The Impact of Pharmacist Counseling on Congestive Heart Failure (CHF) 30-day Readmissions at a Community Hospital

Radhika Patel, Pharm.D., Shelly O’Bryan, Pharm.D., BCPP, Kevin Maginnis, Pharm.D., Megan Webb, Pharm.D., BCPP

Background

• Congestive heart failure (CHF) is the leading cause of hospitalization and mortality in the United States.
• CHF affects 5.7 million adults and is responsible for one in nine adult deaths.
• 30-day hospital readmissions have a significant impact on the health care system with estimated annual cost of $15 billion.
• 30-day hospital readmissions – important quality outcome measure for the Centers for Medicare & Medicaid Services (CMS).

Methods

• Several prospective studies evaluated the impact of implementation of pharmacy facilitated medication reconciliation, patient education, and discharge counseling on 30-day readmissions at academic medical centers or large teaching hospitals.
• Previous studies reported decrease in medication errors and emergency department visits with the use of pharmacy facilitated patient education model.
• Recent prospective, historical control study at academic medical center by Zemaitis et al., found 27% reduction in 30-day readmissions through pharmacists’ services.
• To date, no studies available that identify the effect of pharmacist inpatient counseling on rates of CHF patient readmission at a community hospital.

Hypothesis

Pharmacist provided inpatient counseling for congestive heart failure patients will reduce 30-day hospital readmission rates.

Objectives

Primary Objective:

To determine the incidence of 30-day readmission in CHF patients before and after implementation of inpatient pharmacist counseling.

Secondary Objectives:

• To determine the amount of time required by a pharmacist to provide one patient counseling.
• To determine the incidence of 30-day emergency department (ED) visits before and after implementation of inpatient pharmacist counseling.
• To determine the factors associated with prevention of 30-day readmission rates.

Methods cont.

• Retrospective, single-center, observational cohort study.
• Patients will be identified using electronic health records generated daily report.
• Chart review performed from April 2016 to December 2016.

Intervention:

Full-time clinical outcomes pharmacist providing inpatient counseling with utilization of teach-back method.
• Pre-implementation phase (3 months).
• Post-implementation phase (3 months).

Exclusion Criteria

• Age < 18 years.
• Admission to hospital for heart failure or admission diagnosis of heart failure.
• Admitted to hospital with a history of heart failure or admission diagnosis of heart failure.
• Patients discharged to skilled nursing facilities or long-term care facilities.

Inclusion Criteria

• Age ≥ 18 years.
• Admission to hospital with a history of heart failure or admission diagnosis of heart failure.

Data Collection:

• Age
• LACE score
• Number of medications at day of counseling and at discharge
• Gender
• Length of stay
• Home medications list containing heart failure, cholesterol, and anticoagulation medications
• Race
• Ejection fraction
• Pharmacist’s time spent on counseling
• Weight
• Past medical history
• Number and type of pharmacist interventions

Data Analysis and Statistics:

• Continuous data will be analyzed using student’s t-test as appropriate.
• Nominal or categorical data will be compared using Chi-square method as appropriate.
• Univariate and multivariate logistic regression will be performed to determine factors associated with prevention of 30-day readmissions (with p-value < 0.2).
• A power analysis determined 396 (198 patients per group) need to be enrolled to achieve 80% power, with 5% alpha, a predicted 20% incidence of 30-day readmission in the pre-group and an estimated effect size of 10%.

Ongoing Research:

• Data collection is ongoing.
• Study proposal approved through Baptist Health Louisville Research Oversight Committee (ROC) and Western Institutional Review Board (WIRB).
• Final results will be presented at Great Lakes Pharmacy Resident Conference.

The development of a tool for prevention of inpatient falls based on Beers Criteria and STOPP: a pilot study.

Vishal Patel, Pharm.D., Jessica Covington, Pharm.D., James Terry, Pharm.D., Anna Hitron, Pharm.D., MS, MBA, BCOP • Author Contact Information: Vishal V. Patel <vishal.patel@bhsi.com>

Background

• Falls are the leading source of accidental death in people ≥ 65.
  • Medical cost of fall-related injuries was $34 billion in 2013 and projected to be as high as $44 billion by 2020.
  • On average, falls resulting in an injury can add up to 6.3 days of a hospital stay.
  • Among hospitalized older adults, up to 78% of falls can be predicted based on factors such as the room layout or prescribed medications.
  • The Center for Disease Control and Prevention recommends that older adults should talk with their doctor or pharmacist to review their medications in order to identify ones that may potentially cause side effects or interactions leading to a higher fall risk.
  • The BEERS’ Criteria for Potentially Inappropriate Medication Use in Older Adults and the Screening Tool of Older Persons’ Potentially Inappropriate Prescriptions Criteria (STOPP) are validated tools for identifying potentially inappropriate medications in patients 65 and older.
  • Both lists contain a broad spectrum of agents, many of which may not be realistic targets for intervention in an inpatient setting.
  • There are currently no studies evaluating the application of the Beer’s or STOPP criteria in terms of clinical interventions within a large community hospital.

Objectives

The purpose of this study is to develop a tool based on the Beers criteria and STOPP to assist clinical pharmacists in making interventions to prevent inpatient falls.

• Specific Aim 1: Survey physicians at a large community hospital to identify the decision making process used when considering what interventions should be accepted regarding potentially inappropriate medications.

• Specific Aim 2: Implement the tool in an inpatient setting among patients older than 64.

• Specific Aim 3: Evaluate the pharmacist-recommendation acceptance rate as well as the overall number of falls in patients who were screened by the tool.

This will be compared against patients who are not screened by any tool.

Methods

Phase 1:

An initial review of current evidence on the significance of medications on fall rate will be evaluated allowing for a baseline understanding of which medications to target for the most effect. (Table 1)

</table>

• A voluntary survey will be performed amongst physicians providing care at Baptist Health Louisville. emphasis is placed on admitting providers or consultants associated with medication classes on the Beers/STOPP criteria.

• Survey will be sent to 86 physicians with primary admitting or consulting privileges via SurveyMonkey®

• Survey to assess knowledge of and willingness to change medications based on falls risk (Figure 1 and 2)

• Results of survey will be combined with the data found from previous trials to create a monitoring tool to be used in an inpatient setting.

Results

• Approved by Baptist Health Louisville Research Oversight Committee
• IRB approval pending – submission to Western IRB
• Physician participation secured – Survey ongoing through month of November and December
• Tool development planned for month of December
