CENTER FOR COMPUTATIONAL RESEARCH

University at Buffalo
The State University of New York

Outline

- Basics of R
- Graphics and Plotting in R
- Importing Data into R
- R Resources

The Basics of 

- What is R?
  - An open-source scripting environment
  - Geared toward statistics and data analysis
  - Base R + *many, many* extension packages
- R extensions
  - Package repositories make it easy to locate and install add-ons
  - Most popular repos: CRAN and Bioconductor

The Basics of 

- R is case sensitive (R != r)
- Command line prompt is >
- To run R code: use command line, or save script (.R) and
  > source("script_name")
  or (from Linux prompt or bash script):
  Rscript script_name.R
- To separate commands, use ; or a newline

The Basics of 

- Use the # character for *comments*
- To display help:

  ?<command-name>

  or

  ??<command-name>

R Output

```
> 2 + 3 * 5
[1] 17
```

Q: What's that [1] about?

A: R numbers outputs with [*n*]

```
# Try this in the command line:
> 1:500
```

Naming Variables in R

A variable name may consist of letters, numbers and the dot or underline characters. It should start with a letter.

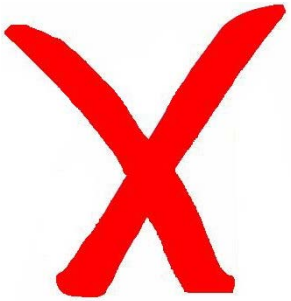
Good:

> y = 2

> try.this = 33.3

> oneMoreTime = “woohoo”

Bad:



> 2y = 2

> _z = 33.3

> function = “woohoo” * *function* is a reserved word

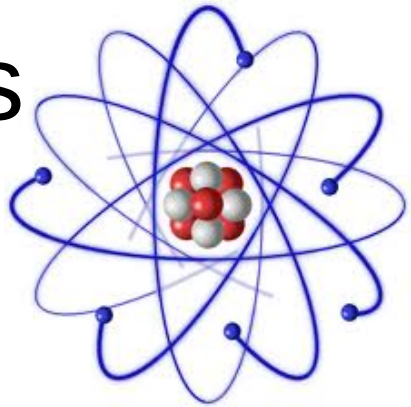
Variables Assignment

- You may use '=' or '<-' to assign values to a variable.

```
> y =  2 + 3 * 5
> z <- 2 + 3 * 5
```

(old fashioned way)

R's Atomic Data Types



Let's take a look at some available data types:

- Numeric (includes integer)
  3.14, 1, 2600
- Character (string)
  “hey, I'm a string”
- Logical
  TRUE or FALSE
- NA
  No value known

Using Logical Operators

```
1==2                    # equivalence test
9 != 19                 # “not equal” test
3 < 204                 # less-than test
18 > 44                 # greater-than test
“tree”==89      # comparing mixed data types
```

Objects in R

R stores everything, variables included, in Objects.

```
> x = 2.71
> print(x) # print the value of the object
[1] 2.71
> class(x)  # what data type or object type?
[1] "numeric"
> is.na(x)  # tests whether x has a known value
[1] FALSE
```

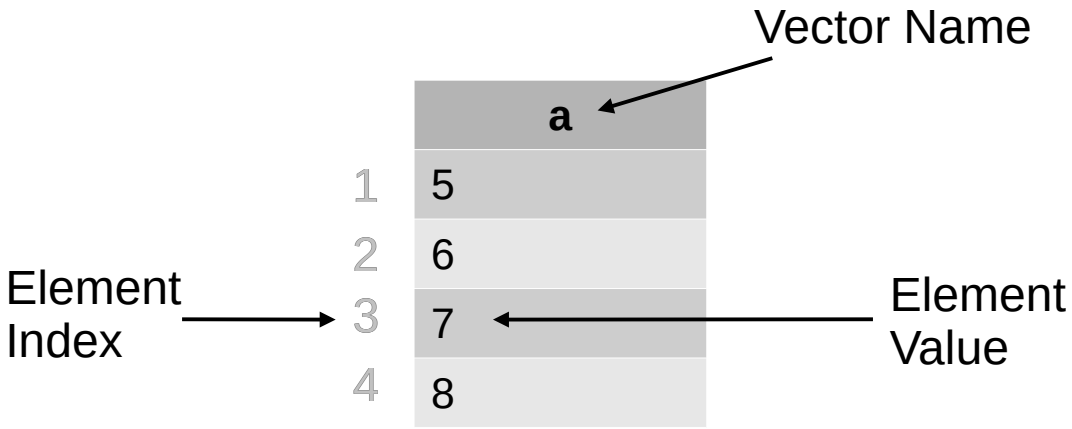
Objects in R

Vectors and Data Frames are the bread and butter of R

- Vector - a list of elements with the same type
- Data Frame - a structure consisting of columns of various types

Vector Data Object

A vector is a list of elements having the *same type*.



Vector Construction

	a
1	5
2	6
3	7
4	8

Use the c() function:

```
> a = c(5,6,7,8) # vector with 4 numeric values
> d = c("red", "orange", "green")  # char vector
```

Accessing Vector Data

	d
1	“red”
2	“orange”
3	“green”

	a
1	5
2	6
3	7
4	8

Access by index or range:

```
> d[1]      # retrieves “red”
> a[3]      # retrieves 7
> d[1:2]    # retrieves “red”, “orange”
```

Element numbering starts at 1 in R

Some Vector Operations

- sum() # Sum of all element values
- length() # Number of elements
- unique() # Generate vector of distinct values
- diff() # Generate vector of first differences
- sort() # Sort elements, omitting NAs
- order() # Sort indices, with NAs last
- rev() # Reverse the element order
- summary() # Information about object contents

Handling Missing Data

Remove NAs prior to calculation:

```
> y = c(1, NA, 3, 2, NA)  # [1, ?, 3, 2, ?]
sum(y, na.rm=TRUE) # removes NAs, then sums
[1] 6  # sum of 1 + 3 + 2
```

Data Frames

- Data frames are handy containers for experimental data.
- Columns - data fields (vectors)
- Rows - tuples of data
- Rows and columns can be named

A Simple Data Frame

```
> n = c(2, 3, 5)
> s = c("aa", "bb", "cc")
> b = c(TRUE, FALSE, TRUE)
> df = data.frame(n, s, b)
```

source: http://www.r-tutor.com/r-introduction/data-frame

Data Frame Information

```
str(data)    # structure (NOT string!)
dim(data)  # dimensions

View(data)        # open View window of data
head(data)        # print beginning of the data frame
tail(data)        # print end of the data frame

names(data)           # names of the columns
rownames(data)        # names of the rows
colnames(data)        # names of the columns
```

User-Defined Functions in R

Basic structure:

```
my_function_name = function(arg1, arg2, ... ){
   statements
   return(object)
}
```

A concrete example:

```
toFahrenheit = function(celsius) {
  f = (9/5) * celsius + 32; # do something
  return(f); # return the result
}
```

Invoking Functions in R

```
temps = c(20:25); # define input temperatures
# define a function to convert temperatures
toFahrenheit = function(celsius) {
  f = (9/5) * celsius + 32;  # perform the conversion
  return(f);
}
# invoke the function:
toFahrenheit(temps);
[1] 68.0  69.8  71.6  73.4  75.2  77.0
```

Loading Functions in R

```
# Functions can be loaded from a separate R file.
# Analogous to an "include" statement in C/C++/FORTRAN
# or an "import" statement in python
source("myFunctions.R")
```

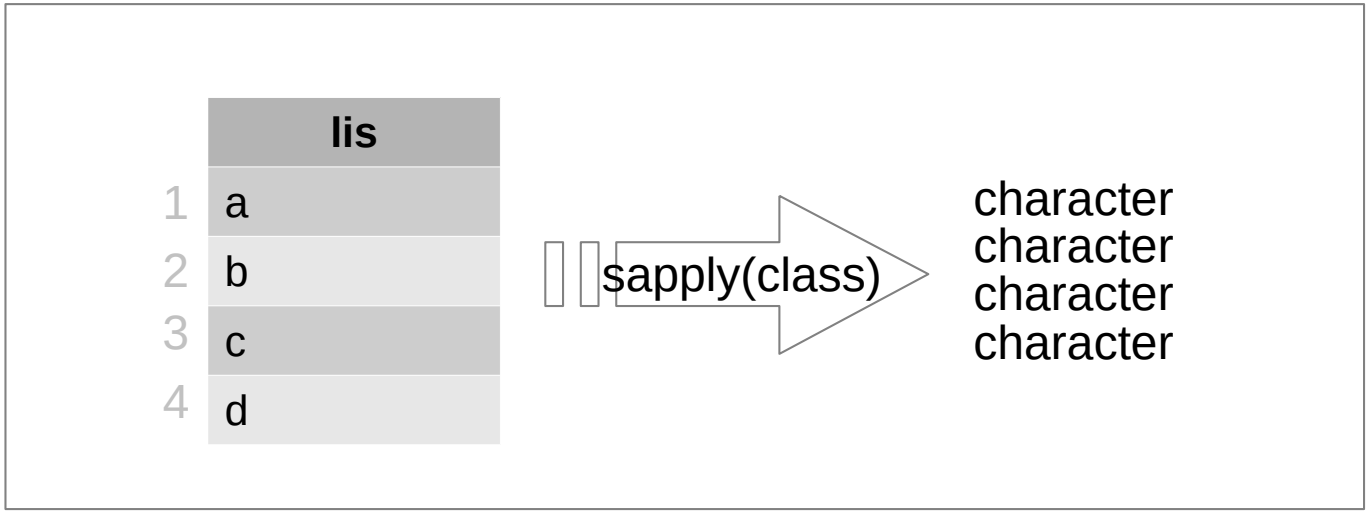
Control Structures: apply() Family

- What if we want to call a function over and over?
- We can do this with a single line of R code!
- Use it on native R functions, or functions you wrote yourself.

sapply(*vector*, *function*)

Control Structures: sapply()

```
> lis = c("a", "b", "c", "d")
> sapply(lis, class)
        a         b         c         d
"character" "character" "character" "character"
```



Statistical Functions in R

- mean()
- median()
- range()
- var() and sd() # variance, standard deviation
- summary() # combination of measures
- *plus many, many others!*

Outline

Basics of R

Graphics and Plotting in R

Importing Data into R

R Resources

Some Plot Types

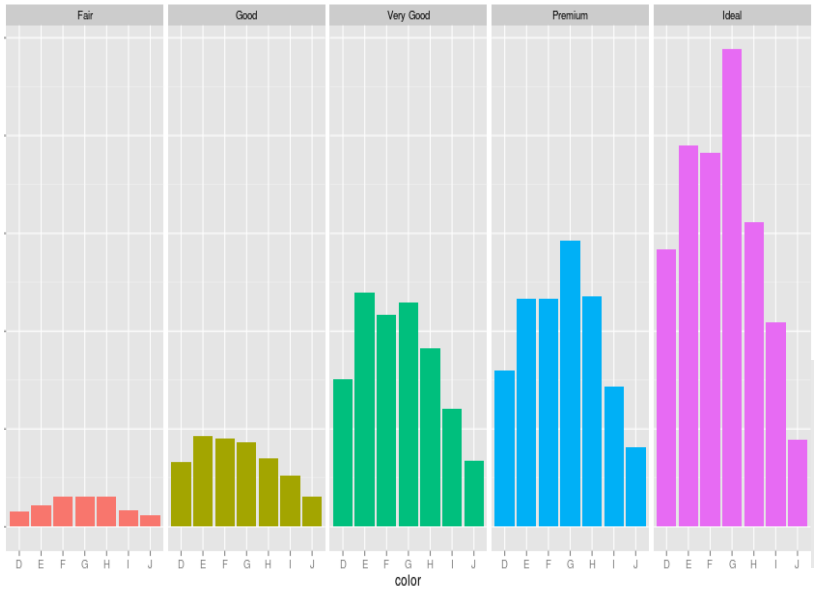
- Pie Chart
  - Display proportions of different values for a variable
- Bar Plot
  - Display counts of values for a categorical variable
- Histogram, Density Plot
  - Display counts of values for a binned, numeric variable
- Scatter Plot
  - y vs. x
- Box Plot
  - Display distributions over different values of a variable

Plotting Packages

- 3 Main Plotting Packages
  - Base graphics, lattice, and ggplot2
- Base graphics
  - Legacy approach (FORTRAN and S)
  - http://www.statmethods.net/graphs/creating.html
- lattice
  - Extends base graphs with support for trellis graphs.
  - http://www.statmethods.net/advgraphs/trellis.html
- ggplot2
  - The "cadillac" of plotting packages. Beautiful plots but complex.
  - http://ggplot2.org/

Plotting Packages

- The best approach: learn by doing but *don't start from scratch*.
- Start with an example that is similar in appearance to what you are trying to achieve.
- Modify this example to use your own data.



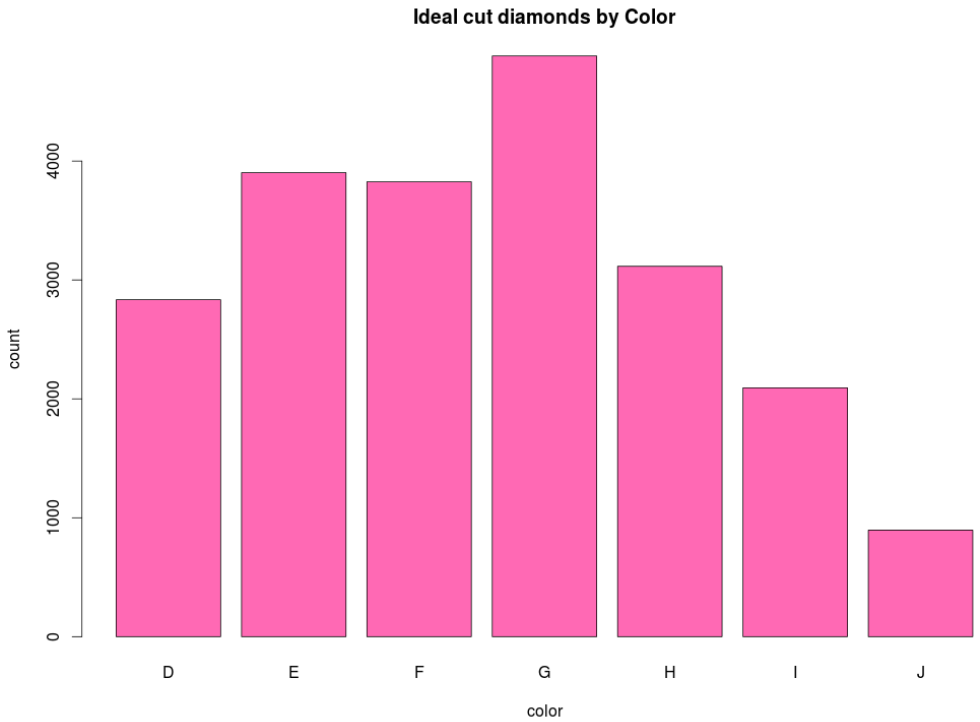
Dataset:
http://docs.ggplot2.org/0.9.3.1/diamonds.html

Tutorial:
http://ggplot2.org/book/qplot.pdf

Code Snippet:

```
ggplot(small)
        +geom_point(aes(x=carat,y=price,colour=cut))
                +scale_y_log10()
                        +facet_wrap(~cut)
                                +ggtitle("First example")
```

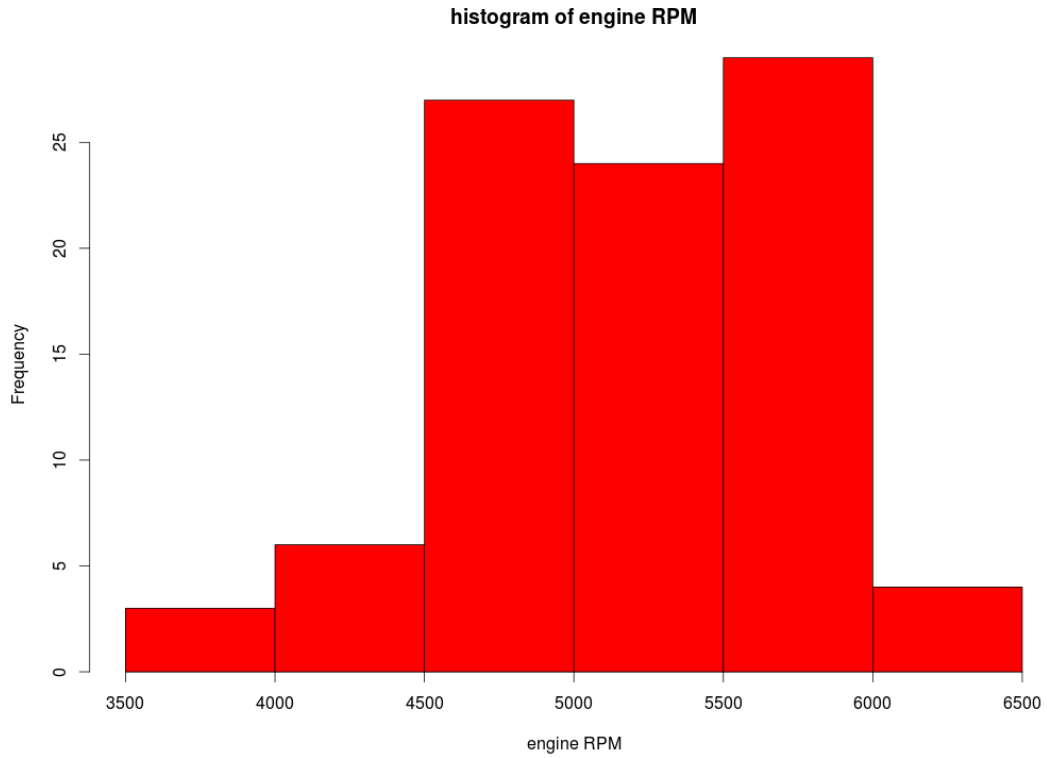
Bar Plot: Counts of Categorical Values



```
ideal=diamonds[diamonds$cut=="Ideal","color"]

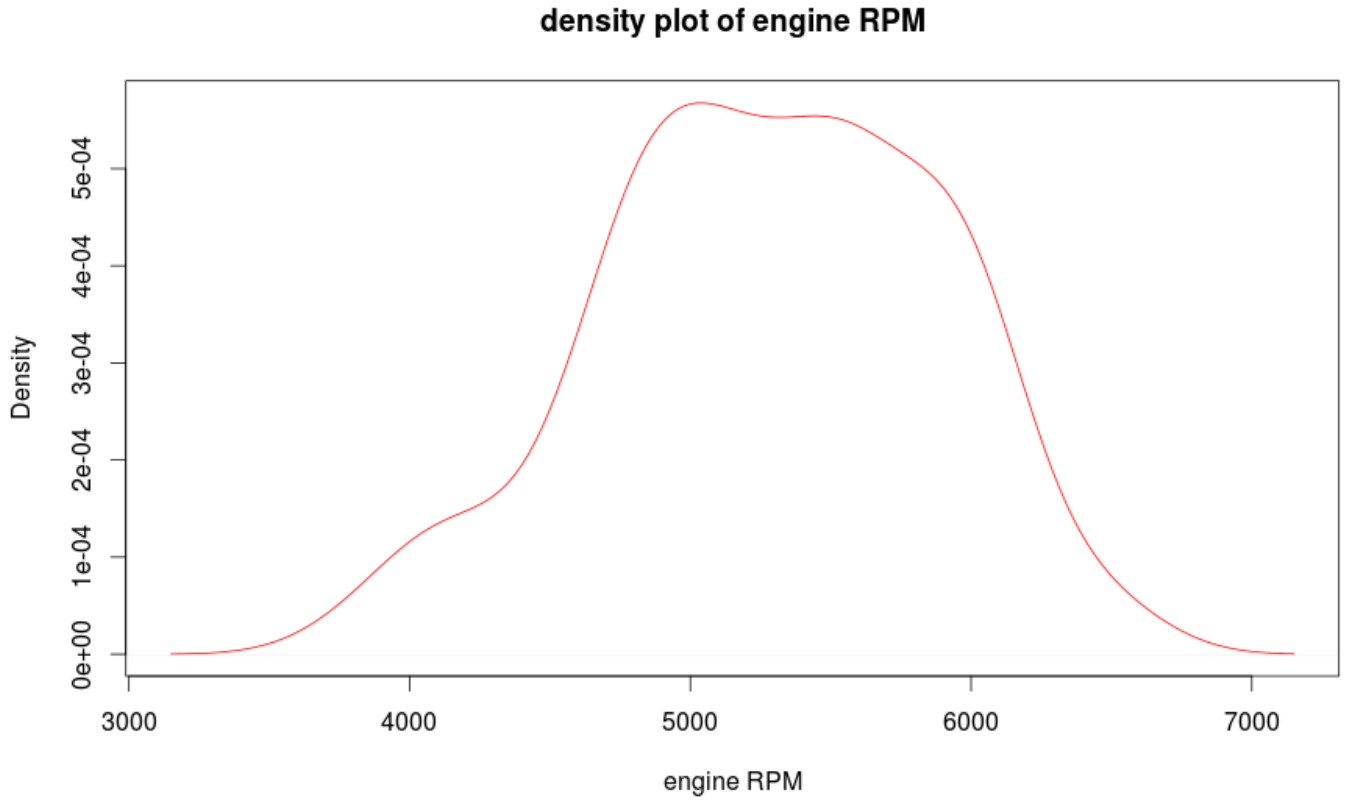
barplot(table(ideal), xlab="color", ylab="count",
        main="Ideal cut diamonds by Color",
        col="hotpink")
```

Histogram: Frequencies of Numeric Values



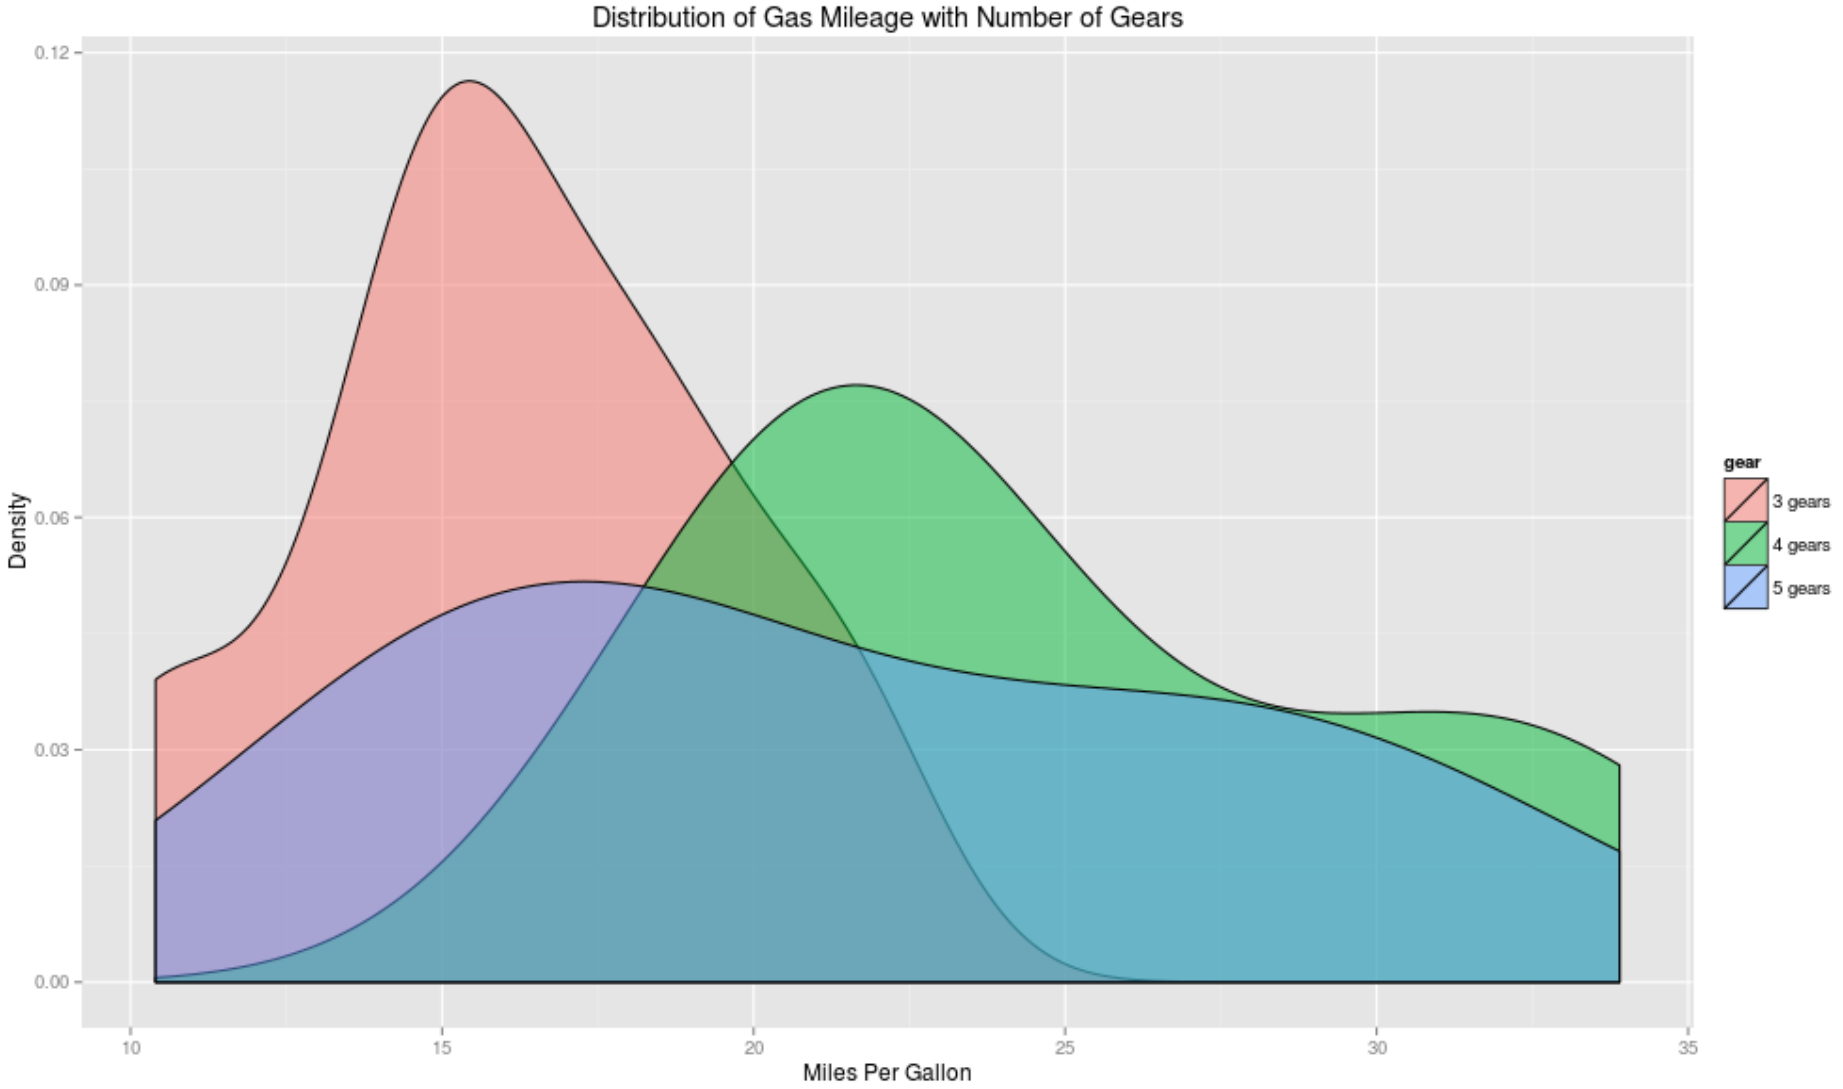
```
hist(Cars93$RPM,
     xlab="engine RPM",
     main="histogram of engine RPM",
     col="red")
```

Kernel Density Plot

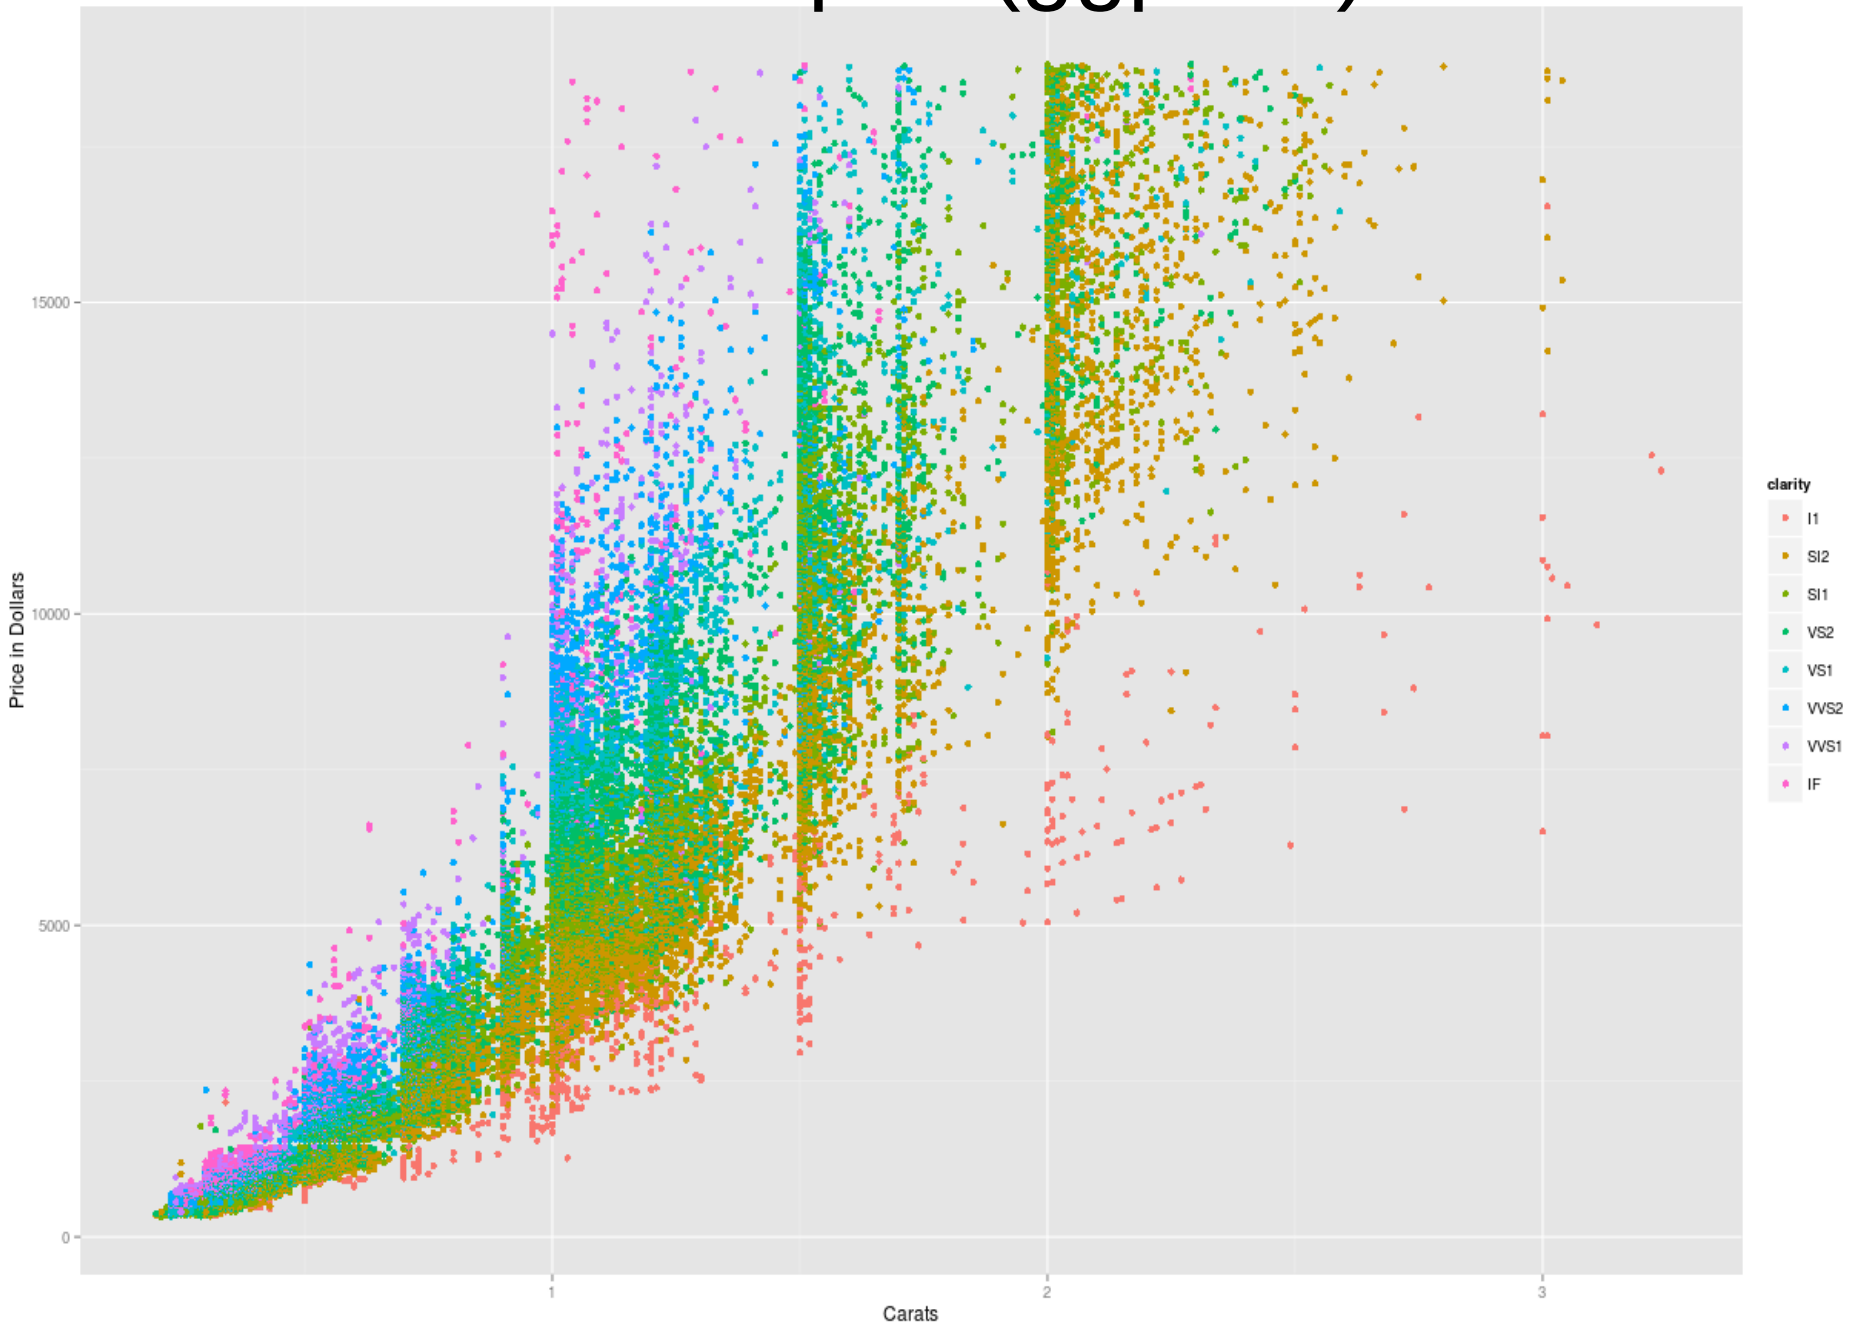


```
plot(density(Cars93$RPM),
     xlab="engine RPM",
     main="density plot of engine RPM",
     col="red")
```

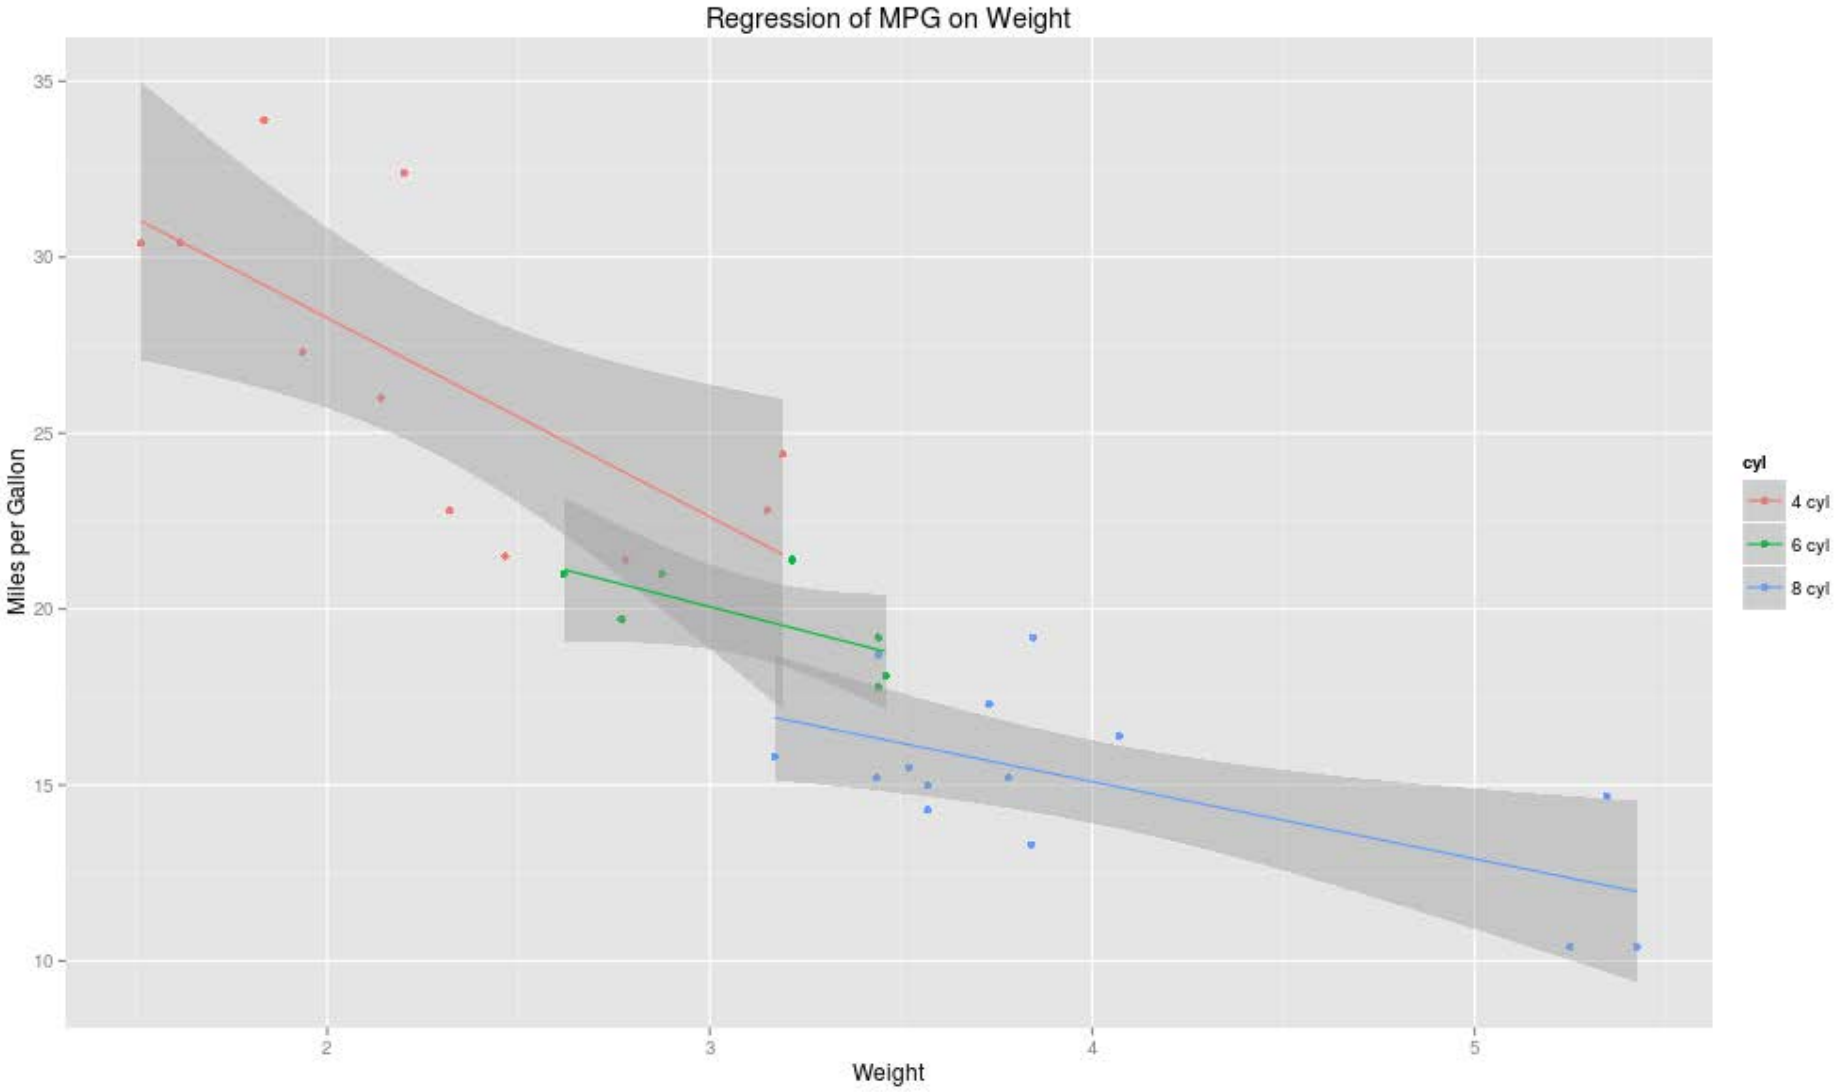
Density Plot (ggplot2)



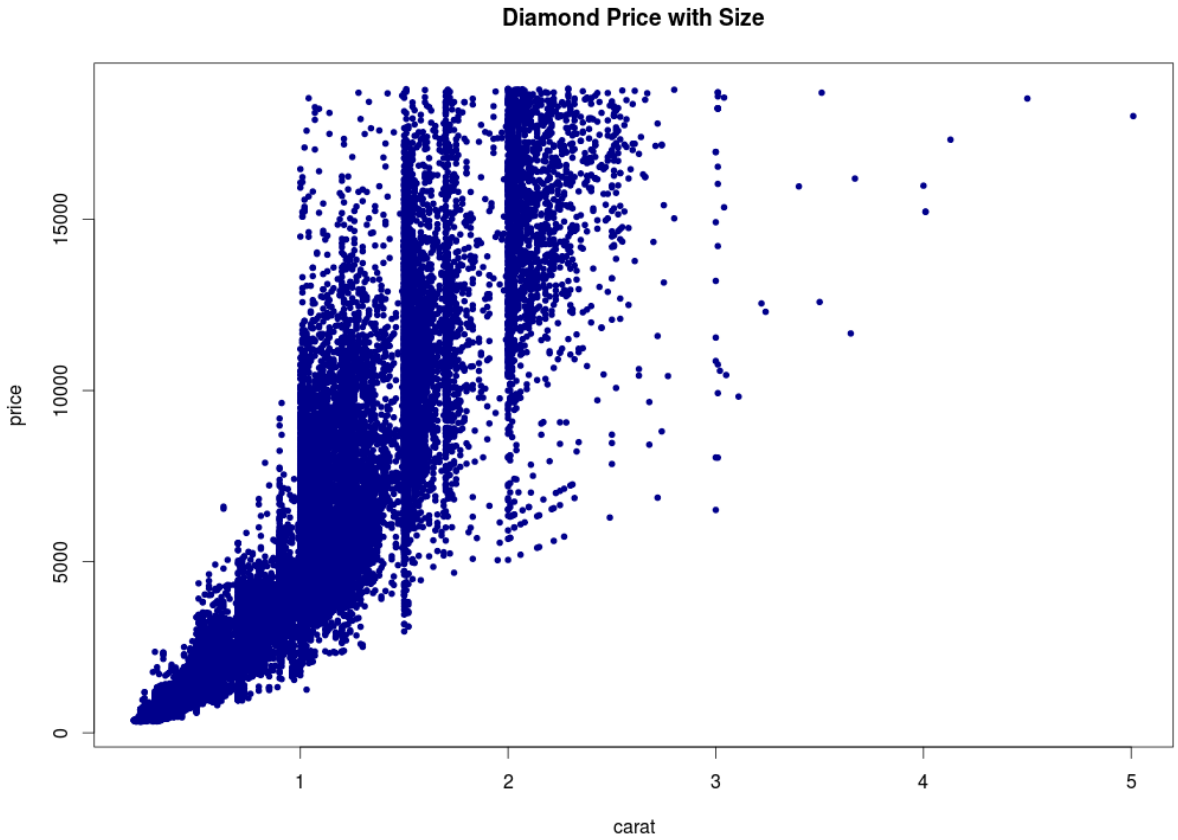
Scatterplot (ggplot2)



Scatterplot w/ Regression Lines (ggplot2)

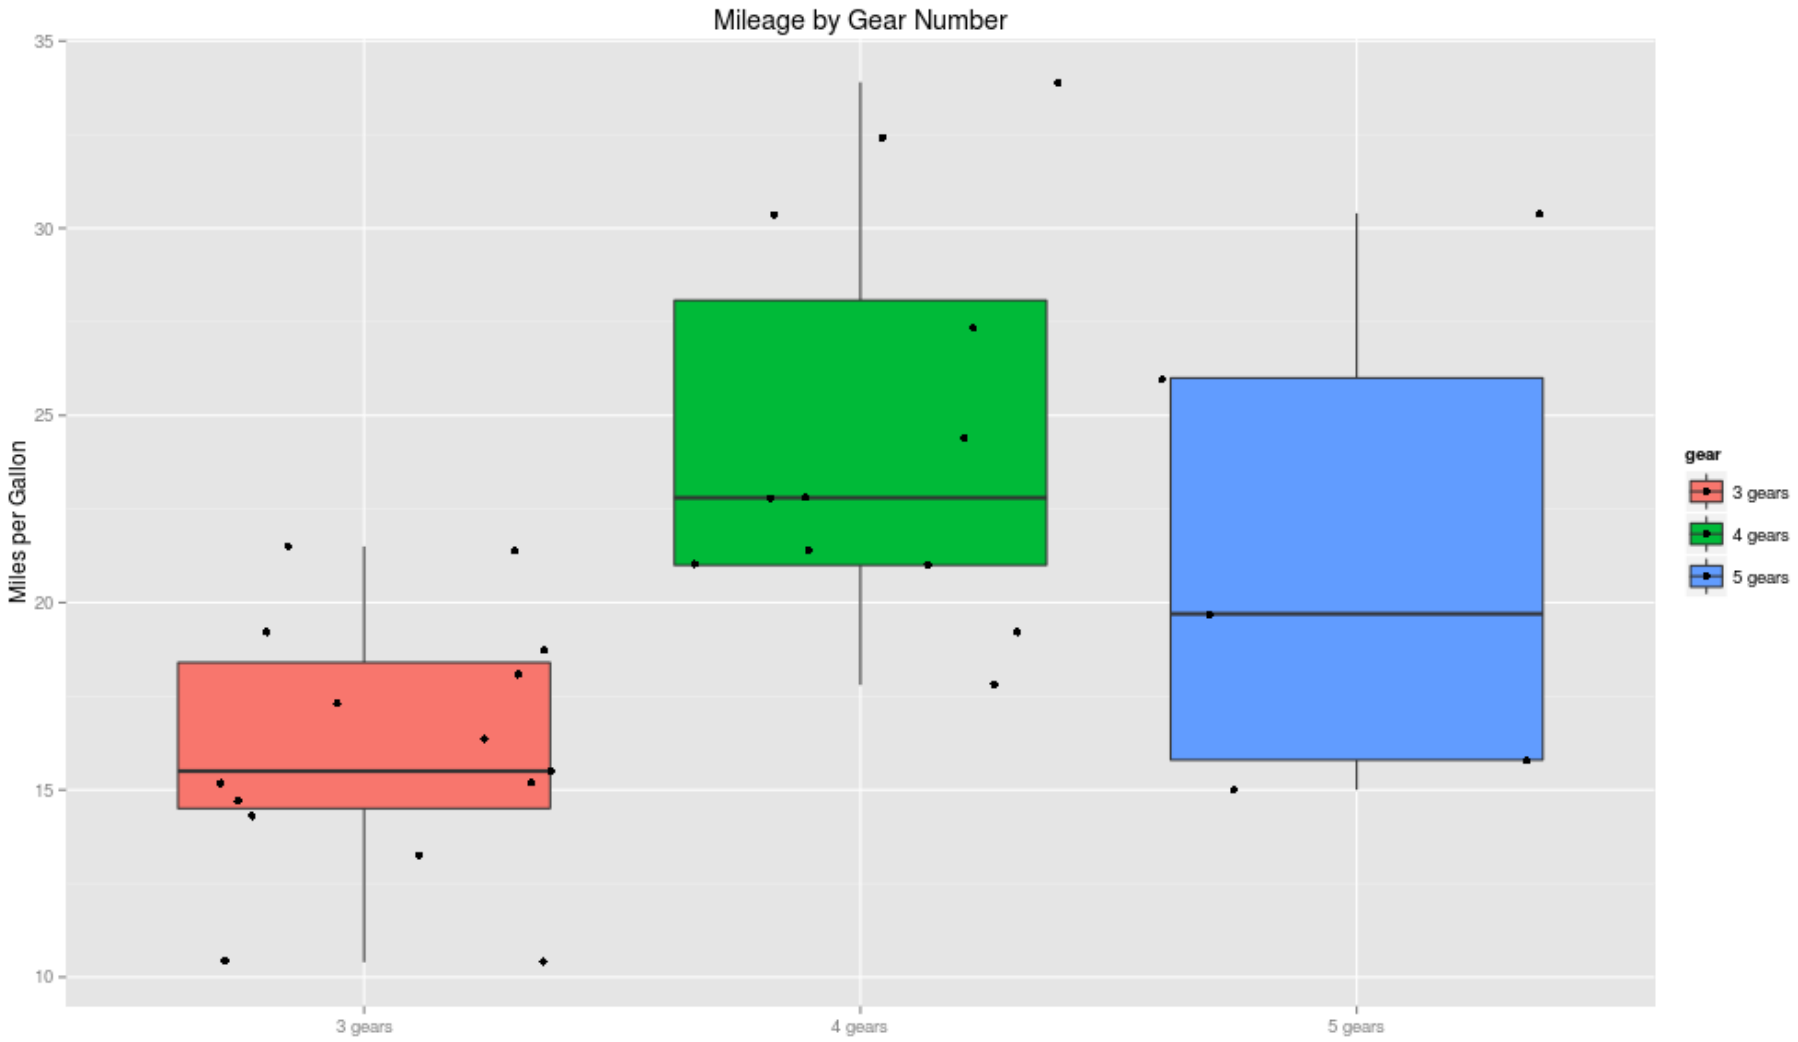


Scatterplot (base graphics)

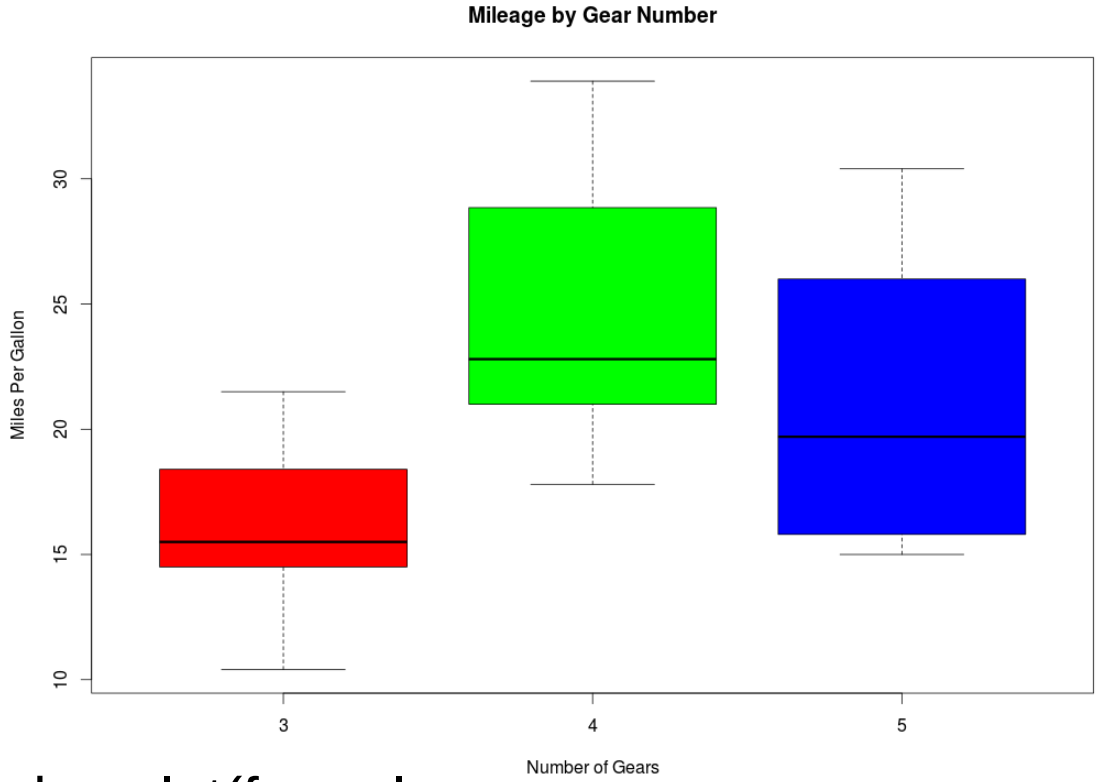


```
plot(formula=price~carat,
     data=diamonds,
     col="darkblue",
     pch=20,
     main="Diamond Price with Size")
```

Box (and Whisker) Plot (ggplot2)



Box (and Whisker) Plot (base graphics)



```
boxplot(formula=mpg~gear,
                data=mtcars,
                main="Mileage by Gear Number",
                xlab="Number of Gears",
                ylab="Miles Per Gallon",
                col=c("red","green","blue"))
```

Outline

Basics of R

Graphics and Plotting in R

Importing Data into R

R Resources

Importing Data

- R has many packages for importing existing data into Vectors and Data Frames
- Existing data can be in the form of:
  - Simply formatted text files (e.g. comma separated)
  - Complex text files (e.g. xml, html)
  - Spreadsheets (e.g. .xls)
  - Databases (e.g. Access, SQL)
  - Data Streams (e.g. twitter and RSS feeds)

Importing Simple Text Data

- csvread package

  http://cran.r-project.org/web/packages/csvread/index.html

- User can specify separator (default is comma)

Importing Complex Text Data

- XML package

  http://cran.r-project.org/web/packages/XML/index.html
- R2HTML package

  http://cran.r-project.org/web/packages/R2HTML/index.html

Also consider using perl to parse html and convert to simple text.

Importing Spreadsheets

- ODBC package

http://cran.r-project.org/web/packages/RODBC/index.html

Use the odbcConnectExcel() functions to establish connection to table and then issue ODBC (open DataBase Connectivity) commands to read entries.

Also consider saving table as .csv and use csvread.

- Foreign package

http://cran.r-project.org/web/packages/foreign/index.html

Provides support for a variety of proprietary data formats.

Importing Databases

- Use ODBC or foreign packages (see previous)

- MySQL package

http://cran.r-project.org/web/packages/RMySQL/index.html

Importing Data Streams

- TwitteR

http://cran.r-project.org/web/packages/twitteR/index.html

- R-does-RSS (Really Simple Syndication)

https://github.com/noahhl/r-does-rss

The XML package also provides support for RSS parsing.

Outline

Basics of R

Graphics and Plotting in R

Importing Data into R

R Resources

...is free

If you want to experiment further with R and RStudio, you can install them on your favorite operating system at home.

First, install R:

http://cran.r-project.org/

Then, install the Rstudio IDE:

http://www.rstudio.com/ide/

On The apply() Family

```
base::apply    Apply Functions Over Array Margins
base::by       Apply a Function to a Data Frame Split by Factors
base::eapply   Apply a Function Over Values in an Environment
base::lapply   Apply a Function over a List or Vector
base::mapply   Apply a Function to Multiple List or Vector Arguments
base::rapply   Recursively Apply a Function to a List
base::tapply   Apply a Function Over a Ragged Array
```

On The apply() Family

See also the plyr package:

Maintainer Hadley Wickham <h.wickham@gmail.com>

Description plyr is a set of tools that solves a common set of problems: you need to break a big problem down into manageable pieces, operate on each pieces and then put all the pieces back together. For example, you might want to fit a model to each spatial location or time point in your study, summarise data by panels or collapse high-dimensional arrays to simpler summary statistics. The development of plyr has been generously supported by BD (Becton Dickinson).
