Your garden can provide food and refuge for pollinators throughout the year.

Flowers provide nectar and pollen sources. Shrubs and ornamental grasses provide shelter and nesting sites. Planning for a season-long sequence of bloom ensures pollinators can find food sources from early spring to late fall. That also makes your garden look beautiful!

Find the right plants for your region:

Native or Non-Native plants?
Both! Plant both natives and non-natives for a biodiverse, season-long, pollinator paradise. Yard and garden conditions are not always well suited to native plants. Non-native plants can fill the gap, extend the season of bloom and offer great nectar sources.

Make a spot for Butterflies
These plants make good host plants for butterfly larvae, or caterpillars. That means they eat the foliage as they grow.

Many native butterflies need specific native host plants for larvae to feed and grow on.
