites”, on page 168

Checking Connectivity Between Zerto Virtual Replication Components

If you think that there are connectivity problems to or from a Zerto Virtual Manager, you can use the Zerto diagnostics utility to check the connectivity.

To check connectivity between Zerto Virtual Manager components:

1. Open the Zerto Diagnostics application. For example, via Start > Programs > Zerto Virtual Replication > Zerto Diagnostics.

   The Zerto Virtual Replication Diagnostics menu dialog is displayed.

2. Select the Test Connectivity to Zerto Virtual Replication components option and click Next.

   The IP Connectivity dialog is displayed.

   You can use this dialog to check the following:
   - TCP communication between the Zerto Virtual Managers (ZVMs) on the protected and recovery sites. The default port, specified during installation, is 9081.
   - Communication between VRAs on the protected and recovery sites, via the control port and the data port.
3. Select the connectivity you want to test and in the case of the Zerto Virtual Manager (ZVM), specify the TCP communication port specified during the installation, if the default port, 9081, was changed.

4. Specify the type of test to perform:
   - **Server**: Test for incoming communication.
   - **Client**: Test for outgoing communication. Specify the IP address of the receiving Zerto Virtual Manager.

5. Click **Next** to test the specified connectivity.

The Server option listens for communication from a paired VRA. Stop listening by clicking **Stop**.

The Client options tests the client; on completion a result dialog is displayed.

6. Click **Stop** (server test) or **OK** (client test) to return to the Zerto Virtual Replication Diagnostics dialog.

---

### Reconfiguring the Zerto Virtual Manager Setup

When installing Zerto Virtual Replication, you provide the IP address of SCVMM to connect the Zerto Virtual Manager with, and the IP address of the machine where the Zerto Virtual Manager runs to enable running the Zerto User Interface.

You can change these IP addresses if necessary, using the Zerto Virtual Replication Diagnostics utility.

**To reconfigure the Zerto Virtual Manager:**

1. Click **Start > Programs > Zerto Virtual Replication > Zerto Diagnostics**.
   
The Zerto Virtual Replication Diagnostics menu dialog is displayed.

2. Select the Reconfigure Zerto Virtual Manager option and click **Next**.
The installation settings for the connection to the SCVMM are displayed.

3. Change the IP and username and password if necessary.
   - **IP / Host Name**: The IP address or host name of the machine where SCVMM runs.
   - **Domain\User Name**: The user name for an administrator to SCVMM. The name can be entered using either of the following formats:
     - `username`
     - `domain\username`
   - **Password**: A valid password for the given user name.

4. Click **Next**.

The dialog for Zerto Virtual Manager setup is displayed:

- **ZVM VM IP to be used by SCVMM**: The IP to access the Zerto Virtual Manager from the Zerto User Interface. If the machine has more than one NIC, select the appropriate IP from the list, otherwise the IP that is displayed is the only option.
- **TCP Port (ZVM<->ZVMs on other sites)**: The port used for communication between Zerto Virtual Managers.
  - **Both the protected and recovery sites belong to the same enterprise**: If you change the value, when pairing sites, use the TCP port value you specify here.
  - **An enterprise using a cloud service provider to supply disaster recovery services**: You must not change this value.
- **TCP Port (ZVM->VBA)**: The port used for communication between the Zerto Virtual Manager and the Virtual Backup Appliance.
- **HTTP Certificate**: Check **Replace SSL Certificate** and browse for a certificate, if you change the certificate you have been using.

5. Click **Next**.
Reconfiguring the Microsoft SQL Server Database Used by the Zerto Virtual Manager

1. Click **Start > Programs > Zerto Virtual Replication > Zerto Diagnostics**.
   The Zerto Virtual Replication Diagnostics menu dialog is displayed.

2. Select the Change SQL Server Credentials option and click **Next**.
   The installation settings for the SQL Server are displayed. Change the IP and username and password if necessary.
Replacing the SSL Certificate

The communication between the Zerto Virtual Manager and the user interface uses HTTPS. On the first login to the Zerto User Interface you must install a security certificate in order to be able to continue working without each login requiring acceptance of the security.

If you want to replace the SSL certificate, perform the procedure described in “To reconfigure the Zerto Virtual Manager:”, on page 165 and select a new SSL certificate when the dialog for Zerto Virtual Manager setup is displayed:

HTTP Certificate – Check Replace SSL Certificate and browse for a replacement certificate.

Pairing to Another Site and Unpairing Sites

See the following sections:

- “Pair to Another Site”, below
- “Unpairing Sites”, on page 169
**Pairing to Another Site**

You can pair to any site where Zerto Virtual Replication is installed.

**To pair to a site:**
1. In the Zerto User Interface, in the SITES tab click **PAIR**.
   The Add Site dialog is displayed.

2. Specify the following:
   - **Host name/IP**: IP address or fully qualified DNS host name of the remote site Zerto Virtual Manager to pair to.
   - **Port**: The TCP port communication between the sites. Enter the port that was specified during the installation. The default port during the installation was 9081.

3. Click **PAIR**.
   The sites are paired, meaning that the Zerto Virtual Manager for the local site is connected to the Zerto Virtual Manager at the remote site.

**Unpairing Sites**

You can unpair any two sites that are paired to each other.

**IMPORTANT**: if there is a VPG on either of the sites you are unpairing, the VPGs will be **deleted**.

**To unpair two sites:**
1. In the Zerto User Interface, in the SITES tab, select the site which you want to unpair.
2. Click **UNPAIR**.
   A message appears warning the user that the sites are about to unpair.
   If there are either protected or recovered VPGs on the paired sites, a message appears warning the user that the VPGs will be deleted.
3. For vSphere, Hyper-V and Azure platforms, you can select to keep disks to use for preseeding if the VMs are re-protected. If you select this option, the disks are not removed from the recovery site.
4. To unpair, click **CONTINUE**.
   The sites are no longer paired. If there are VPGs on either site, they are deleted.
   The VRA on the recovery site that handles the replication for the VPG is updated including keeping or removing the replicated data for the deleted VPG, depending if you selected to keep disks to use for preseeding.
   The locations of the saved target disks are specified in the **Events** tab in the ZVM application on the **Recovery** site.
There are a number of configuration tasks that you can perform, some of which should be done as part of the initial site configuration.

The following topics are described in this chapter:

- “Site Settings”, below
- “Editing Information About a Site”, on page 172
- “Seeing What is Licensed”, on page 178
- “Submitting a Support Ticket”, on page 179
- “Submitting a Feature Request”, on page 180
- “About Zerto Virtual Replication”, on page 181.

Site Settings

The Site Settings dialog enables configuring various site settings. These include the default script timeout and protection policies such as the commit policy for a failover or move operation.

To specify site information:

1. In the Zerto User Interface (top right), click SETTING ( ) and select Site Settings.
   The Site Settings dialog is displayed.

   - In vSphere and Hyper environments, the following window is displayed.
■ In AWS environments, the following window is displayed.

<table>
<thead>
<tr>
<th>Site Details</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Site Name</td>
<td></td>
</tr>
<tr>
<td>Site Location</td>
<td></td>
</tr>
<tr>
<td>Bucket Name</td>

Azure Settings

Application Name

Client ID

Subscription

Resource Name

Storage Account Name

2. Make any required changes to the settings, click **SAVE** and then **APPLY**. The following settings can be defined:

■ “Editing Information About a Site”, below

■ “Defining Performance and Throttling”, on page 172

■ “Defining Site Policies”, on page 175

■ “Configuring Email Settings”, on page 176

■ “Defining Resource Report Sampling Period”, on page 177

■ “Reviewing Supported Host Versions”, on page 177

Licensing is described in "Seeing What is Licensed", on page 178.
**Editing Information About a Site**

You provide information about the site during installation, to make it easier to identify the site in the user interface and to identify the contact person at the site. After installation you can update these settings.

To update information about the local site:

1. In the Zerto User Interface (top right), click **SETTING ( )** and select **Site Settings**. The Site Settings dialog is displayed.

   ![Site Settings dialog](image)

2. Define general information about the site.
   - (Mandatory) **Site Name**: The name used to identify the site.
   - (Mandatory) **Site Location**: Information such as the address of the site or a significant name with which to identify the site location.
   - (AWS environments only) **Bucket Name**: The name of the bucket that was created when Zerto Virtual Replication was installed. This cannot be changed.
   - (Mandatory) **Contact Name**: The name of the person to contact if a need arises. Mandatory.
   - **Contact Email**: An email address to use if a need arises.
   - **Contact Phone**: A phone number to use if a need arises.

3. (On premise environments) To change the **User Credentials** to access the vCenter or Hyper-V SCVMM server from the Zerto Virtual Manager:
   - **User Name**: The administrator name used to access the vCenter or SCVMM server. The name can be entered using one of the following formats:
     - **username**
     - **domain\username**
   - **Password**: The password used to access the vCenter or SCVMM server for the given user name. To ensure security, after saving the settings, the password field is cleared.

4. (Azure environments only) **Azure Settings**:
   - **Application Name**: The name used to access Azure.
   - **Client ID**: A unique identifier that is associated with the access name.
   - **Subscription**: The subscription associated with the user.
   - **Resource Name**: The name of the resource the user created.
   - **Storage Account Name**: The name of the storage account created or selected for this site during installation.

5. Click **SAVE**.

**Defining Performance and Throttling**

Performance and throttling settings include bandwidth settings and the maximum time a script can run before timing out.
You can specify bandwidth throttling, which is the maximum bandwidth that Zerto Virtual Replication uses from this site to all peer recovery sites. The default value is for Zerto Virtual Replication to automatically assign the bandwidth used per VPG, based on using the maximum available and then prioritizing the usage according to priority set for the VPGs sending data over the WAN.

**Note:** For minimum bandwidth requirements, see Zerto Scale and Benchmarking Guidelines.

For details about estimating the bandwidth, see “WAN Sizing”, on page 23.

**Time-based Bandwidth Throttling:** If you know that the bandwidth needs specific throttling during a certain period, for example, during the daily peak transaction period you can override the general throttling of the bandwidth for these specific times.

**To configure bandwidth:**

- Click **Performance and Throttling**.

**Bandwidth Throttling:**

Define this to control the amount of traffic going out of your site. When defined, this is the maximum bandwidth that Zerto Virtual Replication uses from this site to all peer recovery sites.

If you do not specify bandwidth throttling, the default is for Zerto Virtual Replication to automatically assign the bandwidth used per VPG, based on using the maximum available and then prioritizing the usage according to the priority set for the VPGs sending data over the WAN.

**Note:** For minimum bandwidth requirements, see Zerto Scale and Benchmarking Guidelines.

- By default, **Limited** is selected.
- In the text box, set the MB/sec. The valid range is from 0 to 1300 MB/sec.
- With 0 MB/sec, Zerto Virtual Replication automatically assigns the bandwidth used per VPG, based on using the maximum available and then prioritizing the usage according to the priority set for the VPGs sending data over the WAN.
- Enter the MB/sec when the value required is 100 MB/sec or more.

**Time-based Throttling:**

Define this to throttle the bandwidth during specific times. For example, during the daily peak transaction period you can change the bandwidth throttling, to override the general setting.
- **Limited**: Select to define the limit, then define:
  - **From**: The hour and the minute to start the throttling, using a 24-hour clock.
  - **To**: The hour and the minute to end the throttling, using a 24-hour clock.
- Click **Show advanced settings**...

### IMPORTANT:

**Advanced settings must only be changed in coordination with Zerto support.**

![Advanced settings panel]

- **Enable Bandwidth Regulation**: Use this for troubleshooting - to enable regulating the bandwidth.
- **Enable IO throttling**: If a host is handling too many IOs, then the IOs begin to get high latencies. To offset this the VRA sends fewer concurrent IOs. The latency is measured by taking the average latency for all IOs over a set period of time. For example, when the period is 5000 milliseconds and the bad IO latency is 40, the average latency is calculated every 5 seconds, and if the average latency exceeds 40, the VRA sends fewer concurrent IOs.
  - **Bad IO Latency VM**: The threshold above which the latency is considered high, and therefore bad.
  - **Requested Duration (ms)**: The period of time used to measure the average latency.
Defining Site Policies

You can set default recovery and replication policies.

Configuring Disaster Recovery Policies

To configure disaster recovery policies:
1. Click the Policies tab.

2. In the Disaster & Recovery area, choose the Failover/Move Commit Policy to use during a failover or move operation. These policies are described in “Initiating Failover Live”, on page 207 and “Moving Protected Virtual Machines to a Remote Site”, on page 198 respectively. The following options are available:
   - None: The failover or move operation must be manually committed or rolled back by the user.
   - Commit: After the time specified in the Default Timeout field the failover or move operation is committed, unless manually committed or rolled back by the user before the time-out value is reached. During the specified time you can check the recovered VPG virtual machines.
   - Rollback: After the time specified in the Default Timeout field the failover or move operation is rolled back, unless manually committed or rolled back by the user before the time-out value is reached. During the specified time you can check the recovered VPG virtual machines.

   The value set here applies as the default for all failover or move operations from this point on but can be changed when defining a failover or move operation.

3. Specify the Default Timeout after which a Commit or Rollback commit policy is performed. A value of zero indicates that the system will automatically perform the commit policy, without waiting for any user interaction.

4. In the Pre/Post Recovery Operations Scripts area, specify the timeout in seconds for a script to run before or after a failover, move, or test failover in the Default Script Execution Timeout field.

   For information about scripts, see “Running Scripts Before or After Recovering a VPG”, on page 144.

5. In the Replication area:
   - If the same site is to be used as both the protected and recovery site, select Enable Replication to Self.
     For more details, see “Enabling Replication to the Same Site”, on page 22.
   - Choose the Replication Pause Time, which is the time to pause when the journal might have problems, resulting in the loss of all checkpoints. For example, when the datastore for the journal is almost full.
     - Replication pause time is the amount of time that the transfer of data from the protected site to the journal on the recovery site is paused.
     - This time can then be used by the administrator to resolve the issue, for example by cloning the virtual machines in the VPG, described in “Cloning Protected Virtual Machines to the Remote Site”, on page 215.
     - The value defined here is applied to existing and new VPGs.
The value defined here is applied to **this site only**.

To pause the protection in **both directions**, for example to cover reverse protection back to the original site after a move operation, you must define **Replication Pause Time on both sites**.

To preserve the **BIOS UUID** of the **protected** VM after recovery operations, in the **recovery** ZVM Site Settings window, select **For incoming replication, copy the BIOS UUID of the protected VM to the recovered VM**.

**Notes:**
- Preserving of the BIOS UUID is **not** supported in Clone and Self-Replication recovery operations.
- Preserving of the BIOS UUID is **not** supported in Public Cloud.
- Cross replication is **not** supported.

6. Click **APPLY** or **SAVE**.

**Configuring Email Settings**

You can configure Zerto Virtual Replication alerts to be sent to an email address, so as to be better informed when an alert occurs and retention processes are run.

**Email Settings**

**To configure email settings:**
1. Click **Email Settings**.

2. Specify the **SMTP server Address**. The Zerto Virtual Manager must be able to reach this address.

3. If the **SMTP Server Port** was changed from the default, **25**, specify the port number.

4. Specify a valid email address for the email sender name in the **Sender Account** field.

5. Specify a valid email address where you want to send the email in the **To** field.

   You can test that the email notification is set up correctly by clicking **SEND TEST EMAIL**. A test email is sent to the email address specified in the **To** field.

6. Click **APPLY** or **SAVE**.

**Alerts and Reports**

You can configure when to send alerts and retention reports.
To configure when to send emails about alerts and retention sets:
1. To send an email when an alert is issued, select **Enable sending alerts**.
2. To send an email with a retention report, select **Enable retention reports**.
3. Specify whether you want a retention report sent daily or weekly.
   - **Daily:** Send a daily retention report
   - **Weekly:** Send a weekly retention report. Select the day of the week from the drop-down list.
4. Specify day of the week and the time of day to send the retention report.
5. Click **APPLY** or **SAVE**.

**Defining Resource Report Sampling Period**

Specify when you want to take resource samples to identify resource usage, either daily at a specific hour and minute or hourly at a specific minute within each hour.

1. Click **Reports**.

   ![Resource Report Settings](image)

2. Choose the **Sampling Rate**.
   - Information is saved for 90 days when the sampling period is hourly, and for one year when the sampling period is daily.
3. Choose the **Sampling Time**.
   - If you set the daily time to be 12:00, you will get a sample taken at noon every day. Collecting a sample hourly provides a higher resolution picture of replication traffic than if collected daily.
4. Click **APPLY** or **SAVE**.

These samples are used to generate resource reports as described in “Zerto Virtual Replication Reports”, on page 227.

**Reviewing Supported Host Versions**

Zerto Virtual Replication works with Microsoft hypervisor hosts. For a list of supported hosts, click **Compatibility**.

Supported Host Versions

Only Win 2012 R2 is supported
Seeing What is Licensed

The Zerto license includes information such as the number of virtual machines that can be protected and the license expiry date. You can see these details by clicking SETTING in the top right of the header and selecting License.

The Zerto license includes the following details:
- **License**: The license key itself.
- **License Type**: What is licensed: whether the license restricts the number of virtual machines that can be protected or the number of sockets used.
- **Expiry Date**: The license expiry date.
- **Quantity**: The maximum amount licensed, either virtual machines or sockets, based on the license type. If blank, the quantity is unlimited.
- **Usage**: The sites using the license and the number of protected virtual machines in each site.

A warning is generated when either the license expires or more than the licensed number of virtual machines are being protected. Protection continues but the license should be updated. After getting a new license key you can update Zerto Virtual Replication with this key.

**To update a license key:**

1. In the Zerto User Interface, in the top right of the header click SETTING and select License.
2. Enter a valid license key and click APPLY or SAVE.
   The license is updated on the local site and the paired remote sites.
Submitting a Support Ticket

You can open a ticket to Zerto support directly from Zerto Virtual Replication.

**Note:** The clocks on the machines where Zerto Virtual Replication is installed must be synchronized with UTC and with each other (the timezones can be different). Zerto recommends synchronizing the clocks using NTP. If the clocks are not synchronized with UTC, submitting a support ticket can fail.

**To open a support ticket:**
Support cases can be opened directly in the Zerto User Interface.

Creating a support case in the Zerto User Interface simplifies the submission process since much of the information that is required when entering a case using the Zerto Support Portal, such as the version and build numbers, is automatically added to the case when it is submitted via the Zerto User Interface.

In addition, when the case is submitted, a snapshot of the current environment is also attached to the case. The snapshot information includes the lists of alerts, events, tasks, VPGs, and virtual machines that are protected.

This information is used to help Zerto resolve the case quickly and, whenever possible, without the need to request more information from you.

**Note:** The clocks on the machines where Zerto Virtual Replication is installed must be synchronized with UTC and with each other (the timezones can be different). Zerto recommends synchronizing the clocks using NTP. If the clocks are not synchronized with UTC, submitting a support case can fail.
To open a support case:

1. In the Zerto User Interface, click **SETTING** in the top right of the header and select Open a Case. The Open Support Case window for the site opens.

2. Specify the case details:
   - **Subject**: The subject of the support case.
   - **Type**: The type of case being opened. Available options are:
     - Problem
     - Question
   - **Description**: A description of the problem or question in addition to the information supplied in the subject.
   - **Allow remote log collection**: How many logs is Zerto allowed to collect. Available options are:
     - Only for this case
     - For the next 30 days
     - Never
   - **SSP Email Address**: A valid email address registered with Zerto, with permission to open cases.

3. Click **SUBMIT**.

The case is processed and its progress is displayed. If the email address is not valid, the case is rejected. Once the case submission starts, it cannot be canceled.

---

**Submitting a Feature Request**

From the Zerto User Interface, you can access the Feature Requests page in myZerto in order to submit a feature request.
To submit a feature request:
1. In the Zerto User Interface, on the top right of the header, click .
2. Click Submit Feature Request; the Feature Requests page in myZerto opens.

About Zerto Virtual Replication

In the About window, you can do the following:
- View the version of Zerto Virtual Replication being run.
- Enable or disable the **Zerto CALLHOME feature**. The Zerto CALLHOME feature enables support notification and analytics for the following purposes:
  - To improve Zerto Virtual Replication.
  - To send notifications to the user when a new Zerto Virtual Replication version is available, or when new hypervisor versions are supported by Zerto.
- Enable or disable Zerto Virtual Manager to send data to the SaaS platform for monitoring purposes, using the Zerto Mobile App. This action is done by licensed Zerto Virtual Manager users.

When clicking About, the following options appear:

| Enable Support notification and product improvement feedback. |
| Enable SaaS features. Includes Zerto Analytics, Zerto Mobile App and Remote upgrade. |

To perform these actions, do the following:

1. In the Zerto User Interface, in the top right of the header, click SETTING ( ), and then click **About**. The version and build of Zerto Virtual Replication installed in the site are displayed.
2. To enable the Zerto CALLHOME feature, click **Enable Support notification and product improvement feedback**. This is selected by default.
   **Note:** This option is grayed out for Microsoft Azure and AWS.
   If the user deselects Enable Support notification and analytics, a warning appears notifying the user that deselecting this option will stop Zerto Virtual Replication from sending notifications when new Zerto Virtual Replication updates are available, or when new hosts are supported.
3. If you want Zerto Virtual Replication to send information to our Online Services and Zerto Mobile App, and enable remote upgrade, select **Enable SaaS features**. This is selected by default.
   This allows licensed Zerto Virtual Manager users to enable or disable data being sent from the Zerto Virtual Manager to the SaaS platform, thereby enabling site monitoring using the Zerto Mobile App.
   If the user deselects Enable Online Services and Zerto Mobile, a warning appears notifying the user that deselecting this option will stop Zerto Virtual Replication from sending information to Online Services and to the Zerto Mobile Application, rendering these services inoperable for the entire installation.
Zerto Virtual Replication provides a number of operations to recover virtual machines at the remote site. This chapter describes these operations. The following topics are described in this chapter:

- “The Failover Test Operation”, on page 182
- “The Move Operation”, below
- “The Failover Operation”, on page 183
- “The Restore File Operation”, on page 184
- “The Clone Operation”, on page 184

In addition, when extended recovery is defined, a VPG can be restored as described in “Using Zerto’s Long Term Retention”, on page 236.

### The Failover Test Operation

Use the Failover Test operation to test that during recovery the virtual machines are correctly replicated at the recovery site.

The Failover Test operation creates test virtual machines in a sandbox, using the test network specified in the VPG definition as opposed to a production network, to a specified point-in-time, using the virtual disks managed by the VRA. All testing is written to scratch volumes. The longer the test period the more scratch volumes are used, until the maximum size is reached, at which point no more testing can be done. The maximum size of all the scratch volumes is determined by the journal size hard limit and cannot be changed. The scratch volumes reside on the storage defined for the journal. Using scratch volumes makes cleaning up the test failover more efficient. For details, see “Testing Recovery”, on page 186.

During the test, any changes to the protected virtual machines at the protected site are sent to the recovery site and new checkpoints continue to be generated, since replication of the protected machines continues throughout the test. You can also add your own checkpoints during the test period.

The following diagram shows the positioning of the virtual machines before and during a Failover test operation.
The Move Operation

Use the Move operation to transfer protected virtual machines from the protected site to the recovery site in a planned migration.

When you perform a planned migration of the virtual machines to the recovery site, Zerto Virtual Replication assumes that both sites are healthy and that you planned to relocate the virtual machines in an orderly fashion. For details, see “Migrating a VPG to the Recovery Site”, on page 197.

The following diagram shows the positioning of the virtual machines before and after the completion of a Move operation.

Note: The Move operation without reverse protection does not remove the VPG definition but leaves it in a Needs Configuration state.

The Failover Operation

Following a disaster, use the Failover operation to recover protected virtual machines to the recovery site. A failover assumes that connectivity between the sites might be down, and thus the protected virtual machines and disks are not removed, as they are in a planned Move operation.

When you set up a failover you always specify a checkpoint to which you want to recover the virtual machines. When you select a checkpoint – either the last automatically generated checkpoint, an earlier checkpoint, or a tagged checkpoint – Zerto Virtual Replication makes sure that virtual machines at the remote site are recovered to this specified point-in-time. For details, see “Managing Failover Live”, on page 206.

Note: To identify the checkpoint to use, you can perform a number of test failovers, each to a different checkpoint.

Failback after the Original Site is Operational

After completing a failover, when the original site is back up and running you can move the recovered virtual machines back again using the Move operation. The VPG that is now protecting the virtual machines on the recovery site has to be configured and then a Delta Sync is performed with the disks in the original protected site. Once the VPG is in a protecting state the virtual machines can be moved back to the original site. For details, see “Migrating a VPG to the Recovery Site”, on page 197.
The following diagram shows the positioning of the virtual machines before and after the completion of a Failover operation.

![Diagram of virtual machines before and after Failover operation]

**Note:** The Failover operation without reverse protection does not remove the VPG definition but leaves it in a Needs Configuration state.

---

**The Restore File Operation**

Use the **Restore File** operation to recover individual files and folders from the recovery site.

You can recover specific files and folders from the recovery site for virtual machines that are being protected by Zerto Virtual Replication and running Windows operating systems. You can recover the files and folders from a specific point-in-time. For details, see “Recovering Files and Folders”, on page 213.

---

**The Clone Operation**

Use the **Clone** operation to create a copy of the VPG virtual machines on the recovery site in the production network. The virtual machines on the protected site remain protected and live.

**Note:** When the recovery site is VMware vCloud Director, the clone is created in vCenter Server and the virtual machines have to be manually imported into vCD.

You might want to create a clone if you need to have a copy of the virtual machines saved to a specific point-in-time, for example, when the VPG enters a **Replication Paused** state, or when testing the VPG in a live DR test. For details, see “Cloning a VPG to the Recovery Site”, on page 215.

The cloned machines are named after the protected virtual machine name along with the timestamp of the checkpoint used for the clone. The cloned virtual machines are not powered on.
The following diagram shows the positioning of the virtual machines before and after the completion of a Clone operation.
In order to verify that the disaster recovery that you have planned is the one that will be implemented, Zerto recommends testing the recovery of the VPGs defined in the protected site to the recovery site. This section describes how to test VPG recovery.

The following topics are described in this chapter:
- “The Test Failover Process”, below
- “Starting and Stopping Failover Tests”, on page 187
- “Viewing Test Results”, on page 191
- “Live Disaster Recovery Testing”, on page 192

Note: You cannot perform a failover test while a retention process is running.

### The Test Failover Process

Use the Failover Test operation to test that during recovery the virtual machines are correctly replicated at the recovery site.

The Failover Test operation creates test virtual machines in a sandbox, using the test network specified in the VPG definition, as opposed to creating virtual machines in a production network, to a specified point-in-time, using the virtual disks managed by the VRA. All testing is written to scratch volumes. The longer the test period the more scratch volumes are used, until the maximum size is reached, at which point no more testing can be done. The maximum size of all the scratch volumes is determined by the journal size hard limit and cannot be changed. The scratch volumes reside on the storage defined for the journal.

During the test, any changes to the protected virtual machines at the protected site are sent to the recovery site and new checkpoints continue to be generated, since replication of the protected machines continues throughout the test. You can also add your own checkpoints during the test period. You can initiate a failover during a test, as described in “Initiating Failover Live During a Test”, on page 214.

The Failover Test operation has the following basic steps:

1. Starting the test.
   a) The test virtual machines are created at the remote site using the network specified for testing in the VPG settings and configured to the checkpoint specified for the recovery.
   b) The virtual machines are powered on, making them available to the user. If applicable, the boot order defined in the VPG settings is used to power on the machines.

2. Testing. The virtual machines in the VPG are created as test machines in a sandbox and powered on for testing using the test network specified in the VPG definition and using the virtual disks managed by the VRA. All testing is written to scratch volumes. The longer the test period the more scratch volumes are used, until the maximum size is reached, at which point no more testing can be done. The maximum size of all the scratch volumes is determined by the journal size hard limit and cannot be changed. The scratch volumes reside on the storage defined for the journal. Using scratch volumes makes cleaning up the test failover more efficient.

   Note: You must not delete, clone, migrate to another host or change the disk properties of any of the test virtual machines.

3. Stopping the test.
   a) The test virtual machines are powered off and removed from the inventory.
   b) The following tag is added to the checkpoint specified for the test: Tested at startDateAndTimeOfTest

Note: The tagged checkpoint can be used to identify the point-in-time to restore the virtual machines in the VPG during a failover.

Testing that recovery is accomplished successfully should be done periodically so that you can verify that a failover will work. Zerto also recommends testing all the VPGs being recovered to the same cluster together. For example, in a cluster, if the HA configuration in a cluster includes admission control to prevent virtual machines being started if they violate availability...
constraints, testing the failover of every VPG configured for recovery to this cluster, at the same time, will show whether the constraints are violated or not.

When configuring a VPG, specify the period between tests for that VPG in the Test Reminder field in the REPLICATION step of the Create VPG wizard.

---

**Starting and Stopping Failover Tests**

You can test specific VMs in a VPG, a single VPG or multiple VPGs to make sure that if an actual failover is needed, the failover will perform as expected.

By default, test virtual machines are started with the same IPs as the protected machines in the protected site. This can create clashes so Zerto recommends ensuring that different IPs are assigned to the virtual machines when they start, by configuring virtual machine NIC properties in the VPG. For details, refer to "To create a virtual protection group (VPG) to recover in Hyper-V," on page 34. If you have defined the new virtual machines so that they are assigned different IPs, Zerto Virtual Replication changes the machine IPs.

**Note:** You can initiate the failover test from either the protected site or recovery site. You cannot select specific VMs in a VPG for failover test if the protected site is down.

**To test failover:**

1. In the Zerto User Interface set the operation to TEST and click **FAILOVER**.
   The Failover Test wizard is displayed.

2. Select the VPGs to test. By default, all VPGs are listed.
   a) To select specific VMs in a VPG, click the icon next to each VPG to get a list of VMs. The Select VMs to Failover dialog is displayed. By default, all VMs are selected.
b) Select the VMs to test.

**Note:** Selecting specific VMs in a VPG to failover is not supported when replicating from a vCD site.
At the bottom, the selection details show the amount of data and the total number of virtual machines selected. The **Direction** arrow shows the direction of the process: from the protected site to the peer, recovery, site.

3. Click **NEXT**.

The EXECUTION PARAMETERS step is displayed.

You can select the checkpoint to use for the recovery and see if a boot order and scripts are defined for the VPG.

4. By default, the last checkpoint added to the journal is displayed in the Checkpoint column
   - To use this checkpoint, proceed to the next step.
   - To change the checkpoint, click the link that appears as the checkpoint.

   **Latest:** Recovery is to the latest checkpoint. This ensures that the data is crash-consistent for the recovery.
   When selecting the latest checkpoint, the checkpoint used is the latest at this point.
If a **checkpoint is added** between this point and **starting the failover**, this **later** checkpoint is **not used**.

**Latest Tagged Checkpoint:** The recovery operation is to the latest checkpoint added in one of the following situations:
- By a user.
- When a failover test was previously performed on the VPG that includes the virtual machine.
- When the virtual machine was added to an existing VPG after the added virtual machine was synchronized.

5. To use a checkpoint which is **not** the latest checkpoint, or the latest tagged checkpoint, choose **Select from all available checkpoints**. By default, this option displays all checkpoints in the system. You can choose to display only automatic, or tagged checkpoints, or any combination of these types.

6. Click **OK**. If the selected VMs were not protected when the selected checkpoint was taken, a warning will appear informing the user that these VMs cannot be recovered. If all selected VMs cannot be recovered, an error will appear.

7. Click **NEXT**.

   The **FAILOVER TEST** step is displayed. The topology shows the number of VPGs and virtual machines being tested to failover to each recovery site. In the following example, 2 VPGs will be failed over to Site6-Ent2-R2, and they contain 5 virtual machines; and 1 VPG will be failed over to Site5-Ent2-P2-R2 and it contains 2 virtual machines.

8. To start the test, click **START FAILOVER TEST**.

   The test starts for the selected VPGs. The test begins with an initialization period during which the virtual machines are created in the recovery site.

**After Starting a Test, What Happens?**

The virtual machines in the virtual protection group are created at the recovery site with the suffix **testing recovery**.

**Note:** The following conversions are done to a protected virtual machine when it is recovered in vCenter Server:
- Virtual machines are recovered in vCenter Server with the highest hardware version supported by the vCenter Server host version under which the virtual machine is recovered.
- A Generation 1 virtual machine is recovered in vCenter Server with BIOS with the highest supported hardware version.
- A Generation 2 virtual machine is recovered in vCenter Server with EUFI. The host in vCenter must support hardware version 8 or higher.
- Recovered virtual machines use the VMware Virtual E1000 network adapter.

All testing is written to scratch volumes. The longer the test period the more scratch volumes are used, until the maximum size is reached, at which point no more testing can be done. The maximum size of all the scratch volumes is determined by the journal size hard limit and cannot be changed. The scratch volumes reside on the storage defined for the journal. Using these test scratch volumes makes cleaning up the test failover more efficient.
While a test is running:

- The virtual machines in the VPGs continue to be protected throughout the test.
- You can add checkpoints to the VPGs, and if necessary fail over the VPGs, as described in "Initiating Failover Live During a Test", on page 214.
- You cannot take a snapshot of a test machine, since the virtual machine volumes are still managed by the VRA and not by the virtual machine. Using a snapshot of a test machine will create a corrupted virtual machine.
- You cannot delete, clone, migrate to another host or change the disk properties of any of the test virtual machines.
- You cannot initiate a failover while a test is being initialized or closed.

Monitor the status of a failover test by doing the following:

- In the Zerto User Interface, click the VPGs tab. The Operation field in the GENERAL view displays Testing Failover when a failover test is being performed.

- In the Zerto User Interface, click the VPGs tab, and then click the name of a VPG you are testing. A dynamic tab is created displaying the specific VPG details including the status of the failover test.
To stop a failover test:
1. Click the Stop icon, in either the Dashboard or the dynamic tab, to stop the test in the specific VPG tab.

You can also stop the test via the TASKS popup dialog in the status bar, or by selecting MONITORING > TASKS. The Stop Test dialog is displayed.

2. In the Result field specify whether the test succeeded or failed.
3. Optionally, in the Notes field, add a description of the test. For example, specify where external files that describe the tests performed are saved. Notes are limited to 255 characters.
4. Click STOP.

After stopping a test, the following occurs:
- Virtual machines in the recovery site are powered off and removed.
- The resource group created for the operation is deleted.
- The checkpoint that was used for the test has the following tag added to identify the test:
  Tested at startDateAndTimeOfTest.
This checkpoint can be used to identify the point-in-time to use to restore the virtual machines in the VPG during a failover.

Viewing Test Results

After stopping a test, you can see the test results as part of Zerto Virtual Replication reports. Refer to “Recovery Reports”, on page 229.
Live Disaster Recovery Testing

This section describes how to use the basic Zerto Virtual Replication recovery operations to perform live disaster recovery tests, in different situations.

When performing a live DR test you need to consider the following:

- **The purpose of the live DR test**: Do you only want to verify that the VMs can recover properly?  
  - Or -  
  - Do you want to conduct a full DR test that will include running user traffic against the recovered VMs?
- **The length of time** you want to test the recovery, a few hours or several days.
- **Whether the changes** to the recovered machine need to be retained after the test or can they be discarded?
- Whether you are willing to accept temporary downtime of the application.
- Whether you want to simulate an actual disaster at the protected site, for example by simulating a network outage or bringing down the protected site.

The following flowchart shows the testing decision flow:

During any live test, Zerto recommends that you only maintain one working version of the same virtual machine.

As such, the first step in any test, except for a Failover Test or Clone, is to make sure that the protected virtual machines are shut down before starting to test recovered machines.

During a Zerto Virtual Replication Move operation the first step Zerto Virtual Replication performs is to shut down the protected machines, to ensure data integrity.

However, a Zerto Virtual Replication Failover operation assumes that the protected virtual machines are no longer accessible (the total site disaster scenario) and does not attempt to shut them down at the beginning of the operation.

In a live test using a Failover operation you have to manually shut down the virtual machines to be tested at the beginning of the test in order to prevent potential split-brain situations where two instances of the same applications are live at the same time.

If you want to perform a live DR test that includes a simulated disaster you can simulate the disaster, for example, by disconnecting the network between the two sites. In this type of test, once the disaster is simulated a Move operation cannot be used, since it requires both sites to be healthy, while a Failover operation can be used.
Basic Verification – User Traffic Is Not Run against the Recovered VMs

Basic testing that the virtual machines can recover is done using either a Failover Test operation or an uncommitted Move operation, using the Rollback setting.

Using a Failover Test Operation

You use a Failover Test operation if recovering the virtual machines in a sandbox, using the test network specified in the VPG definition for network isolation, is sufficient for a test. The Failover Test operation is described in “The Failover Test Operation”, on page 182 and in “Starting and Stopping Failover Tests”, on page 187.

See the following sections:
- “Using a Failover Test Operation: Recommended Procedure for a Live DR Test”, on page 193
- “Using a Failover Test Operation: Failover Test Considerations”, on page 193

Using a Failover Test Operation: Recommended Procedure for a Live DR Test

1. Change the VPG Failover Test Network to the production network used at the recovery site.
2. Manually shut down the virtual machines in the VPG.
3. Insert a new checkpoint. This avoids potential data loss since the virtual machines are shut down and the new checkpoint is added after all I/Os have been written to disk.
4. Optionally simulate a disaster, for example by disconnecting the two sites.
5. Perform a test failover on the VPG, choosing the checkpoint you added in step 3.
6. Verify that the test machines are recovered as expected.
7. Run user traffic against the virtual machines.
8. Stop the failover test.
9. Reconnect the sites.

Using a Failover Test Operation: Failover Test Considerations

- You do not have to shut down the protected virtual machines, and changes from the test phase are not kept or applied to the protected applications.
- You can recover to a specific point-in-time.
- You can use an isolated network to enable testing in a sandbox environment and not a live DR environment. This is the recommended practice.
- During the testing period, every change is recorded in a scratch volume.
  - Therefore, since both the scratch volume and virtual machines tested are on the same site, performance can be impacted by the increased I/Os during the failover test.
  - In addition, the longer the test period the more scratch volumes are used, until the maximum size is reached, at which point no more testing can be done.
  - The maximum size of all the scratch volumes is determined by the journal size hard limit and cannot be changed.
- The scratch volumes reside on the storage defined for the journal.
- At the end of the test, if you powered off the virtual machines in the protected site, you can power them back on and continue to work without the need to save or replicate back any data changed during the test.
- You can also use a Failover Test operation if you want to simulate an actual disaster for around an hour or less and do not want to save any changes on the recovery site.
Using an Uncommitted Move Operation

Use a Move operation with the commit/rollback policy set to rollback after the test period, if you need to test the recovery of virtual machines in the recovery site production environment. The Move operation is described in “The Move Operation”, on page 183 and in “Migrating a VPG to the Recovery Site”, on page 197.

Note: Committing the Move operation requires failing the migrated virtual machines back to the production site after a Delta Sync has been performed on the committed machines in the recovery site.

Procedure

The Move operation is described in detail in “The Move Process”, on page 197. The following procedure highlights specific steps to enable using the Move functionality for a DR test.

1. In the Move wizard, in the EXECUTION PARAMETERS tab, for commit policy, select None.
2. Either power off the relevant virtual machines or check the Force Shutdown checkbox, in the EXECUTION PARAMETERS tab, to make sure that the virtual machines are shut down, if they cannot be powered off using Microsoft Integration Services.
3. After testing the machines in the recovery site you can roll back the Move operation, which will return the virtual machines to their pre-test state.
   - Changes from the pre-commit phase are not kept or applied to the protected applications.
   - The virtual machines are allocated disks and connected to the network for a full test of the environment.
   - The protected machines are turned off until the end of the test, ensuring that there are no conflicts between the protected site and recovery site.
   - During the testing period, every change is recorded in a scratch volume to enable rolling back.
     - Therefore, since both the scratch volume and virtual machines being moved are on the same site, performance can be impacted by the increased IOs during the testing period.
     - In addition, the longer the test period the more scratch volumes are used, until the maximum size is reached, at which point no more testing can be done.
     - The maximum size of all the scratch volumes is determined by the journal size hard limit and cannot be changed.
     - The scratch volumes reside on the storage defined for the journal.
   - You can only recover to the last checkpoint written to the journal, at the start of the Move operation.

Run User Traffic Against the Recovered VMs

Testing actual user traffic against recovered virtual machines can be done using a Clone, Move, or Failover operation, as follows:

Move operation: When you can shut down the protected virtual machines but you do not want or need to simulate an actual disaster.

Failover operation: When you want to simulate an actual disaster.

Clone operation: When the protected application has to run throughout the test.

Using a Move Operation

Use a Move operation when you can shut down the protected virtual machines but you do not want to simulate an actual disaster. After the virtual machines have been recovered in the target site, they are used as the protected machines for as long as the test lasts. The Move operation is described in “The Move Operation”, on page 183 and in “Moving Protected Virtual Machines to a Remote Site”, on page 198.

See the following sections:
- “Using a Move Operation - Recommended Procedure for a Live DR Test”, on page 195
- “Using a Move Operation - Move Considerations”, on page 195
Using a Move Operation - Recommended Procedure for a Live DR Test

1. To enable using the Move functionality for a DR test, in the Move wizard, in the EXECUTION PARAMETERS tab, for commit policy, select None.
2. Move the VPG back to the original protected site. A Delta Sync is performed to copy the new transactions performed on the virtual machines in the recovery site back to the original protected site.

Using a Move Operation - Move Considerations

- You can test the moved machines before they are committed.
- You can test for as long as you want.
- The virtual machines are allocated disks and connected to the network for a full test of the environment.
- The originally protected disks are maintained for a faster failback when reverse replication is specified.
- The protected machines are turned off until the move is committed and then they are removed from the protected site. This ensures that there are no conflicts between the protected site and recovery site.
- You must test to the last checkpoint, taken after the protected virtual machines are shut down.
- An actual disaster is not simulated.
- During the testing period, if reverse replication is not specified, there is no protection for the recovered machines.

Using a Failover Operation

Use a Failover operation when you can shut down the protected virtual machines and you want to simulate an actual disaster. After the virtual machines have been recovered in the target site they are used as the protected machines for as long as the test lasts.

Using a Failover operation to test DR requires specific steps to ensure that the virtual machines are gracefully migrated to the target site, similar to a Move operation and that, like a Move operation, they can be verified prior to committing the failover. The Failover operation is described in “The Failover Operation”, on page 183 and in “Initiating Failover Live”, on page 207.

See the following sections:
- “Using a Failover Operation - Recommended Procedure for a Live DR Test”, on page 195
- “Using a Failover Operation - Failover Considerations”, on page 196

Using a Failover Operation - Recommended Procedure for a Live DR Test

1. Manually shut down the virtual machines.
2. Insert a new checkpoint. This avoids potential data loss since the virtual machines are shut down and the new checkpoint is added after all I/Os have been written to disk.
3. Optionally simulate a disaster, for example by disconnecting the two sites.
4. Perform a live failover on the VPG, specifying the commit policy and choosing the checkpoint you added in step 2. Choose a commit policy that will give you the necessary time to check that the failed over virtual machines have been successfully recovered to the correct point-in-time and if they are not, you are able to roll back the failover.
5. Continue to use the recovered virtual machines.
6. The VPG is in a Needs configuration state, because there is no access to the protected site.

After testing the recovered virtual machine you can finalize the live DR test and fail the virtual machines back to the original protected site:

1. Reconnect the sites.
2. Enable protection for the virtual machines by editing the VPG and clicking DONE.
3. Zerto Virtual Replication uses the original disks to preseed the volumes and expedite the synchronization between the two sites, using a Delta Sync.
   - The time it will take for the Delta Sync to complete is based on total size of the disks and storage performance at both sites.
   - After the synchronization completes, the VPG enters the Meeting SLA state.
4. Perform a Move operation to fail back the virtual machines to the original protected site.
5. In the Move wizard, in the EXECUTION PARAMETERS tab, for commit policy, set the commit policy to enable basic testing before the move is committed.

The virtual machines are recovered at the original protected site, and the VPG enters a Delta Sync phase before it enters a Meeting SLA state.

**Using a Failover Operation - Failover Considerations**

- The originally protected disks are maintained for a faster failback.
- Using the Failover operation for testing is non-intuitive.
- Testing by using the Failover operation requires performing manual procedures, such as shutting down the protected virtual machines.
- During the testing period, there is no protection for the recovered machines.

**Using a Clone Operation**

Use the Clone operation when the protected application must continue to run throughout the test. Create a clone of the virtual machines in a VPG on the recovery site to a specific point-in-time. The clone is a copy of the protected virtual machines on the recovery site, while the virtual machines on the protected site remain protected and live. The Clone operation is described in “The Clone Operation”, on page 184 and in “Cloning a VPG to the Recovery Site”, on page 215.

The cloned virtual machines are independent of Zerto Virtual Replication. At the end of the test you can remove these machines or leave them.

- You use the Clone operation when the source application has to continue throughout the test.
- You can create a clone of the virtual machines in a VPG on the peer site to a specific point-in-time.
- The clone is a copy of the protected virtual machines on the recovery site, while the virtual machines on the protected site remain protected and live.
- The Clone operation is described above, and in the Zerto Virtual Manager Administration Guide for the Microsoft Hyper-V Environment.
- The cloned virtual machines are independent of Zerto Virtual Replication. At the end of the test you can remove these machines or leave them.

**Using a Clone Operation - Clone Considerations**

- You can clone to a specific point-in-time.
- There is no protection for the cloned machines.
- After use of the clone ends, no changes made to the cloned virtual machines are applied to the protected virtual machines.
- The original virtual machines on the source site are live and online throughout the test.
This section describes a planned migration of a VPG to a remote site. The following topics are described in this section:

- “The Move Process”, below
- “Moving Protected Virtual Machines to a Remote Site”, on page 198
- “Reverse Protection For a Moved VPG”, on page 203

Note: You cannot perform a move while a retention process is running.

### The Move Process

Use the Move operation to move groups of protected virtual machines from a protected site to a recovery site in a planned migration.

When you perform a planned migration of virtual machines to a recovery site, Zerto Virtual Replication assumes that both sites are healthy and that you plan to relocate the virtual machines in an orderly fashion without loss of data.

Note: To recover virtual machines on the recovery site during disaster recovery, see “Managing Failover Live”, on page 206.

The MOVE operation has the following basic steps:

- Shutting down the protected virtual machines gracefully. This ensures data integrity.
  
  If the machines cannot be gracefully shut down, for example, when VMware Tools or Microsoft Integration Services is not available, you must manually shut down the machines before starting the Move operation or forcibly power off the virtual machines as part of the Move operation. If the machines cannot be gracefully shut down automatically and are not shut down manually and the Move operation does not forcibly power them off, the Move operation stops and Zerto Virtual Replication rolls back the virtual machines to their original status.

- Inserting a clean checkpoint. This avoids potential data loss since the virtual machines are not on and the new checkpoint is created after all I/Os have been written to disk.

- Transferring all the latest changes that are still in the queue to the recovery site, including the new checkpoint.

- Creating the virtual machines in the recovery site and attaching each virtual machine to its relevant virtual disks, based on the last checkpoint.

  Note: The virtual machines are created without CD-ROM or DVD drives, even if the protected virtual machines had CD-ROM or DVD drives. Also, as long as the virtual machines are created, the operation is considered successful, even if the virtual machines are not created with their complete definition, for example re-IP cannot be performed.

  VHDX disks are always recovered in the recovery site with dynamic disks. VHD disks are recovered in the recovery site by default with the same configuration as in the protected site.

- Preventing automatically moving virtual machines to other hosts: Setting failover clustering to prevent Dynamic Optimization. This prevents automatic Live Migration of the affected virtual machines during the Move operation.

- Powering on the virtual machines making them available to the user. If applicable, the boot order defined in the VPG settings is used to power on the machines.

  Note: If the virtual machines do not power on, the process continues and the virtual machines must be powered on manually. The virtual machines cannot be powered on automatically in a number of situations, such as when there are not enough resources in the resource pool, or the required MAC address is part of a reserved range, or there is a MAC address conflict or IP conflict, for example, if a clone was previously created with the MAC or IP address.

- Committing the Move operation. The default is to automatically commit the Move operation without testing. However, you can also run basic tests on the machines to ensure their validity to the clean checkpoint. Depending on the commit/rollback policy that you specified for the operation, the operation is committed, finalizing the move, or rolled back, aborting the operation.

- If Keep Source VMs is not selected, the protected virtual machines are removed from the inventory.
Moving Protected Virtual Machines to a Remote Site

You can move the virtual machines in a virtual protection group (VPG) to a remote site, where the virtual machines are replicated. As part of the process you can also set up reverse protection, where you create a VPG on the remote site for the virtual machines being moved, pointing back to the original site. This is commonly used, for example, when the protected site has planned downtime.

To initiate a move:

1. In the Zerto User Interface select ACTIONS > MOVE VPG.

The Move wizard is displayed.
2. Select the VPGs to move.
   At the bottom, the selection details show the amount of data and the total number of virtual machines selected.
   The **Direction** arrow shows the direction of the process: from the protected site to the peer, recovery, site.

3. Click **NEXT**.
   The EXECUTION PARAMETERS step is displayed.

```
You can change the following values to use for the recovery:

- **Commit Policy**
- **Force Shutdown** policy
- **Reverse Protection** settings
- **Keep Source VMs** settings

You can also see if a boot order and scripts are defined for the VPG.
```

4. To change the commit policy, click on the field or select the VPG and click **EDIT SELECTED**.
   a) To commit the recovery operation **automatically**, with **no** testing, select **Auto-Commit** and **0** minutes.
   b) Select **None** if you do **not** want an automatic commit or rollback. You must manually commit or roll back.
   c) To test **before** committing or rolling back, specify an **amount of time** to test the recovered machines, in minutes.
      This is the amount of time that the commit or rollback operation is **delayed**, before the automatic commit or rollback action is performed.
      During this time period, check that the new virtual machines are **OK** and then commit the operation or roll it back.
      The **maximum** amount of time you can **delay** the commit or rollback operation is **1440 minutes**, which is **24 hours**.

   Testing that involves I/O is done on **scratch volumes**.
   - The more I/Os generated, the more scratch volumes are used, until the maximum size is reached, at which point no more testing can be done.
   - The maximum size of all the scratch volumes is determined by the journal size hard limit and cannot be changed.
   - The scratch volumes reside on the storage defined for the journal.

5. To specify the shutdown policy, double-click the **Force Shutdown** field. If the virtual machines cannot be gracefully shut down, for example if Microsoft Integration Services is not installed on one of the virtual machines in the VPG, the Move operation fails unless you specify that you want to force the shutdown. If a utility is installed on the protected virtual machines, the procedure waits five minutes for the virtual machines to be gracefully shut down before forcibly powering them off.

6. To specify reverse protection, where the virtual machines in the VPG are moved to the recovery site and then protected in the recovery site, back to the original site, double-click the **Reverse Protection** field and click the **REVERSE** link.
   The Edit Reverse VPG wizard is displayed.
You can edit the reverse protection configuration. The parameters are the same as described when you create a VPG, described in “To create a virtual protection group (VPG) to recover in Hyper-V.”, on page 34, with the following differences:

- You cannot add or remove virtual machines to the reverse protection VPG.
- By default, reverse replication is to the original protected disks. You can specify a different storage to be used for the reverse replication.
- If Microsoft Integration Services is available, for each virtual machine in the VPG, the IP address of the originally protected virtual machine is used. Thus, during failback the original IP address of the virtual machine on the site where the machine was originally protected is reused. However, if the machine does not contain the utility, DHCP is used.
- When reverse protection is specified for a VPG residing on a vCD site that is replicating to either a vSphere or Hyper-V site, the boot order settings will not reserve the start delay vApp settings for virtual machines with the same order number.

7. To prevent the protected virtual machines from being deleted in the protected site, select the Keep source VMs checkbox.

   **IMPORTANT:**
   - The virtual machines will be removed from the other VPGs that are protecting them if the following conditions apply:
     - The virtual machines are already protected in other VPGs
     - Reverse protection is specified
     - Keep Source VMs is not checked
     - If there are no other virtual machines left to protect, the entire VPG will be removed.

Protecting virtual machines or vCD vApps in several VPGs is enabled only if both the protected site and the recovery site, as well as the VRAs installed on these sites, are of version 5.0 and higher.

8. Click **NEXT**.
   - A warning appears informing the user that the virtual machines will be removed from the other VPGs that are protecting them.
   - If there are no other virtual machines left to protect, the entire VPG will be removed.
   - When reverse protection is specified for a VPG residing on a vCD site that is replicating to either a vSphere or Hyper-V site, the boot order settings will not reserve the start delay vCD vApp settings for virtual machines with the same order number.

   The MOVE step is displayed. The topology shows the number of VPGs and virtual machines being moved to each peer site. In the following example, 2 VPGs will be moved to Site6-Ent2-R2, and they contain 5 virtual machines; and 1 VPG will be moved to Site5-Ent2-P2-R2 and it contains 2 virtual machines.

9. Click **START MOVE** to start the migration.

   A warning message appears, presenting a summary of your Commit Policy.

10. Review the Commit Policy summary, and either click **Change Settings**, or click **START MOVE** to start the migration.
11. If a commit policy was set with a timeout greater than zero, as described in step 4, you can check the moved virtual machines on the recovery site before they are removed from the protected site.

Note: If a virtual machine exists on the recovery site with the same name as a virtual machine being migrated, the machine is moved and named in the peer site with a number added as a suffix to the name, starting with the number 1.

The status icon changes to orange and an alert is issued, to warn you that the procedure is waiting for either a commit or rollback.

All testing done during this period, before committing or rolling back the Move operation, is written to thin-provisioned virtual disks, one per virtual machine in the VPG. These virtual disks are automatically defined when the machines are created on the recovery site for testing. The longer the test period the more scratch volumes are used, until the maximum size is reached, at which point no more testing can be done. The maximum size of all the scratch volumes is determined by the journal size hard limit and cannot be changed. The scratch volumes reside on the storage defined for the journal. Using these scratch volumes makes committing or rolling back the Move operation more efficient.

Note: You cannot take a snapshot of a virtual machine before the Move operation is committed and the data from the journal promoted to the moved virtual machine disks, since the virtual machine volumes are still managed by the VRA and not directly by the virtual machine. Using a snapshot of a moved machine before the Move operation has completed will result in the creation of a corrupted virtual machine.

12. Check the virtual machines on the recovery site, then either:

- Wait for the specified Commit Policy time to elapse, and the specified operation, either Commit or Rollback, is performed automatically.

- Or, in the specific VPG tab, click the Commit or Rollback icon ( ).
  - Click Commit to confirm the commit and, if necessary set, or reset, the reverse protection configuration. If the protected site is still up and you can set up reverse protection, you can reconfigure reverse protection by checking the Reverse Protection checkbox and then click the Reverse link. Configuring reverse protection here overwrites any of settings defined when initially configuring the failover.
  - Click Rollback to roll back the operation, removing the virtual machines that were created on the recovery site and rebooting the machines on the protected site. The Rollback dialog is displayed to confirm the rollback.
You can also commit or roll back the operation in the TASKS popup dialog in the status bar or under MONITORING > TASKS.

After the virtual machines are up and running and committed in the recovery site, the powered off virtual machines in the protected site are removed from the protected site. Finally, data is promoted from the journal to the moved virtual machines.

**Note:** If virtual machines are protected in several VPGs, reverse protection is selected and Keep source VMs is not checked, the virtual machines are deleted from the protected site. This will result in the removal of these virtual machines from other VPGs that are protecting them and to the journals of these VPGs to be reset. If no other virtual machines are left to protect, the entire VPG will be removed.

Protecting virtual machines in several VPGs is enabled only if both the protected site and the recovery site, as well as the VRAs installed on these sites, are of version 5.0 and higher.

During promotion of data, you cannot move a host on the moved virtual machines. If the host is rebooted during promotion, make sure that the VRA on the host is running and communicating with the Zerto Virtual Manager before starting up the recovered virtual machines.

**Note:** If the virtual machines do not power on, the process continues and the virtual machines must be manually powered on. The virtual machines cannot be powered on automatically in a number of situations, such as when there are not enough resources in the resource pool or the required MAC address is part of a reserved range or there is a MAC address conflict or IP conflict, for example, if a clone was previously created with the MAC or IP address.

The following conversions are done to a protected virtual machine when it is recovered in vCenter Server:

- Virtual machines are recovered in vCenter Server with the highest hardware version supported by the vCenter Server host version under which the virtual machine is recovered.
- A Generation 1 virtual machine is recovered in vCenter Server with BIOS with the highest supported hardware version.
- A Generation 2 virtual machine is recovered in vCenter Server with UEFI. The host in vCenter must support hardware version 8 or higher. Also the following restrictions apply for Generation 2 virtual machines:
  - The secure boot option for the machine in Hyper-V must be disabled.
  - The boot disk must be less than 2TB if the recovery host version is lower than ESXi 5.5.
  - All IDE disks are converted to SCSI disks. The boot disk is ported to a disk on a SCSI controller with location 0:0.
  - Recovered virtual machines use the VMware Virtual E1000 network adapter.
Reverse Protection For a Moved VPG

When moving the virtual machines in a VPG you specify whether you want reverse protection from the recovery site back to the original protected site.

Reverse Protection Specified

When you specify reverse protection, the virtual machines are moved to the recovery site and then protected using the values specified during the move. Data is promoted from the journal to the moved virtual machines and then synchronization with the original site is performed so that the VPG is fully protected. The synchronization performed uses the original protected disks and is either a Delta Sync or, if there is only one volume to synchronize, a Volume Delta Sync. A sync is required since the recovered machines can be updated while data is being promoted.

Reverse Protection Not Specified

If you do not specify reverse protection, the protected disks are removed along with the protected virtual machines at the end of the procedure. In this case, if you want to move the virtual machines back again to the original site, you will not be able to use the original disks and an initial synchronization will have to be performed. The VPG definition is kept with the status Needs Configuration and the reverse settings in the VPG definition are not set.

Clicking EDIT VPG displays the Edit VPG wizard with the settings filled in, using the original settings for the virtual machines in the VPG from the original protected site, except for the volumes, since the last step of the Move operation is to delete the virtual machines from the original protected site inventory, including the disks. To start replicating the virtual machines in the VPG, specify the disks to use for replication and optionally, make any other changes to the original settings and click DONE. An initial synchronization is performed.

Notes:

- If virtual machines are protected in several VPGs, reverse protection is selected and Keep source VMs is not checked, the virtual machines are deleted from the protected site. This will result in the removal of these virtual machines from other VPGs that are protecting them and to the journals of these VPGs to be reset. If no other virtual machines are left to protect, the entire VPG will be removed.

  Protecting virtual machines in several VPGs is enabled only if both the protected site and the recovery site, as well as the VRAs installed on these sites, are of version 5.0 and higher.

- You can edit the VPG definition from either of the sites, the site where the VPG virtual machines were initially protected or the site they were moved to.

- When reverse protection is specified for a VPG residing on a vCD site that is replicating to either a vSphere or Hyper-V site, the boot order settings will not reserve the start delay vApp settings for virtual machines with the same order number.
CHAPTER 15: MIGRATING ZERTO VIRTUAL REPLICATION TO A NEW VIRTUAL MACHINE

This section describes how to migrate the Zerto Virtual Replication (ZVR) application to a new Virtual Machine.

When ZVR is installed, the installation includes the following:

- **Zerto Virtual Manager (ZVM):** A Windows service, Zerto Virtual Manager service, that manages the replication at the site level.
- **Virtual Replication Appliance (VRA):** A virtual machine installed on each Hyper-V hosting virtual machines to be protected or recovered, to manage the replication of data from protected virtual machines to the recovery site.
- **Virtual Backup Appliance (VBA):** A Windows service that manages File Level Recovery operations within Zerto Virtual Replication. These repositories can be local or on a shared network.
- **DSS:** Installed on the VRA machine, and runs in the same process as the VRA. IT is responsible for all the retention data path operations.
- **Zerto User Interface:** Recovery using Zerto Virtual Replication is managed in a browser.

**Before you Begin**

From the **Source VM**, make a note of the following information which you will need later:

- Make a note of the exact Zerto Virtual Replication **installation configuration settings**.
- Navigate to **Control Panel > Network and Internet**, and make a note of the **IP address**.
- If a **DNS name** was used instead of an IP address, make a note of the DNS name.

**IMPORTANT:**

- The Optional steps that are included in the procedure below are **highly recommended**.
- Perform them before connecting the new ZVM to peer ZVM sites, in order to verify that the ZVM on the target VM is working correctly, and with the correct configurations.
- If the ZVM on the target VM is not working correctly with the correct configurations, **VPGs could be automatically deleted**.

**To migrate ZVR to a target VM:**

1. Prepare the **target VM** for the ZVR. To do this, review the machine requirements to install ZVR, and make sure that the **target VM** complies with these **minimum requirements**. For these details, see Zerto Virtual Replication Installation Guide for your environment, in the section **Installing Zerto Virtual Replication**.
2. On the **source VM**, verify which version of the Zerto Virtual Replication Installer file is currently installed, and then copy and paste that same version to the **target VM**.
3. On the **source VM**, stop all Zerto related services:
   - Zerto Virtual Manager Service
   - Zerto Virtual Backup Appliance Service
   - Zerto Remote Log Collection Service
4. On the **source VM**, navigate to the **Zerto installation** folder and copy the entire folder, including all its contents. By default, this folder is named **Zerto Virtual Replication**.
   
   **TIP:** To save space, you can leave out, or delete old log files which are no longer relevant. Navigate to the path: `\Zerto Virtual Replication\logs`.
5. On the **target VM**, create a **temp** folder, and into this folder paste the entire **Zerto installation** folder, including all its contents, which you copied in 4.
6. On the **source VM**, first **change the IP address** to a **different** IP address, then **disconnect** the source VM network connection.
7. On the target VM, run the **ZVM Installer** and complete the installation with the **same settings and configurations** as the ZVM that was installed on the source VM.
   - If the ZVM on the source VM was configured to use **VCD**, and in addition the **amqp service** was installed, then on the target VM, the **same amqp services** must be reinstalled. These are the following:
     - amqpInstaller
     - Erlang
     - RabbitMQ

8. On the target VM, stop all Zerto related services:
   - Zerto Virtual Manager Service
   - Zerto Virtual Backup Appliance Service
   - Zerto Remote Log Collection Service

9. **(Optional)** On the target VM, open the Windows Firewall and configure a new rule to **block** all outgoing TCP traffic on ports **9080** and **9081**.

10. On the target VM, navigate to the **temp** folder which you created in 5 and copy the entire **Zerto installation** folder, then navigate to the **Zerto installation** folder which was created when you ran the ZVM installer, and paste and overwrite all files.

11. On the target VM, navigate to **Control Panel > Network and Internet**, and set the **target VM’s IP address** the same IP address as original IP address of the source VM.
   - If a **DNS name** was used instead of the IP address, set the **target VM’s DNS name** the same DNS name as the source VM.

12. **(Optional)** If the **Log Archiver** functionality was configured and in use on the source VM, make sure to create a folder on the target VM to which the logs are archived.

13. On the target VM, **start** all Zerto related services:
   - Zerto Virtual Manager Service
   - Zerto Virtual Backup Appliance Service
   - Zerto Remote Log Collection Service

14. **(Optional)** On the target VM, perform the following **optional validations**:
   a) Open an Internet browser, enter the URL **https://localhost:9669**, and log into the ZVM.
   b) If you blocked all outgoing TCP traffic on ports 9080 and 9081 as described in 9, make sure all the **VPGs** are present. Their state should be **Error** or **Site disconnection**, as there should be no connection to the peer ZVM sites.
   c) Make sure that the **VRA status** is **Installed**.
   d) Open the Windows Firewall and re-enable traffic for ports **9080** and **9081**.

15. From anywhere in the network, log into the ZVM GUI and verify that the **status** of the **VPGs** and **VRAs** is **OK**.
   - If a **DNS name** was used instead of an IP address, it might take a while for the correct routing to occur. The sites will remain with the status **disconnected** until the correct routing occurs.

16. If the **status** of all the **VPGs** and **VRAs** is **OK**, first **power off** and then **delete** the source VM as it is no longer in use.
This section describes how to perform a failover to the recovery site after an unforeseen disaster. The following topics are described in this section:

- “The Failover Live Process”, below
- “Initiating Failover Live”, on page 207
- “Reverse Protection for a Failed Over VPG”, on page 213
- “Initiating Failover Live During a Test”, on page 214

**Note:** If you need to perform a failover while a retention process is running, the retention process is aborted to enable the failover to run.

### The Failover Live Process

Use the Failover operation following a disaster to recover protected virtual machines to the recovery site.

**Note:** You can also move virtual machines from the protected site to the recovery site in a planned migration. For details, see “Migrating a VPG to the Recovery Site”, on page 197.

When you set up a failover you always specify a checkpoint to which you want to recover the virtual machines. When you select a checkpoint – either the last automatically generated checkpoint, an earlier checkpoint, or a tagged checkpoint – Zerto Virtual Replication makes sure that the virtual machines at the remote site are recovered to this specified point-in-time. By setting a commit policy that enables checking the recovered machines before committing the failover, you can check the integrity of the recovered machines. If the machines are OK, you can commit the failover. Otherwise, you can roll back the operation and then repeat the procedure using a different checkpoint.

The Failover operation has the following basic steps:

- If the protected site or Zerto Virtual Manager is down, the process continues with the next step.
  - If the protected site or Zerto Virtual Manager is still running, the failover requirements are determined:
    - If the default is requested, doing nothing to the protected virtual machines, the Failover operation continues with the next step.
    - If shutting down the protected virtual machines is requested and the protected virtual machines do not have Microsoft Integration Services available, the Failover operation fails.
    - If forcibly shutting down the protected virtual machines is requested, the protected virtual machines are shut down and the Failover operation continues.
- Creating the virtual machines at the remote site in the production network and attaching each virtual machine to its relevant virtual disks, configured to the checkpoint specified for the recovery. The virtual machines are created without CD-ROM or DVD drives, even if the protected virtual machines had CD-ROM or DVD drives. Also, as long as the virtual machines are created, the operation is considered successful, even if the virtual machines are not created with their complete definition, for example re-IP cannot be performed.
  **Note:** The original protected virtual machines are not touched since the assumption is that the original protected site is down.
  VHDX disks are always recovered in the recovery site with dynamic disks. VHD disks are recovered in the recovery site by default with the same configuration as in the protected site.
- Preventing automatically moving virtual machines to other hosts: Setting failover clustering to prevent Dynamic Optimization. This prevents automatic live migration of the affected virtual machines during the Failover operation.
- Powering on the virtual machines making them available to the user. If applicable, the boot order defined in the VPG settings is used to power on the machines.
  **Note:** If the virtual machines do not power on, the process continues and the virtual machines must be manually powered on. The virtual machines cannot be powered on automatically in a number of situations, such as when there are not enough...
resources in the resource pool or the required MAC address is part of a reserved range or there is a MAC address conflict or IP conflict, for example, if a clone was previously created with the MAC or IP address.

- The default is to automatically commit the Failover operation without testing. However, you can also run basic tests on the machines to ensure their validity to the specified checkpoint. Depending on the commit/rollback policy that you specified for the operation after testing, either the operation is committed, finalizing the failover, or rolled back, aborting the operation.

- If the protected site is still available, for example, after a partial disaster, and reverse protection is possible and specified for the Failover operation, the protected virtual machines are powered off and removed from the inventory. The virtual disks used by the virtual machines in the protected site are used for the reverse protection. A Delta Sync is performed to make sure that the two copies, the new target site disks and the original site disks, are consistent. A Delta Sync is required since the recovered machines can be updated while data is being promoted.

If reverse protection is selected, and the virtual machines are already protected in other VPGs, continuing with the operation will cause the virtual machines to be deleted from other VPGs that are protecting them and to the journals of these VPGs to be reset. If no other virtual machines are left to protect, the entire VPG will be removed.

Protecting virtual machines or a vCD vApp in several VPGs is enabled only if both the protected site and the recovery site, as well as the VRAs installed on these sites, are of version 5.0 and higher.

Note: If reverse protection is not possible, the original protected site virtual machines are not powered off and removed.

- The data from the journal is promoted to the machines. The machines can be used during the promotion and Zerto Virtual Replication ensures that the user sees the latest image, even if this image, in part, includes data from the journal.  

Note: Virtual machines cannot be moved to another host during promotion. If the host is rebooted during promotion, make sure that the VRA on the host is running and communicating with the Zerto Virtual Manager before starting up the recovered virtual machines.

### Failback After the Original Site is Operational

To fail back to the original protected site, the VPG that is now protecting the virtual machines on the recovery site has to be configured and then a Delta Sync is performed with the disks in the original protected site. Once the VPG is in a protecting state the virtual machines can be moved back to the original protected site, as described in “Migrating a VPG to the Recovery Site”, on page 197.

### Initiating Failover Live

You can initiate a failover, whereby the virtual machines in the virtual protection group (VPG) or specific virtual machines in a virtual protection group (VPG) are replicated to a set checkpoint in the recovery site. As part of the process you can also set up reverse replication, whereby you create a virtual protection group on the recovery machine for the virtual machines being replicated, pointing back to the protected site.

You can initiate a failover to the last checkpoint recorded in the journal, even if the protected site is no longer up. You can initiate a failover during a test, as described in “Initiating Failover Live During a Test”, on page 214.

If you have time to initiate the failover from the protected site you can. However, if the protected site is down, you initiate the failover from the recovery site. You cannot select specific VMs in a VPG for failover if the protected site is down.

Note: Any VPGs that are in the process of being synchronized, cannot be recovered, unless the synchronization is a bitmap synchronization.
To initiate a failover:

1. In the Zerto User Interface set the operation to LIVE and click **FAILOVER**.

   The Failover wizard is displayed.

   ![Failover Wizard](image)

2. Select the VPGs to failover. By default, all VPGs are listed.
   a) To select specific VMs in a VPG, click the icon next to each VPG to get a list of VMs. The Select VMs to Failover dialog is displayed. By default, all VMs are selected.

   ![Select VMs to Failover](image)

   b) Select the VMs to failover.

   **Note:** Selecting specific VMs in a VPG to failover is not supported when replicating from a vCD site.

   At the bottom, the selection details show the amount of data and the total number of virtual machines selected.

   The Direction arrow shows the direction of the process: From the protected site To the peer, recovery, site.

3. Click **NEXT**. If specific VMs are selected for failover, a warning will appear informing the user to review the Pre-recovery and Post-recovery Scripts.

   The **EXECUTION PARAMETERS** step is displayed.
You can change the following values to use for the recovery:

- **Commit Policy**
- **Checkpoint** to use
- **Force Shutdown**
- **Reverse Protection** settings

You can also see if a boot order and scripts are defined for the VPG.

4. By default, the last checkpoint added to the journal is displayed in the Checkpoint column
   - To use this checkpoint, proceed to the next step.
   - To change the checkpoint, click the link that appears as the checkpoint.

   A window appears, displaying a list of the VPGs’ checkpoints.

   **Latest**: Recovery is to the **latest checkpoint**. This ensures that the data is crash-consistent for the recovery.
   
   When selecting the latest checkpoint, the checkpoint used is the latest at this point.
   
   If a checkpoint is added between this point and starting the failover, this later checkpoint is not used.

   **Latest Tagged Checkpoint**: The recovery operation is to the latest checkpoint added in one of the following situations:
   - By a user.
   - When a failover test was previously performed on the VPG that includes the virtual machine.
   - When the virtual machine was added to an existing VPG after the added virtual machine was synchronized.

5. To use a checkpoint which is not the latest checkpoint, or the latest tagged checkpoint, choose **Select from all available checkpoints**. By default, this option displays all checkpoints in the system. You can choose to display only automatic, or tagged checkpoints, or any combination of these types.

6. Click **OK**. If the selected VMs were not protected when the selected checkpoint was taken, a warning will appear informing the user that these VMs cannot be recovered. If all selected VMs cannot be recovered, an error will appear.

7. To change the commit policy, click on the field or select the VPG and click **EDIT SELECTED**.
   a) To commit the recovery operation **automatically**, with **no testing**, select **Auto-Commit** and **0 minutes**.
   b) Select **None** if you do not want an automatic commit or rollback. You must manually commit or roll back.
   c) To test **before** committing or rolling back, specify an **amount of time** to test the recovered machines, in minutes.
      
      This is the amount of time that the commit or rollback operation is **delayed**, before the automatic commit or rollback action is performed.
      
      During this time period, check that the new virtual machines are OK and then commit the operation or roll it back.
      
      The **maximum** amount of time you can **delay** the commit or rollback operation is **1440 minutes**, which is **24 hours**.
      
      Testing that involves I/O is done on **scratch volumes**.
The more I/Os generated, the more scratch volumes are used, until the maximum size is reached, at which point no more testing can be done.

The maximum size of all the scratch volumes is determined by the journal size hard limit and cannot be changed.

The scratch volumes reside on the storage defined for the journal.

Testing that involves I/O is done on scratch volumes.

The more I/Os generated, the more scratch volumes are used, until the maximum size is reached, at which point no more testing can be done.

The maximum size of all the scratch volumes is determined by the journal size hard limit and cannot be changed.

The scratch volumes reside on the storage defined for the journal.

To specify the shutdown policy, double-click the VM Shutdown field and select the shutdown policy:

**No (default):** The protected virtual machines are not touched before starting the failover. This assumes that you do not know the state of the protected machines, or you know that they are not serviceable.

**Yes:** If the protected virtual machines have Microsoft Integration Services available, the virtual machines are gracefully shut down, otherwise the Failover operation fails. This is similar to performing a Move operation to a specified checkpoint.

**Force Shutdown:** The protected virtual machines are forcibly shut down before starting the failover. This is similar to performing a Move operation to a specified checkpoint. If the protected virtual machines have Microsoft Integration Services available, the procedure waits five minutes for the virtual machines to be gracefully shut down before forcibly powering them off.

8. To specify reverse protection, where the virtual machines in the VPG are moved to the recovery site and then protected in the recovery site, back to the original site, double-click the Reverse Protection field and click the REVERSE link. The Edit Reverse VPG wizard is displayed.

You can edit the reverse protection configuration. The parameters are the same as described when you create a VPG, described in “To create a virtual protection group (VPG) to recover in Hyper-V:”, on page 34, with the following differences:

- You cannot add or remove virtual machines to the reverse protection VPG.
- By default, reverse replication is to the original protected disks. You can specify a different storage to be used for the reverse replication.
- If Microsoft Integration Services is available, for each virtual machine in the VPG, the IP address of the originally protected virtual machine is used. Thus, during failback the original IP address of the virtual machine on the site where the machine was originally protected is reused. However, if the machine does not contain the utility, DHCP is used.
- When committing the failover, you can reconfigure reverse protection, regardless of the reverse protection settings specified here.
- When reverse protection is specified for a VPG residing on a vCD site that is replicating to either a vSphere or Hyper-V site, the boot order settings will not reserve the start delay vApp settings for virtual machines with the same order number.

**IMPORTANT:**

- The virtual machines will be removed from the other VPGs that are protecting them if the following conditions apply:
  - The virtual machines are already protected in other VPGs
  - Reverse protection is specified
  - If there are no other virtual machines left to protect, the entire VPG will be removed.

Protecting virtual machines or vCD vApps in several VPGs is enabled only if both the protected site and the recovery site, as well as the VRAs installed on these sites, are of version 5.0 and higher.

9. Click NEXT.

- A warning appears informing the user that the virtual machines will be removed from the other VPGs that are protecting them.
- If there are no other virtual machines left to protect, the entire VPG will be removed.

10. Click OK. If a virtual machine is deleted from other VPGs, the journals of these VPGs are reset.
The FAILOVER step is displayed. The topology shows the number of VPGs and virtual machines being failed over to each recovery site. In the following example, 2 VPGs will be failed over to Site6-Ent2-R2, and they contain 5 virtual machines; and 1 VPG will be failed over to Site5-Ent2-P2-R2 and it contains 2 virtual machines.

11. Click **START FAILOVER**.

A warning message appears, presenting a summary of your Commit Policy.

12. Review the Commit Policy summary, and either click **Change Settings**, or click **START FAILOVER** to start the failover.

If a commit policy was set with a timeout greater than zero, you can check the failed over virtual machines on the recovery site before committing the failover operation.

The failover starts, by creating the virtual machines in the recovery site to the point-in-time specified: either the last data transferred from the protected site or to one of the checkpoints written in the journal.
Managing Failover Live

**Note:** If a virtual machine exists on the recovery site with the same name as a virtual machine being failed over, the machine is created and named in the peer site with a number added as a suffix to the name, starting with the number 1. If the original protected site is still up and reverse replication configured to use the protected virtual machines virtual disks, these virtual machines are powered off.

The status icon changes to orange and an alert is issued, to warn you that the procedure is waiting for either a commit or rollback.

All testing done during this period, before committing or rolling back the failover operation, is written to thin-provisioned scratch virtual disks. These virtual disks are automatically defined when the machines are created on the recovery site for testing. The longer the test period the more scratch volumes are used, until the maximum size is reached, at which point no more testing can be done. The maximum size of all the scratch volumes is determined by the journal size hard limit and cannot be changed. The scratch volumes reside on the storage defined for the journal. Using these scratch volumes makes committing or rolling back the failover operation more efficient.

**Note:** You cannot take a snapshot of a virtual machine before the failover operation is committed and the data from the journal promoted to the moved virtual machine disks, since the virtual machine volumes are still managed by the VRA and not directly by the virtual machine. Using a snapshot of a recovered machine before the failover operation has completed will result in a corrupted virtual machine being created.

13. Check the virtual machines on the recovery site, then either:
   - Wait for the specified Commit Policy time to elapse, and the specified operation, either Commit or Rollback, is performed automatically.
   - Or, in the specific VPG tab, click the Commit or Rollback icon (
     - Commit
     - Rollback
   - a) If you clicked the Commit icon, the Commit window is displayed to confirm the commit and, if necessary set, or reset, the reverse protection configuration.
     - If the protected site is still up and you can set up reverse protection, you can reconfigure reverse protection by selecting the Reverse Protection checkbox and then click the Reverse link.
     - Configuring reverse protection at this point overwrites any of settings defined when initially configuring the move.
     - If specific VMs in a VPG are selected, a new VPG will be created in addition to the original VPG. The additional VPG includes only the VMs selected for recovery. The new VPG name is displayed as {Original-VPG-Name-Partial}. The original VPG will remain intact with its history.
   - b) If you clicked the Rollback icon, this rolls back the operation, removing the virtual machines that were created on the recovery site and reboots the machines on the protected site.

   - The Rollback window is displayed to confirm the rollback.
   - a) You can also commit or roll back the operation via the TASKS popup dialog in the status bar, or by selecting MONITORING > TASKS.

If the original protected site is still up and reverse replication is configured to use the virtual disks of the protected virtual machines, these virtual machines are removed from this site, unless the original protected site does not have enough storage available to fail back the failed over virtual machines. Finally, data is promoted from the journal to the recovered virtual machines.

**Note:** If Reverse Protection is selected and the virtual machines are already protected in other VPGs, the virtual machines are deleted from the protected site and the journals of these VPGs are reset. This will result in the removal of these virtual machines from other VPGs that are protecting them, or the removal of the entire VPG, if no other virtual machines are left to protect.

**Note:** Protecting virtual machines in several VPGs is enabled only if both the protected site and the recovery site, as well as the VRAs installed on these sites, are of version 5.0 and higher.

During promotion of data, you cannot move a host on the recovered virtual machines. If the host is rebooted during promotion, make sure that the VRA on the host is running and communicating with the Zerto Virtual Manager before starting up the recovered virtual machines.

By default the virtual machines are started with the same IPs as the protected machines in the protected site. If you do not specify reverse protection, the original machines still exist in the protected site and this can create clashes. In this case, Zerto recommends ensuring that a different IP is assigned to the virtual machines when they start, when configuring each virtual machine NIC properties in the VPG, during the definition of the VPG. For details, refer to “To create a virtual protection group (VPG) to recover in Hyper-V:”, on page 34. If you have defined the new virtual machines so that they will be assigned different IPs, Zerto Virtual Replication changes the machine IPs. Changing IPs can take several seconds.
Reverse Protection for a Failed Over VPG

When you specify reverse protection, the virtual machines are recovered on the recovery site and then protected using the values specified during the failover. The original virtual machines are removed from the original protected site and then on the target site the data is promoted from the journal to the recovered virtual machines and then synchronization with the original site is performed so that the VPG is fully protected. The synchronization used is either a Delta Sync or if there is only one volume to synchronize, a Volume Delta Sync is performed. A sync is required since the recovered machines can be updated while data is being promoted.

Notes:
- For the Failover operation to complete successfully, when reverse protection is specified, the original protected site must have enough storage available to fail back the failed over virtual machines.
- When reverse protection is specified for a VPG residing on a vCD site that is replicating to either a vSphere or Hyper-V site, the boot order settings will not reserve the start delay vApp settings for virtual machines with the same order number.
- If you do not specify reverse protection, the VPG definition is kept with the status Needs Configuration and the reverse settings in the VPG definition are not set.

Clicking EDIT VPG displays the Edit VPG wizard with the settings filled in, using the original settings for the virtual machines in the VPG from the original protected site, except for the volumes. To start replicating the virtual machines in the VPG, specify the disks to use for replication and optionally, make any other changes to the original settings and click DONE.
Reverse Protection With One-to-Many

Zerto Virtual Replication enables you to protect virtual machines in a maximum of three VPGs. These VPGs cannot be recovered to the same site.

If Reverse Protection is selected, and the virtual machines are already protected in other VPGs, the following occurs:

- The virtual machines are deleted from the protected site.
- The replication of other VPGs containing these machines is paused.
- The recovery of all the virtual machines, including the virtual machine removed from the protected site, is possible.

To resume replication do the following:
1. Open the Edit VPG wizard.
2. Select the virtual machine that was previously deleted from the protected site.
3. Remove the virtual machine from the VPG.

If the protected VPG contains a vCD vApp, and the vCD vApp is protected in other VPGs, Reverse Protection is selected, the following occurs:

- The vCD vApp is deleted from the protected site.
- The vCD vApp is deleted from the other VPGs, and therefore can no longer be recovered.

VPGs enter a state of pause and pause replication if the following conditions apply:

- The ZVM on the protected and recovery sites are of version 5.5 and higher.
- The VRA installed on the recovery site is of version 5.5 and higher.

Protecting virtual machines or a vCD vApp in several VPGs is enabled if:

- The protected site and the recovery site are of version 5.0 and higher.
- The VRAs installed on these sites are of version 5.0 and higher.

What Happens When the Protected Site is Down

If the protected site is down, you can initiate the failover from the recovery site, as described above in “To initiate a failover:”, on page 208.

The tab for a specific VPG tab for a VPG shows that recovery is possible.

If the Zerto Virtual Manager service is down the actual machines that are being protected can still be up, but they are only recoverable to the last checkpoint written before the Zerto Virtual Manager service went down.

When there is no connection with the protected site, the status for recovered VPGs is red with an Error status and green while recovery is being performed. If the protected site restarts so that reverse replication is possible, the status changes to orange.

Initiating Failover Live During a Test

Replication continues during a test. If you need to initiate a failover during a test, you initiate the failover. The test stops to enable the failover and then a normal failover is performed, as described in "Initiating Failover Live", on page 207. Any changes made to test the failover are not replicated, as only changes to the protected machines in the VPG are replicated.

Note: You cannot initiate a failover while a test is being initialized or closed.
CHAPTER 17: CLONING A VPG TO THE RECOVERY SITE

You can create a clone of each virtual machine in a VPG. The clone is a copy of the protected virtual machine, located on the recovery site, while the virtual machine on the protected site remains protected and live.

The following topics are described in this chapter:

- “The Clone Process”, below
- “Cloning Protected Virtual Machines to the Remote Site”, on page 215

Note: You cannot clone virtual machines in a VPG test while a retention process is running. When the recovery site is VMware vCloud Director, the clone is created in vCenter Server and the virtual machines have to be manually moved into vCD.

The Clone Process

Use the Clone operation to create a copy of the VPG virtual machines on the recovery site. The virtual machines on the protected site remain protected and live.

The Clone operation has the following basic steps:

- Creating the cloned disks at the recovery site with the data from the journal to the specified checkpoint.
- Creating the virtual machines at the recovery site in the move/failover network and attach each virtual machine to its relevant cloned disks, configured to the checkpoint specified for the clone.
  
  Note: The virtual machines are created without CD-ROM or DVD drives, even if the protected virtual machines have CD-ROM or DVD drives.

The cloned machines are named with the names of the protected machines, with the timestamp of the checkpoint used to create the clone. The cloned virtual machines are not powered on and are not protected by Zerto Virtual Replication.

VHDX disks are always cloned in the recovery site with dynamic disks. VHD disks are cloned in the recovery site by default with the same configuration as in the protected site.

Cloning Protected Virtual Machines to the Remote Site

You might want to create a clone if you need to have a copy of the virtual machines saved to a specific point-in-time, for example, when a VPG enters a Replication Paused state, or when testing a VPG in a live DR test.

To clone a VPG:

1. In the Zerto User Interface, in the VPGs tab click the name of the VPG to be cloned.
   
   A new tab is added to the Zerto User Interface, with the name of the VPG that you clicked. The tab displays data about the VPG.
   
   Note: If the VPG was previously viewed, and the tab for this VPG is still displayed, you can access the details by selecting the tab.

2. Select the new tab and click MORE > Offsite Clone.
The {VPG-Name}: Offsite Clone dialog is displayed.

a) To clone specific VMs, click ADVANCED. The {VPG-Name}: Select VMs to Clone dialog is displayed. By default, all VMs are selected.

Select VMs to Clone dialog showing VMs with their IP addresses and recovery data sizes.

b) Select the VMs to clone.

Note: Zerto Virtual Replication Version 6.0 supports cloning specific VMs if installed on the protected site only.

3. If you intend to use the last checkpoint, which is displayed in the dialog, go to step 8.

   To select the checkpoint, click SELECT A CHECKPOINT.
The {VPG-Name}: Checkpoints dialog is displayed.

When selecting the point to recover to:
- The refresh button is initially grayed out and is enabled for clicking after 5 seconds. It is also grayed out for 5 seconds after being clicked, before being re-enabled.
- A Click the refresh button to view the latest checkpoints reminder is displayed 10 seconds after the refresh button is clicked to remind the user that there is a new Latest Checkpoint.
- If the user has scrolled to, and selected, a checkpoint anywhere in the checkpoints list, clicking the refresh button will automatically return the user to the selected checkpoint in the list.

4. Select the checkpoint to use:
- To use this checkpoint, proceed to the next step.
- To change the checkpoint, click the link that appears as the checkpoint.

A window appears, displaying a list of the VPGs’ checkpoints.

**Latest:** Recovery is to the latest checkpoint. This ensures that the data is crash-consistent for the recovery.

When selecting the latest checkpoint, the checkpoint used is the latest at this point.

If a **checkpoint is added** between this point and **starting the failover**, this **later** checkpoint is **not used**.

**Latest Tagged Checkpoint:** The recovery operation is to the latest checkpoint added in one of the following situations:
- By a user.
- When a failover test was previously performed on the VPG that includes the virtual machine.
- When the virtual machine was added to an existing VPG after the added virtual machine was synchronized.

6. To use a checkpoint which is **not** the latest checkpoint, or the latest tagged checkpoint, choose **Select from all available checkpoints**. By default, this option displays all checkpoints in the system. You can choose to display only automatic, or tagged checkpoints, or any combination of these types.

7. Click **OK**.
8. Select the recovery storage to use for the cloned virtual machines.
   
   **Note:** All the cloned virtual machines use a single storage, that is accessible by all the recovery site VRAs used by the VPG.

9. Click **CLONE**.

   The cloning starts and the status is displayed in the VPG details tab.

   ![Zerto Virtual Manager Administration Guide for the Microsoft Hyper-V Environment - Version 6.5 Cloning a VPG to the Recovery Site](image)

   The cloned machines are assigned the names of the protected machines with the addition of the timestamp of the checkpoint used for the clone. The cloned virtual machines are not powered on.

When cloning to VMware vSphere environments:

- The cloned virtual machines are created in the **ZertoRecoveryFolder** folder, and not the recovery folder defined in the VPG.
- The cloned virtual machines use a single datastore.
- The VMDKs are renamed `(1).vmdk`, `(2).vmdk`, etc.
- When the recovery site is VMware vCloud Director, the clone is created in vCenter Server and the virtual machines have to be manually imported into vCD.
- If the protected virtual machine has RDMs attached, these disks are always cloned as thin-provisioned VMDKs to the datastore specified in the **Recovery Datastore** field in the **Edit VM** dialog in the **REPLICATION** step in the **Edit VPG** wizard.

When cloning to Microsoft Hyper-V environments:

- The cloned virtual machines use a single storage.
- The VHDs are renamed `(1).vhdx`, `(2).vhdx`, etc.
CHAPTER 18: RECOVERING FILES AND FOLDERS

You can recover specific files and folders from the recovery site for virtual machines that are being protected by Zerto Virtual Replication. You can recover the files and folders from a specific point-in-time. Thus, you can recover files and folders for a virtual machine for as far back as the journal history is configured.

This section describes how to recover files and folders. The following topics are described in this section:
- “The File and Folder Recovery Process”, below
- “Recovering Files and Folders”, on page 220

The File and Folder Recovery Process

Use the RESTORE FILE operation to recover specific files and folders from the recovery site.

When you set up file and folder recovery, you always specify a checkpoint to which you want to recover the files and folders. When you select a checkpoint – either the last automatically generated checkpoint, an earlier automatically generated checkpoint, or a tagged checkpoint – Zerto Virtual Replication makes sure that the files and folders replicated at the remote site are recovered to this specified point-in-time.

The file and folder operation has the following basic steps:
1. Select the virtual machine that is protected, on which the files or folders to recover are located.
2. Select the checkpoint, at which the files and folders will be recovered.
3. Select the disk, which contains the files and folders to recover.
   
   Note: You can only recover files and folders from one disk at a time.
4. Mount the selected disk.
5. Select the files and folders on the disk to recover.
6. Download the selected files and folders.
   - The files are downloaded to the machine where you run the Zerto User Interface.
   - Make sure that this machine has enough space for the recovered files.
7.Unmount the selected disk.

You can only recover files and folders from one disk at a time. After the required disk is mounted, if you want to recover files or folders from another disk, you can begin the mount process for the second disk. Zerto Virtual Replication does not support mounting the same volume twice, for example if you want a file from two different checkpoints.

Considerations:
- You cannot recover files or folders from a virtual machine when a test failover, live failover, move, clone, or retention process is being performed on a VPG that contains the virtual machine.
- You cannot recover files or folders from the Zerto plugin.

For additional file and folder recovery considerations or known issues, see the Release Notes > Known Issues > File Level Restore.
Recovering Files and Folders

The procedure to recover files and folders involves the following steps:

1. **Mounting the Disk that Contains the Required Files and Folders**, on page 220
   - **Note:** While the disk is mounted:
     - If you start a live failover or move, Zerto Virtual Manager forcibly unmounts the disk so the live failover or move can be performed.
     - Scheduled retention processes do not start.
     - You can perform a test failover or clone.

2. **Downloading the Files and Folders from the Disk**, on page 223
   - **Note:** When downloading, you may see grayed out files. These grayed out files are not supported files, and therefore cannot be selected. For a list of unsupported files see Zerto Virtual Replication - Interoperability Matrix for All Versions.

**Mounting the Disk that Contains the Required Files and Folders**

Before you can recover files or folders, you must first select the checkpoint in time from which you will recover the files or folders. Then you must select and access the disk in which the files or folders are contained.

**To mount a disk that includes files and folders to restore:**
1. From either the protected or recovery site, select **ACTIONS > RESTORE FILE**.
   The File and Folder Restore wizard is displayed.

![File and Folder Restore: Select VM](image)

The list of all protected virtual machines is displayed. You can only recover files or folders from one virtual machine at a time.

2. Select the virtual machine on which the file or folder is located and click **NEXT**.
The CHECKPOINT step is displayed. By default, all checkpoints are displayed.

3. Select the checkpoint from which to recover the file or folder.
   - **Auto:** Checkpoints generated by the Zerto Virtual Manager are displayed.
   - **Tagged:** Checkpoints that were added by a user, or were added by the Zerto Virtual Manager when a failover test was performed on the VPG that included the virtual machine, or when the virtual machine was added to an existing VPG after the virtual machine was synchronized.

4. Click **NEXT**.
   The DISK step is displayed. All disks associated with the selected virtual machine are displayed.

5. Select a disk to mount and click **NEXT**.
Recovering Files and Folders

The MOUNT step is displayed. The settings you selected are displayed.

6. Click **START MOUNT** to mount the disk.

   Mounting the disk may take some time, depending on the selected checkpoint and the number of files and folders on the disk.
   - When the first part of the restore process is done, icons appear next to the completed task.
   - By clicking the folder icon ( ) you can browse the folders and files on the disk.
   - By clicking the unmount icon ( ) you can unmount the disk without restoring any files or folders.

7. Continue with “Downloading the Files and Folders from the Disk” on page 223.
Downloading the Files and Folders from the Disk

In this procedure you select the files and folders. The files are downloaded to the machine where you run the Zerto User Interface. Make sure that this machine has enough space for the recovered files.

To download folders or files:

1. Click the folder icon ( ).

   ![Image of File and Folder Restore dialog]

   The File and Folder Restore dialog is displayed.

2. Click NEXT.
The FILE/FOLDER step is displayed.

- Select the files and folders you want to download.
  
  **Note:** Grayed out files are not supported therefore cannot be selected. For a list of unsupported files, see the Interoperability Matrix. When a selected folder contains unsupported files, only the supported files will successfully download. Meaning, only the supported files will appear in the download folder.
Recovering Files and Folders

The selected files or folders are displayed in the right pane of the dialog. The number of items selected is displayed and the size of the selected files is also displayed.

3. Click **NEXT**.

The **DOWNLOAD** step is displayed. It shows the files and folders you selected for downloading.

By default, when you select multiple files or one or more folders, the data is compressed before it is downloaded. If you select only one file, for download, you can choose whether or not the file is compressed.

4. Click **START DOWNLOAD**.

The files and folders are downloaded by default to the downloads folder on the computer where you run the Zerto User Interface.

When a selected folder contains unsupported files, only the supported files will successfully download. Meaning, only the supported files will appear in the download folder.

**Note:** Saving the files and folders to a network share is dependent on the browser used to display the Zerto User Interface and the settings for this browser.

- When you select one file to download, and do not compress the file, the name of the downloaded file is the name of the file. For example, if you download a file called **Important-file.docx**, the name of the file on your computer will be **Important-file.docx**.
- When you choose one file and choose to compress it, or you select multiple files, the files are zipped into a file called **ZertoDownloads.zip**.
5. Zerto recommends that you **unmount the disk** after the files or folders are downloaded. To unmount the disk, click the unmount icon (■).
Zerto Virtual Replication includes reporting for the following:

- “Outbound Protection Over Time”, below
- “Protection Over Time by Site”, on page 228
- “Recovery Reports”, on page 229
- “Resources Report”, on page 231
- “Monthly Usage Report”, on page 235
- “VPG Performance”, on page 235

**Outbound Protection Over Time**

Information about how much data is actually being protected against the amount configured for any of the sites can be displayed in the Outbound Protection Over Time report under the REPORTS tab.

The data displayed can be up to 30 minutes old, since the Zerto Virtual Manager collects the relevant data every 30 minutes.

You can filter the information by the following:

**From** and **To**: The dates for which you want information.

**Recovery Site**: Select the site for which you want information or select all sites. If all sites are selected, All is displayed. The dropdown list displays all sites paired with the local site.

Click **APPLY** to apply the selected filtering and produce the report.

Click **RESET** to reset the display to the default values.
Protection Over Time by Site

Information about the virtual machines and the amount of data on the recovery site can be displayed in the Protection Over Time by Site report under the REPORTS tab. When the report is displayed for the first time, information is shown per 30 minute intervals.

The data displayed can be up to 30 minutes old, since the Zerto Virtual Manager collects the relevant data every 30 minutes.

You can filter the information by the following:

From and To: Select the dates for which you want information.

Protected Site: Select the sites for which you want information. The list displays all sites paired with the local site.

Resolution: Select the resolution for the report: daily, weekly, monthly, or All.

Click APPLY to apply the selected filtering and produce the report.

Click RESET to reset the display to the default values.

Note: By default, the Protection Over Time By Site report is only available for the last 90 days.

Differences might occur between the value displayed in the Used Journal column in this report and the value displayed in the Recovery Journal Used Storage column retrieved from vCenter or Hyper-V in the Resources report.

The Used Journal value displayed here is calculated by the VRA, based on internal journal allocations for each recovery volume.

vCenter and Hyper-V Resources reports are expected to display a larger size than in this report, and may reach up to 500MB per virtual machine higher than reported in this report.
Recovery Reports

Information about recovery operations — failover tests, moves, and failovers — can be displayed in Recovery Reports under the REPORTS tab.

The information includes the name of the user who initiated the report, which recovery operation, the point in time, protected and the recovery sites involved, when the recovery operation was started, when it ended, the time it took to bring up the machines in the recovery site, the RTO, whether the operation succeeded or not, the VPG recovery settings, the virtual machine recovery settings, and detailed recovery steps, and any notes added during a failover test.

Recovery Reports are always kept, and never deleted.

You can filter the tests by the following:
- **Dates**: The dates for which you want information. Only operations performed between these dates are displayed.
- **VPG**: Select the VPGs for which you want information. The number of VPGs you selected is displayed. If you select All, the total number of VPGs is shown.
- **Type**: Select the recovery operations for which you want information: Failover, Move, Failover Test. If more than one operation is selected, the number of recovery operations you selected is displayed.
- **Status**: Select the statuses for which you want information: Success, Failed. If more than one status is selected, the number of statuses you selected is displayed.

Click APPLY to apply the selected filtering.

Click RESET to reset the display to the default values.

Click EXPORT and choose PDF or ZIP to generate a report.

The report displays information by VPG, and then by virtual machine within the VPG.

The VPG information includes who initiated the operation, the type of operation, the start time and the end time of the operation, the recovery host, storage, network, any boot order information, etc.

The information for each machine includes the steps taken during the operation, such as creating a machine and scratch volumes for testing, when each process began and ended, and whether the operation succeeded or not.

**Note**: When FOT is still in progress, the end time in the Recovery Report appears as NA.
The Recovery operation start time and Recovery operation end time values are shown in UTC according to the Zerto Virtual Manager clock in the recovery site. The Point in time value takes the checkpoint UTC time, which was created in the protected site, and converts it to the recovery site time zone.

**Branding the Recovery Report**

A branded logo can be placed in the report in the top left corner by adding the logo as a .png file to the \<ZertoInstallFldr>\Zerto\Zerto Virtual Replication\gui\ folder with the name provider_logo.png.

The folder ZertoInstallFldr is the root folder where Zerto Virtual Replication in the recovery site is installed. For example, C:\Program Files\Zerto.
Resources Report

Information about the resources used by the virtual machines being recovered to a particular site is displayed in the Resources report under the REPORTS tab. The information is collected at fixed times that are defined in the Reports tab of the Site Settings dialog in the recovery site. Information for the report is saved for 90 days when the sampling period is hourly and for one year when the sampling period is daily.

The report collects the resource information for the virtual machines being recovered to the site where the report is run.

If no virtual machines are recovered to the site where the report is run, the report is empty.

You can filter the information by the following:

From and To: The dates for which you want information.

Click EXPORT to generate the report, which is produced as an Excel file.

The information presented in this report is divided into three tabs:

Details Tab: Shows information for each protected virtual machine.

Performance Tab: Shows bandwidth and throughput information for each virtual machine in a table and in a graph.

Target Host Tab: Shows information per host in the recovery site.

Using a REST API to Generate a Report

Zerto Virtual Replication exposes a REST API to produce resource data. The report is generated by passing a URL. For details about the ResourcesReport API (and all other Zerto Virtual Replication REST APIs), see the Zerto Virtual Replication RESTful API Reference Guide.

Details Tab

The Details tab includes the names and IDs of the virtual machines being protected and, for each virtual machine, the timestamp for the information, where it is protected, the CPU used, the memory used by the host and the guest, the storage used, and other information.

Interpreting the Details Tab

The Details tab provides a breakdown of every protected virtual machine, identified by its internal identifier and name in the hypervisor manager. The report also includes the name of the VPG that is protecting the virtual machine and information such as the protected and recovery sites, the protected and recovery vCD Org, cluster, etc.

The Timestamp column displays the time when the last sample, as defined in the Reports tab of the Site Settings dialog, was taken.

The VPG Type column is one of:

VC2VC - vCenter to vCenter replication
VC2VCD - vCenter to vCloud Director replication
VCD2VCD - vCloud Director to vCloud Director replication
VCD2VC - vCloud Director to vCenter replication

The ZORG column defines organizations set up in the Zerto Cloud Manager that use a cloud service provider for recovery.
The **Bandwidth (Bps) and Throughput (Bps)** columns display the average between two consecutive samples. With daily samples, these figures represent the average daily bandwidth and throughput. For hourly samples, the timestamp represents an average between the sample at the timestamp and the previous sample. A value of -1 means that the system failed to calculate the value, which can happen for several reasons, for example:

- Sites were disconnected when the sample was collected. Although the protected site measures the throughput and bandwidth, the recovery site logs the results.
- The bandwidth or throughput values at the time of the sample was lower than the bandwidth or throughput value in the previous sample. This can happen, for example, if the protected site VRA is rebooted since the sample values are not stored persistently by the VRA.
- If `valueInLastSample` does not exist, since `currentValue` is the first sample for the virtual machine, the data is not calculated.

Bandwidth is calculated as: `(currentValue - valueInLastSample)/elapsedTtime`

For example:

<table>
<thead>
<tr>
<th>TIME</th>
<th>ACTION/DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>2:29:59.999</td>
<td>A virtual machine is placed in a VPG</td>
</tr>
<tr>
<td>2:30</td>
<td>A sample is generated. The total transmitted bytes is zero since the virtual machine was just placed in the VPG</td>
</tr>
<tr>
<td>2:30-2:59.999</td>
<td>The VM is writing data at 1MB/minute</td>
</tr>
<tr>
<td>3:00</td>
<td>The virtual machine lowers its write rate to 0.5MB/minute</td>
</tr>
<tr>
<td>3:30</td>
<td>A new sample is calculated. Current value of total data transmitted is 45MB: 1MB/minute*(30 minutes) + (0.5MB/minute)*30 minutes</td>
</tr>
</tbody>
</table>

Last value of total data transmitted is 0, from the 2:30 sample.

\[
\text{Bandwidth} = \frac{(45MB-0)}{60 \text{ minutes}} = 0.75\text{MB/minute} = 13107\text{Bps}
\]

### Report output fields

The following describes the fields in the **Details** tab.

<table>
<thead>
<tr>
<th>PARAMETER</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active Guest Memory (MB)</td>
<td>The active memory of the virtual machine.</td>
</tr>
<tr>
<td>Bandwidth (Bps)</td>
<td>The average bandwidth used between two consecutive samples, in bytes per second.</td>
</tr>
<tr>
<td>Consumed Host Memory (MB)</td>
<td>The amount of host memory consumed by the virtual machine.</td>
</tr>
<tr>
<td>CPU Limit (MHz)</td>
<td>The maximum MHz available for the CPUs in the virtual machine.</td>
</tr>
<tr>
<td>CPU Reserved (MHz)</td>
<td>The MHz reserved for use by the CPUs in the virtual machine.</td>
</tr>
<tr>
<td>CPU Used (MHz)</td>
<td>The MHz used by the CPUs in the virtual machine.</td>
</tr>
<tr>
<td>CrmId</td>
<td>The CRM identifier specified in Zerto Cloud Manager for an organization that uses a cloud service provider for recovery.</td>
</tr>
<tr>
<td>Memory (MB)</td>
<td>The virtual machine defined memory.</td>
</tr>
<tr>
<td>Memory Limit (MB)</td>
<td>The upper limit for this virtual machine’s memory allocation.</td>
</tr>
<tr>
<td>Memory Reserved (MB)</td>
<td>The guaranteed memory allocation for this virtual machine.</td>
</tr>
<tr>
<td>Number Of vCPUs</td>
<td>The number of CPUs for the virtual machine.</td>
</tr>
<tr>
<td>Number Of Volumes</td>
<td>The number of volumes attached to the virtual machine.</td>
</tr>
<tr>
<td>Recovery Journal Provisioned Storage (GB)</td>
<td>The amount of provisioned journal storage for the virtual machine. The provisioned journal size reported can fluctuate considerably when new volumes are added or removed.</td>
</tr>
</tbody>
</table>
### Resources Report

<table>
<thead>
<tr>
<th>PARAMETER</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recovery Journal Used Storage (GB)</td>
<td>The amount of journal storage used by the virtual machine. Differences might occur between the value displayed in the <code>Used Journal</code> column in the Protection Over Time by Site report and the value displayed here, which is retrieved from vCenter or Hyper-V. The <code>Used Journal</code> value displayed in the Protection Over Time by Site report is calculated by the VRA, based on internal journal allocations for each recovery volume. vCenter and Hyper-V Resources reports are expected to display a larger size than in the Protection Over Time by Site report, and may reach up to 500MB higher per virtual machine than reported in the Protection Over Time by Site report.</td>
</tr>
<tr>
<td>Recovery Volumes Provisioned Storage (GB)</td>
<td>The amount of provisioned storage for the virtual machine in the target site. This value is the sum of volumes' provisioned size.</td>
</tr>
<tr>
<td>Recovery Volumes Used Storage (GB)</td>
<td>The amount of storage used by the virtual machine in the target site.</td>
</tr>
<tr>
<td>Service Profile</td>
<td>The service profile used by the VPG.</td>
</tr>
<tr>
<td>Source Cluster</td>
<td>The source cluster name hosting the virtual machine.</td>
</tr>
<tr>
<td>Source Host</td>
<td>The source host name hosting the virtual machine.</td>
</tr>
<tr>
<td>Source Organization VDC</td>
<td>The name of the source vDC organization.</td>
</tr>
<tr>
<td>Source Resource Pool</td>
<td>The source resource pool name hosting the virtual machine.</td>
</tr>
<tr>
<td>Source Site</td>
<td>The source protected site name, defined in the Zerto User Interface.</td>
</tr>
<tr>
<td>Source vCD Organization</td>
<td>The name of the source vCD organization.</td>
</tr>
<tr>
<td>Source Volumes Provisioned Storage (GB)</td>
<td>The amount of provisioned storage for the virtual machine in the source site. This value is the sum of volumes' provisioned size.</td>
</tr>
<tr>
<td>Source Volumes Used Storage (GB)</td>
<td>The amount of storage used by the virtual machine in the source site. This value is the sum of the volumes' used size.</td>
</tr>
<tr>
<td>Source VRA Name</td>
<td>The name of the source VRA used to send data to the recovery site.</td>
</tr>
<tr>
<td>Target Cluster</td>
<td>The target cluster name hosting the virtual machine.</td>
</tr>
<tr>
<td>Target Datastores</td>
<td>The target storage used by the virtual machine if it is recovered.</td>
</tr>
<tr>
<td>Target Host</td>
<td>The target host name hosting the virtual machine when it is recovered.</td>
</tr>
<tr>
<td>Target Organization vDC</td>
<td>The name of the target vDC organization.</td>
</tr>
<tr>
<td>Target Resource Pool</td>
<td>The target resource pool name where the virtual machine will be recovered.</td>
</tr>
<tr>
<td>Target Site</td>
<td>The target site name, defined in the Zerto User Interface.</td>
</tr>
<tr>
<td>Target Storage Policy</td>
<td>The target vCD storage policy used.</td>
</tr>
<tr>
<td>Target vCD Organization</td>
<td>The name of the target vCD organization.</td>
</tr>
<tr>
<td>Target VRA Name</td>
<td>The name of the VRA managing the recovery.</td>
</tr>
<tr>
<td>Throughput (Bps)</td>
<td>The average throughput of the VM used between two consecutive samples, in bytes per second.</td>
</tr>
<tr>
<td>Timestamp</td>
<td>The date and time the resource information was collected. The value can be converted to an understandable date using code similar to the following:</td>
</tr>
<tr>
<td></td>
<td>var date = new Date(jsonDate);</td>
</tr>
<tr>
<td></td>
<td>or code similar to the Perl code example, jsonDateToString($), described in Zerto Virtual Replication RESTful API Reference Guide.</td>
</tr>
<tr>
<td>VM Hardware Version</td>
<td>The VMware hardware version.</td>
</tr>
<tr>
<td>VM Id</td>
<td>The internal virtual machine identifier.</td>
</tr>
<tr>
<td>VM Name</td>
<td>The name of the virtual machine.</td>
</tr>
</tbody>
</table>
The Performance tab shows bandwidth and throughput information for each virtual machine per sampling period in a table and in a graph. The Performance tab enables the user to view the total bandwidth and throughput per sampling period. The graph allows the user to view performance trends over time per VM.

For full explanation of the bandwidth and throughput information, refer to the "Details Tab", on page 231.

You can filter information by date and VM name.

The following describes the fields in the Performance tab:

<table>
<thead>
<tr>
<th>PARAMETER</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time Stamp</td>
<td>For explanation see the Details tab.</td>
</tr>
<tr>
<td>Bandwidth (Bps)</td>
<td>The average bandwidth of the VM used between two consecutive samples, in bytes per second.</td>
</tr>
<tr>
<td>Throughput (Bps)</td>
<td>The average throughput of the VM used between two consecutive samples, in bytes per second.</td>
</tr>
<tr>
<td>Total Bandwidth</td>
<td>The total bandwidth of all VMs during the measured period.</td>
</tr>
<tr>
<td>Total Throughput</td>
<td>The total throughput of all VMs during the measured period.</td>
</tr>
</tbody>
</table>

Target Host Tab

The Target Host tab shows information per host in the recovery site. This enables the user to perform capacity planning on the recovery host. You can filter information by time and by host.

The following describes the fields in the Target Host tab.

<table>
<thead>
<tr>
<th>PARAMETER</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active Guest Memory (MB)</td>
<td>The active memory of the virtual machine.</td>
</tr>
<tr>
<td>CPU Used (MHz)</td>
<td>The MHz used by the CPUs in the virtual machine.</td>
</tr>
<tr>
<td>Host</td>
<td>The Target Host’s IP address or DNS name.</td>
</tr>
<tr>
<td>Total Bandwidth</td>
<td>The total bandwidth of all VMs replicating to the host during the measured period.</td>
</tr>
<tr>
<td>Total Throughput</td>
<td>The total throughput of all VMs replication to the host during the measured period.</td>
</tr>
<tr>
<td>vCPUs</td>
<td>The number of CPUs for the virtual machine.</td>
</tr>
<tr>
<td>VMs</td>
<td>The number of VMs protected.</td>
</tr>
<tr>
<td>Volumes</td>
<td>The number of volumes attached to the virtual machine.</td>
</tr>
</tbody>
</table>
Monthly Usage Report

Information about usage can be displayed in the Monthly Usage report under the REPORTS tab. The Monthly Usage Report can only be viewed with a cloud license.

The information is organized by organization and within each organization by site, then virtual protection group (VPG) and then by the virtual machines in each VPG.

This report is mostly used by cloud service providers.

You can filter the information by the following:

- **Year**: The year of interest.
- **Month**: Select the month to review.

For each month, the usage report displays the number of virtual machines protected during the month and the average number per day in the month. For example, if fifteen virtual machines are protected in a few VPGs starting on the 28th of the month in a thirty day month, the total days will be 30 (two days multiplied by fifteen machines) and the VM Count will be 1 (Total days divided by the number of days in the month).

Click **EXPORT** to a CSV or ZIP file to generate the report.

The ZIP file option saves the report as a zipped CSV file in a zipped file called **UsageReport.zip**.

VPG Performance

Performance graphs for all VPGs or for an individual VPG can be seen in the VPG Performance report under the REPORTS tab. These graphs show more detailed resolution than the corresponding graphs in the DASHBOARD tab.

You can specify the VPGs whose performance should be displayed. When you request information about multiple VPGs, each VPG is shown in a different color, with a key at the top of the report that maps each color to the VPG it represents.

Position the cursor on a graph line to see exact information about that point.

Click **APPLY** to apply the selected filtering and produce the report.

Click **RESET** to reset the display to the default values.
Zerto Virtual Replication enables recovering VPGs from a repository, up to one year back, to the recovery site.

This section contains the following information and procedures:

- **Long Term Retention - Overview**
- **Workflow: Using Zerto’s Long Term Retention**
- **Creating a New Repository for Retention**
- **Editing an Existing Repository for Retention**
- **Enabling Long Term Retention for the VPGs**
- **Manually Running the Retention Process**
- **Monitoring Your Long Term Retention Status**
- **Restoring VPGs from a Repository**
- **Storing Repository Sets**

**Note:**

If you are upgrading Zerto Virtual Replication, and if your site was already configured with Long Term Retention, or retention configurations, review Long Term Retention known issues and limitations, and see the guide, *Upgrading Zerto Virtual Replication*. 
Long Term Retention - Overview

Using Zerto’s data retention to restore data, IT users are able to define a Retention Policy for their organization, where data can be retained for up to a year. The user defines what data is saved where, and for how long the data should be retained, according to the organizations regulation policy. When the user needs to restore the data, they can then select a specific point in time.

What does the Repository Contain?
The repository contains retention sets, where each retention set has its own mapping file (DOM file).

How does the Long Term Retention process work?
When Long Term Retention is first configured, and the first reading of the data has occurred, the retention set consists of:

- All the data copied to the retention repository.

When the second reading of the data occurs, the retention set consists of:

- All the data from the first reading, but not including any original data which was marked as changed during the second reading.
- The changed data from the second reading.

Each retention set is independent of other retention sets, and gives a complete and total picture of the data at the point in time of the reading.

What happens when the Retention Policy period is overdue?
When the defined Retention Policy period is completed, as new retention sets are added, the oldest retention sets are deleted and can no longer be restored.

Before You Begin
Review Long Term Retention limitations and considerations:

- Repository Type:
  - SMB and local repositories are not supported.
  - Only NFS Repository is supported.
  - Supported NFS protocol version 3.
  - NFS repository does not support authentication.
  - NFS repository based on PBBA (e.g., data domains and so on), is not supported.

- Incremental:
  - Zerto can track and maintain up to 40TB of changes between copies (incremental) for long term retention on a single VRA. In the event of exceeding 40TB at any point, the VRA will be locked for running future retention processes. To release that lock, please contact Zerto Support.
  - Performing incrementals is based on identifying the initial copy and maintaining changes which happened since. In the event where either the changes tracked between copies or the reference to the initial copy are lost, a full copy will be created.

- Retention Policy:
  - The retention policy aggregation rule is described in the Administration Guide > Using Zerto’s Long Term Retention > Storing Repository Sets.
  - Deleted retention sets are removed from the repository according to the configured retention policy.
    - In scenarios where the total volume consumed size (meaning, the initial copy and incrementals) exceeds 10TB, some of the unreferenced data blocks will not be removed.

- Only complete Backups and Restores of VMs is allowed. Partial Backups and Restores are not supported.
- Restoring of VPGs is allowed for VPGs which currently exist, or which were deleted.
- Reconnecting to a repository is not supported.
- Attaching an existing repository and leveraging copies for the next incremental is not supported. Therefore, any repository is considered new after defining it, and a complete reading of the volume will be performed.
- Long Term Retention requires Enterprise Cloud Edition, Cloud One2Many or NFR/Trial license.
- Certain failures when running retention sets may require Support intervention to re-enable them.
Zerto is moving away from Offsite Backup into modern Long Term Retention. Therefore, Offsite Backup will no longer be supported. As such, repositories and backup configurations created in previous versions are deleted as part of the upgrade to v6.5.

- Backups created in versions prior to ZVR v6.5 cannot be restored in v6.5.
- Backup configurations in v6.0Ux are deleted upon upgrade to v6.5.
- Configuring a backup from v6.0Ux to v6.5 is not possible.
- Restoring of backups which were created in version 6.0 or prior, requires using ZVM version 6.0Ux.

Performance:
- DSS and VRA consume CPU. As such, if the CPU on the VRA reaches high consumption rates, another CPU should be added to the VRA machine. Adding additional CPUs on top of the additional one is redundant and the additional CPUs will not be utilized.
- When editing a VPG where the protected site is v6.0Ux, and the recovery site is v6.5x, the user will need to ensure that Long Term Retention is disabled in order to save any changes to the VPG.
- Long Term Retention is not supported where the recovery site is a Public Cloud.
- The SETUP tab in the ZCA was removed.
- Backup Reports are no longer available.
- Repository failures such as insufficient space or unavailability are not displayed in the GUI.
Workflow: Using Zerto’s Long Term Retention

**Creating a New Repository for Retention**

Disaster recovery using Zerto Virtual Replication enables recovering from a disaster to any point between the moment just before the disaster and a specified amount of time in the past up to 30 days. The recovery is done in real time at the recovery site with a minimal RTO.

If you need to extend the recovery ability to **more than 30 days**, Zerto Virtual Replication provides Long Term Retention that enables saving the protected VPGs for up to one year in a state where they can be easily deployed.

The VPGs are saved in a repository for a defined retention period. Each VPG will have retention sets created according to a fixed schedule.

The retention process is managed by the ZVM, and the Data Streaming Service (DSS) performs all the data path operations. During the retention process, the DSS communicates with the VRA on the recovery site. The retention sets are fixed points saved either daily, weekly or monthly in the repository. Before you can start a retention process for VPGs, you must first create one or more repositories for the retention process.

Define repositories on the recovery site where retention sets can be stored on a network share that uses the NFS (Network File System) protocol.

The repository where you want this retention set stored is specified when the retention policy is defined.

---

**Workflow: Using Zerto’s Long Term Retention**

</tbody>
</table>
To create a repository for Long Term Retention:

1. In the Zerto User Interface, click SETUP > REPOSITORIES > NEW REPOSITORY.

2. In the General area, specify the following:
   - **Repository Name**: A unique name for the repository.
   - **Repository Type**: The type of repository:
     - **Network Share (NFS)**: The network share drive must be an Network File System (NFS) drive.

3. In the Location area, define the **Path**. This is the path where the repository will reside.
   - The path must be accessible from the Zerto Virtual Manager, so if the repository is on a different domain to the Zerto Virtual Manager, the domain must be included in the path.

4. In the Properties area, you can **Set as default repository**. This will use the repository as the default when defining the retention policy in a VPG.

5. Click **SAVE**. The repository is created.

6. To define an additional repository, repeat this procedure.

7. When using **Zerto Cloud Manager**, you must also add the repository to either the vCenter resources or vCD resources in the Zerto Cloud Manager. For details, see the **Zerto Cloud Manager Administration Guide**.

8. Proceed with **Enabling Long Term Retention for the VPGs**.
Editing an Existing Repository for Retention

You can change the repository name, or define the repository as the default.

To edit a Repository:
1. In the Zerto User Interface, click SETUP tab, REPOSITORIES sub-tab.
2. Select the repository to edit and click the edit pencil icon.
   The Edit Repository dialog is displayed.

   Edit any of the following settings:
   - **Repository Name**: Specify a unique name for the repository.
   - **Repository Type**: This field is not available for editing. **Path**: This field is not available for editing. **Set as default repository**: Select to use the repository as the default when specifying extended recovery in a VPG.

3. Click SAVE. The updated definition of the repository is saved.
Enabling Long Term Retention for the VPGs

Following is the procedure for enabling Long Term Retention for a VPG.

Long Term Retention can be enabled at the same time when you first create the VPG to protect Virtual Machines.

You can also enable Long Term Retention by editing an existing VPG.

**Before You Begin:**

Before you can enable Long Term Retention for the VPG, verify that a repository was first created where the retention sets will be saved.

Repositories are created and configured via the SETUP tab as described in Creating a New Repository for Retention.

**Enabling Long Term Retention for a VPG:**

1. Toggle **Long Term Retention** from OFF to **ON**.
   
   The options on the screen become available.
   
   **Note:** When VPG is restored to a Public Cloud, Long Term retention is not available.

2. Enter the **Target Repository** name. This is the name of the repository where the repository sets are written.

3. Select the **Retention Period** from the drop-down list. The time you select is the length of time to keep repository sets. This is up to a maximum of one year. For details of how this affects the number of repository sets saved, see Storing Repository Sets.
4. **Run Job Every**: The recurrence and time to start the retention process.
5. **Retries**: Select **Automatic retry after failure** to automatically rerun the retention process, if the job fails.
   - If you select this option, you must also define **Number of attempts**, and the **Wait time between retries**.

**Manually Running the Retention Process**

After initializing the VPG, Zerto Virtual Replication periodically checks that the schedule to run a retention process has not passed. At the scheduled retention process time, the job is run and the retention set is stored in the specified repository.

You can decide at any time that you need to run the retention process, without waiting for the scheduled time. Use the following procedure to do this.

**To manually run the retention process:**
1. In the Zerto User Interface, click one of the following tabs: **VPGs / VMs / RETENTION STATUS**.
2. Select one or more VPGs for the retention process, and click **MORE > Run retention process**.
3. Click **OK**. The retention process starts.
   - You can monitor the progress in the RETENTION STATUS tab and the TASKS pane.
   - During the retention process you cannot perform operations on the VPG without first aborting the job.
   - If you start a live failover during the retention process, you are then prompted to abort the job.
   - Scheduled retention process runs for the VPG are skipped, until the manual retention process run ends.

**Monitoring Your Long Term Retention Status**

You can monitor retention status of the VPG via the SETUP tab, or via the RETENTION STATUS tab.

- Monitoring Retention Status via the SETUP Tab
- Monitoring Retention Status via the RETENTION STATUS Tab
Monitoring Retention Status via the SETUP Tab

In the **SETUP tab > REPOSITORIES sub-tab**, view details of all the repositories which were defined, and which can be used for retention. All the repositories created for the site are displayed in this tab.

For each repository, the following information is displayed:

- **Star:** A star indicates that this is the default repository.
- **Repository Name:** The name of the repository. This field contains icons that you can click to edit or delete the repository.
- **Repository Type:** The type of repository.
- **Connectivity:** Whether the repository is connected or not.
- **Path:** The path to the repository.
- **VPGs:** The VPG which uses this repository for Long Term Retention.
- **Restore Points:** The restore points for the retention sets out of the total retention sets saved to the repository.

**TIP**

In this window you can also create a new repository by clicking **NEW REPOSITORY**.
Monitoring Retention Status via the RETENTION STATUS Tab

In the **RETENTION STATUS tab**, view details of all the repositories, either according to VPGs, or according to VMs, which are used for Retention. All the repositories created for the site are displayed in this tab.

The following information is displayed in the **GENERAL view**:

- **VPG Name**: The name of the VPG.
- **Repository Name**: The name of the repository where the repository set is stored.
- **Repository Site**: The site where the VPG repository is saved. The retention sets are stored on a network shared drive which is accessible from this site.
- **Status**: The status of the job: **Running** or **Scheduled**.
- **VPG Size**: The size of the VPG in the last run, which is stored on disk.
- **Result of Last Run**: The result of the last run: **Full success**, **Partial success**, or **Failed**.
- **Restore Points**: The restore points for the retention sets out of the total retention sets run for the VPG.

See also **Adding or Removing Columns from the View**.
Monitoring Your Long Term Retention Status

**RETENTION STATUS tab, VPGs Sub-tab - RUN DETAILS View**

The following information is displayed in the **RUN DETAILS** view:

- **VPG Name:** The name of the VPG.
- **Result of Last Run:** The result of the last run: **Full success**, **Partial success**, or **Failed**.
- **Time of Last Run:** The time of the last run. If a retention process has not yet run on this VPG, the field is empty.
- **Next Scheduled Run:** The time of the next scheduled run.
- **Last Successful Run:** The date and time of the last successful retention process.

See also [Adding or Removing Columns from the View](#).

**Adding or Removing Columns from the View**

Click the configuration icon ( ), then click **Show/Hide Columns** to display a window with a list of additional columns which can be added to the view.

- **Repository Site:** The site where the VPG is backed up. The retention sets are stored on a network shared drive which is accessible from this site.
- **Status:** The status of the job: **Running** or **Scheduled**.
- **ZORG:** A name given to an organization by a cloud service provider. For details refer to [Zerto Cloud Manager Administration Guide](#).
- **No. of Volumes:** The number of volumes protected by the VPG.
- **Repository Name:** The name of the repository where the retention set is stored.
- **Protected Site:** The name of the site.
- **Last Run Size:** The size of the last retention set performed by Zerto Virtual Manager.
- **VPG Size:** The size of the VPG in the last run, which is stored on disk.
- **Restore Points:** The restore points for the retention sets out of the total retention sets run for the VPG.
- **No. of VMs:** The total number of virtual machines protected by the VPG.

**RETENTION STATUS tab, VMs Sub-tab**

View details of the retention sets by virtual machine.

You can filter information in columns via the filter icon next to each column title. You can also sort the list by each column.
RETENTION STATUS tab, VMs Sub-tab - GENERAL View

The following information is displayed in the GENERAL view:

- **VM Name:** The name of the virtual machine.
- **VPG Name:** The name of the VPG.
- **Protected Site:** The name of the site where the VPG is protected.
- **Repository Site:** The site where the virtual machine is backed up. The retention sets are stored on a network shared drive which is accessible from this site.
- **Status:** The status of the retention set.
- **Repository Name:** The name of the repository where the retention set is stored.
- **VM Size:** The size of the VMs stored on disk.
- **Result of Last Run:** The result of the last run: **Full success**, **Partial success**, or **Failed**.
- **Restore Points:** The restore points for the retention sets out of the total retention sets run for the VPG.

RETENTION STATUS tab, VMs Sub-tab - RUN DETAILS View

The following information is displayed in the RUN DETAILS view:

- **VM Name:** The name of the Virtual machine.
- **VPG Name:** The name of the VPG.
- **Protected Site:** The name of the site where the VPG is protected.
- **Result of Last Run:** The result of the last run: **Success**, **Partial success**, or **Failed**.
- **Time of Last Run:** The time of the last run.
- **Next Scheduled Run:** The time of the next scheduled run.
- **Last Successful Run:** The date and time of the last successful retention process.

MORE Options

Click **MORE > Stop Retention Process** to abort a running job. Any virtual machine volumes already stored in the repository are not removed and the job status is partial if there are any stored volumes.
Click **MORE > Run Retention Process** to start a job for a selected VPG, outside of the schedule for that VPG.

**Adding or Removing Columns from the View**

Click the configuration icon ( ), then click **Show/Hide Columns** to display a window with a list of additional columns which can be added to the view.

- **VPG Name:**
- **Repository Site:** The site where the VPG is restored. The retention sets are stored on a network shared drive which is accessible from this site.
- **Repository Name:** The name of the repository where the retention set is stored.
- **ZORG:** A name given to an organization by a cloud service provider. For details refer to Zerto Cloud Manager Administration Guide.
- **Status:** The status of the retention set: **Running** or **Scheduled**.
- **Last Run Size:** The size of the last retention set performed by Zerto Virtual Manager.
- **VM Size:** The size of the VM in the last run, which is stored on disk.
- **Restore Points:** The restore points for the retention sets out of the total retention sets run for the VPG.
- **# of Volumes:** The number of volumes associated with the VM.
Restoring VPGs from a Repository

Use Restore VPG to recover the VPG’s virtual machines on the recovery site from a retention set. The virtual machines on the protected site remain protected and live.

You restore a VPG to the recovery site, by specifying the VPG with retention.

(*vCloud Director only*) When the recovery site, where the retention sets are stored, is managed by a cloud service provider using *vCloud Director*, only the cloud service provider can initiate the restore.

The Restore VPG operation has the following basic steps:

1. The ZVM (via the VRA) finds the specified retention set in the repository.
2. The ZVM creates the virtual machines under the designated host and storage on the recovery site.
   The host and storage can be the same as the recovery host and storage specified in the VPG, or it can be any other host and associated storage in the site.
3. ZVM uses the VRA to restore the disks from the repository to the specified datastores.
   **Note:** If any issues occur while restoring the retained volumes, as long as there are still volumes to restore, the restore process can continue to restore the remaining volumes.
4. If requested, the restored virtual machines are powered on, and IP Settings are configured.

Restoring a VPG

Use the following procedure to restore a VPG from the repository.

**To restore a VPG:**

1. In the Zerto User Interface select **ACTIONS > RESTORE VPG**.
   The Restore from Zerto VPG wizard is displayed.

2. From the drop-down list, select the VPG to restore.
3. Click **NEXT**.
The RESTORE POINT step appears, displaying all the available retention sets.

4. From the list of available retention sets, select the retention set to restore, where:
   - **Point in Time:** The date and time the retention set was performed.
   - **Restore Site:** The recovery site for the VPG.
   - **VMs:** The number of virtual machines with retention, out of the total number of virtual machines.
   - **Volumes:** The number of volumes with retention, out of the total number of volumes for the virtual machines.
   - **Repository:** The name of the repository where the retention set is stored.
   - **ZORG:** *(ZCM sites only)* The Zerto organization for which the retention set was created. This field only has a value if the Zerto Cloud Manager is connected to the site. For details, see *Zerto Cloud Manager Administration Guide*.

5. When you select a retention set to restore, the list of virtual machines in the retention set appear, displaying the following information:
   - **VM Name:** The name of the virtual machine.
   - **# Volumes Retained:** The number of volumes retained, out of the total number of volumes for the virtual machine.

   **Note:** The number of retention sets available depends on the frequency, daily, weekly or monthly, specified and the length of the retention period for the VPG. The exact number of retention sets over time is described in the section, *Storing Repository Sets*.

6. If the restore site has the option to restore to vCD, select where to attach the restored VMs, either to VC or vCD.
7. Click **NEXT**.
   The VM SETTINGS step is displayed.
   The list of virtual machines that can be restored is displayed.
8. You can specify the following which are then applied to all the virtual machines to be restored:
   - **Restore on Host**: The IP address of the host where you want the VPG restored.
     After selecting a host, the **Restore on Datastore** field is displayed.
   - **Restore on Datastore**: The datastore to use for the restored VPG files.

   - **Or** -
     Alternatively, you can use the recovery host and storage specified for each virtual machine in the VPG definition by clicking **APPLY VPG CONFIGURATION**. To use this option, the VPG must still be available.

9. To change the information in a field, click the field and update the information.

10. To change the host or datastore information for several virtual machines at the same time, select the virtual machines and click **EDIT SELECTED**.

   The Configure VM Settings dialog is displayed.

   If one or more of the volumes which was retained, was deleted after the retention set was created, or if one of the volumes failed, the entire retention process for that VM will fail.

   You can specify the following values, which are then applied to all the selected virtual machines:
   - **Restore on Host**: The IP address of the host where you want the virtual machines restored.
   - **Restore on Datastore**: The datastore to use for the restored virtual machine files.
   - **Power On**: Select this if you want the restored virtual machines to be powered on.

   - **Or** -
     Alternatively, you can use the recovery host and storage specified for each virtual machine in the VPG definition by clicking **APPLY VPG CONFIGURATION**.

11. To specify the volume information for each virtual machine, from the Actions column, click **Volumes**.
12. To edit information in a field, click the field and update the information.

13. To edit information for several datastores at the same time, select the datastores and click **EDIT SELECTED**.

The Edit Selected Volumes dialog is displayed.

- If more than one datastore is selected, the path is not displayed.

14. Specify the datastore settings.
   - **Datastore / Raw Disk**: The storage or RDM disk where the virtual machine files will be restored.
   - **Thin**: Whether the virtual machine disks will be thin-provisioned or not.

15. Click **SAVE**.

16. In the Volumes dialog, click **DONE**.

17. To specify the NIC information for each virtual machine, from the Actions column, click **NICs**.

The NICs dialog is displayed:

18. To edit information in one field, click the field and update the information.

19. To edit information for several virtual NICs at the same time, select the NICs and click **EDIT SELECTED**.
20. Specify the NIC settings.

- **NIC Name:** The name of the selected NIC.
- **Network:** The network to use for the restored virtual machine.
- **Create new MAC address:** The Media Access Control address (MAC address) to use. The default is to use the same MAC address for the restored virtual machine that was used in the protected site. Select the checkbox to create a new MAC address on the restore site.
- **Change vNIC IP Configuration:** Whether or not to keep the default virtual NIC (vNIC) IP configuration. You can only change the vNIC IP after the restore has completed with VMware Tools installed.
  - If you select a **static** IP connection, you must set the IP address, subnet mask, and default gateway. Optionally, change the preferred and alternate DNS server IPs and the DNS suffix.
  - If you select **DHCP**, the IP configuration and DNS server configurations are assigned automatically, to match the protected virtual machine. You can change the DNS suffix.
- **IP Address:** The IP for the restored virtual machine. This can be the same IP as the original protected virtual machine.
- **Subnet Mask:** The subnet mask for the network. The default value is **255.255.255.0**.
- **Default Gateway:** The default mask for the network.
- **Preferred DNS Server:** The IP address of the primary DNS server to handle Internet protocol mapping.
- **Alternate DNS Server:** The IP address of the alternate DNS server.
- **DNS Suffix:** The DNS name excluding the host.

21. Click **OK**.

22. Click **DONE**.

23. Click **NEXT**.

   The SUMMARY step is displayed. Review the details of the restore.

24. If this is the retention set which you want to restore, click **RESTORE**.

   The virtual machines are created from the repository at the recovery site.
Storing Repository Sets

After initializing the VPG, Zerto Virtual Replication periodically checks that the schedule to run an retention process has not been passed, either a daily, weekly or monthly retention process. At the scheduled retention process time, the retention process is run and the retention set is stored in the specified repository.

Repository sets are kept on the recovery site for the retention period specified in the Retention Policy in the VPG. However, over time the number of stored retention sets is reduced to save space.

### Note:

Zerto’s calculation is based on the following logic:

1 month = 4 weeks (28 days).

Therefore, 12 months = 343 days (and not 365).

The number of stored retention sets for a daily retention process is as follows:

<table>
<thead>
<tr>
<th>RETENTION PERIOD</th>
<th>DAILY</th>
<th>WEEKLY</th>
<th>MONTHLY</th>
<th>NUMBER OF RETENTION SETS</th>
<th>MAXIMUM NUMBER OF DAYS TO OLDEST RETENTION SET</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 week</td>
<td>7</td>
<td>0</td>
<td>0</td>
<td>7</td>
<td>7</td>
</tr>
<tr>
<td>1 month</td>
<td>7</td>
<td>4</td>
<td>0</td>
<td>11</td>
<td>35</td>
</tr>
<tr>
<td>3 months</td>
<td>7</td>
<td>4</td>
<td>2</td>
<td>13</td>
<td>91</td>
</tr>
<tr>
<td>6 months</td>
<td>7</td>
<td>4</td>
<td>5</td>
<td>16</td>
<td>175</td>
</tr>
<tr>
<td>9 months</td>
<td>7</td>
<td>4</td>
<td>8</td>
<td>19</td>
<td>259</td>
</tr>
<tr>
<td>12 months</td>
<td>7</td>
<td>4</td>
<td>11</td>
<td>22</td>
<td>343</td>
</tr>
</tbody>
</table>

That is, a retention set is kept for each day for the current week and then the oldest retention set for the previous week is kept for the previous four weeks and then the oldest monthly retention set is kept for the rest of the retention period.

The number of stored retention set for a weekly retention process is as follows:

<table>
<thead>
<tr>
<th>RETENTION PERIOD</th>
<th>WEEKLY</th>
<th>MONTHLY</th>
<th>NUMBER OF RETENTION SETS</th>
<th>MAXIMUM NUMBER OF DAYS TO OLDEST RETENTION SET</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 week</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>7</td>
</tr>
<tr>
<td>1 month</td>
<td>4</td>
<td>1</td>
<td>5</td>
<td>58</td>
</tr>
<tr>
<td>3 months</td>
<td>4</td>
<td>3</td>
<td>7</td>
<td>121</td>
</tr>
<tr>
<td>6 months</td>
<td>4</td>
<td>6</td>
<td>10</td>
<td>205</td>
</tr>
<tr>
<td>9 months</td>
<td>4</td>
<td>9</td>
<td>13</td>
<td>289</td>
</tr>
<tr>
<td>12 months</td>
<td>4</td>
<td>12</td>
<td>16</td>
<td>373</td>
</tr>
</tbody>
</table>

That is, a retention set is kept for each week for the current month and then the oldest retention set for the month is kept and then the oldest monthly retention set is kept for the rest of the retention period.
You can handle problems related to the WAN connecting the protecting or recovery sites, or other problems using a variety of
diagnostic and troubleshooting tools.

The following topics are described in this chapter:
- “Ensuring the Zerto Virtual Manager is Running”, below
- “Troubleshooting Needs Configuration Problems”, on page 256
- “Troubleshooting GUI Problems”, on page 256
- “Troubleshooting VRA Problems”, on page 256
- “Handling Lack of Storage Space for Recovered Virtual Machines”, on page 257
- “Zerto Virtual Replication Diagnostics Utility”, on page 257
- “Collecting Zerto Virtual Replication Logs”, on page 258

For details about Zerto Virtual Manager alarms, alerts, and events, refer to Zerto Virtual Replication Guide to Alerts and Events.

**Ensuring the Zerto Virtual Manager is Running**

If you have problems accessing the Zerto User Interface, check under Windows Services, on the machine where Zerto Virtual Replication is installed, that the Zerto Virtual Manager Windows service is started.
Troubleshooting Needs Configuration Problems

When the VPG status changes to Needs Configuration, the settings in the VPG need to be checked and, when necessary, updated.

The following scenarios result in the VPG status changing to Needs Configuration:

- A protected disk resize operation fails, for example when there is not enough disk space.
- Shrinking a protected disk.
- When a volume is added to a protected virtual machine and the added volume has no matching storage or not enough room on the recovery storage.
- When a volume is added to a protected virtual machine and the VPG settings are not updated because of a site disconnection or a SCVMM error. In some situations, after the sites reconnect, the state corrects itself automatically.
- When performing a Failover or Move operation, if you do not specify reverse protection.

Troubleshooting GUI Problems

Host is Not Displayed in List of Hosts in the Manage VPG Dialog

If the installation of a VRA completes successfully, but the allocation of the IP takes too long, when attempting to specify the host to recover a VPG, the host where the VRA is installed does not appear in the list, you must uninstall and then re-install the VRA.

Troubleshooting VRA Problems

VPG Syncing Takes a Long Time – Network Problems

Check the network. If the firewall configuration is modified, the VRA TCP connections must be reset. After a VRA disconnect and reconnect the system can wait for up to fifteen minutes before syncing the sites after the reconnection.
Handling Lack of Storage Space for Recovered Virtual Machines

If a recovery virtual machine does not have enough space on the recovery site, the promotion of data to the recovered virtual machine hangs. If this occurs you should add more space to the machine and then start the machine. The promotion will then continue.

Zerto Virtual Replication Diagnostics Utility

Zerto Virtual Replication includes a diagnostics utility to help resolve actual and potential problems. Using the diagnostics tool, you can do the following:

- Collect logs to help Zerto support resolve problems. The Zerto Virtual Manager must be running on each site for which you want logs. See “To collect logs for Zerto support to use when troubleshooting:”, below.
- Collect local Zerto Virtual Manager logs. Use this option if the Zerto Virtual Manager is not running. See “To collect local Zerto Virtual Manager logs when the Zerto Virtual Manager is not running:”, on page 263.
- Check the connectivity between Zerto Virtual Replication components. See “To check connectivity between Zerto Virtual Manager components:”, on page 164.
- Reconfigure the Zerto Virtual Manager, including the IP addresses of the vCenter Server and of the machine running the Zerto Virtual Manager, and the SSL certificate used when accessing the Zerto User Interface. See “Reconfiguring the Zerto Virtual Manager Setup”, on page 165.
- Export VPG settings to an external file and import these settings.
- Reconfigure access to the Microsoft SQL Server that is used by the Zerto Virtual Manager. This database was specified during the installation of Zerto Virtual Replication. See “Reconfiguring the Microsoft SQL Server Database Used by the Zerto Virtual Manager”, on page 167.

Note: A separate installation kit is available for download from the Zerto Support Portal downloads page that installs the Zerto Virtual Replication Diagnostics utility as a standalone utility on any Windows machine that has Microsoft .NET Framework 4 installed.
Collecting Zerto Virtual Replication Logs

Virtual replication logs can be collected to help Zerto support resolve problems related to Zerto Virtual Replication. Virtual replication logs can be collected in the following ways:

"Using Remote Log Collection", below
"Using the Zerto Diagnostics application", on page 259

Using Remote Log Collection

Remote Log Collection allows customers to authorize Zerto support engineers to collect logs from their environment. By using remote log collection customers can avoid having to use the Diagnostic Tool on their ZVM server in order to collect logs for analysis, a potentially complex and time-consuming procedure.

To enable Remote Log Collection:

1. In the Zerto User Interface, click SETTING ( ) in the top right of the header and select Remote Support. The Remote Support dialog is displayed.

2. Click the drop down menu to display the remote log collection options.

3. Select the remote log collection option you wish to allow:
   - **Never**: Remote log collection is not allowed (default). If remote log collection is currently is allowed, it will be terminated if you select this option.
   - **For the next 30 days**: Remote log collection is allowed. This permission will automatically terminate in 30 days unless terminated by selecting the **Never** option.
   - **Only for a specific case** - You will be prompted to select the **Case number** from the drop-down list. The list contains all the active cases opened under the account that the Zerto Virtual Manager is registered under.
Remote log collection will be allowed for as long as the case is active or until remote log collection is terminated by selecting the **Never** option.

4. Click **Save**.

### Using the Zerto Diagnostics application

You can collect logs using the diagnostics tool to help Zerto support resolve problems when the Zerto Virtual Manager is running or when the Zerto Virtual Manager is not running.

- **When the Zerto Virtual Manager is running,** see “To collect logs for Zerto support to use when troubleshooting:”, below. This option enables you to specify the logs that you want to collect, generated by Zerto Virtual Replication, for example VRA logs, as well as logs generated by VMware, for example, vCenter Server logs or host logs. The Zerto Virtual Replication generated logs can be filtered by any alerts issued and by the VPGs that require analysis to identify problems.

- **When the Zerto Virtual Manager is not running,** see “To collect local Zerto Virtual Manager logs when the Zerto Virtual Manager is not running:”, on page 263.

### To collect logs for Zerto support to use when troubleshooting:

1. Open the Zerto Diagnostics application. For example, via Start > Programs > Zerto Virtual Replication > Zerto Diagnostics. The Zerto Virtual Replication Diagnostics menu dialog is displayed.

2. Select the Collect the Zerto Virtual Replication logs for use by Zerto support option.

3. Click **Next**.
The Initialize dialog is displayed.

4. Specify the following and click Next.
   - **IP / Host Name:** The IP of the Zerto Virtual Manager where the log collection runs from. Logs are collected from this site and from the paired site.
   - **Port:** The port used for inbound communication with the Zerto Virtual Manager.
   - **Your Company Name:** A name to identify the log collection for the customer. This information is used by Zerto support. An account name must be entered. After this information is added, it is displayed in subsequent uses of the diagnostics utility.
   - **Email:** An email address for use by Zerto support when analyzing the logs. An email address must be entered. After this information is added, it is displayed in subsequent uses of the diagnostics utility.
   - **Timeframe:** The amount of time you want to collect logs for. The more time, the bigger the collection package.
   - **Case Number:** The case number assigned by Zerto support, if one already exists. Optional.
   - **Description:** An optional free text description of the reason for collecting the logs.

   After clicking Next the utility connects to the Zerto Virtual Replication and if any alerts have been issued, they are displayed in the Select Alerts dialog.

   If there are no alerts, this dialog is skipped.

5. Select any alerts that need analyzing from the list and click Next.
The Select VPGs dialog is displayed.

6. Select the VPGs that you want analyzed and click **Next**.

The Customize dialogs are displayed. These dialogs can generally be left with their default values.

The following Customize dialogs are displayed:
- The Select Sites dialog
- The Select VRA Hosts dialog
- The Select vSphere Logs dialog (not applicable when all the sites are SCVMM sites)
- The Select vCloud Director Logs dialog (not applicable when all the sites are SCVMM sites)

The Select Sites dialog is displayed, with the list local site and all the sites paired to it listed.

Those sites that are either protecting or used for recovery for any of the selected VPGs from the previous dialog are automatically selected.

**Note:** Zerto Virtual Manager logs from both sites are collected when both sites are trusted sites otherwise only logs from the local site are collected.

7. Verify that the sites that need analyzing are selected and click **Next**.

The Select VRA Hosts dialog is displayed.

Those hosts with VRAs that are used to protect or recover any of the selected VPGs are automatically selected.
You can change the collection criteria using the plus and minus buttons. The expected size of the collection package is updated dependent on the selected VRAs.

8. Verify that the host with VRAs that need analyzing are selected and click **Next** until the Save Log Destinations dialog is displayed.

9. Specify destination for the files that you want collected.
   - **Destination:** The name and location where the log collection will be saved.
   - **Automatically upload files to Zerto FTP Server:** When this option is checked, the log collection is automatically uploaded to a specified FTP site.
   - If you choose to upload the log collection to a site that you specify, make sure that the site is up.

10. Specify the FTP site to send the collection and the protocol to use, either FTP or HTTP.

11. Click **Next**.
    The Review dialog is displayed.

   ![Zerto Diagnostics Collection](image)

   Check that you have specified everything you want to collect and if you want to make changes, click **Back** to change the selection.

12. Click **Start**.
    The data is collected and stored in the destination file which, by default, is timestamped. If specified, the collection is also sent to an FTP site.

   **Note:** The log collection is performed on the server. Canceling the collection in the GUI does not stop the collection from continuing on the server and a new log collection cannot be run until the running collection finishes.
When the log collection has completed the result is displayed. For example:

13. Click **Done** to return to the Zerto Virtual Replication Diagnostics menu dialog.
14. Send the log to Zerto support, unless the Automatically upload files to Zerto FTP Server option was specified, in which case it is automatically sent to Zerto.

**To collect local Zerto Virtual Manager logs when the Zerto Virtual Manager is not running:**

1. Open the Zerto Diagnostics application. For example, via Start > Programs > Zerto Virtual Replication > Zerto Diagnostics. The Zerto Virtual Replication Diagnostics menu dialog is displayed.
2. Select the Local Zerto Virtual Manager diagnostics option and click **Next**.
   You are prompted to use the first option to collect more comprehensive diagnostics. If you continue, the Initialize dialog is displayed.
3. Specify the details that you want collected.
   **IP / Host Name:** The IP of the Zerto Virtual Manager where the log collection runs from. Logs are collected from this site and from the paired site.
   **Port:** The port used for inbound communication with the Zerto Virtual Manager.
   **Your Company Name:** A name to identify the log collection for the customer account. This information is used by Zerto support. An account name must be entered.
   **Email:** An email address for use by Zerto support when analyzing the logs. An email address must be entered.
   **Timeframe:** The amount of time you want to collect logs for. The more time, the bigger the collection package.
   **Case Number:** An optional field for the case number assigned to the issue by Zerto.
   **Description:** An optional free text description of the reason for collecting the logs.
4. Click **Next**.
   The Save Log Destinations dialog is displayed.
5. Specify the details that you want collected.
   **Destination:** The name and location where the log collection will be saved.
   **Automatically upload files to Zerto FTP Server:** When this option is checked, the log collection is automatically uploaded to a specified FTP site.
If you choose to upload the log collection to a site that you specify, make sure that the site is up before clicking **Finish**. The data is collected and stored in the destination file which, by default, is timestamped. If specified, the collection is also sent to an FTP site.

6. Click **Next**.
   
The collection progress is displayed. When the log collection has completed the result is displayed.

7. Click **Done** to return to the Zerto Virtual Replication Diagnostics menu dialog.

8. Send the log to Zerto support, unless the Automatically upload files to Zerto FTP Server option was specified, in which case it is automatically sent to Zerto.

---

**Understanding the Logs**

If problems arise with Zerto Virtual Manager, you can view the Zerto Virtual Manager logs to see what is happening.

The current log is called logfile.csv and resides in the `<Zerto_Install_Dir>`\Zerto Virtual Replication\logs folder, where `Zerto_Install_Dir` is the folder specified during the installation.

When the log reaches 10MB its name is changed to log.nnnn.csv, where nnnn is a number incremented by one each time logfile.csv reaches 10MB. Up to 150 log files are kept.

The log file has the following format:

```
FFFF, yyyy-mm-dd hh:mm:ss, ####, LVL, Component, API, Message
```

where:

- **FFFF**: A HEX code. For internal use.
- **yyyy-mm-dd hh:mm:ss**: Timestamp for the message.
- **####**: Number for internal use.
- **LVL**: Severity level of the message. The more messages written to the log the bigger the impact on performance. The number of messages written to the log decreases from **Debug** to **Error**. The level can be one of the following:
  - **Debug**: All messages are written to the log. This level should only be specified during testing.
  - **Info**: Information messages.
  - **Warn**: Warning messages such as a reconnect ion occurred.
  - **Error**: Error messages that need handling to find the problem.
- **Component**: The specific part in the Zerto Virtual Manager that issued the message.
- **API**: The specific API that issued the message.
- **Message**: The message written in the log.
The following is a sample from a log:

07f4c878, 2010-12-01 19:54:42.7987, Info, 9, Zerto.Infra.ZvmReaderWriterLock, LogLock, Synchronizer: Enter Writer,
07f4c878, 2010-12-01 19:54:43.0643, Debug, 17, Zerto.Zvm.ZvmServices.PingService, Ping, Ping called,

CHAPTER 22: ZERTO VIRTUAL REPLICATION AND MICROSOFT HYPER-V FEATURES

This chapter describes the interaction between Zerto Virtual Replication and commonly used Microsoft Hyper-V features such as live migration, dynamic optimization, and failover clustering.

The following topics are described in this chapter:
- “Stopping and Restarting the SCVMM”, below
- “Dynamic Disks”, on page 266
- “Hyper-V High Availability (HA)”, on page 266
- “Clusters”, on page 267
- “Failover Clustering and Fault Tolerance”, on page 267
- “Pass-through Disks”, on page 267
- “Performance and Resource Optimization or Dynamic Optimization”, on page 267
- “Multi-Pathing and Storage Failures”, on page 267
- “Availability Sets and Anti-Affinity Rules”, on page 267
- “Live Migration”, on page 268
- “Quick Storage Migration”, on page 268
- “SCVMM and Host Maintenance Mode”, on page 268
- “User Management”, on page 268
- “Hyper-V Replica”, on page 268
- “Restart Zerto Virtual Manager After SCVMM Upgrade”, on page 268
- “Resiliency to Hyper-V Environment Changes”, on page 268

Stopping and Restarting the SCVMM

If a host on which Hyper-V is running is restarted, a Zerto Virtual Replication Delta Sync is performed on all protected virtual machines on that host.

Dynamic Disks

Microsoft dynamic disks use multiple hard disks, which can contain many dynamic volumes, to manage data. They enable you to create volumes that span multiple disks and to create fault-tolerant volumes. All volumes on dynamic disks are known as dynamic volumes. Dynamic disks offer greater flexibility for volume management because they use a database to track information about dynamic volumes on the disk. Dynamic disks and volumes rely on the Logical Disk Manager (LDM) and Virtual Disk Service (VDS) for management.

When recovering virtual machines in a VPG, VHDX disks are always recovered in the recovery site with dynamic disks. VHD disks are recovered in the recovery site by default with the same configuration as in the protected site.

Hyper-V High Availability (HA)

Highly available virtual machines in Hyper-V reside on highly available storage such as a cluster shared volume (CSV) and can only handle disks residing on this type of storage. Therefore, when Zerto replicates a virtual machine, the type of virtual machine created on the recovery site is determined by the type of storage designated for it.

When high availability is enabled, a copy of each cached object or region is maintained on a separate cache host. The cache cluster manages these copies and supplies them to the application if the primary copies are not available.

High availability is automatically disabled by Zerto Virtual Replication while updating recovered virtual machines in the recovery site from the VRA journal. After promotion of data from the journal to the recovered virtual machine completes, high availability is automatically re-enabled.
Clusters

A cluster is a group of tightly coupled hosts, called nodes, that work closely together so that in many respects they can be viewed as though they are a single computer. With a cluster, you define two or more physical machines that provide resources for the hosts that are assigned to that cluster. By using clusters, you can achieve high availability and load balancing of virtual machines.

When protecting a virtual machine on a host that is part of a cluster, Zerto recommends that you install a VRA on each host in the cluster, to ensure coverage if the virtual machine is migrated with Live Migration.

Failover Clustering and Fault Tolerance

Setting up a failover cluster for Hyper-V hosts makes the virtual machines fault tolerant. The Failover Clustering feature requires you to manually specify the virtual machines that you wish to make fault tolerant. Fault tolerant virtual machines are treated as clustered roles. Virtual machines automatically restart when a node in a cluster unexpectedly failed.

Pass-through Disks

Storage on pass-through disks provides the following:

- Very fast performance.
- A very simple storage path because the file system on the host is not involved.
- Better alignment under SAN.
- Lower CPU utilization.
- Support for very large disks.

Zerto Virtual Replication cannot protect virtual machines with pass-through disks. Also, a Hyper-V host with a pass-through disk is ignored by the Zerto Virtual Manager.

Performance and Resource Optimization or Dynamic Optimization

Performance and Resource Optimization (PRO) ensures that virtual machine hosts and virtual machines are operating in the most efficient possible manner. PRO generates recommendations for remedial actions based on alerts that the Operations Manager generates. You can configure PRO to implement the pre-defined corrective actions automatically or you can choose to perform these actions manually. During Dynamic Optimization, SCVMM migrates virtual machines within a host cluster to improve load balancing among hosts.

PRO is ignored by Zerto Virtual Replication. Dynamic Optimization is automatically disabled by Zerto Virtual Replication when updating recovered virtual machines in the recovery site from their journals. After promotion of data from the journal to the recovered virtual machine completes, Dynamic Optimization is automatically re-enabled.

Multi-Pathing and Storage Failures

Hyper-V can use multiple paths to a storage array, which is called multi-pathing. If all paths from a Hyper-V node to the storage array fail, an alternative route using the network LAN can be used to reach the storage. This is called Redirected IO.

Zerto Virtual Replication supports Multi Path IOs.

Availability Sets and Anti-Affinity Rules

Availability sets keep virtual machines separate from each other so they do not run on the same host whenever possible. If you create an availability set in SCVMM for two different virtual machines, SCVMM attempts to keep those virtual machines on separate hosts and avoids placing them on the same host. Availability sets implement this by defining anti-affinity rules within a Hyper-V host cluster or in standalone hosts.

VRAs are defined with affinity rules to prevent their migration. Do not change these affinity rules.

During a recovery operation, when new virtual machines are created in the recovery site, migration of these virtual machines is prevented by Zerto-defined affinity rules. Once the recovery process is complete, the affinity rules are deleted and these virtual machines can be migrated.
Live Migration
If you use live migration to migrate a virtual machine, which is part of a VPG, from one host to another host, before moving the virtual machine make sure that:

- The host to which you are moving the virtual machine has a Virtual Replication Appliance (VRA) installed on it, as described in the Zerto Virtual Replication Installation Guide.
- The virtual machine is not a test virtual machine running on the recovery site during the performance of a failover test, as described in “Testing Recovery”, on page 186.

Do not migrate a Virtual Replication Appliance (VRA) from one host to another. Also, do not migrate a virtual machine on the recovery site that is being updated from the VRA journal until promotion of data to the virtual machine completes.

Quick Storage Migration
Microsoft quick storage migration enables you to move virtual machine storage from one location to another. The virtual disks of a running virtual machine can be migrated independently of their storage protocols or storage types. Downtime is minimal because quick storage migration takes a snapshot of the virtual machine and transfers data without requiring the virtual machine to be turned off.

Zerto Virtual Replication supports quick storage migration for protected virtual machine volumes and for journal volumes in the recovery site, but not for machine volumes in a VPG being promoted.

SCVMM and Host Maintenance Mode
In SCVMM, you can configure maintenance mode for a virtual machine host anytime that you need to perform maintenance tasks on the physical host, such as applying security updates or replacing hardware on the physical host computer.

Before maintaining a host that is being used for recovery, edit VPGs that contain virtual machines that are replicating to this host and change their recovery host. Assuming that you only change the recovery host, the resulting update uses live migration and should be very quick.

User Management
Hyper-V Manager allows users designated as administrators of the management operating system to manage virtual machines on a host. Authorized users can perform management tasks on the host, such as starting and stopping VMs, importing and deploying VMs, and managing snapshots. By default, anyone who is a local administrator of the management operating system can use Hyper-V Manager on the host. In addition, a user can also use Hyper-V Manager to remotely manage Hyper-V on other servers in a domain to which the user has administrative access.

SCVMM may use run-as-account to perform operations on the Hyper-V host. Zerto Virtual Manager also uses the default run-as-account to perform operations on this host.

Hyper-V Replica
Hyper-V Replica asynchronously replicates Hyper-V virtual machines in a primary site to replica virtual machines in a secondary site.

Zerto Virtual Replication cannot protect virtual machines that are protected using Hyper-V Replica.

Restart Zerto Virtual Manager After SCVMM Upgrade
Zerto Virtual Manager must be restarted after SCVMM is upgraded.

Resiliency to Hyper-V Environment Changes
SCVMM identifies and manages all its objects: VMs, hosts, networks, data stores, etc. using an internal database. Identifiers are allocated to hosts, virtual machines and other objects incrementally by SCVMM.

Each host has its own database and allocates its own IDs for the objects it holds (VM’s, Volumes, etc.). While the SCVMM database assigns IDs independently, it also receives data fields from the independent hosts’ databases.
When Zerto maps an environment within SCVMM for its configuration and operations, for example when creating a VPG, it acquires and maps the Identifiers of the available virtual machines, and refers to these Identifiers in its own environment management and replication operations.

If a host is removed from inventory and is then re-added, everything that was on it gets a new Identifier. As a result, a virtual machine, protected by Zerto that was running on that host, is allocated a new Identifier by the SCVMM. In order for Zerto to continue protecting virtual machines, Zerto Virtual Replication maintains an Identifier map containing the original Identifiers as well as unique persistent identifiers of the hosts and VMs. Zerto Virtual Manager constantly monitors the Hyper-V environment and maps the new identifiers to the same object identified by the original SCVMM identifier. This is done using the unique identifiers.

The mapping of Identifiers can take several minutes.

When system administration tasks require the importing of VPG definitions of a host that was removed and then re-added, it is advisable to wait several minutes from when the host was re-added before performing the import of the VPGs.
Configuration and management of the disaster recovery for a site is performed in the Zerto User Interface.

The following dialogs and tabs are described in this chapter:

- “About Dialog”, on page 270
- “Add Checkpoint Dialog”, below
- “Add Site Dialog”, on page 272
- “Advanced Journal Settings Dialog”, on page 273
- “Advanced VM Replication Settings Dialog”, on page 275
- “Advanced VM Settings for Cloud Dialog”, on page 275
- “ALERTS”, on page 276
- “Boot Order Dialog” on page 276
- “Browse for File Dialog”, on page 277
- “Change VM Recovery VRA Dialog”, on page 277
- “Checkpoints Dialog”, on page 278
- “Configure and Install VRA Dialog”, on page 279
- “Configure Paired Site Routing Dialog”, on page 280
- “Configure VM Settings Dialog”, on page 280
- “Edit NIC Dialog”, on page 281
- “Edit Repository Dialog”, on page 281
- “Edit Selected Volumes Dialog”, on page 282
- “Edit VM Dialog” on page 282
- “Edit VM Settings (AWS)” on page 283
- “Edit VM Settings (Azure)”, on page 284
- “Edit vNIC Dialog”, on page 285
- “Edit Volumes Dialog”, on page 285
- “Edit VRA Dialog”, on page 286
- “License Dialog”, on page 287
- “New Repository Dialog”, on page 287
- “Offsite Clone Dialog”, on page 289
- “Open Support Ticket Dialog”, on page 289
- “Remote Support Dialog”, on page 291
- “Restore VPG - NICs Dialog”, on page 292
- “Restore VPG - Volumes Dialog”, on page 292
- “Site Settings Dialog”, on page 292
- “Stop Failover Test Dialog”, on page 298
- “TASKS”, on page 299

**About Dialog**

In the About window, you can do the following:

- View the version of Zerto Virtual Replication being run.
- Enable or disable the **Zerto CALLHOME feature**. The Zerto CALLHOME feature enables support notification and analytics for the following purposes:
  - To improve Zerto Virtual Replication.
  - To send notifications to the user when a new Zerto Virtual Replication version is available, or when new hypervisor versions are supported by Zerto.
Enable or disable Zerto Virtual Manager to send data to the SaaS platform for monitoring purposes, using the Zerto Mobile App. This action is done by licensed Zerto Virtual Manager users.

When clicking About, the following options appear:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Support notification and product improvement feedback.</td>
<td>This option is selected by default.</td>
</tr>
<tr>
<td>Enable Zerto SaaS features. Includes Zerto Analytics, Zerto Mobile App</td>
<td>This option is grayed out for Microsoft Azure and AWS.</td>
</tr>
<tr>
<td>Enable SaaS features.</td>
<td>This option is selected by default.</td>
</tr>
</tbody>
</table>

To perform these actions, do the following:

1. In the Zerto User Interface, in the top right of the header, click SETTING ( ), and then click About. The version and build of Zerto Virtual Replication installed in the site are displayed.

2. To enable the Zerto CALLHOME feature, click Enable Support notification and product improvement feedback. This is selected by default.
   
   **Note:** This option is grayed out for Microsoft Azure and AWS.

   If the user deselects Enable Support notification and analytics, a warning appears notifying the user that deselecting this option will stop Zerto Virtual Replication from sending notifications when new Zerto Virtual Replication updates are available, or when new hosts are supported.

3. If you want Zerto Virtual Replication to send information to our Online Services and Zerto Mobile App, and enable remote upgrade, select Enable SaaS features. This is selected by default.

   This allows licensed Zerto Virtual Manager users to enable or disable data being sent from the Zerto Virtual Manager to the SaaS platform, thereby enabling site monitoring using the Zerto Mobile App.

   If the user deselects Enable Online Services and Zerto Mobile, a warning appears notifying the user that deselecting this option will stop Zerto Virtual Replication from sending information to Online Services and to the Zerto Mobile Application, rendering these services inoperable for the entire installation.

---

Add Checkpoint Dialog
Checkpoints are recorded automatically every few seconds in the journal. These checkpoints ensure crash-consistency and are written to the virtual machine journals by the Zerto Virtual Manager. Each checkpoint has a timestamp set by the Zerto Virtual Manager. In addition to the automatically generated checkpoints, you can manually add checkpoints to identify events that might influence the recovery, such as a planned switch over to a secondary generator.

The list of VPGs is displayed. You can select more VPGs to add the same checkpoint.

- **Enter a name for the checkpoint**: The name to assign to the checkpoint.
- **Dir**: The direction of the protection.
- **VPG Name**: The name of the VPG.
- **Protected Site Name**: The name of the site where virtual machines are protected.
- **Recovery Site Name**: The name of the site where protected virtual machines are recovered.

You can filter columns in the list via the filter icon next to each column title. You can also sort the list by each column. Clicking the cog on the right side of the table enables you to change the columns that are displayed and to create a permanent view of the columns you want displayed.
Pair sites
- **Host name/IP:** IP address or fully qualified DNS host name of the remote site Zerto Virtual Manager to pair to.
- **Port:** The TCP port communication between the sites. Enter the port that was specified during installation. The default port during the installation is 9081.

### Advanced Journal Settings Dialog

Manage the journal used for recovery.

<table>
<thead>
<tr>
<th>SETTING &amp; DESCRIPTION</th>
<th>SELECT...</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Journal History</strong></td>
<td></td>
</tr>
<tr>
<td>The time that all write commands are saved in the journal. The longer the information is saved in the journal, the more space is required for each journal in the VPG.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Number of <strong>hours</strong> from 1 to 24</td>
</tr>
<tr>
<td></td>
<td>Number of <strong>days</strong> from 2 to 30</td>
</tr>
<tr>
<td><strong>Default Journal Storage</strong> (Hyper-V), or <strong>Default Journal Datastore</strong> (vSphere)</td>
<td></td>
</tr>
<tr>
<td>The storage/datastore used for the journal data for each virtual machine in the VPG.</td>
<td></td>
</tr>
<tr>
<td><strong>Note:</strong> This field is <strong>not</strong> relevant when replicating to a vCD recovery site.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Select the storage/datastore accessible to the host.</td>
</tr>
<tr>
<td></td>
<td>When you select a specific journal storage/datastore, the journals for each virtual machine in the VPG are stored in this storage/datastore, regardless of where the recovery storage/datastore is for each virtual machine. All protected virtual machines are recovered to the hosts that can access the specified journal storage/datastore.</td>
</tr>
<tr>
<td>SETTING &amp; DESCRIPTION</td>
<td>SELECT...</td>
</tr>
<tr>
<td>----------------------------------------</td>
<td>----------------------------------</td>
</tr>
<tr>
<td><strong>Journal Size Hard Limit</strong></td>
<td></td>
</tr>
<tr>
<td>The maximum size that the journal can grow, either as a percentage or a fixed amount.</td>
<td><strong>Unlimited:</strong> The size of the journal is unlimited and it can grow to the size of the recovery storage/datastore. If Unlimited is selected, Size and Percentage options are not displayed.</td>
</tr>
<tr>
<td>The journal is always thin-provisioned.</td>
<td></td>
</tr>
<tr>
<td><strong>Note:</strong> The Journal Size Hard Limit applies independently both to the Journal History and also to the Scratch Journal Volume.</td>
<td></td>
</tr>
<tr>
<td><strong>For Example:</strong> If the Journal Size Hard Limit is configured to a maximum size of 160 GB limit, then during Failover Test, both the Journal History and the Scratch Journal Volume together can take up to 320 GB. Each one with a maximum size of 160 GB limit.</td>
<td></td>
</tr>
<tr>
<td><strong>Journal Size Warning Threshold</strong></td>
<td></td>
</tr>
<tr>
<td>The size of the journal that triggers a warning that the journal is nearing its hard limit.</td>
<td><strong>Unlimited:</strong> The size of the journal is unlimited and it can grow to the size of the recovery storage/datastore. If Unlimited is selected, Size and Percentage options are not displayed.</td>
</tr>
<tr>
<td><strong>Size</strong> (GB): The maximum journal size in GB.</td>
<td><strong>Size</strong> (GB): The minimum journal size, set by Zerto Virtual Replication, is 8GB for Hyper-V and vSphere environments, and 10GB for Microsoft Azure environments.</td>
</tr>
<tr>
<td><strong>Percentage:</strong> The percentage of the virtual machine volume size to which the journal can grow.</td>
<td><strong>Percentage:</strong> The percentage of the virtual machine volume size to which the journal can grow. This value can be configured to more than 100% of the protected VM's volume size.</td>
</tr>
</tbody>
</table>

*The values of Size and Percentage must be less than the configured Journal Size Hard Limit so that the warning will be generated when needed. In addition to the warning threshold, Zerto Virtual Replication will issue a message when the free space available for the journal is almost full.*
The Zerto Virtual Manager User Interface

Advanced VM Replication Settings Dialog

Displays the replication settings for the virtual machines in the VPG. You can choose to edit information in one field by clicking the field and updating the information. You can choose to edit information for several virtual machines at the same time by selecting the virtual machines and clicking EDIT SELECTED.

Advanced VM Settings for Cloud Dialog

Displays the recovery settings for the virtual machines in the VPG. You can choose to edit information in one field by clicking the field and updating the information. You can choose to edit information for several virtual machines at the same time by selecting the virtual machines and clicking EDIT SELECTED.
ALERTS

Monitor the recent alerts by clicking the ALERTS area in the status bar at the bottom of the Zerto User Interface. The following information is displayed for the most recent alerts:

- The alert status.
- The site where the alert is issued.
- A description of the alert.

Click All Alerts to access MONITORING > ALERTS.

Boot Order Dialog

To specify the boot order of virtual machines in a VPG. When machines are started up on recovery, for example, after a move operation, the virtual machines in the VPG are not started up in a particular order. If you want specific virtual machines to start before other machines, you can specify a boot order. The virtual machines are defined in groups and the boot order applies to the groups and not to individual virtual machines in the groups. You can specify a delay between groups during startup.

Initially, virtual machines in the VPG are displayed together under the default group. If you want specific machines to start before other virtual machines, define new groups with one or more virtual machines in each group.

There is no boot order for virtual machines within a group, only between groups.
ADD GROUP button: Adds a group. After adding a group you can edit the group name by clicking the Edit icon at the right of the group name and remove the group via the delete icon at the right of the group. You cannot remove the Default group nor a group that contains a virtual machine.

Boot Delay: Specifies a time delay between starting up the virtual machines in the group and starting up the virtual machines in the next group. For example, assume three groups, Default, Server, and Client defined in this order. The Start-up delay defined for the Default group is 10, for the Server group is 100 and for the Client group 0. The virtual machines in the Default group are started together and after 10 seconds the virtual machines in the Server group are started. After 100 seconds the virtual machines in the Client group are started up.

Browse for File Dialog

To select the folder with the preseeded disk to use. Drill-down to select the disk.

Note: Disks that are not viable for preseeding are grayed out.

Change VM Recovery VRA Dialog

To change the recovery host required by the VRA to access the host.

- Alert icon status indicator: The color indicates the status of the alert:
  - Green icon: The virtual machine can be moved to the replacement host.
  - Red icon: The virtual machine cannot be moved to the replacement host.
- Direction: The direction of the replication, from this site to the remote site or from the remote site to this site.
- VM Name: The name of the virtual machine.
- VPG Name: The name of the VPG.
■ **ZORG**: The Zerto name given to the organization, the ZORG, by a cloud service provider. For details, refer to *Zerto Cloud Manager Administration Guide*.

■ **VM Size GB**: The virtual machine size in gigabytes.

■ **# of Volumes**: The number of volumes used by the virtual machine.

■ **VM Hardware Version**: The hardware version of the virtual machine.

■ **Select the replacement host**: The name of the host to move the recovery virtual machines information.

### Checkpoints Dialog

When selecting the point to recover to, remember the following:

■ The refresh button is initially grayed out and is enabled for clicking after 5 seconds. It is also grayed out for 5 seconds after being clicked, before being re-enabled.

■ A reminder, **Click the refresh button to view the latest checkpoints** is displayed 10 seconds after the refresh button is clicked to remind the user that there is a new Latest Checkpoint.

■ If the user has scrolled to, and selected, a checkpoint anywhere in the checkpoints list, clicking the refresh button will automatically return the user to the selected checkpoint in the list.

Use the following filters:

■ **Latest**: Recovery is to the latest checkpoint. This ensures that the data is crash-consistent for the recovery. When selecting the latest checkpoint, the checkpoint used is the latest at this point. If a checkpoint is added between this point and starting the failover, the later checkpoint is not used.

■ **Latest Tagged Checkpoint**: The recovery operation is to the latest checkpoint added in one of the following situations:
  ■ By a user.
  ■ When a failover test was previously performed on the VPG which includes the virtual machine.
  ■ When the virtual machine was added to an existing VPG after the added virtual machine was synchronized.

■ **Select from all available checkpoints**: If you do not want to use the latest checkpoint, latest tagged checkpoint, choose **Select from all available checkpoints**. By default, this option displays all checkpoints in the system. You can choose to display only automatic, or tagged checkpoints, or any combination of these types.
Configure and Install VRA Dialog

**Host**: The host under which the VRA is installed. The drop-down displays the hosts managed by the hypervisor manager that do not have a VRA installed, with the selected host displayed by default.

**Host Root Password**: For future use.

**Storage**: The storage that contains the OS disks of the VRA VM. You can install more than one VRA on the same storage.

**Network**: The network used to access the VRA.

**VRA RAM**: The amount of memory to allocate to the VRA. The amount determines the maximum buffer size for the VRA for buffering IOs written by the protected virtual machines, before the writes are sent over the network to the recovery VRA. The recovery VRA also buffers the incoming IOs until they are written to the journal. If a buffer becomes full, a Bitmap Sync is performed after space is freed up in the buffer. For details, refer to Zerto Scale and Benchmarking Guidelines.

**VRA Group**: Specify the VRA Group as free text to identify the group or select from a previously specified group. You group VRAs together when VRAs use different networks so they can be grouped by network, for example when the protected and recovery sites are the same site and you want to replicate to different storage in the site. The group name is free text you use to identify the group.

The priority assigned to a VPG dictates the bandwidth used. The Zerto Virtual Manager distributes bandwidth among the VRAs based on this priority and the VPGs with higher priorities are handled before writes from VPGs with lower priorities.

To create a new group, enter the new group name over the text *New group* and click CREATE.

**Configuration**: Either have the IP address allocated via a static IP address or a DHCP server. The Static option is the recommended option.

**Address**: The IP address for the VRA.

**Subnet Mask**: The subnet mask for the network. The default value is 255.255.255.0.

**Default Gateway**: The default mask for the network.
Configure Paired Site Routing Dialog

The IP address, subnet mask, and gateway to access the peer site VRAs when access to the peer site VRAs is not via the default gateway.

**Enable Paired Site Routing:** When checked, enables paired site routing.

**Address:** The IP address of the next hop at the local site, the router, or gateway address that is used to access the peer site network.

**Subnet Mask:** The subnet mask for the peer site network.

**Gateway:** The gateway for the peer site network.

These access details are used to access the VRAs on the peer site.

The settings in the *Configure Paired Site Routing* dialog apply to all VRAs installed after the information is saved. Any existing VRA is not affected and access to these VRAs continues via the default gateway. If the default gateway stops being used, you must reinstall the VRAs that were installed before setting up paired site routing.

Configure VM Settings Dialog

Specifies the values to use when restoring the selected virtual machines.

**Restore on Host:** The IP address of the host where you want the virtual machine restored.

**Restore on Datastore:** The datastore to use for the restored virtual machine files.

**Power On:** Check this if you want the restored virtual machine to be powered on.
**Edit NIC Dialog**

Specify the NIC settings when restoring a retention set to the recovery site.

**NIC Name:** The name of the selected NIC.

**Network:** The network to use for the restored virtual machine.

**Create new MAC address:** The Media Access Control address (MAC address) to use. The default is to use the same MAC address for the restored virtual machine that was used in the protected site. Check the box to create a new MAC address on the restore site.

**Change vNIC IP Configuration:** Whether or not to keep the default virtual NIC (vNIC) IP configuration. The vNIC IP is changed after the restore has completed when Integration Services are installed. If Static is selected, the IP address, subnet mask, and default gateway must be set. If DHCP is selected, the IP configuration and DNS server configurations are assigned automatically, to match the protected virtual machine.

**IP Address:** The IP for the restored virtual machine. This can be the same IP as the original protected virtual machine.

**Subnet Mask:** The subnet mask for the network. The default value is 255.255.255.0.

**Default Gateway:** The default mask for the network.

**Preferred DNS Server:** The IP address of the primary DNS server to handle Internet protocol mapping.

**Alternate DNS Server:** The IP address of the alternate DNS server.

**DNS Suffix:** The DNS name excluding the host.

---

**Edit Repository Dialog**

You can change the repository name, or define the repository as the default.

**To edit a Repository:**

1. In the Zerto User Interface, click SETUP tab, REPOSITORIES sub-tab.
2. Select the repository to edit and click the edit pencil icon.
   - The Edit Repository dialog is displayed.
Edit any of the following settings:

- Repository Name: Specify a unique name for the repository.
- Repository Type: This field is not available for editing. Path: This field is not available for editing. Set as default repository: Select to use the repository as the default when specifying extended recovery in a VPG.

3. Click SAVE. The updated definition of the repository is saved.

Edit Selected Volumes Dialog

If more than one storage is selected, the path is not displayed.

Storage: The storage where the virtual machine files will be restored.
Thin: Whether the virtual machine disks will be dynamic disks or not.

Edit VM Dialog
Edit the replication settings for a particular virtual machine in a VPG.

- **Recovery Host:** The cluster, resource pool, or host that will host the recovered virtual machine. If the site is defined in Zerto Cloud Manager, only a resource pool can be specified and the resource pool must also have been defined in Zerto Cloud Manager. For details about Zerto Cloud Manager, see *Zerto Cloud Manager Administration Guide*.

  When a resource pool is specified, Zerto Virtual Replication checks that the resource pool capacity is enough for the specified virtual machine.

- **Recovery Storage:** The location where the metadata files for the virtual machine are stored. If a cluster or resource pool is selected for the host, only storage that is accessible by every host in the cluster or resource pool is displayed. When specifying the recovery storage for a virtual machine with a storage cluster, specify storage in the cluster.

- **Journal Size Hard Limit:** The maximum size that the journal can grow, either as a percentage or a fixed amount. The minimum journal size, set by Zerto Virtual Replication, is 8GB. The journal is always thin-provisioned.

  - **Unlimited:** The size of the journal is unlimited and it can grow to the size of the recovery storage.
  - **Size (GB):** The maximum journal size in GB.
  - **Percentage:** The percentage of the virtual machine volume size the journal can grow to.

- **Journal Size Warning Threshold:** The size of the journal that triggers a warning that the journal is nearing its hard limit.

  - **Unlimited:** The size of the journal is unlimited and it can grow to the size of the recovery storage.
  - **Size (GB):** The size in GB that will generate a warning.
  - **Percentage:** The percentage of the virtual machine volume size that will generate a warning.

Both the value of Size and Percentage must be less than the configured hard limit so that the warning will be generated when needed. In addition to the warning threshold, Zerto Virtual Replication will issue a message when the free space available for the journal is almost full.

- **Journal Storage:** The storage used for the journal data for each virtual machine in the VPG. To change the default, specify a host and then select a storage location accessible by this host to be used as the journal storage. When you select specific journal storage, the journals for each virtual machine in the VPG are stored in it, regardless of where recovery storage is for each virtual machine. In this case, all the protected virtual machines must be recovered to hosts that can access the specified journal storage.

  - For Edit VM Setting in AWS, see “Edit VM Settings (AWS), on page 283.
  - For Edit VM Settings in Azure, see “Edit VM Settings (Azure), on page 284.

### Edit VM Settings (AWS)

![Edit VM Settings (AWS) dialog box](image)

Edit the network settings for one or more virtual machines in a VPG that will be recovered to AWS. There are recovery settings for failovers and moves, and for failover tests.

- **Import Method**
The Zerto Virtual Manager User Interface

- **AWS Import**: The method that has been used in all past implementations.
- **Zerto Import for all volumes**: This is the fastest import method and uses a zImport VM for all volumes. A zImport virtual machine is created, per volume. For each recovered volume, the zImport virtual machine is terminated when all the data has been imported and its disk has been attached to the recovered virtual machine.
- **Zerto Import for data volumes**: Uses the zImport method for data volumes only. This is the default setting and has a faster RTO than AWS Import.

**VPC Network**: A virtual network dedicated to your AWS account.

**Subnet**: A range of IP addresses in your VPC.

**Security Group**: The AWS security to be associated with the virtual machines in this VPG. You can associate one or more security groups with the virtual machines.

**Instance Family**: The instance family from which to select the type. AWS instance families are optimized for different types of applications. Choose the instance family appropriate for the application in the virtual machine protected in the VPG.

**Instance Type**: The instance type, within the instance family, to assign to recovered instances. Different types within an instance family vary primarily in vCPU, ECU, RAM, and local storage size. The price per instance is directly related to the instance size.

**Private IP**: The private IP of an instance from the selected subnet. If you do not set the private IP, during recovery, AWS sets the private IP from the defined subnet range.

---

**Edit VM Settings (Azure)**

Edit the network settings for one or more virtual machines in a VPG that will be recovered to Azure. There are recovery settings for failovers and moves, and for failover tests.

**VNet**: A virtual network dedicated to your Azure subscription.

**Subnet**: A range of IP addresses in your VPC.

**Network Security Group**: The Azure network security to be associated with the virtual machines in this VPG. You can associate one or more network security groups with the virtual machines.

**Instance Family**: The instance family from which to select the type. Azure instance families are optimized for different types of applications. Choose the instance family appropriate for the application in the virtual machine protected in the VPG.

**Instance Type**: The instance size, within the instance family, to assign to recovered instances. Different sizes within an instance family vary primarily in vCPU, ECU, RAM, and local storage size. The price per instance is directly related to the instance size.

**Private IP**: The private IP of an instance from the selected subnet. If you do not set the private IP, during recovery, Azure sets the private IP from the defined subnet range.
To configure the NIC used for the replicated VM disks. You can configure a maximum of four NICs.

**Note:** You can only change the vNIC IP for virtual machines with Microsoft Integration Services running.

Specify the network details to use for the recovered virtual machines after a live recovery or migration, in the Failover/Move column, and for the recovered virtual machines when testing the replication, in the Test column.

- **Network:** The recovery site network to use. For testing, this network can be a fenced-out network to avoid impacting the production network.
- **Create New MAC Address:** Whether the Media Access Control address (MAC address) used on the protected site should be replicated on the recovery site. The default is to use the same MAC address on both sites.
- **Change vNIC IP Configuration:** Whether or not to keep the default virtual NIC (vNIC) IP configuration. You can only change the vNIC IP after recovery has completed by installing Integration Services.

To change the vNIC IP, select Yes in the Failover/Move or Test column. If you select a static IP connection, set the IP address, subnet mask, and default gateway. Optionally, change the preferred and alternate DNS server IPs and the DNS suffix. If you select DHCP, the IP configuration and DNS server configurations are assigned automatically, to match the protected virtual machine. You can change the DNS suffix.

If the virtual machine has multiple NICs but is configured to only have a single default gateway, fill in a 0 for each octet in the Default gateway field for the NICs with no default gateway.

**Note:** During a failover, move, or test failover, if the recovered virtual machine is assigned a different IP than the original IP, after the virtual machine has started it is automatically rebooted so that it starts up with the correct IP. If the same network is used for both production and test failovers, Zerto recommends changing the IP address for the virtual machines started for the test, so that there is no IP clash between the test machines and the production machines.

- **Copy to failover test:** When clicked, copies the settings in the Failover/Move column to the Test column.
- **Copy to failover/move:** When clicked, copies the settings in the Test column to the Failover/Move column.

---

**Edit Volumes Dialog**

Select the volume you want to edit and specify the storage location, then click OK to apply the changes.
To edit recovery storage information for a protected virtual machine.

**Volume Source:** The source on the recovery site for the replicated data.

**Storage:** A new volume is used for replicated data.

**Preseed:** Whether to copy the protected data to a virtual disk in the recovery site. Zerto recommends using this option particularly for large disks so that the initial synchronization will be faster since a Delta Sync can be used to synchronize any changes written to the recovery site after the creation of the preseeded disk. When not using a preseeded disk, the initial synchronization phase must copy the whole disk over the WAN. When using a preseeded virtual disk, you select the storage and exact location, folder, and name of the preseeded disk. Zerto Virtual Replication takes ownership of the preseeded disk, moving it from its source folder to the folder used by the VRA. Only disks with the same size as the protected disk can be selected when browsing for a preseeded disk. The storage where the preseeded disk is placed is also used as the recovery storage for the replicated data.

**Temp Data disk:** If the virtual machine to be replicated includes a temp data disk as part of its configuration, specify a mirror disk for replication that is marked as a temp data disk. In this case, data is not replicated to the temp data disk after initial synchronization.

**Storage:** The storage to use to create disks for the replicated data.

The storage specified for the replication must have at least the same amount of space as the protected volume and then an additional amount for the journal. The amount of additional space needed for the journal can be fixed by specifying a maximum size for the journal, or can be calculated as the average change rate for the virtual machines in the VPG, multiplied by the length of time specified for the journal history.

---

**Edit VRA Dialog**

![Edit VRA Dialog](image)

To change the network settings for a VRA, for example when the gateway to the VRA is changed.

- **Host:** The IP of the host on which the VRA is installed.
- **Host Root Password:** The password required by the VRA to access the host.
- **VRA Group:** The free text to identify the group to which a VRA belongs. If you create a group and then change the name when editing the VRA so that there is no VRA in the site that belongs to the originally specified group, the group is automatically deleted from the system.

To create a new group, enter the new group name over the text *New group* and click *CREATE*.

- **Configuration:** Either have the IP address allocated via a static IP address or a DHCP server. If the VRA was originally installed with a static IP, you cannot change this to DHCP. If the VRA was originally installed to use a DHCP server, you can change this to use a static IP. Zerto always recommends using a static IP.
- **Address:** The static IP address for the VRA to communicate with the Zerto Virtual Manager.
- **Subnet Mask:** The subnet mask for the network. The default value is 255.255.255.0.
- **Default Gateway:** The default gateway for the network.
License Dialog

The Zerto license includes information such as the number of virtual machines that can be protected and the license expiry date. You can see these details by clicking SETTING ( ) in the top right of the header and selecting License.

The Zerto license includes the following details:

- **License**: The license key itself.
- **License Type**: What is licensed: whether the license restricts the number of virtual machines that can be protected or the number of sockets used.
- **Expiry Date**: The license expiry date.
- **Quantity**: The maximum amount licensed, either virtual machines or sockets, based on the license type. If blank, the quantity is unlimited.
- **Usage**: The sites using the license and the number of protected virtual machines in each site.

A warning is generated when either the license expires or more than the licensed number of virtual machines are being protected. Protection continues but the license should be updated. After getting a new license key you can update Zerto Virtual Replication with this key.

New Repository Dialog

Define repositories on the recovery site where retention sets can be stored on a network share that uses the NFS (Network File System) protocol.

The repository where you want this retention set stored is specified when the retention policy is defined.
To create a repository for Long Term Retention:

1. In the Zerto User Interface, click SETUP > REPOSITORIES > NEW REPOSITORY.

2. In the General area, specify the following:
   - **Repository Name**: A unique name for the repository.
   - **Repository Type**: The type of repository:
     - **Network Share (NFS)**: The network share drive must be an Network File System (NFS) drive.

3. In the Location area, define the **Path**. This is the path where the repository will reside.
   The path must be accessible from the Zerto Virtual Manager, so if the repository is on a different domain to the Zerto Virtual Manager, the domain must be included in the path.

4. In the Properties area, you can **Set as default repository**. This will use the repository as the default when defining the retention policy in a VPG.

5. Click **SAVE**. The repository is created.
Offsite Clone Dialog

To create a clone of each virtual machine in a VPG on the recovery site in the production network. The clone is a copy of the protected virtual machines on the recovery site, while the virtual machines on the protected site remain protected and live.

**SELECT A CHECKPOINT button** - Opens the Checkpoints Dialog to select the checkpoint to use to make the clone.

**Recovery Datastore** - Select the datastore to use for the recovery virtual machines.

**Advanced** - Select specific VMs to clone.

Open Support Ticket Dialog

Support cases can be opened directly in the Zerto User Interface.

Creating a support case in the Zerto User Interface simplifies the submission process since much of the information that is required when entering a case using the Zerto Support Portal, such as the version and build numbers, is automatically added to the case when it is submitted via the Zerto User Interface.

In addition, when the case is submitted, a snapshot of the current environment is also attached to the case. The snapshot information includes the lists of alerts, events, tasks, VPGs, and virtual machines that are protected.

This information is used to help Zerto resolve the case quickly and, whenever possible, without the need to request more information from you.

**Note:** The clocks on the machines where Zerto Virtual Replication is installed must be synchronized with UTC and with each other (the timezones can be different). Zerto recommends synchronizing the clocks using NTP. If the clocks are not synchronized with UTC, submitting a support case can fail.
To open a support case:

1. In the Zerto User Interface, click **SETTING** ( ) in the top right of the header and select Open a Case. The Open Support Case window for the site opens.

2. Specify the case details:
   - **Subject**: The subject of the support case.
   - **Type**: The type of case being opened. Available options are:
     - Problem
     - Question
   - **Description**: A description of the problem or question in addition to the information supplied in the subject.
   - **Allow remote log collection**: How many logs is Zerto allowed to collect. Available options are:
     - Only for this case
     - For the next 30 days
     - Never
   - **SSP Email Address**: A valid email address registered with Zerto, with permission to open cases.

3. Click **SUBMIT**.

The case is processed and its progress is displayed. If the email address is not valid, the case is rejected. Once the case submission starts, it cannot be canceled.
Remote Support Dialog

Remote Log Collection allows customers to authorize Zerto support engineers to collect logs from their environment. By using remote log collection customers can avoid having to use the Diagnostic Tool on their ZVM server in order to collect logs for analysis, a potentially complex and time-consuming procedure.

- **Never**: Remote log collection is not allowed (default). If remote log collection is currently allowed, it will be terminated if you select this option.
- **For the next 30 days**: Remote log collection is allowed. This permission will automatically terminate in 30 days unless terminated by selecting the **Never** option.
- **Only for a specific case** - You will be prompted to select the **Case number** from the drop-down list. The list contains all the active cases opened under the account that the Zerto Virtual Manager is registered under.

Remote log collection will be allowed for as long as the case is active or until remote log collection is terminated by selecting the **Never** option.

**Restore from Repositories**

To restore from repositories, see *Using Zerto’s Long Term Retention*. 
**Restore VPG - NICs Dialog**

When restoring a retention set to the recovery site, this dialog shows the NIC settings for the virtual machines in the VPG. You can choose to edit information in one field by clicking the field and updating the information. You can choose to edit the NIC settings for several virtual machines at the same time by selecting the NICs and clicking EDIT SELECTED.

For more details, see “Restore VPG - Volumes Dialog”, on page 292.

**Restore VPG - Volumes Dialog**

When restoring a retention set to the recovery site, this dialog shows the storage for a selected virtual machine in the VPG. You can choose to edit information in a field by clicking the field and updating the information. You can choose to edit several storage settings at the same time by selecting the volumes and clicking EDIT SELECTED.

**Site Settings Dialog**

Contains site-wide settings:

- “Site Information Dialog”, below
- “Performance and Throttling Dialog”, on page 293
- “Policies Dialog”, on page 295
- “Email Settings Dialog”, on page 296
- “Reports Dialog”, on page 297
- “Compatibility Dialog”, on page 298
- “License Dialog”, on page 287
Site Information Dialog

Site Details

- **Site Name:** Unconfigured location
- **Site Location:** Unconfigured contact info
- **Contact Name:** Unconfigured contact info
- **Contact Email:** Unconfigured contact email
- **Contact Phone:** Unconfigured contact phone

User Credentials

- **Username:** ummadmin
- **Password:** 

During installation, information about the site is entered to identify the site in the user interface and to identify the contact person at the site. After installation you can update this information.

- **Site Name:** The name used to identify the site.
- **Site Location:** Information such as the address of the site or a significant name to identify it.
- **Contact Name:** The name of the person to contact if a need arises.
- **Contact Email:** An email address to use if a need arises.
- **Contact Phone:** A phone number to use if a need arises.
- **User Name:** The administrator name used to access the hypervisor management tool. The name can be entered using either of the following formats:
  - `username`
  - `domain\username`
- **Password:** The password used to access the hypervisor management tool for the given user name. If the password changes, specify the new password. To ensure security, after saving the settings, the password field is cleared.

Performance and Throttling Dialog
Bandwidth Throttling:

Define this to control the amount of traffic going out of your site. When defined, this is the maximum bandwidth that Zerto Virtual Replication uses from this site to all peer recovery sites.

If you do not specify bandwidth throttling, the default is for Zerto Virtual Replication to automatically assign the bandwidth used per VPG, based on using the maximum available and then prioritizing the usage according to the priority set for the VPGs sending data over the WAN.

**Note:** For minimum bandwidth requirements, see Zerto Scale and Benchmarking Guidelines.

- By default, **Limited** is selected.
- In the text box, set the MB/sec. The valid range is from 0 to 1300 MB/sec.
- With 0 MB/sec, Zerto Virtual Replication automatically assigns the bandwidth used per VPG, based on using the maximum available and then prioritizing the usage according to the priority set for the VPGs sending data over the WAN.
- Enter the MB/sec when the value required is 100 MB/sec or more.

Time-based Throttling:

Define this to throttle the bandwidth during specific times. For example, during the daily peak transaction period you can change the bandwidth throttling, to override the general setting.

**Limited:** Select to define the limit, then define:
- **From:** The hour and the minute to start the throttling, using a 24-hour clock.
- **To:** The hour and the minute to end the throttling, using a 24-hour clock.

- **Click Show advanced settings...**

**IMPORTANT:**

Advanced settings must only be changed in coordination with Zerto support.
Enable Bandwidth Regulation: Use this for troubleshooting - to enable regulating the bandwidth.

Enable IO throttling: If a host is handling too many IOs, then the IOs begin to get high latencies. To offset this the VRA sends fewer concurrent IOs. The latency is measured by taking the average latency for all IOs over a set period of time. For example, when the period is 5000 milliseconds and the bad IO latency is 40, the average latency is calculated every 5 seconds, and if the average latency exceeds 40, the VRA sends fewer concurrent IOs.

- **Bad IO Latency VM**: The threshold above which the latency is considered high, and therefore bad.
- **Requested Duration (ms)**: The period of time used to measure the average latency.

**Policies Dialog**

- **Failover/Move Commit Policy**: The commit policy to use during a failover or move operation. The value set here is the default for all failover or move operations from this point on but can be changed when defining a failover or move operation. The following options are available:
  - **None**: The failover or move operation must be manually committed or rolled back by the user.
  - **Commit**: After the time specified in the Default Timeout field, the failover or move operation is committed. During the specified time you can check the recovered VPG virtual machines, and you can manually commit or roll back.
  - **Rollback**: After the time specified in the Default Timeout field the failover or move operation is rolled back, unless you manually commit it or roll it back before the time out value is reached. During the specified time you can check the recovered VPG virtual machines.

- **Default Timeout**: The time-out in minutes after which a Commit or Rollback is performed. A value of zero indicates that the system automatically performs the commit policy, without waiting for any user interaction.

- **Default Script Execution Timeout**: The length of time in seconds after which a script times out.

- **Enable Replication to Self**: Enable the same site to be used as both the protected and recovery site.

- **Replication Pause Time**: The time to pause when synchronizing a VPG if continuing the synchronization will cause all the checkpoints in the journal to be removed.
For incoming replication, copy the BIOS UUID of the protected VM to the recovered VM: Select this to preserve the BIOS UUID of the protected VM after recovery operations, in the recovery ZVM Site Settings window.

Note:
- Preserving of the BIOS UUID is not supported in Clone and Self-Replication recovery operations.
- Preserving of the BIOS UUID is not supported in Public Cloud.
- Cross replication is not supported.

Email Settings Dialog
Define an email address to receive Zerto Virtual Replication alerts and retention reports.

- **SMTP Server Address**: The SMTP server address. The Zerto Virtual Manager must be able to reach this address.
- **SMTP Server Port**: The SMTP server port, if it was changed from the default, 25.
- **Sender Account**: A valid email address for the email sender name.
- **To**: A valid email address where you want to send the email.
- **SEND TEST EMAIL** button: Tests that the email notification is set up correctly. A test email is sent to the email address specified in the **To** field.
- **Enable sending alerts**: Check to be notified by email about any Zerto Virtual Replication alerts issued. An email is sent when the alert is issued, and after it has been successfully handled and the alert is no longer valid.
- **Enable retention reports**: Defines when retention reports will be emailed.

**Reports Dialog**

Configures the Resource Report.

- **Sampling Rate**: When to take resource samples to identify resource usage, either daily at a specific hour and minute or hourly at a specific minute within each hour. Note that collecting a sample hourly provides a higher resolution picture of replication traffic than if samples are only collected once a day.
- **Sampling Time**: The time that the sample is taken.
Compatibility Dialog

Lists supported host versions.

Stop Failover Test Dialog

Stops the testing of the selected VPG.
- **Result**: Whether the test passed or failed.
- **Notes**: A description of the test. For example, defines where external files that describe the tests are saved. Notes are limited to 255 characters.

Clicking the **Stop** button stops the testing. After stopping a test, the virtual machines in the recovery site are powered off and then removed, and the checkpoint that was used for the test has the following tag added to identify the test:
Tested at startDateAndTimeOfTest.
Monitor the recent tasks by clicking the TASKS area in the status bar at the bottom of the Zerto User Interface. The following information is displayed for the most recent tasks:

- The task status.
- The name of the task.
- A description of the task.

Also, actions, such as stopping a failover test, can be performed from this dialog.

Click **See All Tasks** to access MONITORING > TASKS.
## ACCESS KEY (AWS)
An alphanumeric text string that uniquely identifies the AWS account owner. No two accounts can have the same AWS Access Key.

### AMAZON WEB SERVICES (AWS)
A collection of remote computing services, also called web services, that make up a cloud computing platform by Amazon.com. The most central and well-known of these services are Amazon EC2 and Amazon S3. The service is advertised as providing a large computing capacity (potentially many servers) much faster and cheaper than building a physical server farm.

### ASYNCH REPLICATION
See Replication, Asynchronous.

### BACKUP
See Long Term Retention.

### BARE METAL
A computer system or network in which a virtual machine is installed directly on hardware rather than within the host operating system (OS).

### BITMAP SYNC
A change tracking mechanism of the protected machines during a disconnected state when Zerto Virtual Replication starts to maintain a smart bitmap in memory to track and record changed storage areas. Since the bitmap is kept in memory, Zerto Virtual Replication does not require any LUN or volume per VPG at the source side.

The bitmap is small and scales dynamically, containing references to the areas of the source disk that have changed but not the actual I/O. The bitmap is stored locally on the VRA within the available resources. For example, when a VRA goes down and is then rebooted.

When required, Zerto Virtual Replication starts to maintain a smart bitmap in memory, to track and record storage areas that change. When the issue that caused the bitmap sync is resolved, the bitmap is used to check updates to the source disks and send any updates to the recovery site. A bitmap sync occurs during the following conditions:

- Synchronization after WAN failure or when the load over the WAN is too great for the WAN to handle, in which case the VPGs with the lower priorities will be the first to enter a Bitmap Sync.
- When there is storage congestion at the recovery site, for example when the VRA at the recovery site cannot handle all the writes received from the protected site in a timely fashion.
- When the VRA at the recovery site goes down and is then rebooted.

During the synchronization, new checkpoints are not added to the journal but recovery operations are still possible. If a disaster occurs requiring a failover during a bitmap synchronization, you can recover to the last checkpoint written to the journal.

**Note:** For the synchronization to work, the protected virtual machines must be powered on. The VRA requires an active IO stack to access the virtual machine data to be synchronized across the sites. If the virtual machine is not powered on, there is no IO stack to use to access the source data to replicate to the target recovery disks.

### BUCKET (AWS)
Amazon buckets are like a container for your files. You can name your buckets the way you like but it should be unique across the Amazon system.

### BUSINESS CONTINUITY & DISASTER RECOVERY (BC/DR)
An organization's ability to recover from a disaster and/or unexpected event and resume or continue operations. A disaster recovery, DR, plan is a subset of a Business Continuity plan. Organizations should have a business continuity, BC, plan in place that outlines the logistics and business operations. The key metrics to be measured in a disaster recovery environment are the Recovery Point Objective (RPO) and Recovery Time Objective (RTO).

### BUSINESS CONTINUITY MANAGEMENT (BCM)
Holistic management process that identifies potential threats to an organization and the impacts to business operations that those threats, if realized, might cause, and which provides a framework for building organizational resilience with the capability for an effective response that safeguards the interests of its key stakeholders, reputation, brand and value-creating activities. (ISO 22313, formerly BS 25999-1).
<table>
<thead>
<tr>
<th>Glossary Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Business Continuity Plan</td>
<td>Contains the instructions, procedures and guidelines that are developed and maintained in readiness for use during and after any potentially disruptive event in order to enable the organization to continue to deliver its critical activities at an acceptable, predefined level.</td>
</tr>
<tr>
<td>Business Impact Analysis (BIA)</td>
<td>The process of analyzing business functions and processes and the effects that a business disruption might have upon them.</td>
</tr>
<tr>
<td>Checkpoint</td>
<td>Zerto Virtual Replication ensures crash consistency by writing checkpoints to the journal every few seconds. These checkpoints ensure write order fidelity and crash-consistency to each checkpoint. During recovery you pick one of these crash-consistent checkpoints and recover to this point. Additionally, checkpoints can be manually added by the administrator, with a description of the checkpoint. For example, when an event is going to take place that might result in the need to perform a recovery, you can pinpoint when this event occurs as a checkpoint in each journal.</td>
</tr>
<tr>
<td>Cloud Service Provider (CSP)</td>
<td>A service provider that offers customers storage or software services available via a private (private cloud) or public network (cloud). Usually, it means the storage and software is available for access via the Internet. Typically Infrastructure as a Service (IaaS), Software as a Service (SaaS), or Platform as a Service (PaaS) – are offered to their customers. Zerto enables them to offer Disaster Recovery As A Service (DRaaS) and In-Cloud DR (ICDR), too.</td>
</tr>
<tr>
<td>Crisis Management Plan</td>
<td>Provides the overall coordination of the organization’s response to a crisis (which is a critical event that needs to be handled appropriately to prevent a damaging impact to the organization’s profitability, reputation or ability to operate).</td>
</tr>
<tr>
<td>Delta Sync</td>
<td>The Delta Sync uses a checksum comparison to minimize the use of network resources. A Delta Sync is used when the protected virtual machine disks and the recovery disks should already be synchronized, except for a possible few changes to the protected disks, for example, when the target recovery disk is defined as a preseeded (not available in the cloud) disk or after a VRA upgrade, or for reverse protection after a move or failover. During the synchronization, new checkpoints are not added to the journal but recovery operations are still possible. If a disaster occurs requiring a failover during a delta synchronization, you can recover to the last checkpoint written to the journal. It is <strong>not possible</strong> to perform a move during a delta sync. <strong>Note:</strong> For the synchronization to work, the protected virtual machines must be powered on. The VRA requires an active IO stack to access the virtual machine data to be synchronized across the sites. If the virtual machine is not powered on, there is no IO stack to use to access the source data to replicate to the target recovery disks.</td>
</tr>
<tr>
<td>Disaster</td>
<td>The occurrence of one or more events which, either separately or cumulatively, activate disaster recovery.</td>
</tr>
<tr>
<td>Disaster Recovery</td>
<td>The ability to restart operations after an interruption to the business according to a plan that ensures an orderly and timely restoration.</td>
</tr>
<tr>
<td>Disaster Recovery Plan</td>
<td>The disaster recovery, DR, plan is a component of the Business Continuity plan that details the process and procedures to recover the organization’s resources to continue business operations. The Technology DR plan focuses on the IT disaster recovery. Also see Business Continuity Plan.</td>
</tr>
<tr>
<td>Disaster Recovery As A Service (DRaaS)</td>
<td>A disaster recovery solution that incorporates a service provider to replace or augment the organization’s data protection implementation. In a DRaaS scenario, the customer may manage and have complete control over the production data. The Cloud Service Provider (CSP) may provide a partial or completely managed service. In either case, the CSP must ensure the availability of the data and adapt as the customers infrastructure changes. An advantage of this model is the CSP has dedicated resources skilled in DR operations.</td>
</tr>
<tr>
<td>DRS (vSphere)</td>
<td>Enables balancing computing workloads with available resources in a VMware vCenter cluster.</td>
</tr>
<tr>
<td>Emergency Management</td>
<td>Covers the immediate response to a situation or set of circumstances that present a clear and present threat to the safety of personnel or other assets of the organization.</td>
</tr>
<tr>
<td>Estimated Recovery Time (ERT)</td>
<td>This is the estimated timings based on full resource provision available during a live invocation. This time typically sits between the Net Recovery Time and the Recovery Time Achieved (RTA) time.</td>
</tr>
<tr>
<td><strong>ESX/ESXi (vSphere)</strong></td>
<td>Bare-metal hypervisor from VMware, meaning it installs directly on top of the physical server and partitions it into multiple virtual machines that can run simultaneously, sharing the physical resources of the underlying server. ESXi is the most recent version.</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Extended DR</strong></td>
<td>VMware includes the ability to configure both disaster recovery and Long Term Retention for the protected virtual machines in the VPG, according to a user-defined data retention policy.</td>
</tr>
<tr>
<td><strong>High Availability (VMHA)</strong></td>
<td>VMware high availability decreases downtime and improves reliability with business continuity by enabling another ESX/ESXi host to start up virtual machines that were running on another ESX/ESXi host that went down. High availability is automatically disabled by Zerto Virtual Replication while updating recovered virtual machines in the recovery site from the VRA journal. After the promotion of the data from the journal to the virtual machine completes, high availability is automatically re-enabled. The HA configuration can include admission control to prevent virtual machines being started if they violate availability constraints. If this is the case, then a failover, test failover or migration of the virtual machines in a VPG to the cluster with this configuration will fail, if the availability constraints are violated when the virtual machines are recovered.</td>
</tr>
<tr>
<td><strong>Hyper-V</strong></td>
<td>A hybrid hypervisor, which is installed in the operating system. However, during installation it redesigns the operating system architecture and becomes just like a next layer on the physical hardware.</td>
</tr>
<tr>
<td><strong>Hypervisor</strong></td>
<td>The host for multiple VMs in a virtualized environment. vSphere, ESX/ESXi, is the VMware brand hypervisor. The hypervisor is the virtualization architecture layer that allows multiple operating systems, termed guests, to run concurrently on a host computer.</td>
</tr>
<tr>
<td><strong>Hypervisor Manager</strong></td>
<td>The tool used to manage the host. For example VMware vCenter Server and Microsoft SCVMM.</td>
</tr>
<tr>
<td><strong>I/O (Input/Output)</strong></td>
<td>Describes any operation, program, or device that transfers data to or from a computer. Typical I/O devices are printers, hard disks, keyboards, and mouses. In fact, some devices are basically input-only devices (keyboards and mouses); others are primarily output-only devices (printers); and others provide both input and output of data (hard disks, diskettes, writable CD-ROMs). In computer architecture, the combination of the CPU and main memory (memory that the CPU can read and write to directly, with individual instructions) is considered the brain of a computer, and from that point of view any transfer of information from or to that combination, for example to or from a disk drive, is considered I/O.</td>
</tr>
<tr>
<td><strong>In-Cloud DR (ICDR)</strong></td>
<td>A disaster recovery solution that incorporates a service provider to replace or augment the organization’s data protection implementation. When customers leverage an ICDR service, the CSP hosts the production and DR sites. The virtual machines (VMs) are typically replicated from one CSP datacenter to another CSP datacenter as a managed service or as managed co-located datacenters. The customers have the ability to interact with their applications as if they were locally hosted.</td>
</tr>
<tr>
<td><strong>Initial Sync</strong>¹</td>
<td>Synchronization performed after creating the VPG to ensure that the protected disks and recovery disks are the same. Recovery operations cannot occur until after the initial synchronization has completed.</td>
</tr>
<tr>
<td></td>
<td>Adding a virtual machine to a VPG is equivalent to creating a new VPG and an initial synchronization is performed. In this case, any checkpoints in the journal become unusable and only new checkpoints added after the initial synchronization completes can be used in a recovery. The data in the journal however remains and is promoted to the recovered virtual machine as part of a recovery procedure.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> For the synchronization to work, the protected virtual machines must be powered on. The VRA requires an active IO stack to access the virtual machine data to be synchronized across the sites. If the virtual machine is not powered on, there is no IO stack to use to access the source data to replicate to the target recovery disks.</td>
</tr>
<tr>
<td><strong>iSCSI</strong></td>
<td>An Internet Protocol (IP)-based storage networking standard for linking data storage facilities. By carrying SCSI commands over IP networks, iSCSI is used to facilitate data transfers over intranets and to manage storage over long distances.</td>
</tr>
<tr>
<td><strong>Journal</strong></td>
<td>Every write to a protected virtual machine is intercepted by Zerto Virtual Replication and a copy of the write is sent, asynchronously, to the recovery site, while the write continues to be processed on the protected site. On the recovery site the write is written to a journal managed by the Virtual Replication Appliance. Each protected virtual machine has its own journal. Each journal can expand to a size specified in the VPG definition and automatically shrinks when the expanded size is not needed.</td>
</tr>
<tr>
<td><strong>Long Term Retention</strong></td>
<td>Providing Zerto customers a comprehensive Data Protection solution - preserve their virtualized environment production data, for a long period - from months to several years. The data is copied from the Recovery site, to a local or remotely attached storage repository, without any impact on production data or performance, via a single management platform. Data Retention is enforced by built-in scheduling and retention mechanisms. Data can later be restored easily, and with minimal RTO.</td>
</tr>
<tr>
<td><strong>LUN</strong></td>
<td>Disk drives are the foundation of data storage, but operating systems cannot use physical disk storage directly. The platters, heads, tracks and sectors of a physical disk drive must be translated into a logical space, which an OS sees as a linear address space comprised of fixed-size blocks. This translation creates a logical entity that allows operating systems to read/write files. Storage networks must also partition their physical disks into logical entities so that host servers can access storage area network (SAN) storage. Each logical portion is called a logical unit number (LUN). A LUN is a logical entity that converts raw physical disk space into logical storage space, which a host server’s OS can access and use. Any computer user recognizes the logical drive letter that has been carved out of their disk drive. For example, a computer may boot from the C: drive and access file data from a different D: drive. LUNs do the same basic job.</td>
</tr>
<tr>
<td><strong>Level of Business Continuity</strong></td>
<td>The reduced level of service that has been agreed if there is an interruption to business operations.</td>
</tr>
<tr>
<td><strong>Managed Service Provider (MSP)</strong></td>
<td>See Cloud Service Provider (CSP).</td>
</tr>
<tr>
<td><strong>Maximum Tolerable Data Loss</strong></td>
<td>The maximum tolerable data loss an organization can endure without compromising its business objectives.</td>
</tr>
<tr>
<td><strong>Maximum Tolerable Outage (MTO)</strong></td>
<td>The maximum time after which an outage will compromise the ability of the organization to achieve its business objectives.</td>
</tr>
<tr>
<td><strong>Maximum Tolerable Period of Disruption</strong></td>
<td>The duration after which an organization’s viability will be irrevocably threatened if product and service delivery cannot be resumed.</td>
</tr>
<tr>
<td><strong>NAS</strong></td>
<td>A network-attached storage (NAS) device is a server that is dedicated to nothing more than file sharing. NAS does not provide any of the activities that a server in a server-centric system typically provides, such as e-mail, authentication or file management. NAS allows more hard disk storage space to be added to a network that already utilizes servers without shutting them down for maintenance and upgrades. With a NAS device, storage is not an integral part of the server. Instead, in this storage-centric design, the server still handles all of the processing of data but a NAS device delivers the data to the user. A NAS device does not need to be located within the server but can exist anywhere in a LAN and can be made up of multiple networked NAS devices.</td>
</tr>
<tr>
<td><strong>Net Recovery Time</strong></td>
<td>The net time achieved in recovering one or more VPGs after a disaster.</td>
</tr>
<tr>
<td><strong>Operational Level Agreement (OLA)</strong></td>
<td>The agreement between the service management and the Service Provision Partners. It defines the responsibilities for support and delivery of the services provided.</td>
</tr>
<tr>
<td><strong>Pair</strong></td>
<td>Zerto Virtual Replication can be installed at one or more sites and each of these sites can connect to any of the other sites enabling enterprises to protect virtual machines across multiple vCenters or within the same vCenter. Two sites connected to each other are considered paired. Also see Replication to Self.</td>
</tr>
<tr>
<td>Glossary Item</td>
<td>Definition</td>
</tr>
<tr>
<td>---------------</td>
<td>------------</td>
</tr>
<tr>
<td>Preseed</td>
<td>A virtual disk (a .vmdk flat file and descriptor or a .vhdx file) in the recovery site that has been prepared with a copy of the protected data. Using this option is recommended particularly for large disks so that the initial synchronization is much faster. When not using a preseeded disk the initial synchronization phase has to copy the whole disk over the WAN. Zerto Virtual Replication takes ownership of the preseeded disk, moving it from its source folder to the folder used by the VRA.</td>
</tr>
<tr>
<td>Quiesce</td>
<td>Pausing or altering the state of running processes on a computer, particularly those that might modify information stored on disk during a backup, in order to guarantee a consistent and usable backup. Critical applications, such as databases have quiescent mechanisms that Zerto Virtual Replication can use to get application consistent checkpoints.</td>
</tr>
<tr>
<td>RBAC</td>
<td>Role-based Access control, available in the Zerto Cloud Manager via the Permissions tab.</td>
</tr>
<tr>
<td>RDM (vSphere)</td>
<td>RDM is a mapping file in a separate VMFS volume that acts as a proxy for a raw physical storage device. The RDM allows a virtual machine to directly access and use the storage device. The RDM contains metadata for managing and redirecting disk access to the physical device. The file gives you some of the advantages of direct access to a physical device while keeping some advantages of a virtual disk in VMFS. As a result, it merges VMFS manageability with raw device access. Zerto Virtual Replication supports both physical and virtual mode RDMs.</td>
</tr>
<tr>
<td>Recovery Point Objective (RPO)</td>
<td>The maximum amount of data that may be lost when the activity or service is restored after an interruption. Expressed as a length of time before the interruption.</td>
</tr>
<tr>
<td>Recovery Time Achieved (RTA)</td>
<td>The actual times achieved during a DR test.</td>
</tr>
<tr>
<td>Recovery Time Objective (RTO)</td>
<td>Related to downtime. The metric refers to the amount of time it takes to recover from a data loss event and how long it takes to return to service. The metric is an indication of the amount of time the system’s data is unavailable or inaccessible, thus preventing normal service.</td>
</tr>
<tr>
<td>Replication, Asynchronous</td>
<td>Technique for replicating data between databases or file systems where the system being replicated does not wait for the data to have been recorded on the duplicate system before proceeding. Asynchronous Replication has the advantage of speed, at the increased risk of data loss during due to communication or duplicate system failure.</td>
</tr>
<tr>
<td>Replication to Self</td>
<td>When a single vCenter is used, for example with remote branch offices, when replicating from one datacenter to another datacenter, both managed by the same vCenter Server, you have to enable replication to the same vCenter Server and pairing is not required.</td>
</tr>
<tr>
<td>Resource</td>
<td>The elements (such as staff, site, data, IT systems) that are required to deliver an activity or service.</td>
</tr>
<tr>
<td>Resource Recovery Plan</td>
<td>Contains the instructions, procedures and guidelines to recover one or more resources and return conditions to a level of operation that is acceptable to the organization. Recovery Plans include detailed recovery procedures for IT equipment and infrastructure.</td>
</tr>
<tr>
<td>Rolling Back</td>
<td>Rolling back to an initial status, for example, after canceling a cloning operation on the VPG.</td>
</tr>
<tr>
<td>RPO</td>
<td>See Recovery Point Objective (RPO).</td>
</tr>
<tr>
<td>RTO</td>
<td>See Recovery Time Objective (RTO).</td>
</tr>
<tr>
<td>SAN</td>
<td>A storage area network (SAN) is any high-performance network whose primary purpose is to enable storage devices to communicate with computer systems and with each other. A storage device is a machine that contains nothing but a disk or disks for storing data. A SAN’s architecture works in a way that makes all storage devices available to all servers on a LAN or WAN. As more storage devices are added to a SAN, they too will be accessible from any server in the larger network. In this case, the server merely acts as a pathway between the end user and the stored data. Because stored data does not reside directly on any of a network’s servers, server power is utilized for business applications, and network capacity is released to the end user.</td>
</tr>
</tbody>
</table>
**SCSI**  
Acronym for Small Computer System Interface. SCSI is a parallel interface standard used by many servers for attaching peripheral devices to computers. SCSI interfaces provide for faster data transmission rates (up to 80 megabytes per second) than standard serial and parallel ports. In addition, you can attach many devices to a single SCSI port, so that SCSI is really an I/O bus rather than simply an interface.

**SCVMM**  
A Microsoft management solution for the virtualized datacenter, enabling you to configure and manage your virtualization host, networking, and storage resources in order to create and deploy virtual machines and services to private clouds that you have created.

**Secret Access Key (AWS)**  
A password. The Secret Access Key with the Access Key forms a secure information set that confirms the user’s identity.

**Security Group**  
A virtual firewall that controls the traffic for one or more instances.

**Service Continuity Plan**  
The continuity plan that acts as an umbrella document for a service, referencing other plans as required and providing service-specific emergency management and recovery plans.

**Service Level Agreement (SLA)**  
The agreement between the customer and service provider which defines the service that is to be delivered to the customer.

**Service Profile**  
A predefined set of default properties to use when VPGs are defined or edited. Zerto provides a default service profile and the option for the organization to specify their own requirements. The cloud service provider can define service profiles to manage specific service level agreements (SLAs) with its customers.

**Service Test Plan**  
Detailed plan defining the activities required to test the recovery of an individual IT service to meet business requirements documented in the RTO and RPO.

**Shadow VRA**  
During normal operation, a VRA might require more disks than a single virtual machine can support. If this situation arises, the VRA creates new shadow VRA virtual machines, used by the VRA to maintain additional disks. These virtual machines must not be removed. A VRA can manage a maximum of 1500 volumes, whether these are volumes being protected or recovered.

**Snapshots**  
A snapshot is a block device which presents an exact copy of a logical volume, frozen at some point in time. Typically this would be used when some batch processing, a retention process for instance, needs to be performed on the logical volume, but you don't want to halt a live system that is changing the data. Zerto does NOT use a snapshot mechanism, but is constantly replicating data writes.

**Storage Account (Azure)**  
Storage accounts re like a container for your files. You can name your storage account the way you like but it should be unique across the Azure system.

**Subnet**  
A logical, visible subdivision of an IP network.[1] The practice of dividing a network into two or more networks is called subnetting.

**Subscription (Azure)**  
The description uses information derived from the following site:  
https://blogs.msdn.microsoft.com/arunrakwal/2012/04/09/create-windows-azure-subscription/  
An Azure subscription grants access to Azure services and Platform Management Portal. A subscription has two aspects:  
- The Windows Azure account, through which resource usage is reported and services are billed.  
- The subscription itself, which governs access to and use of the Azure services that are subscribed to.

**System Center Virtual Machine Manager**  
See SCVMM.

**Virtual Machine (VM)**  
A virtual machine (VM) is an environment, usually a program or operating system, which does not physically exist but is created within another environment. In this context, a VM is called a guest while the environment it runs within is called a host.

**Virtual Network (VNet) (Azure)**  
A virtual network dedicated to an Azure subscription.
| **Virtual Private Cloud (VPC) (AWS)** | An on demand configurable pool of shared computing resources allocated within a public cloud environment, providing a certain level of isolation between the different organizations (denoted as users hereafter) using the resources. The isolation between one VPC user and all other users of the same cloud (other VPC users as well as other public cloud users) is achieved normally through allocation of a Private IP Subnet and a virtual communication construct (such as a VLAN or a set of encrypted communication channels) per user. |
| **Virtual Protection Group** | See VPG. |
| **Virtual Replication Appliance** | See VRA. |
| **VMDK, Virtual Machine Disk** | Virtual Machines created with VMware products typically use virtual disks. The virtual disks, stored as files on the host computer or remote storage device, appear to the guest operating systems as standard disk drives. |
| **Volume Delta Sync** | Synchronization when only delta changes for a volume needs synchronizing, for example, when a virtual machine is added to a VPG using a preseeded disk.  
During the synchronization, new checkpoints are not added to the journal. Also, recovery operations are not possible during a **Volume Delta Sync**.  
For the synchronization to work, the protected virtual machines must be powered on. The VRA requires an active IO stack to access the virtual machine data to be synchronized across the sites. If the virtual machine is not powered on, there is no IO stack to use to access the source data to replicate to the target recovery disks. |
| **Volume Full Sync** | Synchronization when a full synchronization is required on a single volume.  
During the synchronization, new checkpoints are not added to the journal. Also, recovery operations are not possible during a **Volume Full Sync**.  
**Note:** For the synchronization to work, the protected virtual machines must be powered on. The VRA requires an active IO stack to access the virtual machine data to be synchronized across the sites. If the virtual machine is not powered on, there is no IO stack to use to access the source data to replicate to the target recovery disks. |
| **Volume Initial Sync** | Synchronization when a full synchronization is required on a single volume, for example, when changing the target datastore or adding a virtual machine to the VPG without using a preseeded (not available in the cloud) disk.  
During the synchronization, new checkpoints are not added to the journal. Also, recovery operations are not possible during a **Volume Initial Sync**.  
For the synchronization to work, the protected virtual machines must be powered on. The VRA requires an active IO stack to access the virtual machine data to be synchronized across the sites. If the virtual machine is not powered on, there is no IO stack to use to access the source data to replicate to the target recovery disks. |
<p>| <strong>VPG</strong> | Virtual machines are protected in virtual protection groups. A virtual protection groups (VPG) is a group of virtual machines that you want to group together for replication purposes. For example, the virtual machines that comprise an application like Microsoft Exchange, where one virtual machine is used for the software, one for the database and a third for the Web Server, require that all three virtual machines are replicated to maintain data integrity. |
| <strong>VRA</strong> | A virtual machine installed on each hypervisor hosting virtual machines to be protected or recovered, that manages the replication of protected virtual machine writes across sites. A VRA must be installed on every hypervisor that hosts virtual machines that require protecting in the protected site and on every hypervisor that will host the replicated virtual machines in the recovery site. |
| <strong>vSphere</strong> | VMware’s server virtualization platform for building a cloud infrastructure. |</p>
<table>
<thead>
<tr>
<th><strong>Glossary</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Zerto Cloud Connector (ZCC)</strong></td>
<td>A virtual machine installed on the cloud side, one for each customer organization replication network. The Zerto Cloud Connector requires both cloud-facing and customer-facing static IP addresses. The ZCC routes traffic between the customer network and the cloud replication network, in a secure manner ensuring complete separation between the customer network and the cloud service provider network. The ZCC has two Ethernet interfaces, one to the customer's network and one to the cloud service provider's network. Within the cloud connector a bidirectional connection is created between the customer and cloud service provider networks. Thus, all network traffic passes through the ZCC, where the incoming traffic on the customer network is automatically configured to IP addresses of the cloud service provider network.</td>
</tr>
<tr>
<td><strong>Zerto Cloud Manager (ZCM)</strong></td>
<td>A Windows service, which enables managing all the cloud sites offering disaster recovery using a single interface. The ZCM manages the DR either as a service (DRaaS) or completely within the cloud environment, protecting on one cloud site and recovering to a second site (ICDR).</td>
</tr>
<tr>
<td><strong>Zerto User Interface</strong></td>
<td>Recovery using Zerto Virtual Replication is managed via a user interface: in a browser via the Zerto Virtual Manager Web Client, or in either the vSphere Web Client or vSphere Client console in the Zerto tab.</td>
</tr>
<tr>
<td><strong>Zerto Self-service Portal (ZSSP)</strong></td>
<td>An out-of-the-box DR portal solution with a fully functioning browser-based service portal to enable cloud service providers to quickly introduce disaster recovery as part of their portal offering.</td>
</tr>
<tr>
<td><strong>Zerto Virtual Backup Appliance (VBA)</strong></td>
<td>A Windows service that manages File Level Recovery operations within Zerto Virtual Replication. These repositories can be local or on a shared network.</td>
</tr>
<tr>
<td><strong>Zerto Virtual Manager (ZVM)</strong></td>
<td>A Windows service, which manages everything required for the replication between the protection and recovery sites, except for the actual replication of data. The ZVM interacts with the vCenter Server to get the inventory of VMs, disks, networks, hosts, etc. The ZVM also monitors changes in the VMware environment and responds accordingly. For example, a vMotion operation of a protected VM from one host to another is intercepted by the ZVM so the Zerto User Interface is updated accordingly.</td>
</tr>
<tr>
<td><strong>ZORG, Zerto Organization</strong></td>
<td>Cloud customers are defined to Zerto Cloud Manager as Zerto organizations, ZORGs. A ZORG is defined with the cloud resources it can use, the permissions that it has to perform operations, such as testing a failover or defining a VPG.</td>
</tr>
</tbody>
</table>

1. Synchronization after a recovery starts after the promotion of data from the journal to the virtual machine disks ends. Thus, synchronization of virtual machines can start at different times, dependent on when the promotion for the virtual machine ends. All synchronizations are done in parallel, whether a delta sync or full sync, etc.

Zerto helps customers accelerate IT transformation by eliminating the risk and complexity of modernization and cloud adoption. Replacing multiple legacy solutions with a single IT Resilience Platform™, Zerto is changing the way disaster recovery, data protection and cloud are managed. With unmatched scale, Zerto’s software platform delivers continuous availability for an always-on customer experience while simplifying workload mobility to protect, recover and move applications freely across hybrid and multi-clouds. Zerto is trusted by over 6,000 enterprise customers globally, and is powering resiliency offerings for Microsoft Azure, IBM Cloud, AWS, Sungard and more than 350 cloud services providers.
